1. If this element is an input \({ }^{\text {p493 }}\) element, and selectionEnd \({ }^{\text {p587 }}\) does not apply \({ }^{\text {p496 }}\) to this element, return null.
2. If there is no selection \({ }^{\mathrm{p586}}\), return the code unit offset within the relevant value \({ }^{\mathrm{p586}}\) to the character that immediately follows the text entry cursor \({ }^{p 586}\).
3. Return the code unit offset within the relevant value \({ }^{\text {p586 }}\) to the character that immediately follows the end of the selection \({ }^{\text {p586 }}\).

The selectionEnd \({ }^{p 587}\) attribute's setter must run the following steps:
1. If this element is an input \({ }^{\text {p493 }}\) element, and selectionEnd \({ }^{\text {p587 }}\) does not apply \({ }^{\text {p496 }}\) to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range \({ }^{\mathrm{p588}}\) with the value of this element's selectionStart \({ }^{\mathrm{p587}}\) attribute, the given value, and the value of
this element's selectionDirection \({ }^{\text {p588 }}\) attribute.
The selectionDirection attribute's getter must run the following steps:
1. If this element is an \(\underline{\text { input }}^{\text {p493 }}\) element, and selectionDirection \({ }^{\text {p588 }}\) does not apply \({ }^{\text {p496 }}\) to this element, return null.
2. Return this element's selection direction \({ }^{p 586}\).

The selectionDirection \({ }^{\text {p588 }}\) attribute's setter must run the following steps:
 "InvalidStateError" DOMException.
2. Set the selection range \({ }^{p 588}\) with the value of this element's selectionStart \({ }^{p 587}\) attribute, the value of this element's selectionEnd \({ }^{p 587}\) attribute, and the given value.

The setSelectionRange(start, end, direction) method, when invoked, must run the following steps:
1. If this element is an input \({ }^{\text {p493 }}\) element, and setSelectionRange( \()^{\text {p588 }}\) does not apply \({ }^{\text {p496 }}\) to this element, throw an "InvalidStateError" DOMException.
2. Set the selection range \({ }^{\mathrm{p} 588}\) with start, end, and direction.

To set the selection range with an integer or null start, an integer or null or the special value infinity end, and optionally a string direction, run the following steps:
1. If start is null, let start be zero.
2. If end is null, let end be zero.
3. Set the selection \({ }^{\text {p586 }}\) of the text control to the sequence of code units within the relevant value \({ }^{\text {p586 }}\) starting with the code unit at the startth position (in logical order) and ending with the code unit at the (end-1)th position. Arguments greater than the length of the relevant value \({ }^{\text {p586 }}\) of the text control (including the special value infinity) must be treated as pointing at the end of the text control. If end is less than or equal to start then the start of the selection and the end of the selection must both be placed immediately before the character with offset end. In UAs where there is no concept of an empty selection, this must set the cursor to be just before the character with offset end.
4. If direction is not identical to either "backward" or "forward", or if the direction argument was not given, set direction to "none".
5. Set the selection direction \({ }^{\text {p587 }}\) of the text control to direction.
6. If the previous steps caused the selection \({ }^{\text {p586 }}\) of the text control to be modified (in either extent or direction \({ }^{\text {p586 }}\) ), then queue an element task \({ }^{\text {p946 }}\) on the user interaction task source \({ }^{\text {p952 }}\) given the element to fire an event named select \({ }^{p 1282}\) at the element, with the bubbles attribute initialized to true.

The setRangeText(replacement, start, end, selectMode) method, when invoked, must run the following steps:
1. If this element is an input \({ }^{\text {p493 }}\) element, and setRangeText () \({ }^{\text {p588 }}\) does not apply \({ }^{\text {p496 }}\) to this element, throw an "InvalidStateError" DOMException.
2. Set this element's dirty value flag \({ }^{\mathrm{p} 566}\) to true.
3. If the method has only one argument, then let start and end have the values of the selectionStart \({ }^{\text {p587 }}\) attribute and the selectionEnd \({ }^{\text {p587 }}\) attribute respectively.

Otherwise, let start, end have the values of the second and third arguments respectively.
4. If start is greater than end, then throw an "IndexSizeError" DOMException.
5. If start is greater than the length of the relevant value \({ }^{\text {p586 }}\) of the text control, then set it to the length of the relevant value \({ }^{\text {p586 }}\) of the text control.
6. If end is greater than the length of the relevant value \({ }^{\text {p586 }}\) of the text control, then set it to the length of the relevant value \({ }^{\text {p586 }}\) of the text control.
7. Let selection start be the current value of the selectionStart \({ }^{p 587}\) attribute.
8. Let selection end be the current value of the selectionEnd \({ }^{p 587}\) attribute.
9. If start is less than end, delete the sequence of code units within the element's relevant value \({ }^{\text {p586 }}\) starting with the code unit at the starth position and ending with the code unit at the (end-1)th position.
10. Insert the value of the first argument into the text of the relevant value \({ }^{\mathrm{p586}}\) of the text control, immediately before the startth code unit.
11. Let new length be the length of the value of the first argument.
12. Let new end be the sum of start and new length.
13. Run the appropriate set of substeps from the following list:

\section*{\(\hookrightarrow\) If the fourth argument's value is "select"}

Let selection start be start.

Let selection end be new end.
\(\rightarrow\) If the fourth argument's value is "start"
Let selection start and selection end be start.
\(\rightarrow\) If the fourth argument's value is "end"
Let selection start and selection end be new end.
\(\hookrightarrow\) If the fourth argument's value is "preserve"
\(\rightarrow\) If the method has only one argument
1. Let old length be end minus start.
2. Let delta be new length minus old length.
3. If selection start is greater than end, then increment it by delta. (If delta is negative, i.e. the new text is shorter than the old text, then this will decrease the value of selection start.)

Otherwise: if selection start is greater than start, then set it to start. (This snaps the start of the selection to the start of the new text if it was in the middle of the text that it replaced.)
4. If selection end is greater than end, then increment it by delta in the same way.

Otherwise: if selection end is greater than start, then set it to new end. (This snaps the end of the selection to the end of the new text if it was in the middle of the text that it replaced.)
14. Set the selection range \({ }^{p 588}\) with selection start and selection end.

The setRangeText() \({ }^{\text {p588 }}\) method uses the following enumeration:

IDL enum SelectionMode \{
"select",
"start",
"end",
"preserve" // default
\};

\section*{Example}

To obtain the currently selected text, the following JavaScript suffices:
```
var selectionText = control.value.substring(control.selectionStart, control.selectionEnd);
```
...where control is the input \({ }^{\text {p493 }}\) or textarea \({ }^{\mathrm{p} 548}\) element.

\section*{Example}

To add some text at the start of a text control, while maintaining the text selection, the three attributes must be preserved:
```
var oldStart = control.selectionStart;
var oldEnd = control.selectionEnd;
var oldDirection = control.selectionDirection;
var prefix = "http://";
control.value = prefix + control.value;
control.setSelectionRange(oldStart + prefix.length, oldEnd + prefix.length, oldDirection);
```
...where control is the input \({ }^{\text {p493 }}\) or textarea \({ }^{p 548}\) element.

\subsection*{4.10.20 Constraints \(\S^{p 59}\)}

\subsection*{4.10.20.1 Definitions \({ }^{\text {p }}{ }_{0}^{59}\)}

A submittable element \({ }^{\text {p486 }}\) is a candidate for constraint validation except when a condition has barred the element from constraint validation. (For example, an element is barred from constraint validation \({ }^{\text {p590 }}\) if it is an object \({ }^{\text {p373 }}\) element.)

An element can have a custom validity error message defined. Initially, an element must have its custom validity error message \({ }^{\text {p590 }}\) set to the empty string. When its value is not the empty string, the element is suffering from a custom error \({ }^{\text {p591 }}\). It can be set using the setCustomValidity ( ) \({ }^{\text {p593 }}\) method, except for form-associated custom elements \({ }^{\text {p704 }}\). Form-associated custom elements \({ }^{\text {p704 }}\) can have a custom validity error message \({ }^{p 590}\) set via their ElementInternals \({ }^{p 714}\) object's setValidity () \()^{\text {p717 }}\) method. The user agent should use the custom validity error message \({ }^{\text {p590 }}\) when alerting the user to the problem with the control.

An element can be constrained in various ways. The following is the list of validity states that a form control can be in, making the control invalid for the purposes of constraint validation. (The definitions below are non-normative; other parts of this specification define more precisely when each state applies or does not.)

\section*{Suffering from being missing}

When a control has no value \({ }^{\mathrm{p} 566}\) but has a required attribute (input \({ }^{\mathrm{p} 493}\) required \({ }^{\mathrm{p} 523}\), textarea \({ }^{\mathrm{p} 548}\) required \({ }^{\mathrm{p} 551}\) ); or, more complicated rules for select \({ }^{\text {p537 }}\) elements and controls in radio button groups \({ }^{\text {p514 }}\), as specified in their sections.

When the setValidity ( \()^{\text {p717 }}\) method sets valueMissing flag to true for a form-associated custom element \({ }^{\text {p704 }}\).

\section*{Suffering from a type mismatch}

When a control that allows arbitrary user input has a value \({ }^{\text {p566 }}\) that is not in the correct syntax (Email \({ }^{\text {p502 }}, \underline{U R L^{p 501}}\) ).

When the setValidity ( \({ }^{p 717}\) method sets typeMismatch flag to true for a form-associated custom element \({ }^{\text {p704 }}\).

\section*{Suffering from a pattern mismatch}

When a control has a value \({ }^{\text {p566 }}\) that doesn't satisfy the pattern \({ }^{\text {p525 }}\) attribute.

When the setValidity ( \()^{p 717}\) method sets patternMismatch flag to true for a form-associated custom element \({ }^{p 704}\).

\section*{Suffering from being too long}

When a control has a value \({ }^{\text {p566 }}\) that is too long for the form control maxlength attribute \({ }^{\mathrm{p} 569}\) (input \({ }^{\text {p493 }}\) maxlength \({ }^{\text {p522 }}\), textarea \({ }^{\mathrm{p548}}\) maxlength \({ }^{\text {p551 }}\) ).

When the setValidity ( \({ }^{p 717}\) method sets tooLong flag to true for a form-associated custom element \({ }^{\text {p704 }}\).

\section*{Suffering from being too short}

When a control has a value \({ }^{\text {p566 }}\) that is too short for the form control minlength attribute \({ }^{\text {p569 }}\) (input \({ }^{\text {p493 }}\) minlength \({ }^{\text {p522 }}\), textarea \({ }^{\text {p548 }}\) minlength \({ }^{\text {p551 }}\) ).

When the setValidity ( ) \({ }^{\text {p717 }}\) method sets tooShort flag to true for a form-associated custom element \({ }^{\text {p704 }}\).

\section*{Suffering from an underflow}

When a control has a value \({ }^{\mathrm{p566}}\) that is not the empty string and is too low for the min \({ }^{\mathrm{p} 526}\) attribute.
When the setValidity ( ) \({ }^{\text {p717 }}\) method sets rangeUnderflow flag to true for a form-associated custom element \({ }^{\text {p704 }}\).

\section*{Suffering from an overflow}

When a control has a value \({ }^{p 566}\) that is not the empty string and is too high for the max \({ }^{p 526}\) attribute.
When the setValidity() \()^{\text {p717 }}\) method sets rangeOverflow flag to true for a form-associated custom element \({ }^{\text {p704 }}\).

\section*{Suffering from a step mismatch}

When a control has a value \({ }^{\text {p566 }}\) that doesn't fit the rules given by the step \({ }^{p 527}\) attribute.
When the setValidity ( \()^{\mathrm{p} 717}\) method sets stepMismatch flag to true for a form-associated custom element \({ }^{\mathrm{p} 704}\).

\section*{Suffering from bad input}

When a control has incomplete input and the user agent does not think the user ought to be able to submit the form in its current state.

When the setValidity ( \()^{\mathrm{p} 717}\) method sets badInput flag to true for a form-associated custom element \({ }^{\mathrm{p} 704}\).

\section*{Suffering from a custom error}

When a control's custom validity error message \({ }^{\text {p590 }}\) (as set by the element's setCustomValidity () \({ }^{\text {p593 }}\) method or ElementInternals \({ }^{p 714}\) 's setValidity () \({ }^{\mathrm{p} 717}\) method) is not the empty string.

\section*{Note}

An element can still suffer from these states even when the element is disabled \({ }^{p 570}\); thus these states can be represented in the DOM even if validating the form during submission wouldn't indicate a problem to the user.

An element satisfies its constraints if it is not suffering from any of the above validity states \({ }^{\text {p590 }}\).

\subsection*{4.10.20.2 Constraint validation \(\S^{p 59}\)}

When the user agent is required to statically validate the constraints of form \({ }^{\mathrm{p} 886}\) element form, it must run the following steps, which return either a positive result (all the controls in the form are valid) or a negative result (there are invalid controls) along with a (possibly empty) list of elements that are invalid and for which no script has claimed responsibility:
1. Let controls be a list of all the submittable elements \({ }^{\text {p486 }}\) whose form owner \({ }^{\mathrm{p566}}\) is form, in tree order.
2. Let invalid controls be an initially empty list of elements.
3. For each element field in controls, in tree order:
1. If field is not a candidate for constraint validation \({ }^{\mathrm{p} 590}\), then move on to the next element.
2. Otherwise, if field satisfies its constraints \({ }^{\mathrm{p} 591}\), then move on to the next element.
3. Otherwise, add field to invalid controls.
4. If invalid controls is empty, then return a positive result.
5. Let unhandled invalid controls be an initially empty list of elements.
6. For each element field in invalid controls, if any, in tree order:
1. Let notCanceled be the result of firing an event named invalid \({ }^{p 1281}\) at field, with the cancelable attribute initialized to true.
2. If notCanceled is true, then add field to unhandled invalid controls.
7. Return a negative result with the list of elements in the unhandled invalid controls list.

If a user agent is to interactively validate the constraints of \(f\) orm \({ }^{\text {p486 }}\) element form, then the user agent must run the following steps:
1. Statically validate the constraints \({ }^{\mathrm{p591}}\) of form, and let unhandled invalid controls be the list of elements returned if the result was negative.
2. If the result was positive, then return that result.
3. Report the problems with the constraints of at least one of the elements given in unhandled invalid controls to the user.
- User agents may focus one of those elements in the process, by running the focusing steps \({ }^{\text {p776 }}\) for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. For elements that are form-associated custom elements \({ }^{\mathrm{p} 704}\), user agents should use their validation anchor \({ }^{\mathrm{p717}}\) instead, for the purposes of these actions.
- User agents may report more than one constraint violation.
- User agents may coalesce related constraint violation reports if appropriate (e.g. if multiple radio buttons in a group \({ }^{\text {p514 }}\) are marked as required, only one error need be reported).
- If one of the controls is not being rendered \({ }^{\text {p1192 }}\) (e.g. it has the hidden \({ }^{\text {p765 }}\) attribute set) then user agents may report a script error.
4. Return a negative result.

\subsection*{4.10.20.3 The constraint validation API \(\S_{2}^{p 59}\)}

\section*{For web developers (non-normative)}

\section*{element . willValidate \({ }^{\text {p593 }}\)}

Returns true if the element will be validated when the form is submitted; false otherwise.
element . setCustomValidity \({ }^{\text {p593 }}\) (message)
Sets a custom error, so that the element would fail to validate. The given message is the message to be shown to the user when reporting the problem to the user.

If the argument is the empty string, clears the custom error.
element . validity \({ }^{\text {p593 }} \cdot\) valueMissing \(^{\text {p594 }}\)
Returns true if the element has no value but is a required field; false otherwise.
element . validity \({ }^{\text {p593 }}\) • typeMismatch \({ }^{\text {p594 }}\)
Returns true if the element's value is not in the correct syntax; false otherwise.
element . validity \({ }^{\text {p593 }}\). patternMismatch \({ }^{\text {p594 }}\)
Returns true if the element's value doesn't match the provided pattern; false otherwise.
element . validity \({ }^{\mathrm{p} 593}\) •tooLong \({ }^{\text {p594 }}\)
Returns true if the element's value is longer than the provided maximum length; false otherwise.
element . validity \({ }^{\text {p593 }} \cdot\) tooShort \(^{\text {p594 }}\)
Returns true if the element's value, if it is not the empty string, is shorter than the provided minimum length; false otherwise.
element . validity \({ }^{\text {p593 }} \cdot\) rangeUnderflow \({ }^{\text {p594 }}\)
Returns true if the element's value is lower than the provided minimum; false otherwise.
element . validity \({ }^{\text {p593 }} \cdot\) rangeOverflow \(^{\text {p594 }}\)
Returns true if the element's value is higher than the provided maximum; false otherwise.
element . validity \({ }^{\text {p593 }}\). stepMismatch \({ }^{\text {p594 }}\)
Returns true if the element's value doesn't fit the rules given by the step \({ }^{p 527}\) attribute; false otherwise.
element . validity \({ }^{\text {p593 }} \cdot\) badInput \({ }^{\text {p594 }}\)
Returns true if the user has provided input in the user interface that the user agent is unable to convert to a value; false otherwise.
element \(\cdot\) validity \(^{\text {p593 }} \cdot\) customError \({ }^{\text {p594 }}\)
Returns true if the element has a custom error; false otherwise.
element . validity \({ }^{\text {p593 }} \cdot\) valid \(^{\text {p594 }}\)
Returns true if the element's value has no validity problems; false otherwise.
valid \(=\) element . checkValidity \({ }^{\text {p594 }}\) ()
Returns true if the element's value has no validity problems; false otherwise. Fires an invalid \({ }^{\text {p1281 }}\) event at the element in the latter case.
```
valid = element . reportValidity }\mp@subsup{}{}{\mathbf{p595}}(
```

Returns true if the element's value has no validity problems; otherwise, returns false, fires an invalid \({ }^{\text {p1281 }}\) event at the element, and (if the event isn't canceled) reports the problem to the user.

\section*{element . validationMessage \({ }^{\text {p595 }}\)}

Returns the error message that would be shown to the user if the element was to be checked for validity.

The willvalidate attribute's getter must return true, if this element is a candidate for constraint validation \({ }^{\text {p590 }}\), and false otherwise (i.e., false if any conditions are barring it from constraint validation \({ }^{\text {p590 }}\) ).

The willValidate attribute of ElementInternals \({ }^{p 714}\) interface, on getting, must throw a "NotSupportedError" DOMException if the target element \({ }^{\mathrm{p715}}\) is not a form-associated custom element \({ }^{\mathrm{p} 704}\). Otherwise, it must return true if the target element \({ }^{\mathrm{p715}}\) is a candidate for constraint validation \({ }^{\text {D590 }}\), and false otherwise.

The setCustomValidity(message) method, when invoked, must set the custom validity error message \({ }^{\text {p590 }}\) to message.

\section*{Example}

In the following example, a script checks the value of a form control each time it is edited, and whenever it is not a valid value, uses the setCustomValidity () \({ }^{\mathrm{p593}}\) method to set an appropriate message.
```
<label>Feeling: <input name=f type="text" oninput="check(this)"></label>
<script>
    function check(input) {
        if (input.value == "good" ||
                input.value == "fine" ||
                input.value == "tired") {
                input.setCustomValidity('"' + input.value + '" is not a feeling.');
        } else {
            // input is fine -- reset the error message
            input.setCustomValidity('');
        }
}
</script>
```

The validity attribute's getter must return a ValidityState \({ }^{\text {p593 }}\) object that represents the validity states \({ }^{\mathrm{p590}}\) of this element. This object is live \({ }^{\text {p45 }}\).

The validity attribute of ElementInternals \({ }^{\text {p714 }}\) interface, on getting, must throw a "NotSupportedError" DOMException if the target element \({ }^{\mathrm{p715}}\) is not a form-associated custom element \({ }^{\mathrm{p} 704}\). Otherwise, it must return a ValidityState \({ }^{\mathrm{p593}}\) object that represents the validity states \({ }^{\mathrm{p} 590}\) of the target element \({ }^{\mathrm{p} 715}\). This object is live \({ }^{\mathrm{p} 45}\).

IDL [Exposed=Window]
```
interface ValidityState \{
    readonly attribute boolean valueMissing;
    readonly attribute boolean typeMismatch;
    readonly attribute boolean patternMismatch;
    readonly attribute boolean tooLong;
    readonly attribute boolean tooShort;
    readonly attribute boolean rangeUnderflow;
    readonly attribute boolean rangeOverflow;
    readonly attribute boolean stepMismatch;
    readonly attribute boolean badInput;
    readonly attribute boolean customError;
    readonly attribute boolean valid;
\};
```

A ValidityState \({ }^{\text {p593 }}\) object has the following attributes. On getting, they must return true if the corresponding condition given in the following list is true, and false otherwise.
```
valueMissing
```

The control is suffering from being missing \({ }^{\mathrm{p} 590}\).

\section*{typeMismatch}

The control is suffering from a type mismatch \({ }^{\mathrm{p590}}\).
patternMismatch
The control is suffering from a pattern mismatch \({ }^{\mathrm{p} 590}\).
tooLong
The control is suffering from being too long \({ }^{\mathrm{p} 590}\).
tooShort
The control is suffering from being too short \({ }^{\mathrm{p590}}\).
rangeUnderflow
The control is suffering from an underflow \({ }^{\text {p590 }}\).
range0verflow
The control is suffering from an overflow \({ }^{\text {p591 }}\).
stepMismatch
The control is suffering from a step mismatch \({ }^{\text {p591 }}\).
badInput
The control is suffering from bad input \({ }^{\mathrm{p} 591}\).
customError
The control is suffering from a custom error \({ }^{\mathrm{p591}}\).
valid
None of the other conditions are true.

The check validity steps for an element element are:
1. If element is a candidate for constraint validation \({ }^{\mathrm{p} 590}\) and does not satisfy its constraints \({ }^{\text {p591 }}\), then:
1. Fire an event named invalid \({ }^{p 1281}\) at element, with the cancelable attribute initialized to true (though canceling has no effect).
2. Return false.
2. Return true.

The checkValidity () method, when invoked, must run the check validity steps \({ }^{\text {p594 }}\) on this element.

The checkValidity() method of the ElementInternals \({ }^{p 714}\) interface must run these steps:
1. Let element be this ElementInternals \({ }^{p 714}\) 's target element \({ }^{\mathrm{p715}}\).
2. If element is not a form-associated custom element \({ }^{p 704}\), then throw a "NotSupportedError" DOMException.
3. Run the check validity steps \({ }^{\mathrm{p} 594}\) on element.

The report validity steps for an element element are:
1. If element is a candidate for constraint validation \({ }^{\text {p590 }}\) and does not satisfy its constraints \({ }^{\text {p591 }}\), then:
1. Let report be the result of firing an event named invalid \({ }^{p 1281}\) at element, with the cancelable attribute initialized to true.
2. If report is true, then report the problems with the constraints of this element to the user. When reporting the problem with the constraints to the user, the user agent may run the focusing steps \({ }^{\text {p776 }}\) for element, and may change the scrolling position of the document, or perform some other action that brings element to the user's attention. User agents may report more than one constraint violation, if element suffers from multiple problems at
once. If element is not being rendered \({ }^{\text {p1192 }}\), then the user agent may, instead of notifying the user, report the error \(^{\text {p936 }}\) for the running script \({ }^{\text {p936 }}\).
3. Return false.
2. Return true.

The reportValidity () method, when invoked, must run the report validity steps \({ }^{\mathrm{p} 594}\) on this element.
The reportValidity() method of the ElementInternals \({ }^{\mathrm{p} 714}\) interface must run these steps:
1. Let element be this ElementInternals \({ }^{\text {p714 }}\) 's target element \({ }^{p 715}\).
2. If element is not a form-associated custom element \({ }^{\text {p704 }}\), then throw a "NotSupportedError" DOMException.
3. Run the report validity steps \({ }^{\mathrm{p} 594}\) on element.

The validationMessage attribute's getter must run these steps:
1. If this element is not a candidate for constraint validation \({ }^{\mathrm{p590}}\) or if this element satisfies its constraints \({ }^{\mathrm{p5911}}\), then return the empty string.
2. Return a suitably localized message that the user agent would show the user if this were the only form control with a validity constraint problem. If the user agent would not actually show a textual message in such a situation (e.g., it would show a graphical cue instead), then return a suitably localized message that expresses (one or more of) the validity constraint(s) that the control does not satisfy. If the element is a candidate for constraint validation \({ }^{\mathrm{p} 590}\) and is suffering from a custom error \({ }^{\mathrm{p591}}\), then the custom validity error message \({ }^{\mathrm{p590}}\) should be present in the return value.

\subsection*{4.10.20.4 Security \({ }_{5}{ }_{5}^{p 59}\)}

Servers should not rely on client-side validation. Client-side validation can be intentionally bypassed by hostile users, and unintentionally bypassed by users of older user agents or automated tools that do not implement these features. The constraint validation features are only intended to improve the user experience, not to provide any kind of security mechanism.

\subsection*{4.10.21 Form submission \(\S^{p 59}\)}

\subsection*{4.10.21.1 Introduction \({ }^{\text {p599 }}\)}

This section is non-normative.
When a form is submitted, the data in the form is converted into the structure specified by the enctype \({ }^{\text {p572 }}\), and then sent to the destination specified by the action \({ }^{p 571}\) using the given method \({ }^{p 571}\).

For example, take the following form:
```
<form action="/find.cgi" method=get>
    <input type=text name=t>
    <input type=search name=q>
    <input type=submit>
</form>
```

If the user types in "cats" in the first field and "fur" in the second, and then hits the submit button, then the user agent will load /find.cgi?t=cats\&q=fur.

On the other hand, consider this form:
```
<form action="/find.cgi" method=post enctype="multipart/form-data">
    <input type=text name=t>
    <input type=search name=q>
    <input type=submit>
</form>
```

Given the same user input, the result on submission is quite different: the user agent instead does an HTTP POST to the given URL, with as the entity body something like the following text:
```
-----kYFrd4jNJEgCervE
Content-Disposition: form-data; name="t"
cats
-----kYFrd4jNJEgCervE
Content-Disposition: form-data; name="q"
fur
-----kYFrd4jNJEgCervE--
```

\subsection*{4.10.21.2 Implicit submission \(\S^{p 59}\)}

A form \({ }^{\text {p486 }}\) element's default button is the first submit button \({ }^{\text {p486 }}\) in tree order whose form owner \({ }^{\text {p566 }}\) is that form \({ }^{\text {p486 }}\) element.
If the user agent supports letting the user submit a form implicitly (for example, on some platforms hitting the "enter" key while a text control is focused \({ }^{\text {p771 }}\) implicitly submits the form), then doing so for a form, whose default button \({ }^{\mathrm{p} 596}\) has activation behavior and is not disabled \({ }^{\text {p570 }}\), must cause the user agent to fire a click event \({ }^{\text {p965 }}\) at that default button \({ }^{\text {p596 }}\).

\section*{Note}

There are pages on the web that are only usable if there is a way to implicitly submit forms, so user agents are strongly encouraged to support this.

If the form has no submit button \({ }^{\text {p486 }}\), then the implicit submission mechanism must do nothing if the form has more than one field that blocks implicit submission, and must submit \({ }^{p 596}\) the form \({ }^{\text {p486 }}\) element from the form \({ }^{\text {p486 }}\) element itself otherwise.

For the purpose of the previous paragraph, an element is a field that blocks implicit submission of a form \({ }^{\text {p486 }}\) element if it is an input \({ }^{\text {p493 }}\) element whose form owner \({ }^{\text {p566 }}\) is that form \({ }^{\text {p486 }}\) element and whose type \({ }^{\text {p495 }}\) attribute is in one of the following states: Text \({ }^{\text {p499 }}\), Search \({ }^{\text {p499 }}\), URL \({ }^{\text {p501 }}\), Telephone \({ }^{\text {p500 }}\), Email \({ }^{\text {p502 }}\), Password \({ }^{\text {p503 }}\), Date \({ }^{\text {p504 }}\), Month \({ }^{\text {p505 }}\), Week \({ }^{\text {p506 }}\), Time \({ }^{\text {p507 }}\), Local Date and Time \({ }^{\text {p508 }}\), Number \({ }^{\text {p509 }}\)

\subsection*{4.10.21.3 Form submission algorithm \(\S^{p 59}\)}

Each form \({ }^{\text {p486 }}\) element has a constructing entry list boolean, initially false.
Each form \({ }^{p 486}\) element has a firing submission events boolean, initially false.
When a form \({ }^{\text {p486 }}\) element form is submitted from an element submitter (typically a button), optionally with a submitted from submit () \({ }^{\text {p490 }}\) method flag set, the user agent must run the following steps:
1. If form cannot navigate \({ }^{\text {p289 }}\), then return.
2. If form's constructing entry list \({ }^{\mathrm{p} 996}\) is true, then return.
3. Let form document be form's node document.
4. If form document's active sandboxing flag set \({ }^{\mathrm{p844}}\) has its sandboxed forms browsing context flag \({ }^{\mathrm{p842}}\) set, then return.
5. Let form browsing context be the browsing context \({ }^{\text {p811 }}\) of form document.
6. If the submitted from submit () \({ }^{\text {p499 }}\) method flag is not set, then:
1. If form's firing submission events \({ }^{\mathrm{p} 596}\) is true, then return.
2. Set form's firing submission events \({ }^{\text {p596 }}\) to true.
3. If the submitter element's no-validate state \({ }^{\mathrm{p} 572}\) is false, then interactively validate the constraints \({ }^{\mathrm{p} 591}\) of form and examine the result. If the result is negative (i.e., the constraint validation concluded that there were invalid fields and probably informed the user of this), then:
1. Set form's firing submission events \({ }^{\mathrm{p} 596}\) to false.
2. Return.
4. Let submitterButton be null if submitter is form. Otherwise, let submitterButton be submitter.
5. Let continue be the result of firing an event named submit \({ }^{\text {p1282 }}\) at form using SubmitEvent \({ }^{\text {p683 }}\), with the submitter \({ }^{p 603}\) attribute initialized to submitterButton, the bubbles attribute initialized to true, and the cancelable attribute initialized to true.
6. Set form's firing submission events \({ }^{\text {p596 }}\) to false.
7. If continue is false, then return.
8. If form cannot navigate \({ }^{\text {p289 }}\), then return.
```
Note
    Cannot navigate p289}\mathrm{ is run again as dispatching the submit }\mp@subsup{}{}{p1282}\mathrm{ event could have changed the outcome.
```
7. Let encoding be the result of picking an encoding for the form \({ }^{\text {p601 }}\).
8. Let entry list be the result of constructing the entry list \({ }^{\mathrm{p599}}\) with form, submitter, and encoding.
9. If form cannot navigate \({ }^{\text {p289 }}\), then return.

\section*{Note}

Cannot navigate \({ }^{p 289}\) is run again as dispatching the formdata \({ }^{\text {p1281 }}\) event in constructing the entry list \({ }^{p 599}\) could have changed the outcome.
10. Let action be the submitter element's action \({ }^{\text {p571 }}\).
11. If action is the empty string, let action be the URL of the form document.
12. Parse \({ }^{\text {p89 }}\) the URL action, relative to the submitter element's node document. If this fails, return.
13. Let parsed action be the resulting URL record \({ }^{\text {p89 }}\).
14. Let scheme be the scheme of parsed action.
15. Let enctype be the submitter element's enctype \({ }^{\text {p572 }}\).
16. Let method be the submitter element's method \({ }^{\mathrm{p} 571}\).
17. Let target be the submitter element's formtarget \({ }^{\text {p572 }}\) attribute value, if the element is a submit button \({ }^{\text {p486 }}\) and has such an attribute. Otherwise, let it be the result of getting an element's target \({ }^{\text {p156 }}\) given submitter's form owner \({ }^{\text {p566 }}\).
18. Let noopener be the result of getting an element's noopener \({ }^{p 289}\) with form and targetAttributeValue.
19. Let target browsing context and windowType be the result of applying the rules for choosing a browsing context \({ }^{\text {p820 }}\) using target, form browsing context, and noopener.
20. Let historyHandling be "replace \({ }^{\text {p866" }}\) if windowType is either "new and unrestricted" or "new with no opener"; otherwise "default \({ }^{\text {p866" }}\).
21. If target browsing context is null, then return.
22. If form document has not yet completely loaded \({ }^{\text {p885 }}\) and the submitted from submit( ) \()^{\text {p490 }}\) method flag is set, then set historyHandling to "replace \({ }^{\text {p866". }}\)
23. If the value of method is dialog \({ }^{\mathrm{p} 571}\) then jump to the submit dialog \({ }^{\mathrm{p} 599}\) steps.

Otherwise, select the appropriate row in the table below based on the value of scheme as given by the first cell of each row. Then, select the appropriate cell on that row based on the value of method as given in the first cell of each column. Then, jump to the steps named in that cell and defined below the table.
\begin{tabular}{|c|c|c|}
\hline & GET \({ }^{\text {p571 }}\) & POST \(^{\text {p571 }}\) \\
\hline http & Mutate action URL \({ }^{\text {p598 }}\) & Submit as entity body \({ }^{\text {p598 }}\) \\
\hline https & Mutate action URL \({ }^{\text {p598 }}\) & Submit as entity body \({ }^{\text {p598 }}\) \\
\hline ftp & Get action URL \({ }^{\text {p598 }}\) & Get action URL \({ }^{\text {p598 }}\) \\
\hline javascript & Get action URL \({ }^{\text {p598 }}\) & Get action URL \({ }^{\text {p598 }}\) \\
\hline
\end{tabular}
\begin{tabular}{l|l|l} 
& \multicolumn{1}{|c|}{ GET \(^{\text {p571 }}\)} & \multicolumn{1}{c}{ POST \(^{\text {p571 }}\)} \\
\hline data & Mutate action URL \({ }^{\text {p598 }}\) & Get action URL \({ }^{\text {p598 }}\) \\
\hline mailto & Mail with headers \(^{\text {p599 }}\) & Mail as body \({ }^{\text {p599 }}\) \\
\hline
\end{tabular}

If scheme is not one of those listed in this table, then the behavior is not defined by this specification. User agents should, in the absence of another specification defining this, act in a manner analogous to that defined in this specification for similar schemes.

Each form \({ }^{\text {p486 }}\) element has a planned navigation, which is either null or a task \({ }^{\text {p944 }}\); when the form \({ }^{\text {p486 }}\) is first created, its planned navigation \({ }^{\text {p598 }}\) must be set to null. In the behaviors described below, when the user agent is required to plan to navigate to a particular resource destination, it must run the following steps:
1. If destination is not a request, then set destination to a new request whose URL is destination.
2. If the form \({ }^{\text {p486 }}\) element's link types \({ }^{\text {p294 }}\) include the noreferrer \({ }^{\text {p304 }}\) keyword, then set destination's referrer to "noreferrer".
3. If the form \({ }^{\text {p486 }}\) has a non-null planned navigation \({ }^{\text {p598 }}\), remove it from its task queue \({ }^{\text {p944 }}\).
4. Queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the form \({ }^{\text {p486 }}\) element and the following steps:
1. Set the form \({ }^{\text {p486 }}\) 's planned navigation \({ }^{\text {p598 }}\) to null.
2. Navigate \({ }^{\text {p866 }}\) target browsing context to destination, with historyHandling \({ }^{\text {p866 }}\) set to historyHandling.
5. Set the form \({ }^{\mathrm{p} 486}\) 's planned navigation \({ }^{\mathrm{p} 598}\) to the just-queued task \({ }^{\mathrm{p} 944}\).

The behaviors are as follows:

\section*{Mutate action URL}

Let query be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.
Set parsed action's query component to query.
Plan to navigate \({ }^{\text {p598 }}\) to parsed action.

\section*{Submit as entity body}

Switch on enctype:
\(\rightarrow\) application/x-www-form-urlencoded \({ }^{\text {p572 }}\)
Let body be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.
Set body to the result of encoding body.
Let MIME type be "application/x-www-form-urlencoded".
\(\rightarrow\) multipart/form-data \({ }^{\text {p572 }}\)
Let body be the result of running the multipart/form-data encoding algorithm \({ }^{\text {p602 }}\) with entry list and encoding.
Let MIME type be the concatenation of the string "multipart/form-data;", a U+0020 SPACE character, the string
"boundary=", and the multipart/form-data boundary string \({ }^{\text {p602 }}\) generated by the multipart/form-data
encoding algorithm \({ }^{\text {p602 }}\).
\(\rightarrow\) text/plain \({ }^{\text {p572 }}\)
Let body be the result of running the text/plain encoding algorithm \({ }^{\text {p602 }}\) with entry list.

Set body to the result of encoding body using encoding.
Let MIME type be "text/plain".
Plan to navigate \({ }^{\mathrm{p} 598}\) to a new request whose url is parsed action, method is method, header list consists of 'ContentType`/MIME type, and body is body.

\section*{Get action URL}

Plan to navigate \({ }^{\text {p598 }}\) to parsed action.
entry list is discarded.

\section*{Mail with headers}

Let headers be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.
Replace occurrences of U+002B PLUS SIGN characters (+) in headers with the string "\%20".

Set parsed action's query to headers.
Plan to navigate \({ }^{\mathrm{p} 598}\) to parsed action.

\section*{Mail as body}

Switch on enctype:
\(\rightarrow\) text/plain \({ }^{\text {p572 }}\)
Let body be the result of running the text/plain encoding algorithm \({ }^{\text {p602 }}\) with entry list.
Set body to the result of running UTF-8 percent-encode on body using the default encode set. [URL] \({ }^{\text {p1292 }}\)

\section*{\(\hookrightarrow\) Otherwise}

Let body be the result of running the application/x-www-form-urlencoded serializer with entry list and encoding.
If parsed action's query is null, then set it to the empty string.
If parsed action's query is not the empty string, then append a single \(\mathrm{U}+0026\) AMPERSAND character \((\&)\) to it.

Append "body=" to parsed action's query.
Append body to parsed action's query.
Plan to navigate \({ }^{\text {p598 }}\) to parsed action.

\section*{Submit dialog}

Let subject be the nearest ancestor dialog \({ }^{\text {p610 }}\) element of form, if any.
If there isn't one, or if it does not have an open \({ }^{\text {p611 }}\) attribute, do nothing. Otherwise, proceed as follows:
If submitter is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Image Button \({ }^{\text {p518 }}\) state, then let result be the string formed by concatenating the selected coordinate \({ }^{\mathrm{p519}}\) 's \(x\)-component, expressed as a base-ten number using ASCII digits, a U+002C COMMA character (, ), and the selected coordinate \({ }^{\text {p519 }}\) 's \(y\)-component, expressed in the same way as the \(x\)-component.

Otherwise, if submitter has a value \({ }^{\mathrm{p} 566}\), then let result be that value \({ }^{\mathrm{p} 566}\).
Otherwise, there is no result.
Then, close the dialog \({ }^{\mathrm{p} 612}\) subject. If there is a result, let that be the return value.

\subsection*{4.10.21.4 Constructing the entry list \(\$^{p 59}\)}

The algorithm to construct the entry list given a form, an optional submitter, and an optional encoding, is as follows. If not specified otherwise, submitter is null.
1. If form's constructing entry list \({ }^{\text {p596 }}\) is true, then return null.
2. Set form's constructing entry list \({ }^{\mathrm{p} 596}\) to true.
3. Let controls be a list of all the submittable elements \({ }^{\text {p486 }}\) whose form owner \({ }^{p 566}\) is form, in tree order.
4. Let entry list be a new empty list of entries.
5. For each element field in controls, in tree order:
1. If any of the following is true:
- The field element has a datalist \({ }^{p 543}\) element ancestor.
- The field element is disabled \({ }^{\mathrm{p} 570}\).
- The field element is a button \({ }^{\text {p486 }}\) but it is not submitter.
- The field element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Checkbox \({ }^{\text {p513 }}\) state and whose checkedness \({ }^{\text {p566 }}\) is false.
- The field element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Radio Button \({ }^{\text {p514 }}\) state and whose checkedness \({ }^{\text {p566 }}\) is false.
- The field element is an object \({ }^{\mathrm{p} 373}\) element that is not using a plugin \({ }^{\mathrm{p} 45}\).

Then continue.
2. If the field element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Image Button \({ }^{\mathrm{p} 518}\) state, then:
1. If the field element has a name \({ }^{p 568}\) attribute specified and its value is not the empty string, let name be that value followed by a single U+002E FULL STOP character (.). Otherwise, let name be the empty string.
2. Let namex be the string consisting of the concatenation of name and a single U+0078 LATIN SMALL LETTER \(X\) character ( x ).
3. Let namey be the string consisting of the concatenation of name and a single U+0079 LATIN SMALL LETTER Y character (y).
4. The field element is submitter, and before this algorithm was invoked the user indicated a coordinate \({ }^{\text {p519 }}\). Let \(x\) be the \(x\)-component of the coordinate selected by the user, and let \(y\) be the \(y\)-component of the coordinate selected by the user.
5. Append an entry \({ }^{\mathrm{p} 601}\) to entry list with namex and \(x\).
6. Append an entry \({ }^{\text {p601 }}\) to entry list with namey and \(y\).
7. Continue.
3. If the field is a form-associated custom element \({ }^{\text {p704 }}\), then perform the entry construction algorithm \({ }^{\text {p717 }}\) given field and entry list, then continue.
4. If either the field element does not have a name \({ }^{p 568}\) attribute specified, or its name \({ }^{p 568}\) attribute's value is the empty string, then continue.
5. Let name be the value of the field element's name \({ }^{p 568}\) attribute.
6. If the field element is a select \({ }^{p 537}\) element, then for each option \({ }^{\text {p545 }}\) element in the select \({ }^{p 537}\) element's list of options \({ }^{\text {p539 }}\) whose selectedness \({ }^{\text {p547 }}\) is true and that is not disabled \({ }^{\mathrm{p546}}\), append an entry \({ }^{\mathrm{p} 601}\) to entry list with name and the value \({ }^{\text {p546 }}\) of the option \({ }^{\text {p545 }}\) element.
7. Otherwise, if the field element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Checkbox \({ }^{\text {p513 }}\) state or the Radio Button \({ }^{\text {p514 }}\) state, then:
1. If the field element has a value \({ }^{\text {p497 }}\) attribute specified, then let value be the value of that attribute; otherwise, let value be the string "on".
2. Append an entry \({ }^{\mathrm{p} 601}\) to entry list with name and value.
8. Otherwise, if the field element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the File Upload \({ }^{\text {p515 }}\) state, then:
1. If there are no selected files \({ }^{\mathrm{p} 515}\), then append an entry \({ }^{\mathrm{p} 601}\) to entry list with name and a new File object with an empty name, application/octet-stream as type, and an empty body.
2. Otherwise, for each file in selected files \({ }^{\mathrm{p515}}\), append an entry \({ }^{\mathrm{p601}}\) to entry list with name and a File object representing the file.
9. Otherwise, if the field element is an object \({ }^{\mathrm{p} 73}\) element: try to obtain a form submission value from the plugin \({ }^{\text {p45 }}\), and if that is successful, append an entry \({ }^{\mathrm{p} 601}\) to entry list with name and the returned form submission value.
10. Otherwise, if the field element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Hidden \({ }^{\text {p499 }}\) state and name is "_charset \({ }^{\mathrm{p} 568 \text { ": }}\)
1. Let charset be the name of encoding if encoding is given, and "UTF-8" otherwise.
2. Append an entry \({ }^{\mathrm{p601}}\) to entry list with name and charset.
11. Otherwise, if the field element is a textarea \({ }^{\mathrm{p548}}\) element, append an entry \({ }^{\mathrm{p} 601}\) to entry list with name and the value \({ }^{p 566}\) of the field element, and the prevent line break normalization flag set.

\section*{Note}

In the case of the value \({ }^{p 566}\) of textarea \({ }^{p 548}\) elements, the line break normalization is already performed during the conversion of the control's raw value \({ }^{p 549}\) into the control's value \({ }^{p 566}\) (which also performs any necessary line wrapping).
12. Otherwise, append an entry \({ }^{\mathrm{p} 601}\) to entry list with name and the value \({ }^{\mathrm{p566}}\) of the field element.
13. If the element has a dirname \({ }^{\mathrm{p} 568}\) attribute, and that attribute's value is not the empty string, then:
1. Let dirname be the value of the element's dirname \({ }^{p 568}\) attribute.
2. Let dir be the string " \(l t r\) " if the directionality \({ }^{p 142}\) of the element is ' \(\operatorname{lt}{ }^{p 142}\) ', and "rtl" otherwise (i.e., when the directionality \({ }^{p 142}\) of the element is ' \(\mathrm{rt} \mathrm{l}^{\mathrm{pl42}}\) ').
3. Append an entry \({ }^{\mathrm{p} 601}\) to entry list with dirname and dir.

\section*{Note}

An element can only have a dirname \({ }^{\text {p568 }}\) attribute if it is a textarea \({ }^{\text {p548 }}\) element or an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in either the Text \({ }^{\text {p499 }}\) state or the Search \({ }^{\text {p499 }}\) state.
6. Let form data be a new FormData object associated with entry list.
7. Fire an event named formdata \({ }^{p 1281}\) at form using FormDataEvent \({ }^{p 693}\), with the formData \({ }^{\text {p603 }}\) attribute initialized to form data and the bubbles attribute initialized to true.
8. Set form's constructing entry list \({ }^{\text {p596 }}\) to false.
9. Return a clone of entry list.

To append an entry to entry list, given name, value, and optional prevent line break normalization flag, run these steps:
1. For name, replace every occurrence of \(U+000 \mathrm{D}(\mathrm{CR})\) not followed by \(\mathrm{U}+000 \mathrm{~A}(\mathrm{LF})\), and every occurrence of \(U+000 \mathrm{~A}\) (LF) not preceded by \(U+000 \mathrm{D}(C R)\), by a string consisting of a \(U+000 \mathrm{D}(C R)\) and \(U+000 \mathrm{~A}\) (LF).
2. Replace name with the result of converting to a sequence of Unicode scalar values.
3. If value is not a File object, then:
1. If the prevent line break normalization flag is unset, then replace every occurrence of \(U+000 \mathrm{D}(\mathrm{CR})\) not followed by \(U+000 \mathrm{~A}(L F)\), and every occurrence of \(U+000 \mathrm{~A}\) (LF) not preceded by \(U+000 \mathrm{D}(\mathrm{CR})\) in value, by a string consisting of a U+000D (CR) and U+000A (LF).
2. Replace value with the result of converting to a sequence of Unicode scalar values.
4. Create an entry with name and value, and append it to entry list.

\subsection*{4.10.21.5 Selecting a form submission encoding \(\S_{1}^{\text {p60 }}\)}

If the user agent is to pick an encoding for a form, it must run the following steps:
1. Let encoding be the document's character encoding.
2. If the form \({ }^{\text {p486 }}\) element has an accept-charset \({ }^{\mathrm{p} 487}\) attribute, set encoding to the return value of running these substeps:
1. Let input be the value of the form \({ }^{\text {p486 }}\) element's \(\underline{\text { accept-charset } t^{p 487}}\) attribute.
2. Let candidate encoding labels be the result of splitting input on ASCII whitespace.
3. Let candidate encodings be an empty list of character encodings.
4. For each token in candidate encoding labels in turn (in the order in which they were found in input), get an encoding for the token and, if this does not result in failure, append the encoding to candidate encodings.
5. If candidate encodings is empty, return UTF-8.
6. Return the first encoding in candidate encodings.
3. Return the result of getting an output encoding from encoding.

\subsection*{4.10.21.6 URL-encoded form data \(\S^{\text {p60 }}\)}

See URL for details on application/x-www-form-urlencoded. [URL] \({ }^{\text {p1292 }}\)

\subsection*{4.10.21.7 Multipart form data \(\S^{p 60}\)}

The multipart/form-data encoding algorithm, given an entry list and encoding, is as follows:
1. Let result be the empty string.
2. For each entry in entry list:
1. For each character in the entry's name and value that cannot be expressed using the selected character encoding, replace the character by a string consisting of a U+0026 AMPERSAND character ( \(\&\) ), a U+0023 NUMBER SIGN character (\#), one or more ASCII digits representing the code point of the character in base ten, and finally a U+003B (;).
3. Encode the (now mutated) entry list using the rules described by RFC 7578, Returning Values from Forms: multipart/formdata, and return the resulting byte stream. [RFC7578] \({ }^{\text {p1291 }}\)

Each entry in entry list is a field, the name of the entry is the field name and the value of the entry is the field value.
The order of parts must be the same as the order of fields in entry list. Multiple entries with the same name must be treated as distinct fields.

The parts of the generated multipart/form-data \({ }^{\text {p1283 }}\) resource that correspond to non-file fields must not have a `contentType \({ }^{\text {p90. }}\). header specified. Their names and values must be encoded using the character encoding selected above.

File names included in the generated multipart/form-data \({ }^{\text {p1283 }}\) resource (as part of file fields) must use the character encoding selected above, though the precise name may be approximated if necessary (e.g. newlines could be removed from file names, quotes could be changed to "\%22", and characters not expressible in the selected character encoding could be replaced by other characters).

The boundary used by the user agent in generating the return value of this algorithm is the multipart/form-data boundary string. (This value is used to generate the MIME type of the form submission payload generated by this algorithm.)

For details on how to interpret multipart/form-data \({ }^{\text {p1283 }}\) payloads, see RFC 7578. [RFC7578] \({ }^{\text {p1291 }}\)

\subsection*{4.10.21.8 Plain text form data \(\S^{p 60}\)}

The text/plain encoding algorithm, given an entry list, is as follows:
1. Let result be the empty string.
2. For each entry in entry list:
1. If the entry's value is a File object, then set its value to the File object's name.
2. Append the entry's name to result.
3. Append a single U+003D EQUALS SIGN character (=) to result.
4. Append the entry's value to result.
5. Append a U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) character pair to result.
3. Return result.

Payloads using the text/plain format are intended to be human readable. They are not reliably interpretable by computer, as the format is ambiguous (for example, there is no way to distinguish a literal newline in a value from the newline at the end of the value).
4.10.21.9 The SubmitEvent \({ }^{\text {p603 }}\) interface \(\S^{\text {p } 60}\)

IDL [Exposed=Window]
interface SubmitEvent : Event \{ constructor(DOMString type, optional SubmitEventInit eventInitDict = \{\}); readonly attribute HTMLElement? submitter;
\};
dictionary SubmitEventInit : EventInit \{ HTMLElement? submitter = null;
```
};
```

\section*{For web developers (non-normative)}

\section*{event . submitter \({ }^{\text {p603 }}\)}

Returns the element representing the submit button \({ }^{\text {p486 }}\) that triggered the form submission \({ }^{\text {p595 }}\), or null if the submission was not triggered by a button.

The submitter attribute must return the value it was initialized to.

\subsection*{4.10.21.10 The FormDataEvent \({ }^{p 603}\) interface \(\S_{3}^{\text {p60 }}\)}

IDL [Exposed=Window]
interface FormDataEvent : Event \{ constructor(DOMString type, FormDataEventInit eventInitDict); readonly attribute FormData formData;
\};
dictionary FormDataEventInit : EventInit \{
required FormData formData;
\};

\section*{For web developers (non-normative)}

\section*{event . formData \({ }^{\text {p603 }}\)}

Returns a FormData object representing names and values of elements associated to the target form \({ }^{\text {p486 }}\). Operations on the FormData object will affect form data to be submitted.

The formData attribute must return the value it was initialized to. It represents a FormData object associated to the entry list that is constructed \({ }^{\text {p599 }}\) when the form \({ }^{\text {p486 }}\) is submitted.

\subsection*{4.10.22 Resetting a form \(\underbrace{\text { p6o }}_{3}\)}

When a form \({ }^{\text {p486 }}\) element form is reset, run these steps:
1. Let reset be the result of firing an event named reset \({ }^{\text {p1282 }}\) at form, with the bubbles and cancelable attributes initialized to true.
2. If reset is true, then invoke the reset algorithm \({ }^{\text {p604 }}\) of each resettable element \({ }^{\text {p486 }}\) whose form owner \({ }^{\text {p566 }}\) is form.

Each resettable element \({ }^{\text {p486 }}\) defines its own reset algorithm. Changes made to form controls as part of these algorithms do not count as changes caused by the user (and thus, e.g., do not cause input \({ }^{p 1281}\) events to fire).

\subsection*{4.11 Interactive elements \(\S^{p 60}\)}
4.11.1 The details element \(\S^{p 60}\)

Categories \({ }^{\text {p128 }}\) :
Flow content \({ }^{\text {p131 }}\).
Sectioning root \({ }^{\text {p199 }}\).
Interactive content \({ }^{\text {p132 }}\).
Palpable content \({ }^{\text {p133 }}\).
Contexts in which this element can be used \({ }^{\text {p128 }}\) :
Where flow content \({ }^{\text {p131 }}\) is expected.

\section*{Content model \({ }^{\text {p128 }}\) :}

One summary \({ }^{\mathrm{p} 607}\) element followed by flow content \({ }^{\text {p131 }}\).
Tag omission in text/html \({ }^{\text {p128 }}\) :
Neither tag is omissible.
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{\text {p136 }}\)
open \({ }^{\text {p604 }}\) - Whether the details are visible
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
DOM interface \({ }^{\text {p129 }}\) :
IDL [Exposed=Window]
interface HTMLDetailsElement : HTMLElement \{
[HTMLConstructor] constructor();
[CEReactions] attribute boolean open;
\};

The details \({ }^{p 604}\) element represents \({ }^{\text {p123 }}\) a disclosure widget from which the user can obtain additional information or controls.
```
Note
    The details}\mp@subsup{}{}{p604}\mathrm{ element is not appropriate for footnotes. Please see the section on footnotes p721 for details on how to mark up
    footnotes.
```

The first summary \({ }^{p 607}\) element child of the element, if any, represents \({ }^{\text {p123 }}\) the summary or legend of the details. If there is no child summary \({ }^{\text {p607 }}\) element, the user agent should provide its own legend (e.g. "Details").

The rest of the element's contents represents \({ }^{\text {p123 }}\) the additional information or controls.
The open content attribute is a boolean attribute \({ }^{\mathrm{p} 67}\). If present, it indicates that both the summary and the additional information is to be shown to the user. If the attribute is absent, only the summary is to be shown.

When the element is created, if the attribute is absent, the additional information should be hidden; if the attribute is present, that information should be shown. Subsequently, if the attribute is removed, then the information should be hidden; if the attribute is added, the information should be shown.

The user agent should allow the user to request that the additional information be shown or hidden. To honor a request for the details to be shown, the user agent must set the open \({ }^{p 664}\) attribute on the element to the empty string. To honor a request for the information to be hidden, the user agent must remove the open \({ }^{\text {p6e4 }}\) attribute from the element.

\section*{Note}

This ability to request that additional information be shown or hidden may simply be the activation behavior of the appropriate summary \({ }^{\text {p607 }}\) element, in the case such an element exists. However, if no such element exists, user agents can still provide this ability through some other user interface affordance.

Whenever the open \({ }^{\text {p604 }}\) attribute is added to or removed from a details \({ }^{\text {p664 }}\) element, the user agent must queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given then details \({ }^{\text {p604 }}\) element that runs the following steps, which are known as the details notification task steps, for this details \({ }^{p 604}\) element:
1. If another task \({ }^{\text {p944 }}\) has been queued \({ }^{p 946}\) to run the details notification task steps \({ }^{\mathrm{p} 605}\) for this details \({ }^{\mathrm{p} 604}\) element, then return.

\section*{Note}

When the open \({ }^{\text {p604 }}\) attribute is toggled several times in succession, these steps essentially get coalesced so that only one event is fired.
2. Fire an event named toggle \({ }^{p 1282}\) at the details \({ }^{p 604}\) element.

The open IDL attribute must reflect \({ }^{\text {p94 }}\) the open \({ }^{\text {p604 }}\) content attribute.

\section*{Example}

The following example shows the details \({ }^{\text {p604 }}\) element being used to hide technical details in a progress report.
```
<section class="progress window">
    <hl>Copying "Really Achieving Your Childhood Dreams"</h1>
    <details>
        <summary>Copying... <progress max="375505392" value="97543282"></progress> 25%</summary>
        <dl>
        <dt>Transfer rate:</dt> <dd>452KB/s</dd>
        <dt>Local filename:</dt> <dd>/home/rpausch/raycd.m4v</dd>
        <dt>Remote filename:</dt> <dd>/var/www/lectures/raycd.m4v</dd>
        <dt>Duration:</dt> <dd>01:16:27</dd>
        <dt>Color profile:</dt> <dd>SD (6-1-6)</dd>
        <dt>Dimensions:</dt> <dd>320\times240</dd>
        </dl>
    </details>
</section>
```

\section*{Example}

The following shows how a details \({ }^{\text {p604 }}\) element can be used to hide some controls by default:
```
<details>
    <summary><label for=fn>Name & Extension:</label></summary>
    <p><input type=text id=fn name=fn value="Pillar Magazine.pdf">
    <p><label><input type=checkbox name=ext checked> Hide extension</label>
</details>
```

One could use this in conjunction with other details \({ }^{p 604}\) in a list to allow the user to collapse a set of fields down to a small set of headings, with the ability to open each one.

In these examples, the summary really just summarizes what the controls can change, and not the actual values, which is less than ideal.

\section*{Example}

Because the open \({ }^{p 604}\) attribute is added and removed automatically as the user interacts with the control, it can be used in CSS to style the element differently based on its state. Here, a style sheet is used to animate the color of the summary when the element is opened or closed:
```
<style>
    details > summary { transition: color 1s; color: black; }
details[open] > summary { color: red; }
</style>
<details>
    <summary>Automated Status: Operational</summary>
    <p>Velocity: 12m/s</p>
```
```
<p>Direction: North</p>
```
</details>

\section*{}

\section*{Categories \({ }^{\text {p128 }}\) :}

None.
Contexts in which this element can be used \({ }^{\text {p128 }}\) :
As the first child of a details \({ }^{\text {p604 }}\) element.
Content model \({ }^{\text {p128 }}\) :
Phrasing content \({ }^{\mathrm{p} 132}\), optionally intermixed with heading content \({ }^{\mathrm{p} 132}\).
Tag omission in text/html \({ }^{\text {p128 }}\) :
Neither tag is omissible.
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{\text {p136 }}\)
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
DOM interface \({ }^{\text {p129 }}\) :
Uses HTMLElement \({ }^{\text {p124 }}\).
The summary \({ }^{p 607}\) element represents \({ }^{\text {p123 }}\) a summary, caption, or legend for the rest of the contents of the summary \({ }^{p 607}\) element's parent details \({ }^{\text {p604 }}\) element, if any.

A summary \({ }^{\text {p607 }}\) element is a summary for its parent details if the following algorithm returns true:
1. If this summary \({ }^{\text {p607 }}\) element has no parent, then return false.
2. Let parent be this summary \({ }^{p 697}\) element's parent.
3. If parent is not a details \({ }^{\text {p604 }}\) element, then return false.
4. If parent's first summary \({ }^{\text {p607 }}\) element child is not this summary \({ }^{\text {p687 }}\) element, then return false.
5. Return true.

The activation behavior of summary \({ }^{\text {p607 }}\) elements is to run the following steps:
1. If this summary \({ }^{p 607}\) element is not the summary for its parent details \({ }^{p 607}\), then return.
2. Let parent be this summary \({ }^{\mathrm{p} 667}\) element's parent.
3. If the open \(n^{p 604}\) attribute is present on parent, then remove it. Otherwise, set parent's open \({ }^{\text {p664 }}\) attribute to the empty string.

Note
This will then run the details notification task steps \({ }^{p 605}\).

\subsection*{4.11.3 Commands \(\S^{\text {p60 }}\)}

\subsection*{4.11.3.1 Facets \({ }_{7}^{8 p 60}\)}

A command is the abstraction behind menu items, buttons, and links. Once a command is defined, other parts of the interface can refer to the same command, allowing many access points to a single feature to share facets such as the Disabled State \({ }^{\text {p608 }}\).

Commands are defined to have the following facets:

\section*{Label}

The name of the command as seen by the user.

\section*{Access Key}

A key combination selected by the user agent that triggers the command. A command might not have an Access Key.

\section*{Hidden State}

Whether the command is hidden or not (basically, whether it should be shown in menus).

\section*{Disabled State}

Whether the command is relevant and can be triggered or not.

\section*{Action}

The actual effect that triggering the command will have. This could be a scripted event handler, a URL to which to navigate \({ }^{\text {p866 }}\), or a form submission.

User agents may expose the commands \({ }^{\mathrm{p} 607}\) that match the following criteria:
- The Hidden State \({ }^{\text {p608 }}\) facet is false (visible)
- The element is in a document with a non-null browsing context \({ }^{\text {p811 }}\).
- Neither the element nor any of its ancestors has a hidden \({ }^{\text {p765 }}\) attribute specified.

User agents are encouraged to do this especially for commands that have Access Keys \({ }^{\text {p608 }}\), as a way to advertise those keys to the user.

\section*{Example}

For example, such commands could be listed in the user agent's menu bar.

\subsection*{4.11.3.2 Using the a element to define a command \(\S^{p 60}\)}

An \(\underline{a}^{p 238}\) element with an href \(f^{\text {p284 }}\) attribute defines a command \({ }^{\text {p607 }}\).
The Label \({ }^{\text {p608 }}\) of the command is the element's descendant text content.
The Access Key \({ }^{\mathrm{p} 608}\) of the command is the element's assigned access \(\mathrm{Key}^{\mathrm{p} 786}\), if any.
The Hidden State \({ }^{\text {p608 }}\) of the command is true (hidden) if the element has a hidden \({ }^{\text {p765 }}\) attribute, and false otherwise.
The Disabled State \({ }^{\text {p608 }}\) facet of the command is true if the element or one of its ancestors is inert \({ }^{\text {p766 }}\), and false otherwise.
The Action \({ }^{\text {p608 }}\) of the command is to fire a click event \({ }^{\text {p965 }}\) at the element.

\subsection*{4.11.3.3 Using the button element to define a command \(\S_{8}^{\text {p6o }}\)}

A button \({ }^{\text {p535 }}\) element always defines a command \({ }^{\text {p607 }}\).
The Label \({ }^{p 608}\), Access Key \({ }^{\text {p608 }}\), Hidden State \({ }^{\text {p608 }}\), and Action \({ }^{\text {p608 }}\) facets of the command are determined as for a elements \({ }^{p 608}\) (see the previous section).

The Disabled State \({ }^{\mathrm{p} 608}\) of the command is true if the element or one of its ancestors is inert \({ }^{\mathrm{p} 766}\), or if the element's disabled \({ }^{\mathrm{p} 570}\) state is set, and false otherwise.

\subsection*{4.11.3.4 Using the input element to define a command \(\S^{p 60}\)}
 Button \({ }^{\text {p514 }}\), or Checkbox \({ }^{\text {p513 }}\) states defines a command \({ }^{\text {p607 }}\).

The Label \({ }^{\text {p608 }}\) of the command is determined as follows:
- If the \(\underline{\text { type }}{ }^{\text {p495 }}\) attribute is in one of the Submit Button \({ }^{\text {p518 }}\), Reset Button \({ }^{\text {p520 }}\), Image Button \({ }^{\text {p518 }}\), or Button \({ }^{\text {p521 }}\) states, then the Label \({ }^{\text {p608 }}\) is the string given by the value \({ }^{\text {p497 }}\) attribute, if any, and a UA-dependent, locale-dependent value that the UA uses to label the button itself if the attribute is absent.
- Otherwise, if the element is a labeled control \({ }^{\text {p491 }}\), then the Label \(I^{p 608}\) is the descendant text content of the first label \(l^{\text {p499 }}\) element in tree order whose labeled control \({ }^{\text {p491 }}\) is the element in question. (In JavaScript terms, this is given by element. labels[0].textContent.)
- Otherwise, if the value \({ }^{\text {p497 }}\) attribute is present, then the Label \({ }^{p 608}\) is the value of that attribute.
- Otherwise, the Label \({ }^{\text {p608 }}\) is the empty string.

\section*{Note}

Even though the value \({ }^{\text {p497 }}\) attribute on input \({ }^{\text {p493 }}\) elements in the Image Button \({ }^{p 518}\) state is non-conformant, the attribute can still contribute to the Label \({ }^{p 608}\) determination, if it is present and the Image Button's alt \({ }^{\text {p519 }}\) attribute is missing.

The Access Key \({ }^{\text {p608 }}\) of the command is the element's assigned access key \({ }^{\text {p786 }}\), if any.
The Hidden State \({ }^{\text {p608 }}\) of the command is true (hidden) if the element has a hidden \({ }^{\text {p765 }}\) attribute, and false otherwise.
The Disabled State \({ }^{\mathrm{p} 608}\) of the command is true if the element or one of its ancestors is inert \({ }^{\mathrm{p} 766}\), or if the element's disabled \({ }^{\mathrm{p} 570}\) state is set, and false otherwise.

The Action \({ }^{\text {p608 }}\) of the command is to fire a click event \({ }^{\text {p965 }}\) at the element.

\subsection*{4.11.3.5 Using the option element to define a command \(\S^{\text {p60 }}\)}

An option \({ }^{\text {p545 }}\) element with an ancestor select \({ }^{\text {p537 }}\) element and either no value \({ }^{p 546}\) attribute or a value \({ }^{\text {p546 }}\) attribute that is not the empty string defines a command \({ }^{\text {p607 }}\).

The Label \({ }^{\mathrm{p} 608}\) of the command is the value of the option \({ }^{\mathrm{p} 545}\) element's label \({ }^{\mathrm{p} 546}\) attribute, if there is one, or else the option \({ }^{\mathrm{p} 545}\) element's descendant text content, with ASCII whitespace stripped and collapsed.

The Access Key \({ }^{\text {p608 }}\) of the command is the element's assigned access key \({ }^{\text {p786 }}\), if any.
The Hidden State \({ }^{\text {p608 }}\) of the command is true (hidden) if the element has a hidden \({ }^{\text {p765 }}\) attribute, and false otherwise.
The Disabled State \({ }^{\mathrm{p} 608}\) of the command is true if the element is disabled \({ }^{\mathrm{p} 546}\), or if its nearest ancestor select \({ }^{\mathrm{p} 537}\) element is disabled \({ }^{\mathrm{p} 570}\), or if it or one of its ancestors is inert \({ }^{\mathrm{p766}}\), and false otherwise.

If the option \({ }^{\mathrm{p545}}\) 's nearest ancestor select \({ }^{\mathrm{p} 537}\) element has a multiple \({ }^{\mathrm{p539}}\) attribute, the Action \({ }^{\text {p608 }}\) of the command is to toggle \({ }^{\text {p540 }}\) the option \({ }^{\text {p545 }}\) element. Otherwise, the Action \({ }^{\text {p608 }}\) is to pick \({ }^{\text {p539 }}\) the option \({ }^{\text {p545 }}\) element.

\subsection*{4.11.3.6 Using the accesskey attribute on a legend element to define a command \({ }_{9}^{\text {p60 }}\)}

A legend \({ }^{p 565}\) element defines a command \({ }^{p 607}\) if all of the following are true:
- It has an assigned access key \({ }^{\text {p786 }}\).
- It is a child of a fieldset \({ }^{p 562}\) element.
- Its parent has a descendant that defines a command \({ }^{p 607}\) that is neither a label \({ }^{p 49 \theta}\) element nor a legend \({ }^{p 565}\) element. This element, if it exists, is the legend element's accesskey delegatee.

The Label \({ }^{\text {p608 }}\) of the command is the element's descendant text content.
The Access Key \({ }^{\text {p608 }}\) of the command is the element's assigned access key \({ }^{\text {p786 }}\).
The Hidden State \({ }^{\text {p608 }}\), Disabled State \({ }^{\text {p608 }}\), and Action \({ }^{\text {p608 }}\) facets of the command are the same as the respective facets of the legend element's accesskey delegatee \({ }^{\text {p609 }}\).

In this example, the legend \({ }^{p 565}\) element specifies an accesskey \({ }^{\text {p785 }}\), which, when activated, will delegate to the input \({ }^{\text {p493 }}\) element inside the legend \({ }^{\text {p565 }}\) element.
```
<fieldset>
    <legend accesskey=p>
    <label>I want <input name=pizza type=number step=1 value=1 min=0>
        pizza(s) with these toppings</label>
    </legend>
    <label><input name=pizza-cheese type=checkbox checked> Cheese</label>
    <label><input name=pizza-ham type=checkbox checked> Ham</label>
    <label><input name=pizza-pineapple type=checkbox> Pineapple</label>
</fieldset>
```

\subsection*{4.11.3.7 Using the accesskey attribute to define a command on other elements \(\mathbb{\S}_{\substack{p 61}}^{\text {0 }}\)}

An element that has an assigned access key \({ }^{\text {p786 }}\) defines a command \({ }^{\text {p607 }}\).
If one of the earlier sections that define elements that define commands \({ }^{\text {p607 }}\) define that this element defines a command \({ }^{p 607}\), then that section applies to this element, and this section does not. Otherwise, this section applies to that element.

The Label \({ }^{p 608}\) of the command depends on the element. If the element is a labeled control \({ }^{\text {p491 }}\), the descendant text content of the first label \({ }^{\text {p49 }}\) element in tree order whose labeled control \({ }^{\text {p491 }}\) is the element in question is the Label \({ }^{\text {p608 }}\) (in JavaScript terms, this is given by element. labels[0].textContent). Otherwise, the Label \({ }^{\text {p608 }}\) is the element's descendant text content.

The Access Key \({ }^{\text {p608 }}\) of the command is the element's assigned access key \({ }^{\text {p786 }}\).
The Hidden State \({ }^{\text {p608 }}\) of the command is true (hidden) if the element has a hidden \({ }^{\mathrm{p} 765}\) attribute, and false otherwise.
The Disabled State \({ }^{\mathrm{p} 608}\) of the command is true if the element or one of its ancestors is inert \({ }^{\mathrm{p} 766}\), and false otherwise.
The Action \({ }^{\text {p608 }}\) of the command is to run the following steps:
1. Run the focusing steps \({ }^{\mathrm{p} 776}\) for the element.
2. Fire a click event \({ }^{\mathrm{p} 965}\) at the element.

\subsection*{4.11.4 The dialog element \(\S^{\text {p61 }}\)}

\section*{Categories \({ }^{\text {p128 }}\) :}

Flow content \({ }^{\text {p131 }}\).
Sectioning root \({ }^{\text {p199 }}\).

\section*{Contexts in which this element can be used \({ }^{\text {p128 }}\) :}

Where flow content \({ }^{\text {p131 }}\) is expected.

\section*{Content model \({ }^{\text {p128 }}\) :}

Flow content \({ }^{\text {p131 }}\).
Tag omission in text/html \({ }^{\text {p128 }}\) :
Neither tag is omissible.
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{\text {p136 }}\)
open \({ }^{\text {p611 }}\) - Whether the dialog box is showing
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
```
IDL [Exposed=Window]
interface HTMLDialogElement : HTMLElement {
    [HTMLConstructor] constructor();
    [CEReactions] attribute boolean open;
    attribute DOMString returnValue;
    [CEReactions] undefined show();
    [CEReactions] undefined showModal();
    [CEReactions] undefined close(optional DOMString returnValue);
};
```

The dialog \({ }^{\text {p610 }}\) element represents a part of an application that a user interacts with to perform a task, for example a dialog box, inspector, or window.

The open attribute is a boolean attribute \({ }^{\mathrm{p} 67}\). When specified, it indicates that the dialog \({ }^{\text {p610 }}\) element is active and that the user can interact with it.

A dialog \({ }^{p 610}\) element without an open \({ }^{\text {p611 }}\) attribute specified should not be shown to the user. This requirement may be implemented indirectly through the style layer. For example, user agents that support the suggested default rendering \({ }^{\text {p47 }}\) implement this requirement using the CSS rules described in the rendering section \({ }^{\text {p1192 }}\).

\section*{Note}

Removing the open \({ }^{\text {p611 }}\) attribute will usually hide the dialog. However, doing so has a number of strange additional consequences:
- The close \({ }^{p 1281}\) event will not be fired.
- The close() \({ }^{\text {p612 }}\) method, and any user-agent provided cancelation interface \({ }^{\text {p613 }}\), will no longer be able to close the dialog.
- If the dialog was shown using its showModal() \({ }^{\text {p612 }}\) method, the Document \({ }^{\text {p114 }}\) will still be blocked \({ }^{p 766}\).

For these reasons, it is generally better to never remove the open \({ }^{\text {p611 }}\) attribute manually. Instead, use the close() \()^{\text {p612 }}\) method to close the dialog, or the hidden \({ }^{\text {p765 }}\) attribute to hide it

The tabindex \({ }^{p 773}\) attribute must not be specified on dialog \({ }^{\text {p610 }}\) elements.

\section*{For web developers (non-normative)}
dialog . show \({ }^{\text {p611 }}\) ()
Displays the dialog \({ }^{\text {p610 }}\) element.
dialog . showModal \({ }^{\text {p612 }}\) ()
Displays the dialog \({ }^{\text {p610 }}\) element and makes it the top-most modal dialog.
This method honors the autofocus \({ }^{\mathrm{p} 782}\) attribute.
dialog . close \({ }^{\text {p612 }}([\) result ])
Closes the dialog \({ }^{\text {p610 }}\) element.
The argument, if provided, provides a return value.
dialog . returnValue \({ }^{\text {p613 }}\) [ = result ]
Returns the dialog \({ }^{p 610}\) 's return value.
Can be set, to update the return value.

When the show() method is invoked, the user agent must run the following steps:
1. If the element already has an open \({ }^{\mathrm{p611}}\) attribute, then return.
2. Add an open \({ }^{p 611}\) attribute to the dialog \({ }^{p 610}\) element, whose value is the empty string.
3. Set the dialog \({ }^{\text {p610 }}\) to the normal alignment \({ }^{p 613}\) mode.
4. Run the dialog focusing steps \({ }^{\text {p612 }}\) for the dialog \({ }^{\text {p610 }}\) element.

When the showModal () method is invoked, the user agent must run the following steps:
1. Let subject be the dialog \({ }^{\text {p610 }}\) element on which the method was invoked.
2. If subject already has an open \({ }^{\text {p611 }}\) attribute, then throw an "InvalidStateError" DOMEXception.
3. If subject is not connected, then throw an "InvalidStateError" DOMException.
4. Add an open \({ }^{p 611}\) attribute to subject, whose value is the empty string.
5. Set the dialog \({ }^{\mathrm{p} 610}\) to the centered alignment \({ }^{\mathrm{p} 613}\) mode.
6. Let subject's node document be blocked by the modal dialog \({ }^{\mathrm{p766}}\) subject.

\section*{Note}

This will cause the focused area of the document \({ }^{p 771}\) to become inert \({ }^{p 766}\) (unless that currently focused area is a shadowincluding descendant of subject). In such cases, the focus fixup rule \({ }^{\text {p777 }}\) will kick in and reset the focused area of the document \({ }^{\text {p771 }}\) to the viewport for now. In a couple steps we will attempt to find a better candidate to focus.
7. If subject's node document's top layer does not already contain subject, then add subject to subject's node document's top layer.
8. Run the dialog focusing steps \({ }^{\text {p612 }}\) for subject.

The dialog focusing steps for a dialog \({ }^{p 610}\) element subject are as follows:
1. If subject is inert \({ }^{\text {p766 }}\), return.
2. Let control be the first descendant element of subject, in tree order, that is not inert \({ }^{p 766}\) and has the autofocus \({ }^{\text {p782 }}\) attribute specified.

If there isn't one, then let control be the first non-inert \({ }^{\mathrm{p} 766}\) descendant element of subject, in tree order.
If there isn't one of those either, then let control be subject.
3. Run the focusing steps \({ }^{\text {p776 }}\) for control.

\section*{Note}

If control is not focusable \({ }^{\text {p772 }}\), this will do nothing. For modal dialogs, this means that any earlier modifications \({ }^{\text {p612 }}\) to the focused area of the document \({ }^{\text {p771 }}\) will apply.
4. Let topDocument be the active document \({ }^{\mathrm{p811}}\) of control's node document's browsing context \({ }^{\text {p811 }}\) 's top-level browsing context \({ }^{\text {p814 }}\).
5. If control's node document's origin \({ }^{\mathrm{p837}}\) is not the same \({ }^{\mathrm{p} 838}\) as the origin \({ }^{\mathrm{p} 837}\) of topDocument, then return.
6. Empty topDocument's autofocus candidates \({ }^{\mathrm{p} 782}\).
7. Set topDocument's autofocus processed flag \({ }^{\mathrm{p} 782}\) to true.

If at any time a dialog \({ }^{p 61 \theta}\) element is removed from a Document \({ }^{\text {p44 }}\), then if that dialog \({ }^{\text {p610 }}\) is in that Document \({ }^{\text {p114' }} \mathrm{s}\) top layer, it must be removed from it.

When the close() method is invoked, the user agent must close the dialog \({ }^{\text {p612 }}\) that the method was invoked on. If the method was invoked with an argument, that argument must be used as the return value; otherwise, there is no return value.

When a dialog \({ }^{\text {p610 }}\) element subject is to be closed, optionally with a return value result, the user agent must run the following steps:
1. If subject does not have an open \({ }^{\text {p611 }}\) attribute, then return.
2. Remove subject's open \({ }^{\text {p611 }}\) attribute.
3. If the argument result was provided, then set the returnValue \({ }^{\text {p613 }}\) attribute to the value of result.
4. If subject is in its Document \({ }^{\text {p114 }}\) 's top layer, then remove it.
5. Queue an element task \({ }^{\text {p946 }}\) on the user interaction task source \({ }^{\text {p952 }}\) given the subject element to fire an event named close \({ }^{\text {p1281 }}\) at subject.

The returnValue IDL attribute, on getting, must return the last value to which it was set. On setting, it must be set to the new value. When the element is created, it must be set to the empty string.

Canceling dialogs: When Document \({ }^{\text {p114 }}\) is blocked by a modal dialog \({ }^{\text {p766 }}\) dialog, user agents may provide a user interface that, upon activation, queues an element task \({ }^{\text {p946 }}\) on the user interaction task source \({ }^{\text {p952 }}\) given the dialog element to run these steps:
1. Let close be the result of firing an event named cancel \({ }^{p 1281}\) at dialog, with the cancelable attribute initialized to true.
2. If close is true and dialog has an open \({ }^{\text {p611 }}\) attribute, then close the dialog \({ }^{\text {p612 }}\) with no return value.

Note
An example of such a UI mechanism would be the user pressing the "Escape" key.

A dialog \({ }^{p 61 \theta}\) element is in one of two modes: normal alignment or centered alignment. When a dialog \({ }^{p 61 \theta}\) element is created, it must be placed in the normal alignment \({ }^{\text {p613 }}\) mode. In this mode, normal CSS requirements apply to the element. The centered alignment \({ }^{\text {p613 }}\) mode is only used for dialog \({ }^{\text {p610 }}\) elements that are in the top layer. [FULLSCREEN] \({ }^{\text {p1287 }}\) [CSS] \({ }^{\text {p1285 }}\)

When an element subject is placed in centered alignment \({ }^{\text {p613 }}\) mode, and when it is in that mode and has new rendering boxes created, the user agent must set up the element such that its static position of the edge that corresponds to subject's parent's block-start edge, for the purposes of calculating the used value of the appropriate box offset property ('top', 'right', 'bottom', or 'left'), is the value that would place the element's margin edge on the side that corresponds to subject's parent's block-start side as far from the same-side edge of the viewport as the element's opposing side margin edge from that same-side edge of the viewport, if the element's dimension ('width' or 'height') in subject's parent's block flow direction is less than the same-axis dimension of the viewport, and otherwise is the value that would place the element's margin edge on the side that corresponds to subject's parent's block-start side at the same-side edge of the viewport.

If there is a dialog \({ }^{p 61 \theta}\) element with centered alignment \({ }^{\mathrm{p} 613}\) and that is being rendered \({ }^{\text {p1192 }}\) when its browsing context \({ }^{\text {p811 }}\) changes viewport dimensions (as measured in CSS pixels), or when this dialog \({ }^{\text {p610 }}\) element's parent changes block flow direction, then the user agent must recreate the element's boxes, recalculating its edge that corresponds to this dialog \({ }^{\text {p610 }}\) element's parent's block-start edge as in the previous paragraph.

This static position of a dialog \({ }^{p 610}\) element's edge with centered alignment \({ }^{\text {p613 }}\) must remain the element's static position of that edge until its boxes are recreated. (The element's static position is only used in calculating the used value of the appropriate box offset property ('top', 'right', 'bottom', or 'left') in certain situations; it's not used, for instance, to position the element if its 'position' property is set to 'static'.)

User agents in visual interactive media should allow the user to pan the viewport to access all parts of a dialog \({ }^{\text {p610 }}\) element's border box, even if the element is larger than the viewport and the viewport would otherwise not have a scroll mechanism (e.g. because the viewport's 'overflow' property is set to 'hidden').

The open IDL attribute must reflect \({ }^{\text {p94 }}\) the open \({ }^{\text {p611 }}\) content attribute.

\section*{Example}

This dialog box has some small print. The strong \({ }^{\text {p242 }}\) element is used to draw the user's attention to the more important part.
```
<dialog>
    <h1>Add to Wallet</h1>
    <p><strong><label for=amt>How many gold coins do you want to add to your
wallet?</label></strong></p>
    <p><input id=amt name=amt type=number min=0 step=0.01 value=100></p>
    <p><small>You add coins at your own risk.</small></p>
    <p><label><input name=round type=checkbox> Only add perfectly round coins </label></p>
    <p><input type=button onclick="submit()" value="Add Coins"></p>
</dialog>
```

\subsection*{4.12 Scripting \(\S^{p 61}\)}

Scripts allow authors to add interactivity to their documents.
Authors are encouraged to use declarative alternatives to scripting where possible, as declarative mechanisms are often more maintainable, and many users disable scripting.

\section*{Example}

For example, instead of using script to show or hide a section to show more details, the details \({ }^{\text {p604 }}\) element could be used.

Authors are also encouraged to make their applications degrade gracefully in the absence of scripting support.

\section*{Example}

For example, if an author provides a link in a table header to dynamically resort the table, the link could also be made to function without scripts by requesting the sorted table from the server.

\subsection*{4.12.1 The script element \(\S_{4}^{\text {p61 }}\)}

Categories \({ }^{\text {p128 }}\) :
Metadata content \({ }^{\text {p131 }}\).
Flow content \({ }^{\mathrm{p131}}\).
Phrasing content \({ }^{\mathrm{p} 132}\).
Script-supporting element \({ }^{\text {p133 }}\).

\section*{Contexts in which this element can be used \({ }^{\text {p128 }}\) :}

Where metadata content \({ }^{p 131}\) is expected.
Where phrasing content \({ }^{\mathrm{p} 132}\) is expected.
Where script-supporting elements \({ }^{\text {p133 }}\) are expected.

\section*{Content model \({ }^{\text {p128 }}\) :}

If there is no srcc \({ }^{p 615}\) attribute, depends on the value of the type \({ }^{p 615}\) attribute, but must match script content restrictions \({ }^{\text {p624 }}\). If there is a src \({ }^{\text {p615 }}\) attribute, the element must be either empty or contain only script documentation \({ }^{\text {p626 }}\) that also matches script content restrictions \({ }^{p 624}\).

Tag omission in text/html \({ }^{\text {p128 }}\) :
Neither tag is omissible.
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{\text {p136 }}\)
src \({ }^{\text {p615 }}\) - Address of the resource
type \({ }^{\text {p615 }}\) - Type of script
nomodule \({ }^{\text {p615 }}\) - Prevents execution in user agents that support module scripts \({ }^{\text {p925 }}\)
async \({ }^{\text {p615 }}\) - Execute script when available, without blocking while fetching
defer \({ }^{\text {p615 }}\) - Defer script execution
crossorigin \({ }^{\text {p616 }}\) - How the element handles crossorigin requests
integrity \({ }^{\text {p616 }}\) - Integrity metadata used in Subresource Integrity checks [SRI] \({ }^{\text {p1291 }}\)
referrerpolicy \({ }^{\text {p616 }}\) - Referrer policy for fetches initiated by the element
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
DOM interface \({ }^{\text {p129 }}\) :
IDL [Exposed=Window]
interface HTMLScriptElement : HTMLElement \{
[HTMLConstructor] constructor();
[CEReactions] attribute USVString src;
[CEReactions] attribute DOMString type;
```
[CEReactions] attribute boolean noModule;
[CEReactions] attribute boolean async;
[CEReactions] attribute boolean defer;
[CEReactions] attribute DOMString? crossOrigin;
[CEReactions] attribute DOMString text;
[CEReactions] attribute DOMString integrity;
[CEReactions] attribute DOMString referrerPolicy;
// also has obsolete members
};
```

The script \({ }^{\text {p614 }}\) element allows authors to include dynamic script and data blocks in their documents. The element does not represent \({ }^{\text {p123 }}\) content for the user.

The type attribute allows customization of the type of script represented:
- Omitting the attribute, setting it to the empty string, or setting it to a JavaScript MIME type essence match, means that the script is a classic script \({ }^{\mathrm{p} 925}\), to be interpreted according to the JavaScript Script top-level production. Classic scripts are affected by the async \({ }^{p 615}\) and defer \({ }^{\text {p615 }}\) attributes, but only when the src \({ }^{\text {p615 }}\) attribute is set. Authors should omit the type \({ }^{\text {p615 }}\) attribute instead of redundantly setting it.
- Setting the attribute to an ASCII case-insensitive match for the string "module" means that the script is a module script \({ }^{\text {p925 }}\), to be interpreted according to the JavaScript Module top-level production. Module scripts are not affected by the defer \({ }^{\text {p615 }}\) attribute, but are affected by the async \({ }^{\mathrm{p} 615}\) attribute (regardless of the state of the \(\mathrm{src}^{\mathrm{p} 615}\) attribute).
- Setting the attribute to any other value means that the script is a data block, which is not processed. None of the script \({ }^{\text {p614 }}\) attributes (except type \({ }^{\text {p615 }}\) itself) have any effect on data blocks. Authors must use a valid MIME type string that is not a JavaScript MIME type essence match to denote data blocks.

\section*{Note}

The requirement that data blocks \({ }^{p 615}\) must be denoted using a valid MIME type string is in place to avoid potential future collisions. If this specification ever adds additional types of script \({ }^{p 925}\), they will be triggered by setting the type \({ }^{p 615}\) attribute to something which is not a MIME type, like how the "module" value denotes module scripts \({ }^{p 925}\). By using a valid MIME type string now, you ensure that your data block will not ever be reinterpreted as a different script type, even in future user agents.

Classic scripts \({ }^{\text {p925 }}\) and module scripts \({ }^{\text {p925 }}\) can be embedded inline, or be imported from an external file using the src attribute, which if specified gives the URL of the external script resource to use. If \(\underline{s r c^{p 615}}\) is specified, it must be a valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\). The contents of inline script \({ }^{\text {p614 }}\) elements, or the external script resource, must conform with the requirements of the JavaScript specification's Script or Module productions, for classic scripts \({ }^{\text {p925 }}\) and module scripts \({ }^{\text {p925 }}\) respectively. [JAVASCRIPT] \({ }^{p 1288}\)

When used to include data blocks \({ }^{\text {p615 }}\), the data must be embedded inline, the format of the data must be given using the type \({ }^{\text {p615 }}\) attribute, and the contents of the script \({ }^{\text {p614 }}\) element must conform to the requirements defined for the format used. The src \({ }^{\text {p615 }}\), async \({ }^{p 615}\), nomodule \({ }^{p 615}\), defer \({ }^{p 615}\), crossorigin \({ }^{p 616}\), integrity \({ }^{p 616}\), and referrerpolicy \({ }^{p 616}\) attributes must not be specified.

The nomodule attribute is a boolean attribute \({ }^{\mathrm{p67}}\) that prevents a script from being executed in user agents that support module scripts \({ }^{\text {p925 }}\). This allows selective execution of module scripts \({ }^{\text {p925 }}\) in modern user agents and classic scripts \({ }^{\text {p925 }}\) in older user agents, as shown below \({ }^{\text {p618 }}\). The nomodule \({ }^{\text {p615 }}\) attribute must not be specified on module scripts \({ }^{\text {p925 }}\) (and will be ignored if it is).

The async and defer attributes are boolean attributes \({ }^{\text {p67 }}\) that indicate how the script should be evaluated. Classic scripts \({ }^{\text {p925 }}\) may specify defer \({ }^{p 615}\) or async \({ }^{p 615}\), but must not specify either unless the src \({ }^{p 615}\) attribute is present. Module scripts \({ }^{\text {p925 }}\) may specify the async \(^{\text {p615 }}\) attribute, but must not specify the defer \({ }^{\text {p615 }}\) attribute.

There are several possible modes that can be selected using these attributes, and depending on the script's type.
For classic scripts \({ }^{p 925}\), if the async \({ }^{p 615}\) attribute is present, then the classic script will be fetched in parallel \({ }^{p 42}\) to parsing and evaluated as soon as it is available (potentially before parsing completes). If the async \({ }^{p 615}\) attribute is not present but the defer \({ }^{\text {p615 }}\) attribute is present, then the classic script will be fetched in parallel \({ }^{\text {p42 }}\) and evaluated when the page has finished parsing. If neither attribute is present, then the script is fetched and evaluated immediately, blocking parsing until these are both complete.

For module scripts \({ }^{\text {p925 }}\), if the async \({ }^{p 615}\) attribute is present, then the module script and all its dependencies will be fetched in parallel \({ }^{p 42}\) to parsing, and the module script will be evaluated as soon as it is available (potentially before parsing completes). Otherwise, the
module script and its dependencies will be fetched in parallel \({ }^{\mathrm{p} 42}\) to parsing and evaluated when the page has finished parsing. (The defer \({ }^{p 615}\) attribute has no effect on module scripts.)

This is all summarized in the following schematic diagram:
\begin{tabular}{|c|c|c|}
\hline <script> & Scripting: HTML Parser: &  \\
\hline <script defer> & Scripting: HTML Parser: &  \\
\hline <script async> & Scripting: HTML Parser: &  \\
\hline <script type="module"> & Scripting: HTML Parser: & \[
\rightarrow 0
\] \\
\hline <script type="module" async> & Scripting: HTML Parser: & \[
\because \rightarrow
\] \\
\hline
\end{tabular}

\section*{Note}

The exact processing details for these attributes are, for mostly historical reasons, somewhat non-trivial, involving a number of aspects of HTML. The implementation requirements are therefore by necessity scattered throughout the specification. The algorithms below (in this section) describe the core of this processing, but these algorithms reference and are referenced by the parsing rules for script \({ }^{p 614}\) start \({ }^{p 1136}\) and end \({ }^{p 1149}\) tags in HTML, in foreign content \({ }^{p 1164}\), and in XML \({ }^{\text {p1189 }}\), the rules for the document. write( () \({ }^{\text {p970 }}\) method, the handling of scripting \({ }^{\text {p913 }}\), etc.

The defer \({ }^{p 615}\) attribute may be specified even if the async \({ }^{p 615}\) attribute is specified, to cause legacy web browsers that only support defer \({ }^{\text {p615 }}\) (and not async \({ }^{\text {p615 }}\) ) to fall back to the defer \({ }^{\text {p615 }}\) behavior instead of the blocking behavior that is the default.

The crossorigin attribute is a CORS settings attribute \({ }^{\mathrm{p91}}\). For classic scripts \({ }^{\mathrm{p} 925}\), it controls whether error information will be exposed, when the script is obtained from other origins \({ }^{\mathrm{p837}}\). For module scripts \({ }^{\mathrm{p925}}\), it controls the credentials mode used for cross-origin requests.

\section*{Note}

Unlike classic scripts \({ }^{p 925}\) module scripts \({ }^{p 925}\) require the use of the CORS protocol for cross-origin fetching.

The integrity attribute represents the integrity metadata for requests which this element is responsible for. The value is text. The integrity \({ }^{\text {p616 }}\) attribute must not be specified when the \(\underline{s r c}^{\mathrm{p} 615}\) attribute is not specified. [SRI] \({ }^{\text {p1291 }}\)

The referrerpolicy attribute is a referrer policy attribute \({ }^{\mathrm{p91}}\). Its purpose is to set the referrer policy used when fetching the script, as well as any scripts imported from it. [REFERRERPOLICY] \({ }^{\text {p1290 }}\)

\section*{Example}

An example of a script \({ }^{\text {p614 }}\) element's referrer policy being used when fetching imported scripts but not other subresources:
```
<script referrerpolicy="origin">
    fetch('/api/data'); // not fetched with <script>'s referrer policy
    import('./utils.mjs'); // is fetched with <script>'s referrer policy ("origin" in this case)
</script>
```

Changing the src \({ }^{\text {p615 }}\), type \({ }^{\text {p615 }}\), nomodule \(e^{\text {p615 }}\), async \({ }^{\text {p615 }}\), defer \(r^{\text {p615 }}\), crossorigin \({ }^{\text {p616 }}\), integrity \({ }^{\text {p616 }}\), and referrerpolicy \({ }^{\text {p616 }}\) attributes dynamically has no direct effect; these attributes are only used at specific times described below.

The IDL attributes src, type, defer, and integrity, must each reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.
The referrerPolicy IDL attribute must reflect \({ }^{\text {p94 }}\) the referrerpolicy \({ }^{p 616}\) content attribute, limited to only known values \({ }^{\text {p95 }}\).
The crossOrigin IDL attribute must reflect \({ }^{\text {p94 }}\) the crossorigin \({ }^{\mathrm{p616}}\) content attribute, limited to only known values \({ }^{\mathrm{p95}}\).
The noModule IDL attribute must reflect \({ }^{\text {p94 }}\) the nomodule \({ }^{\text {p615 }}\) content attribute.

The async IDL attribute controls whether the element will execute asynchronously or not. If the element's "non-blocking" 6619 flag is set, then, on getting, the async \({ }^{\text {p617 }}\) IDL attribute must return true, and on setting, the "non-blocking"p619 flag must first be unset, and then the content attribute must be removed if the IDL attribute's new value is false, and must be set to the empty string if the IDL attribute's new value is true. If the element's "non-blocking"p619 flag is not set, the IDL attribute must reflect \({ }^{\text {p94 }}\) the async \({ }^{\text {p615 }}\) content attribute.

\section*{For web developers (non-normative)}

\section*{script. text \(^{\text {p617 }}\) [ = value ]}

Returns the child text content of the element.
Can be set, to replace the element's children with the given value.

The text attribute's getter must return this script \({ }^{\text {p614 }}\) element's child text content.
The text \({ }^{\text {p617 }}\) attribute's setter must string replace all with the given value within this script \({ }^{\text {p614 }}\) element.

\section*{Note}

When inserted using the document. write() \({ }^{\text {p970 }}\) method, script \({ }^{\text {p614 }}\) elements usually \({ }^{\text {p1136 }}\) execute (typically blocking further script execution or HTML parsing). When inserted using the innerHTML and outerHTML attributes, they do not execute at all.

\section*{Example}

In this example, two script \({ }^{\text {p614 }}\) elements are used. One embeds an external classic script \({ }^{\text {p925 }}\), and the other includes some data as a data block \({ }^{\text {p615 }}\).
```
<script src="game-engine.js"></script>
<script type="text/x-game-map">
........U.........e
0...................e
.....A.....AAA.....e
.A..AAA...AAAAA...e
</script>
```

The data in this case might be used by the script to generate the map of a video game. The data doesn't have to be used that way, though; maybe the map data is actually embedded in other parts of the page's markup, and the data block here is just used by the site's search engine to help users who are looking for particular features in their game maps.

\section*{Example}

The following sample shows how a script \({ }^{\text {p614 }}\) element can be used to define a function that is then used by other parts of the document, as part of a classic script \({ }^{\text {p925 }}\). It also shows how a script \({ }^{p 614}\) element can be used to invoke script while the document is being parsed, in this case to initialize the form's output.
```
<script>
    function calculate(form) {
        var price = 52000;
        if (form.elements.brakes.checked)
            price += 1000;
        if (form.elements.radio.checked)
            price += 2500;
        if (form.elements.turbo.checked)
            price += 5000;
        if (form.elements.sticker.checked)
            price += 250;
        form.elements.result.value = price;
}
</script>
<form name="pricecalc" onsubmit="return false" onchange="calculate(this)">
<fieldset>
    <legend>Work out the price of your car</legend>
    <p>Base cost: £52000.</p>
```
```
    <p>Select additional options:</p>
    <ul>
        <li><label><input type=checkbox name=brakes> Ceramic brakes (£1000)</label></li>
        <li><label><input type=checkbox name=radio> Satellite radio (£2500)</label></li>
        <li><label><input type=checkbox name=turbo> Turbo charger (£5000)</label></li>
        <li><label><input type=checkbox name=sticker> "XZ" sticker (£250)</label></li>
    </ul>
    <p>Total: f<output name=result></output></p>
    </fieldset>
    <script>
    calculate(document.forms.pricecalc);
    </script>
</form>
```

\section*{Example}

The following sample shows how a script \({ }^{\text {p614 }}\) element can be used to include an external module script \({ }^{\text {p925 }}\).
```
<script type="module" src="app.mjs"></script>
```

This module, and all its dependencies (expressed through JavaScript import statements in the source file), will be fetched. Once the entire resulting module graph has been imported, and the document has finished parsing, the contents of app.mjs will be evaluated.

Additionally, if code from another script \({ }^{\text {p614 }}\) element in the same Window \({ }^{\text {p824 }}\) imports the module from app.mjs (e.g. via import "./app.mjs";), then the same module script \({ }^{\text {p925 }}\) created by the former script \({ }^{\text {p614 }}\) element will be imported.

\section*{Example}

This example shows how to include a module script \({ }^{\text {p925 }}\) for modern user agents, and a classic script \({ }^{\text {p925 }}\) for older user agents:
```
<script type="module" src="app.mjs"></script>
<script nomodule defer src="classic-app-bundle.js"></script>
```

In modern user agents that support module scripts \({ }^{p 925}\), the script \({ }^{p 614}\) element with the nomodule \({ }^{\text {p615 }}\) attribute will be ignored, and the script \({ }^{\text {p614 }}\) element with a type \({ }^{\text {p615 }}\) of "module" will be fetched and evaluated (as a module script \({ }^{\text {p925 }}\) ). Conversely, older user agents will ignore the script \({ }^{p 614}\) element with a type \({ }^{p 615}\) of "module", as that is an unknown script type for them - but they will have no problem fetching and evaluating the other script \({ }^{\text {p614 }}\) element (as a classic script \({ }^{\text {p925 }}\) ), since they do not implement the nomodule \({ }^{\text {p615 }}\) attribute.

\section*{Example}

The following sample shows how a script \({ }^{\text {p614 }}\) element can be used to write an inline module script \({ }^{\text {p925 }}\) that performs a number of substitutions on the document's text, in order to make for a more interesting reading experience (e.g. on a news site):
[XKCD1288] \({ }^{\text {p1293 }}\)
```
<script type="module">
    import { walkAllTextNodeDescendants } from "./dom-utils.mjs";
    const substitutions = new Map([
        ["witnesses", "these dudes I know"]
        ["allegedly", "kinda probably"]
        ["new study", "Tumblr post"]
        ["rebuild", "avenge"]
        ["space", "spaaace"]
        ["Google glass", "Virtual Boy"]
        ["smartphone", "Pokédex"]
        ["electric", "atomic"]
        ["Senator", "Elf-Lord"]
```
```
    ["car", "cat"]
    ["election", "eating contest"]
    ["Congressional leaders", "river spirits"]
    ["homeland security", "Homestar Runner"]
    ["could not be reached for comment", "is guilty and everyone knows it"]
    ]);
    function substitute(textNode) {
    for (const [before, after] of substitutions.entries()) {
        textNode.data = textNode.data.replace(new RegExp(`\\b${before}\\b`, "ig"), after);
    }
}
    walkAllTextNodeDescendants(document.body, substitute);
</script>
```

Some notable features gained by using a module script include the ability to import functions from other JavaScript modules, strict mode by default, and how top-level declarations do not introduce new properties onto the global object \({ }^{\text {p918 }}\). Also note that no matter where this script \({ }^{p 614}\) element appears in the document, it will not be evaluated until both document parsing has complete and its dependency (dom-utils.mjs) has been fetched and evaluated.

\subsection*{4.12.1.1 Processing model \(\S^{p 61}\)}

A script \({ }^{\text {p614 }}\) element has several associated pieces of state.
A script \({ }^{p 614}\) element has a flag indicating whether or not it has been "already started". Initially, script \({ }^{\text {p614 }}\) elements must have this flag unset (script blocks, when created, are not "already started"). The cloning steps for script \({ }^{\text {p614 }}\) elements must set the "already started" flag on the copy if it is set on the element being cloned.

A script \({ }^{\text {p614 }}\) element has a parser document, which is either null or a Document \({ }^{\text {p114 }}\). Initially, its value must be null. It is set by the HTML parser \({ }^{\text {p1079 }}\) and the XML parser \({ }^{\text {p1188 }}\) on script \(t^{\text {p614 }}\) elements they insert, and affects the processing of those elements. script \({ }^{\text {p614 }}\) elements with non-null parser documents \({ }^{\mathrm{p} 619}\) are known as "parser-inserted".

A script \({ }^{\text {p614 }}\) element has a flag indicating whether the element will be "non-blocking". Initially, script \({ }^{\text {p614 }}\) elements must have this flag set. It is unset by the HTML parser \({ }^{\text {p1079 }}\) and the XML parser \({ }^{\text {p1188 }}\) on script \({ }^{\text {p614 }}\) elements they insert. In addition, whenever a script \({ }^{\text {p614 }}\) element whose "non-blocking" p619 flag is set has an async \({ }^{\text {p615 }}\) content attribute added, the element's "non-blocking" p619 flag must be unset.

A script \({ }^{\text {p614 }}\) element has a flag indicating whether or not the script block is "ready to be parser-executed". Initially, script \({ }^{\text {p614 }}\) elements must have this flag unset (script blocks, when created, are not "ready to be parser-executed"). This flag is used only for elements that are also "parser-inserted" \({ }^{6619}\), to let the parser know when to execute the script.

The script's type for a script \({ }^{\text {p614 }}\) element is either "classic" or "module". It is determined when the script is prepared \({ }^{\text {p620 }}\), based on the type \({ }^{\text {p615 }}\) attribute of the element at that time.

A script \({ }^{\text {p614 }}\) element has a preparation-time document, which is a Document \({ }^{\text {p114 }}\) determined near the beginning of the prepare a script \({ }^{\text {p620 }}\) algorithm. It is used to prevent scripts that move between documents during preparation \({ }^{\text {p620 }}\) from executing \({ }^{\text {p623 }}\).

A script \({ }^{\text {p614 }}\) element has a flag indicating whether or not the script is from an external file. It is determined when the script is prepared \({ }^{p 620}\), based on the \(s_{r c} c^{p 615}\) attribute of the element at that time.

The script's script for a script \({ }^{p 614}\) element is either null or a script \({ }^{p 925}\) resulting from preparing \({ }^{\mathrm{p} 620}\) the element. This is set asynchronously after the classic script or module graph is fetched. Once it is set, either to a script \({ }^{\text {p925 }}\) in the case of success or to null in the case of failure, the fetching algorithms will note that the script is ready, which can trigger other actions. The user agent must delay the load event \({ }^{\text {p1165 }}\) of the element's node document until the script is ready \({ }^{\text {p619 }}\).

When a script \({ }^{\text {p614 }}\) element that is not "parser-inserted"p619 experiences one of the events listed in the following list, the user agent must immediately \({ }^{\text {p42 }}\) prepare \({ }^{p 620}\) the script \({ }^{p 614}\) element:
- The script \({ }^{p 614}\) element becomes connected \({ }^{p 45}\).
- The script \({ }^{p 614}\) element is connected and a node or document fragment is inserted \({ }^{p 44}\) into the script \({ }^{p 614}\) element, after any script \({ }^{\text {p614 }}\) elements inserted \({ }^{\text {p44 }}\) at that time.
- The script \({ }^{p 614}\) element is connected and has a src \({ }^{\text {p615 }}\) attribute set where previously the element had no such attribute.

To prepare a script, the user agent must act as follows:
1. If the script \({ }^{\text {p614 }}\) element is marked as having "already started" \({ }^{p 619}\), then return. The script is not executed.
2. Let parser document be the element's parser document \({ }^{\mathrm{p} 619}\).
3. Set the element's parser document \({ }^{\mathrm{p} 619}\) to null.

\section*{Note}

This is done so that if parser-inserted script \({ }^{\text {p614 }}\) elements fail to run when the parser tries to run them, e.g. because they are empty or specify an unsupported scripting language, another script can later mutate them and cause them to run again.
4. If parser document is non-null and the element does not have an async \({ }^{\text {p615 }}\) attribute, then set the element's "nonblocking" p619 flag to true.

\section*{Note}

This is done so that if a parser-inserted script \({ }^{\text {p614 }}\) element fails to run when the parser tries to run it, but it is later executed after a script dynamically updates it, it will execute in a non-blocking fashion even if the async \({ }^{\text {p615 }}\) attribute isn't set.
5. Let source text be the element's child text content.
6. If the element has no \(s_{r c}{ }^{p 615}\) attribute, and source text is the empty string, then return. The script is not executed.
7. If the element is not connected, then return. The script is not executed.
8. If either:
- the script \({ }^{\text {p614 }}\) element has a type \({ }^{\text {p615 }}\) attribute and its value is the empty string, or
- the script \({ }^{p 614}\) element has no type \({ }^{p 615}\) attribute but it has a language \({ }^{p 1235}\) attribute and that attribute's value is the empty string, or
- the script \({ }^{\text {p614 }}\) element has neither a type \({ }^{\text {p615 }}\) attribute nor a language \({ }^{\text {p1235 }}\) attribute, then
...let the script block's type string for this script \({ }^{\text {p614 }}\) element be "text/javascript".
Otherwise, if the script \({ }^{\text {p614 }}\) element has a type \({ }^{p 615}\) attribute, let the script block's type string for this script \({ }^{\text {p614 }}\) element be the value of that attribute with leading and trailing ASCII whitespace stripped.

Otherwise, the element has a non-empty language \({ }^{\text {p1235 }}\) attribute; let the script block's type string for this script \({ }^{\text {p614 }}\) element be the concatenation of the string "text/" followed by the value of the language \({ }^{\text {p1235 }}\) attribute.

\section*{Note}

The language \({ }^{\text {p1235 }}\) attribute is never conforming, and is always ignored if there is a type \({ }^{\text {p615 }}\) attribute present.
Determine the script's type \({ }^{\text {p619 }}\) as follows:
- If the script block's type string is a JavaScript MIME type essence match, the script's type \({ }^{\text {p619 }}\) is "classic".
- If the script block's type string is an ASCII case-insensitive match for the string "module", the script's type \({ }^{\text {p619 }}\) is "module".
- If neither of the above conditions are true, then return. No script is executed.
9. If parser document is non-null, then set the element's parser document \({ }^{p 619}\) back to parser document and set the element's "non-blocking" p619 flag to false.
10. Set the element's "already started"p619 flag.
11. Set the element's preparation-time document \({ }^{\text {p619 }}\) to its node document.
12. If parser document is non-null, and parser document is not equal to the element's preparation-time document \({ }^{\text {p619 }}\), then
return.
13. If scripting is disabled \({ }^{p 924}\) for the script \({ }^{\text {p614 }}\) element, then return. The script is not executed.

\section*{Note}

The definition of scripting is disabled \({ }^{p 924}\) means that, amongst others, the following scripts will not execute: scripts in XMLHttpRequest's responseXML documents, scripts in DOMParser \({ }^{\text {p971 }}\)-created documents, scripts in documents created by XSLTProcessor \({ }^{p 50}\) 's transformToDocument \({ }^{\mathrm{p50}}\) feature, and scripts that are first inserted by a script into a Document \({ }^{p 114}\) that was created using the createDocument () API. [XHR] \(]^{p 1292}\) [DOMPARSING] \({ }^{p 1287}\) [XSLTP] \({ }^{p 1293}\) [DOM] \({ }^{p 1287}\)
14. If the script \({ }^{\mathrm{p} 614}\) element has a nomodule \({ }^{\mathrm{p} 615}\) content attribute and the script's type \({ }^{\mathrm{p} 619}\) is "classic", then return. The script is not executed.

\section*{Note}

This means specifying nomodule \({ }^{p 615}\) on a module script \({ }^{p 925}\) has no effect; the algorithm continues onward.
15. If the script \({ }^{\mathrm{p} 614}\) element does not have a src \({ }^{\mathrm{p} 615}\) content attribute, and the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon the script \({ }^{\text {p614 }}\) element, "script", and source text, then return. The script is not executed. [CSP] \({ }^{p 1285}\)
16. If the script \({ }^{p 614}\) element has an event \({ }^{p 1235}\) attribute and a for \({ }^{p 1235}\) attribute, and the script's type \({ }^{p 619}\) is "classic", then:
1. Let for be the value of the for \({ }^{p 1235}\) attribute.
2. Let event be the value of the event \({ }^{\text {p1235 }}\) attribute.
3. Strip leading and trailing ASCII whitespace from event and for.
4. If for is not an ASCII case-insensitive match for the string "window", then return. The script is not executed.
5. If event is not an ASCII case-insensitive match for either the string "onload" or the string "onload()", then return. The script is not executed.
17. If the script \({ }^{p 614}\) element has a charset \({ }^{p 1233}\) attribute, then let encoding be the result of getting an encoding from the value of the charset \({ }^{\text {p1233 }}\) attribute.

If the script \({ }^{p 614}\) element does not have a charset \({ }^{p 1233}\) attribute, or if getting an encoding failed, let encoding be the same as the encoding of the script \({ }^{\text {p614 }}\) element's node document.

\section*{Note}

If the script's type \({ }^{p 619}\) is "module", this encoding will be ignored.
18. Let classic script CORS setting be the current state of the element's crossorigin \({ }^{\text {p616 }}\) content attribute.
19. Let module script credentials mode be the CORS settings attribute credentials mode \({ }^{\text {p91 }}\) for the element's crossorigin \({ }^{\text {p616 }}\) content attribute.
20. Let cryptographic nonce be the element's [[CryptographicNonce] ] \({ }^{\text {p92 }}\) internal slot's value.
21. If the script \({ }^{\text {p614 }}\) element has an integrity \({ }^{p 616}\) attribute, then let integrity metadata be that attribute's value. Otherwise, let integrity metadata be the empty string.
22. Let referrer policy be the current state of the element's referrerpolicy \({ }^{\text {p616 }}\) content attribute.
23. Let parser metadata be "parser-inserted" if the script \({ }^{\text {p614 }}\) element is "parser-inserted"p619 , and "not-parser-inserted" otherwise.
24. Let options be a script fetch options \({ }^{\mathrm{p} 926}\) whose cryptographic nonce \({ }^{\mathrm{p} 926}\) is cryptographic nonce, integrity metadata \({ }^{\mathrm{p} 926}\) is integrity metadata, parser metadata \({ }^{\text {p926 }}\) is parser metadata, credentials mode \({ }^{\text {p926 }}\) is module script credentials mode, and referrer policy \({ }^{\text {p926 }}\) is referrer policy.
25. Let settings object be the element's node document's relevant settings object \({ }^{\mathrm{p} 924}\).
26. If the element has a \(s_{r c}{ }^{p 615}\) content attribute, then:
1. Let src be the value of the element's \(\underline{s r c}^{p 615}\) attribute.
2. If \(s r c\) is the empty string, queue a task \({ }^{\text {p945 }}\) to fire an event named error \({ }^{p 1281}\) at the element, and return.
3. Set the element's from an external file \({ }^{\text {p619 }}\) flag.
4. Parse \({ }^{\mathrm{p} 89}\) src relative to the element's node document.
5. If the previous step failed, queue a task \({ }^{\text {p945 }}\) to fire an event named error \({ }^{p 1281}\) at the element, and return. Otherwise, let url be the resulting URL record \({ }^{\mathrm{p89}}\).
6. Switch on the script's type \({ }^{\text {p619 }}\) :
\(\rightarrow\) "classic"
Fetch a classic script \({ }^{\mathrm{p} 927}\) given url, settings object, options, classic script CORS setting, and encoding.
\(\rightarrow\) "module"
Fetch an external module script graph \({ }^{\text {p929 }}\) given url, settings object, and options.
When the chosen algorithm asynchronously completes, set the script's script \({ }^{p 619}\) to the result. At that time, the script is ready \({ }^{\text {p619 }}\).

For performance reasons, user agents may start fetching the classic script or module graph (as defined above) as soon as the src \({ }^{p 615}\) attribute is set, instead, in the hope that the element will be inserted into the document (and that the crossorigin \({ }^{p 616}\) attribute won't change value in the meantime). Either way, once the element is inserted into the document \({ }^{\text {p44 }}\), the load must have started as described in this step. If the UA performs such prefetching, but the element is never inserted in the document, or the src \({ }^{p 615}\) attribute is dynamically changed, or the crossorigin \({ }^{p 616}\) attribute is dynamically changed, then the user agent will not execute the script so obtained, and the fetching process will have been effectively wasted.
27. If the element does not have a \(\mathrm{src}^{\mathrm{p} 615}\) content attribute, run these substeps:
1. Let base URL be the script \({ }^{\text {p614 }}\) element's node document's document base URL \({ }^{\mathrm{p} 88}\).
2. Switch on the script's type \({ }^{\mathrm{p} 619}\) :
```
@ "classic"
```
1. Let script be the result of creating a classic script \({ }^{\text {p933 }}\) using source text, settings object, base URL, and options.
2. Set the script's script \({ }^{p 619}\) to script.
3. The script is ready \({ }^{\text {p619 }}\).
\(\rightarrow\) "module"
1. Fetch an inline module script graph \({ }^{\text {p929 }}\), given source text, base URL, settings object, and options. When this asynchronously completes, set the script's script \({ }^{\text {p619 }}\) to the result. At that time, the script is ready \({ }^{\text {p619 }}\).
28. Then, follow the first of the following options that describes the situation:
\(\rightarrow\) If the script's type \({ }^{\text {p619 }}\) is "classic", and the element has a src \({ }^{\text {p615 }}\) attribute, and the element has a defer \({ }^{\text {p615 }}\) attribute, and the element is "parser-inserted" \({ }^{p 619}\), and the element does not have an async \({ }^{p 615}\) attribute
\(\leftrightarrow\) If the script's type \({ }^{\text {p619 }}\) is "module", and the element is "parser-inserted" \({ }^{p 619}\), and the element does not have an async \({ }^{\text {p615 }}\) attribute

Add the element to the end of the list of scripts that will execute when the document has finished parsing associated with the Document \({ }^{\text {p114 }}\) of the parser that created the element.

When the script is ready \({ }^{\text {p619 }}\), set the element's "ready to be parser-executed" \({ }^{\text {p619 }}\) flag. The parser will handle executing the script.

\section*{\(\rightarrow\) If the script's type \({ }^{p 619}\) is "classic", and the element has a \(s r c^{p 615}\) attribute, and the element is "parser-} inserted" \({ }^{\mathrm{p} 619}\), and the element does not have an async \({ }^{\text {p615 }}\) attribute

The element is the pending parsing-blocking script \({ }^{\mathrm{p} 623}\) of the Document \({ }^{\mathrm{p} 114}\) of the parser that created the element. (There can only be one such script per Document \({ }^{\text {p114 }}\) at a time.)

When the script is ready \({ }^{\text {p619 }}\), set the element's "ready to be parser-executed" \({ }^{p 619}\) flag. The parser will handle executing
the script.
\(\rightarrow\) If the script's type \({ }^{\mathrm{p} 619}\) is "classic", and the element has a src \({ }^{p 615}\) attribute, and the element does not have an async \({ }^{\text {p615 }}\) attribute, and the element does not have the "non-blocking" p619 flag set
\(\rightarrow\) If the script's type \({ }^{\text {p619 }}\) is "module", and the element does not have an async \({ }^{\text {p615 }}\) attribute, and the element does not have the "non-blocking"p619 flag set

Add the element to the end of the list of scripts that will execute in order as soon as possible associated with the element's preparation-time document \({ }^{\mathrm{p} 619}\).

When the script is ready \({ }^{p 619}\), run the following steps:
1. If the element is not now the first element in the list of scripts that will execute in order as soon as possible \({ }^{\text {p623 }}\) to which it was added above, then mark the element as ready but return without executing the script yet.
2. Execution: Execute the script block \({ }^{p 623}\) corresponding to the first script element in this list of scripts that will execute in order as soon as possible \({ }^{\text {p623 }}\).
3. Remove the first element from this list of scripts that will execute in order as soon as possible \({ }^{\text {p623 }}\).
4. If this list of scripts that will execute in order as soon as possible \({ }^{\text {p623 }}\) is still not empty and the first entry has already been marked as ready, then jump back to the step labeled execution.
\(\rightarrow\) If the script's type \({ }^{\text {p619 }}\) is "classic", and the element has a src \({ }^{p 615}\) attribute
\(\rightarrow\) If the script's type \({ }^{\text {p619 }}\) is "module"
The element must be added to the set of scripts that will execute as soon as possible of the element's preparation-time document \({ }^{\text {p619 }}\).

When the script is ready \({ }^{\text {p619 }}\), execute the script block \({ }^{\text {p623 }}\) and then remove the element from the set of scripts that will execute as soon as possible \({ }^{\text {p623 }}\).
\(\rightarrow\) If the element does not have a src \({ }^{p 615}\) attribute, and the element is "parser-inserted" \({ }^{p 619}\), and either the parser that created the script \({ }^{\text {p614 }}\) is an XML parser \({ }^{\text {p1188 }}\) or it's an HTML parser \({ }^{\text {p1079 }}\) whose script nesting level \({ }^{\text {p1081 }}\) is not greater than one, and the element's parser document \({ }^{\text {p619 }}\) has a style sheet that is blocking scripts \({ }^{\text {p178 }}\)

The element is the pending parsing-blocking script \({ }^{\text {p623 }}\) of its parser document \({ }^{\text {p619 }}\). (There can only be one such script per Document \({ }^{\text {p114 }}\) at a time.)

Set the element's "ready to be parser-executed" 0619 flag. The parser will handle executing the script.

\section*{\(\leftrightarrow\) Otherwise}

Immediately \({ }^{\text {p42 }}\) execute the script block \({ }^{\text {p623 }}\), even if other scripts are already executing.
The pending parsing-blocking script of a Document \({ }^{\text {p114 }}\) is used by the Document \({ }^{\text {p114' }}\) 's parser(s).

\section*{Note}

If a script \({ }^{\text {p614 }}\) element that blocks a parser gets moved to another Document \({ }^{\text {p114 }}\) before it would normally have stopped blocking that parser, it nonetheless continues blocking that parser until the condition that causes it to be blocking the parser no longer applies (e.g., if the script is a pending parsing-blocking script \({ }^{p 623}\) because the original Document \({ }^{\text {p114 }}\) has a style sheet that is blocking scripts \({ }^{p 178}\) when it was parsed, but then the script is moved to another Document \({ }^{\text {p114 }}\) before the blocking style sheet(s) loaded, the script still blocks the parser until the style sheets are all loaded, at which time the script executes and the parser is unblocked).

To execute a script block given a script \({ }^{p 614}\) element scriptElement:
1. Let document be scriptElement's node document.
2. If scriptElement's preparation-time document \({ }^{\text {p619 }}\) is not equal to document, then return.
3. If the script's script \({ }^{\text {p619 }}\) is null for scriptElement, then fire an event named error \({ }^{p 1281}\) at scriptElement, and return.
4. If scriptElement is from an external file \({ }^{\text {p619 }}\), or the script's type \({ }^{\text {p619 }}\) for scriptElement is "module", then increment document's ignore-destructive-writes counter \({ }^{\text {p970 }}\).
5. Switch on the script's type \({ }^{\text {p619 }}\) for scriptElement:
```
↔"classic"
```
1. Let oldCurrentScript be the value to which document's currentScript \({ }^{\text {p120 }}\) object was most recently set.
2. If scriptElement's root is not a shadow root, then set document's currentScript \({ }^{p 12 \theta}\) attribute to scriptElement. Otherwise, set it to null.

\section*{Note}

This does not use the in a document tree check, as scriptElement could have been removed from the document prior to execution, and in that scenario currentScript \({ }^{\text {p120 }}\) still needs to point to it.
3. Run the classic script \({ }^{\mathrm{p934}}\) given by the script's script \({ }^{\mathrm{p} 619}\) for scriptElement.
4. Set document's currentScript \({ }^{p 12 \theta}\) attribute to oldCurrentScript.
\(\rightarrow\) "module"
1. Assert: document's currentScript \({ }^{\text {p120 }}\) attribute is null.
2. Run the module script \({ }^{p 935}\) given by the script's script \({ }^{\text {p619 }}\) for scriptElement.
6. Decrement the ignore-destructive-writes counter \({ }^{\text {p970 }}\) of document, if it was incremented in the earlier step.
7. If scriptElement is from an external file \({ }^{\mathrm{p} 619}\), then fire an event named load \({ }^{\text {p1282 }}\) at scriptElement.

\subsection*{4.12.1.2 Scripting languages \(\S^{p 62}\)}

User agents are not required to support JavaScript. This standard needs to be updated if a language other than JavaScript comes along and gets similar wide adoption by web browsers. Until such a time, implementing other languages is in conflict with this standard, given the processing model defined for the script \({ }^{\text {p614 }}\) element.

Servers should use text/javascript \({ }^{\text {p1283 }}\) for JavaScript resources. Servers should not use other JavaScript MIME types for JavaScript resources, and must not use non-JavaScript MIME types.

For external JavaScript resources, MIME type parameters in `Content-Type \({ }^{\text {p99`` }}\) headers are generally ignored. (In some cases the `charset` parameter has an effect.) However, for the script \({ }^{\text {p614 }}\) element's type \({ }^{\text {p615 }}\) attribute they are significant; it uses the JavaScript MIME type essence match concept.

\section*{Note}

For example, scripts with their type \({ }^{p 615}\) attribute set to "text/javascript; charset=utf-8" will not be evaluated, even though that is a valid JavaScript MIME type when parsed.

Furthermore, again for external JavaScript resources, special considerations apply around `Content-Type \({ }^{\text {p90`` }}\) header processing as detailed in the prepare a script \({ }^{\text {p620 }}\) algorithm and Fetch. [FETCH] \({ }^{\text {p1287 }}\)

\subsection*{4.12.1.3 Restrictions for contents of script elements \(\S^{p 62}\)}

\section*{Note}

The easiest and safest way to avoid the rather strange restrictions described in this section is to always escape an ASCII caseinsensitive match for "<!--" as "<\!--", "<script" as "<\script", and "</script" as "<\/script" when these sequences appear in literals in scripts (e.g. in strings, regular expressions, or comments), and to avoid writing code that uses such constructs in expressions. Doing so avoids the pitfalls that the restrictions in this section are prone to triggering: namely, that, for historical reasons, parsing of script \({ }^{p 614}\) blocks in HTML is a strange and exotic practice that acts unintuitively in the face of these sequences.

The script \({ }^{\text {p614 }}\) element's descendant text content must match the script production in the following ABNF, the character set for which is Unicode. [ABNF] \({ }^{\text {p1285 }}\)
```
script = outer *( comment-open inner comment-close outer )
outer = < any string that doesn't contain a substring that matches not-in-outer >
not-in-outer = comment-open
inner = < any string that doesn't contain a substring that matches not-in-inner >
not-in-inner = comment-close / script-open
comment-open = "<!--"
comment-close = "-->"
script-open = "<" s c r i p t tag-end
S = %x0053 ; U+0053 LATIN CAPITAL LETTER S
s =/ %x0073 ; U+0073 LATIN SMALL LETTER S
C = %x0043 ; U+0043 LATIN CAPITAL LETTER C
c =/ %x0063 ; U+0063 LATIN SMALL LETTER C
r = %x0052 ; U+0052 LATIN CAPITAL LETTER R
r =/ %x0072 ; U+0072 LATIN SMALL LETTER R
i = %x0049 ; U+0049 LATIN CAPITAL LETTER I
i =/ %x0069 ; U+0069 LATIN SMALL LETTER I
p = %x0050 ; U+0050 LATIN CAPITAL LETTER P
p =/ %x0070 ; U+0070 LATIN SMALL LETTER P
t = %x0054 ; U+0054 LATIN CAPITAL LETTER T
t =/ %x0074 ; U+0074 LATIN SMALL LETTER T
tag-end = %x0009 ; U+0009 CHARACTER TABULATION (tab)
tag-end =/ %x000A ; U+000A LINE FEED (LF)
tag-end =/ %x000C ; U+000C FORM FEED (FF)
tag-end =/ %x0020 ; U+0020 SPACE
tag-end =/ %x002F ; U+002F SOLIDUS (/)
tag-end =/ %x003E ; U+003E GREATER-THAN SIGN (>)
```

When a script \({ }^{\text {p614 }}\) element contains script documentation \({ }^{\text {p626 }}\), there are further restrictions on the contents of the element, as described in the section below.

\section*{Example}

The following script illustrates this issue. Suppose you have a script that contains a string, as in:
```
var example = 'Consider this string: <!-- <script>';
console.log(example);
```

If one were to put this string directly in a script \({ }^{\mathrm{p} 614}\) block, it would violate the restrictions above:
```
<script>
    var example = 'Consider this string: <!-- <script>';
    console.log(example);
</script>
```

The bigger problem, though, and the reason why it would violate those restrictions, is that actually the script would get parsed weirdly: the script block above is not terminated. That is, what looks like a "</script>" end tag in this snippet is actually still part of the script \({ }^{p 614}\) block. The script doesn't execute (since it's not terminated); if it somehow were to execute, as it might if the markup looked as follows, it would fail because the script (highlighted here) is not valid JavaScript:
```
<script>
    var example = 'Consider this string: <!-- <script>';
    console.log(example);
</script>
<!-- despite appearances, this is actually part of the script still! -->
<script>
... // this is the same script block still...
</script>
```

What is going on here is that for legacy reasons, " < ! - " " and "<script" strings in script \({ }^{\text {p614 }}\) elements in HTML need to be balanced in order for the parser to consider closing the block.

By escaping the problematic strings as mentioned at the top of this section, the problem is avoided entirely:
```
<script>
    // Note: `\s` is an escape sequence for `s`.
    var example = 'Consider this string: <\!-- <\script>';
    console.log(example);
</script>
<!-- this is just a comment between script blocks -->
<script>
    ... // this is a new script block
</script>
```

It is possible for these sequences to naturally occur in script expressions, as in the following examples:
```
if (x<!--y) { ... }
if ( player<script ) { ... }
```

In such cases the characters cannot be escaped, but the expressions can be rewritten so that the sequences don't occur, as in:
```
if (x < !--y) { ... }
if (!--y > x) { ... }
if (!(--y) > x) { ... }
if (player < script) { ... }
if (script > player) { ... }
```

Doing this also avoids a different pitfall as well: for related historical reasons, the string "<!--" in classic scripts \({ }^{\text {p925 }}\) is actually treated as a line comment start, just like "//".

\subsection*{4.12.1.4 Inline documentation for external scripts \(\S_{6}^{p 62}\)}

If a script \({ }^{p 614}\) element's \(\underline{s r c}{ }^{p 615}\) attribute is specified, then the contents of the script \({ }^{\text {p614 }}\) element, if any, must be such that the value of the text \({ }^{\text {p617 }}\) IDL attribute, which is derived from the element's contents, matches the documentation production in the following \(A B N F\), the character set for which is Unicode. [ABNF] \({ }^{\text {p1285 }}\)
```
documentation = *( *( space / tab / comment ) [ line-comment ] newline )
comment = slash star *( not-star / star not-slash ) 1*star slash
line-comment = slash slash *not-newline
; characters
tab = %x0009 ; U+0009 CHARACTER TABULATION (tab)
newline = %x000A ; U+000A LINE FEED (LF)
space = %x0020 ; U+0020 SPACE
star = %x002A ; U+002A ASTERISK (*)
slash = %x002F ; U+002F SOLIDUS (/)
not-newline = %x0000-0009 / %x000B-10FFFF
    ; a scalar value other than U+000A LINE FEED (LF)
not-star = %x0000-0029 / %x002B-10FFFF
    ; a scalar value other than U+002A ASTERISK (*)
not-slash = %x0000-002E / %x0030-10FFFF
    ; a scalar value other than U+002F SOLIDUS (/)
```

Note
This corresponds to putting the contents of the element in JavaScript comments.

This requirement is in addition to the earlier restrictions on the syntax of contents of script \({ }^{\text {p614 }}\) elements.

\section*{Example}

This allows authors to include documentation, such as license information or API information, inside their documents while still referring to external script files. The syntax is constrained so that authors don't accidentally include what looks like valid script while also providing a src \({ }^{p 615}\) attribute.
```
<script src="cool-effects.js">
    // create new instances using:
    // var e = new Effect();
    // start the effect using .play, stop using .stop:
    // e.play();
    // e.stop();
</script>
```

\section*{}

This section is non-normative.
This specification does not define how XSLT interacts with the script \({ }^{p 614}\) element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, based on existing implementations:
- When an XSLT transformation program is triggered by an <?xml-stylesheet?> processing instruction and the browser implements a direct-to-DOM transformation, script \({ }^{\text {p614 }}\) elements created by the XSLT processor need to have its parser document \({ }^{\text {p619 }}\) set correctly, and run in document order (modulo scripts marked defer \({ }^{\text {p615 }}\) or async \({ }^{\text {p615 }}\) ), immediately \({ }^{\text {p42 }}\), as the transformation is occurring.
- The XSLTProcessor \({ }^{p 5 \theta}\) transformToDocument () \()^{p 50}\) method adds elements to a Document \({ }^{\text {p114 }}\) object with a null browsing context \({ }^{\text {p811 }}\), and, accordingly, any script \({ }^{\text {p614 }}\) elements they create need to have their "already started" \({ }^{p 619}\) flag set in the prepare a script \({ }^{\text {p620 }}\) algorithm and never get executed (scripting is disabled \({ }^{\text {p924 }}\) ). Such script \({ }^{\text {p614 }}\) elements still need to have their parser document \({ }^{\text {p619 }}\) set, though, such that their async \({ }^{\text {p617 }}\) IDL attribute will return false in the absence of an async \({ }^{\text {p615 }}\) content attribute.
- The XSLTProcessor \({ }^{p 5 \theta}\) transformToFragment () \()^{p 5 \theta}\) method needs to create a fragment that is equivalent to one built manually by creating the elements using document. createElementNS (). For instance, it needs to create script \({ }^{\text {p614 }}\) elements with null parser document \({ }^{\text {p619 }}\) and that don't have their "already started" 6619 flag set, so that they will execute when the fragment is inserted into a document.

The main distinction between the first two cases and the last case is that the first two operate on Document \({ }^{\text {p114 }} \mathrm{S}\) and the last operates on a fragment.

\subsection*{4.12.2 The noscript element \(\S^{\text {p62 }}\)}

Categories \({ }^{\text {p128 }}\) :
Metadata content \({ }^{\text {p131 }}\).
Flow content \({ }^{\text {p131 }}\).
Phrasing content \({ }^{\text {p132 }}\).
Contexts in which this element can be used \({ }^{\text {p128 }}\) :
In a head \({ }^{\text {p153 }}\) element of an HTML document, if there are no ancestor noscript \({ }^{\text {p627 }}\) elements.
Where phrasing content \({ }^{\text {p132 }}\) is expected in HTML documents, if there are no ancestor noscript \({ }^{\text {p627 }}\) elements.

\section*{Content model \({ }^{\text {p128 }}\) :}

When scripting is disabled \({ }^{p 924}\), in a head \({ }^{p 153}\) element: in any order, zero or more link \({ }^{p 157}\) elements, zero or more style \({ }^{p 174}\) elements, and zero or more meta \({ }^{\text {p164 }}\) elements.
When scripting is disabled \({ }^{\text {p924 }}\), not in a head \({ }^{p 153}\) element: transparent \({ }^{\text {p133 }}\), but there must be no noscript \({ }^{\text {p627 }}\) element descendants.

Otherwise: text that conforms to the requirements given in the prose.
Tag omission in text/html \({ }^{\text {p128 }}\) :
Neither tag is omissible.
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{\text {p136 }}\)
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
DOM interface \({ }^{\text {p129 }}\) :
Uses HTMLElement \({ }^{\text {p124 }}\).

The noscript \({ }^{\text {p627 }}\) element represents \({ }^{\text {p123 }}\) nothing if scripting is enabled \({ }^{\text {p924 }}\), and represents \({ }^{p 123}\) its children if scripting is disabled \({ }^{\text {p924 }}\). It is used to present different markup to user agents that support scripting and those that don't support scripting, by affecting how the document is parsed.

When used in HTML documents, the allowed content model is as follows:
In a head \({ }^{\text {p153 }}\) element, if scripting is disabled \({ }^{\text {p924 }}\) for the noscript \({ }^{\text {p627 }}\) element
The noscript \({ }^{\text {p627 }}\) element must contain only link \({ }^{\text {p157 }}\), style \({ }^{\text {p174 }}\), and meta \({ }^{\text {p164 }}\) elements.
In a head \({ }^{\text {p153 }}\) element, if scripting is enabled \({ }^{\text {p924 }}\) for the noscript \({ }^{\text {p627 }}\) element
The noscript \({ }^{\text {p627 }}\) element must contain only text, except that invoking the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\) with the noscript \({ }^{\text {p627 }}\) element as the context \({ }^{p 1177}\) element and the text contents as the input must result in a list of nodes that consists only of \(\underline{l i n k}{ }^{p 157}\), style \({ }^{\text {p174 }}\), and meta \({ }^{p 164}\) elements that would be conforming if they were children of the noscript \({ }^{\text {p627 }}\) element, and no parse errors \({ }^{\text {p1081 }}\).

Outside of head \({ }^{p 153}\) elements, if scripting is disabled \({ }^{\text {p924 }}\) for the noscript \({ }^{\text {p627 }}\) element
The noscript \({ }^{p 627}\) element's content model is transparent \({ }^{p 133}\), with the additional restriction that a noscript \({ }^{\text {p627 }}\) element must not have a noscript \({ }^{\text {p627 }}\) element as an ancestor (that is, noscript \({ }^{\text {p627 }}\) can't be nested).

Outside of head \({ }^{\text {p153 }}\) elements, if scripting is enabled \({ }^{\text {p924 }}\) for the noscript \({ }^{\text {p627 }}\) element
The noscript \({ }^{\text {p627 }}\) element must contain only text, except that the text must be such that running the following algorithm results in a conforming document with no noscript \({ }^{p 627}\) elements and no script \({ }^{\text {p614 }}\) elements, and such that no step in the algorithm throws an exception or causes an HTML parser \({ }^{\text {p1079 }}\) to flag a parse error \({ }^{\text {p1081 }}\) :
1. Remove every script \({ }^{\text {p614 }}\) element from the document.
2. Make a list of every noscript \({ }^{\text {p627 }}\) element in the document. For every noscript \({ }^{\text {p627 }}\) element in that list, perform the following steps:
1. Let \(s\) be the child text content of the noscript \({ }^{\text {p627 }}\) element.
2. Set the outerHTML attribute of the noscript \({ }^{\text {p627 }}\) element to the value of \(s\). (This, as a side-effect, causes the noscript \({ }^{\text {p627 }}\) element to be removed from the document.) [DOMPARSING] \({ }^{\text {p1287 }}\)

\section*{Note}

All these contortions are required because, for historical reasons, the noscript \({ }^{p 627}\) element is handled differently by the HTML parser \({ }^{p 1079}\) based on whether scripting was enabled or not \({ }^{p 1096}\) when the parser was invoked.

The noscript \({ }^{\text {p627 }}\) element must not be used in XML documents.

\section*{Note}

The noscript \({ }^{\text {p627 }}\) element is only effective in the HTML syntax \({ }^{\text {p1067 }}\), it has no effect in the XML syntax \({ }^{p 1188}\). This is because the way it works is by essentially "turning off" the parser when scripts are enabled, so that the contents of the element are treated as pure text and not as real elements. XML does not define a mechanism by which to do this.

The noscript \({ }^{\text {p627 }}\) element has no other requirements. In particular, children of the noscript \({ }^{\text {p627 }}\) element are not exempt from form submission \({ }^{\text {p595 }}\), scripting, and so forth, even when scripting is enabled \({ }^{\text {p924 }}\) for the element.

In the following example, a noscript \({ }^{\text {p627 }}\) element is used to provide fallback for a script.
```
<form action="calcSquare.php">
    <p>
        <label for=x>Number</label>:
        <input id="x" name="x" type="number">
    </p>
    <script>
    var x = document.getElementById('x');
    var output = document.createElement('p');
    output.textContent = 'Type a number; it will be squared right then!';
    x.form.appendChild(output);
    x.form.onsubmit = function () { return false; }
    x.oninput = function () {
            var v = x.valueAsNumber;
            output.textContent = v + ' squared is ' + v * v;
    };
    </script>
    <noscript>
    <input type=submit value="Calculate Square">
    </noscript>
</form>
```

When script is disabled, a button appears to do the calculation on the server side. When script is enabled, the value is computed on-the-fly instead.

The noscript \({ }^{\text {p627 }}\) element is a blunt instrument. Sometimes, scripts might be enabled, but for some reason the page's script might fail. For this reason, it's generally better to avoid using noscript \({ }^{\text {p627 }}\), and to instead design the script to change the page from being a scriptless page to a scripted page on the fly, as in the next example:
```
<form action="calcSquare.php">
    <p>
        <label for=x>Number</label>:
        <input id="x" name="x" type="number">
    </p>
    <input id="submit" type=submit value="Calculate Square">
    <script>
        var x = document.getElementById('x');
        var output = document.createElement('p');
        output.textContent = 'Type a number; it will be squared right then!';
        x.form.appendChild(output);
        x.form.onsubmit = function () { return false; }
        x.oninput = function () {
            var v = x.valueAsNumber;
            output.textContent = v + ' squared is ' + v * v;
        };
        var submit = document.getElementById('submit');
        submit.parentNode.removeChild(submit);
    </script>
</form>
```

The above technique is also useful in XML documents, since noscript \({ }^{\text {p627 }}\) is not allowed there.

\subsection*{4.12.3 The template element \(\S^{p 62}\)}

\section*{Categories \({ }^{\text {p128 }}\) :}

Metadata content \({ }^{p 131}\).
Flow content \({ }^{\text {p131 }}\).

Phrasing content \({ }^{\mathrm{p} 132}\).
Script-supporting element \({ }^{\text {p133 }}\).

\section*{Contexts in which this element can be used \({ }^{\text {p128 }}\) :}

Where metadata content \({ }^{p 131}\) is expected.
Where phrasing content \({ }^{\mathrm{p} 132}\) is expected.
Where script-supporting elements \({ }^{\text {p133 }}\) are expected.
As a child of a colgroup \({ }^{\text {p459 }}\) element that doesn't have a span \({ }^{\text {p460 }}\) attribute.

\section*{Content model \({ }^{\text {p128 }}\) :}

Nothing \({ }^{\text {p130 }}\) (for clarification, see example \({ }^{\text {p630 }}\) ).

\section*{Tag omission in text/html \({ }^{\text {p128 }}\) :}

Neither tag is omissible.

\section*{Content attributes \({ }^{\text {p128 }}\) :}

Global attributes \({ }^{\text {p136 }}\)

\section*{Accessibility considerations \({ }^{\text {p129 }}\) :}

For authors.
For implementers.

\section*{DOM interface \({ }^{\text {p129 }}\) :}

IDL [Exposed=Window]
interface HTMLTemplateElement : HTMLElement \{ [HTMLConstructor] constructor(); readonly attribute DocumentFragment content; \};

The template \({ }^{\text {p629 }}\) element is used to declare fragments of HTML that can be cloned and inserted in the document by script.
In a rendering, the template \({ }^{\text {p629 }}\) element represents \({ }^{\text {p123 }}\) nothing.
The template contents \({ }^{\mathrm{p} 631}\) of a template \({ }^{\text {p629 }}\) element are not children of the element itself \({ }^{\text {p1069 }}\).

\section*{Note}

It is also possible, as a result of DOM manipulation, for a template \({ }^{\text {p629 }}\) element to contain Text nodes and element nodes; however, having any is a violation of the template \({ }^{\text {p629 }}\) element's content model, since its content model is defined as nothing \({ }^{p 130}\).

\section*{Example}

For example, consider the following document:
```
<!doctype html>
<html lang="en">
    <head>
        <title>Homework</title>
        <body>
        <template id="template"><p>Smile!</p></template>
        <script>
        let num = 3;
        const fragment = document.getElementById('template').content.cloneNode(true);
        while (num-- > 1) {
            fragment.firstChild.before(fragment.firstChild.cloneNode(true));
            fragment.firstChild.textContent += fragment.lastChild.textContent;
        }
        document.body.appendChild(fragment);
        </script>
</html>
```

The \(p^{p 211}\) element in the template \({ }^{p 629}\) is not a child of the template \({ }^{p 629}\) in the DOM; it is a child of the DocumentFragment returned by the template \({ }^{\text {p629 }}\) element's content \({ }^{\text {p631 }}\) IDL attribute.

If the script were to call appendChild() on the template \({ }^{\text {p629 }}\) element, that would add a child to the template \({ }^{\text {p629 }}\) element (as for any other element); however, doing so is a violation of the template \({ }^{p 629}\) element's content model.

\section*{For web developers (non-normative)}
template . content \({ }^{\text {p631 }}\)
Returns the template contents \({ }^{\mathrm{p} 631}\) (a DocumentFragment).

Each template \({ }^{p 629}\) element has an associated DocumentFragment object that is its template contents. The template contents \({ }^{\text {p631 }}\) have no conformance requirements \({ }^{p 123}\). When a template \({ }^{\text {p629 }}\) element is created, the user agent must run the following steps to establish the template contents \({ }^{\text {p631 }}\) :
1. Let doc be the template \({ }^{p 629}\) element's node document's appropriate template contents owner document \({ }^{\text {p631 }}\).
2. Create a DocumentFragment object whose node document is doc and host is the template \({ }^{\text {p629 }}\) element.
3. Set the template \({ }^{p 629}\) element's template contents \({ }^{p 631}\) to the newly created DocumentFragment object.

A Document \({ }^{\mathrm{p114}}\) doc's appropriate template contents owner document is the Document \({ }^{\text {p114 }}\) returned by the following algorithm:
1. If doc is not a Document \({ }^{\text {p114 }}\) created by this algorithm, then:
1. If doc does not yet have an associated inert template document, then:
1. Let new doc be a new Document \({ }^{p 114}\) (whose browsing context \({ }^{p 811}\) is null). This is "a Document \({ }^{\text {p114 }}\) created \(^{\text {D }}\) by this algorithm" for the purposes of the step above.
2. If doc is an HTML document, mark new doc as an HTML document also.
3. Let doc's associated inert template document \({ }^{\text {p631 }}\) be new doc.
2. Set doc to doc's associated inert template document \({ }^{\mathrm{p} 631}\).

\section*{Note}

Each Document \({ }^{\mathrm{p} 114}\) not created by this algorithm thus gets a single Document \({ }^{\mathrm{p} 114}\) to act as its proxy for owning the template contents \({ }^{p 631}\) of all its template \({ }^{p 629}\) elements, so that they aren't in a browsing context \({ }^{p 811}\) and thus remain inert (e.g. scripts do not run). Meanwhile, template \({ }^{p 629}\) elements inside Document \({ }^{\text {p114 }}\) objects that are created by this algorithm just reuse the same Document \({ }^{\text {p114 }}\) owner for their contents.
2. Return doc.

The adopting steps (with node and oldDocument as parameters) for template \({ }^{\text {p629 }}\) elements are the following:
1. Let doc be node's node document's appropriate template contents owner document \({ }^{\mathrm{p} 631}\).

Note
node's node document is the Document \({ }^{\text {p114 }}\) object that node was just adopted into.
2. Adopt node's template contents \({ }^{\text {p631 }}\) (a DocumentFragment object) into doc.

The content IDL attribute must return the template \({ }^{p 629}\) element's template contents \({ }^{p 631}\).

The cloning steps for a template \({ }^{\text {p629 }}\) element node being cloned to a copy copy must run the following steps:
1. If the clone children flag is not set in the calling clone algorithm, return.
2. Let copied contents be the result of cloning all the children of node's template contents \({ }^{\text {p631 }}\), with document set to copy's template contents \({ }^{\text {p631 }}\) 's node document, and with the clone children flag set.
3. Append copied contents to copy's template contents \({ }^{\text {p631 }}\).

In this example, a script populates a table four-column with data from a data structure, using a template \({ }^{\text {p629 }}\) to provide the element structure instead of manually generating the structure from markup.
```
<!DOCTYPE html>
<html lang='en'>
<title>Cat data</title>
<script>
    // Data is hard-coded here, but could come from the server
    var data = [
        { name: 'Pillar', color: 'Ticked Tabby', sex: 'Female (neutered)', legs: 3 },
        { name: 'Hedral', color: 'Tuxedo', sex: 'Male (neutered)', legs: 4 },
    ];
</script>
<table>
    <thead>
        <tr>
        <th>Name <th>Color <th>Sex <th>Legs
    <tbody>
        <template id="row">
        <tr><td><td><td><td>
        </template>
</table>
<script>
    var template = document.querySelector('#row');
    for (var i = 0; i < data.length; i += 1) {
        var cat = data[i];
        var clone = template.content.cloneNode(true);
        var cells = clone.querySelectorAll('td');
        cells[0].textContent = cat.name;
        cells[1].textContent = cat.color;
        cells[2].textContent = cat.sex;
        cells[3].textContent = cat.legs;
        template.parentNode.appendChild(clone);
}
</script>
```

This example uses cloneNode() on the template \({ }^{\text {p629 }}\) 's contents; it could equivalently have used document.importNode(), which does the same thing. The only difference between these two APIs is when the node document is updated: with cloneNode() it is updated when the nodes are appended with appendChild(), with document.importNode() it is updated when the nodes are cloned.

\subsection*{4.12.3.1 Interaction of template \({ }^{\text {p629 }}\) elements with XSLT and XPath \(\underset{{ }_{2}}{\S^{p 63}}\)}

This section is non-normative.
This specification does not define how XSLT and XPath interact with the template \({ }^{\text {p629 }}\) element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, which are intended to be consistent with other processing described in this specification:
- An XSLT processor based on an XML parser that acts as described in this specification \({ }^{\text {p1188 }}\) needs to act as if template \({ }^{\text {p629 }}\) elements contain as descendants their template contents \({ }^{\text {p631 }}\) for the purposes of the transform.
- An XSLT processor that outputs a DOM needs to ensure that nodes that would go into a template \({ }^{\text {p629 }}\) element are instead placed into the element's template contents \({ }^{\text {p631 }}\).
- XPath evaluation using the XPath DOM API when applied to a Document \({ }^{p 114}\) parsed using the HTML parser \({ }^{\text {p1079 }}\) or the XML parser \({ }^{p 1188}\) described in this specification needs to ignore template contents \({ }^{\text {p631 }}\).
4.12.4 The slot element \(\S^{p 63}\)

\section*{Categories \({ }^{\text {p128 }}\) :}

Flow content \({ }^{\text {p131 }}\).
Phrasing content \({ }^{\mathrm{p} 132}\).

\section*{Contexts in which this element can be used \({ }^{\text {p128 }}\) :}

Where phrasing content \({ }^{\text {p132 }}\) is expected.

\section*{Content model \({ }^{\text {p128 }}\) :}

Transparent \({ }^{\text {p133 }}\)
Tag omission in text/html \({ }^{\text {p128 }}\) :
Neither tag is omissible.
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{\text {p136 }}\)
name \({ }^{\text {p633 }}\) - Name of shadow tree slot
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
DOM interface \({ }^{\text {p129 }}\) :
IDL [Exposed=Window]
interface HTMLSlotElement : HTMLElement \{
[HTMLConstructor] constructor();
[CEReactions] attribute DOMString name;
sequence<Node> assignedNodes(optional AssignedNodesOptions options = \{\});
sequence<Element> assignedElements(optional AssignedNodesOptions options = \{\});
\};
dictionary AssignedNodesOptions \{
boolean flatten = false;
\};

The slot \({ }^{\text {p633 }}\) element defines a slot. It is typically used in a shadow tree. A slot \({ }^{\text {p633 }}\) element represents \({ }^{\text {p123 }}\) its assigned nodes, if any, and its contents otherwise.

The name content attribute may contain any string value. It represents a slot's name.

\section*{Note}

The name \({ }^{\text {p633 }}\) attribute is used to assign slots to other elements: a slot \({ }^{\text {p633 }}\) element with a name \({ }^{\text {p633 }}\) attribute creates a named slot to which any element is assigned if that element has a slot \({ }^{\text {p137 }}\) attribute whose value matches that name \({ }^{\text {p633 }}\) attribute's value, and the slot \({ }^{\text {p633 }}\) element is a child of the shadow tree whose root's host has that corresponding slot \({ }^{\text {p137 }}\) attribute value.

\section*{For web developers (non-normative)}

\section*{slot . name \({ }^{\text {p634 }}\)}

Can be used to get and set slot's name.
slot . assignedNodes \({ }^{\text {p634 }}\) ()
Returns slot's assigned nodes.
slot . assignedNodes \({ }^{\text {p634 }}\) ( \(\{\) flatten: true \})
Returns slot's assigned nodes, if any, and slot's children otherwise, and does the same for any slot \({ }^{\text {p633 }}\) elements encountered therein, recursively, until there are no slot \({ }^{\text {p633 }}\) elements left.
slot. assignedElements \({ }^{\text {p634 }}\) ()
Returns slot's assigned nodes, limited to elements.
slot. assignedElements \({ }^{\text {p634 }}\) ( \(\{\) flatten: true \})
Returns the same as assignedNodes(\{ flatten: true \}) \({ }^{\text {p634 }}\), limited to elements.

The name IDL attribute must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.
The assignedNodes(options) method, when invoked, must run these steps:
1. If the value of options's flatten member is false, then return this element's assigned nodes.
2. Return the result of finding flattened slottables with this element.

The assignedElements(options) method, when invoked, must run these steps:
1. If the value of options's flatten member is false, then return this element's assigned nodes, filtered to contain only Element nodes.
2. Return the result of finding flattened slottables with this element, filtered to contain only Element nodes.

\subsection*{4.12.5 The canvas element \(\S^{p 63}\)}

\section*{Categories \({ }^{\text {p128 }}\) :}

Flow content \({ }^{\text {p131 }}\).
Phrasing content \({ }^{\text {p132 }}\).
Embedded content \({ }^{\mathrm{p} 132}\).
Palpable content \({ }^{\text {p133 }}\).
Contexts in which this element can be used \({ }^{\text {p128 }}\) :
Where embedded content \({ }^{\text {p132 }}\) is expected.

\section*{Content model \({ }^{\text {p128 }}\) :}

Transparent \({ }^{\text {p133 }}\), but with no interactive content \({ }^{p 132}\) descendants except for \(\underline{a}^{\text {p238 }}\) elements, img \({ }^{\text {p320 }}\) elements with usemap \({ }^{\text {p445 }}\) attributes, button \({ }^{\text {p535 }}\) elements, input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute are in the Checkbox \({ }^{\text {p513 }}\) or Radio Button \({ }^{\text {p514 }}\) states, input \({ }^{\text {p493 }}\) elements that are buttons \({ }^{\text {p486 }}\), and select \({ }^{\text {p537 }}\) elements with a multiple \({ }^{\text {p539 }}\) attribute or a display size \({ }^{\text {p539 }}\) greater than 1.

width \({ }^{\text {p635 }}\) - Horizontal dimension
height \({ }^{\text {p635 }}\) - Vertical dimension
Accessibility considerations \({ }^{\text {p129 }}\) :
For authors.
For implementers.
DOM interface \({ }^{\text {p129 }}\) :
IDL
```
typedef (CanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext) RenderingContext;
[Exposed=Window]
interface HTMLCanvasElement : HTMLElement {
    [HTMLConstructor] constructor();
    [CEReactions] attribute unsigned long width;
    [CEReactions] attribute unsigned long height;
    RenderingContext? getContext(DOMString contextId, optional any options = null);
    USVString toDataURL(optional DOMString type = "image/png", optional any quality);
    undefined toBlob(BlobCallback _callback, optional DOMString type = "image/png", optional any
quality);
    OffscreenCanvas transferControlToOffscreen();
};
```
```
callback BlobCallback = undefined (Blob? blob);
```

The canvas \({ }^{\text {p634 }}\) element provides scripts with a resolution-dependent bitmap canvas, which can be used for rendering graphs, game graphics, art, or other visual images on the fly.

Authors should not use the canvas \({ }^{\text {p634 }}\) element in a document when a more suitable element is available. For example, it is inappropriate to use a canvas \({ }^{\text {p634 }}\) element to render a page heading: if the desired presentation of the heading is graphically intense, it should be marked up using appropriate elements (typically \(\underline{h 1^{p 190}}\) ) and then styled using CSS and supporting technologies such as shadow trees.

When authors use the canvas \({ }^{\text {p634 }}\) element, they must also provide content that, when presented to the user, conveys essentially the same function or purpose as the canvas \({ }^{\text {p634' }} \mathrm{s}\) bitmap. This content may be placed as content of the canvas \({ }^{\text {p634 }}\) element. The contents of the canvas \({ }^{\mathrm{p} 634}\) element, if any, are the element's fallback content \({ }^{\mathrm{pp32}}\).

In interactive visual media, if scripting is enabled \({ }^{\text {p924 }}\) for the canvas \({ }^{\text {p634 }}\) element, and if support for canvas \({ }^{\text {p634 }}\) elements has been enabled, then the canvas \({ }^{\rho 634}\) element represents \({ }^{p 123}\) embedded content \({ }^{\text {p132 }}\) consisting of a dynamically created image, the element's bitmap.

In non-interactive, static, visual media, if the canvas \({ }^{\text {p634 }}\) element has been previously associated with a rendering context (e.g. if the page was viewed in an interactive visual medium and is now being printed, or if some script that ran during the page layout process painted on the element), then the canvas \({ }^{\text {p634 }}\) element represents \({ }^{\text {p123 }}\) embedded content \(^{\text {p132 }}\) with the element's current bitmap and size. Otherwise, the element represents its fallback content \({ }^{\text {p132 }}\) instead.

In non-visual media, and in visual media if scripting is disabled \({ }^{\text {p924 }}\) for the canvas \({ }^{\text {p634 }}\) element or if support for canvas \({ }^{\text {p634 }}\) elements has been disabled, the canvas \({ }^{\text {p634 }}\) element represents \({ }^{\text {p123 }}\) its fallback content \({ }^{\text {p132 }}\) instead.

When a canvas \({ }^{p 634}\) element represents \({ }^{p 123}\) embedded content \({ }^{\text {p132 }}\), the user can still focus descendants of the canvas \({ }^{p 634}\) element (in the fallback content \({ }^{\mathrm{p} 332}\) ). When an element is focused \({ }^{\mathrm{p} 771}\), it is the target of keyboard interaction events (even though the element itself is not visible). This allows authors to make an interactive canvas keyboard-accessible: authors should have a one-to-one mapping of interactive regions to focusable areas \({ }^{\text {p770 }}\) in the fallback content \({ }^{\text {p132 }}\). (Focus has no effect on mouse interaction events.) [UIEVENTS] \({ }^{\text {p1292 }}\)

An element whose nearest canvas \({ }^{\text {p634 }}\) element ancestor is being rendered \({ }^{p 1192}\) and represents \({ }^{\text {p123 }}\) embedded content \(^{\text {p132 }}\) is an element that is being used as relevant canvas fallback content.

The canvas \({ }^{\text {p634 }}\) element has two attributes to control the size of the element's bitmap: width and height. These attributes, when specified, must have values that are valid non-negative integers \({ }^{\mathrm{p} 69}\). The rules for parsing non-negative integers \({ }^{\mathrm{p} 69}\) must be used to obtain their numeric values. If an attribute is missing, or if parsing its value returns an error, then the default value must be used instead. The width \({ }^{p 635}\) attribute defaults to 300, and the height \({ }^{p 635}\) attribute defaults to 150 .

When setting the value of the width \({ }^{p 635}\) or height \({ }^{\text {p635 }}\) attribute, if the context mode \({ }^{\text {p636 }}\) of the canvas \({ }^{\text {p634 }}\) element is set to placeholder \({ }^{\text {p636 }}\), the user agent must throw an "InvalidStateError" DOMException and leave the attribute's value unchanged.

The intrinsic dimensions of the canvas \({ }^{\text {p634 }}\) element when it represents \({ }^{\text {p123 }}\) embedded content \({ }^{\text {p132 }}\) are equal to the dimensions of the element's bitmap.

The user agent must use a square pixel density consisting of one pixel of image data per coordinate space unit for the bitmaps of a canvas \({ }^{\text {p634 }}\) and its rendering contexts.

\section*{Note}

A canvas \({ }^{\text {p634 }}\) element can be sized arbitrarily by a style sheet, its bitmap is then subject to the 'object-fit' CSS property.

The bitmaps of canvas \({ }^{\text {p634 }}\) elements, the bitmaps of ImageBitmap \({ }^{\text {p99日 }}\) objects, as well as some of the bitmaps of rendering contexts, such as those described in the sections on the CanvasRenderingContext2D \({ }^{\text {p638 }}\) and ImageBitmapRenderingContext \({ }^{\text {p687 }}\) objects below, have an origin-clean flag, which can be set to true or false. Initially, when the canvas \({ }^{\text {p634 }}\) element or ImageBitmap \({ }^{\text {p990 }}\) object is created, its bitmap's origin-clean \({ }^{\text {p635 }}\) flag must be set to true.

A canvas \({ }^{\text {p634 }}\) element can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of
whether it has a rendering context or not, and what kind of rendering context it is, a canvas \({ }^{p 634}\) also has a canvas context mode, which is initially none but can be changed to either placeholder, 2d, bitmaprenderer, webgl, or webgl2 by algorithms defined in this specification.

When its canvas context mode \({ }^{\text {p636 }}\) is none \({ }^{\text {p636 }}\), a canvas \({ }^{p 634}\) element has no rendering context, and its bitmap must be transparent black with an intrinsic width equal to the numeric value \({ }^{\text {p635 }}\) of the element's width \({ }^{p 635}\) attribute and an intrinsic height equal to the numeric value \({ }^{\text {p635 }}\) of the element's height \({ }^{\text {p635 }}\) attribute, those values being interpreted in CSS pixels, and being updated as the attributes are set, changed, or removed.

When its canvas context mode \({ }^{p 636}\) is placeholder \({ }^{p 636}\), a canvas \({ }^{p 634}\) element has no rendering context. It serves as a placeholder for an OffscreenCanvas \({ }^{\text {p689 }}\) object, and the content of the canvas \({ }^{\text {p634 }}\) element is updated by calling the commit () \()^{\text {p698 }}\) method of the OffscreenCanvas \({ }^{\text {p689 }}\) object's rendering context.

When a canvas \({ }^{\mathrm{p} 634}\) element represents embedded content \({ }^{\mathrm{p132}}\), it provides a paint source whose width is the element's intrinsic width, whose height is the element's intrinsic height, and whose appearance is the element's bitmap.

Whenever the width \({ }^{\text {p635 }}\) and height \({ }^{\text {p635 }}\) content attributes are set, removed, changed, or redundantly set to the value they already have, then the user agent must perform the action from the row of the following table that corresponds to the canvas \({ }^{\text {p634 }}\) element's context mode \({ }^{\text {p636 }}\).
\begin{tabular}{|c|c|}
\hline Context Mode \({ }^{\text {p636 }}\) & Action \\
\hline \(\underline{2 d}{ }^{\text {p636 }}\) & Follow the steps to set bitmap dimensions \({ }^{\text {p644 }}\) to the numeric values \({ }^{\text {p635 }}\) of the width \({ }^{\text {p635 }}\) and height \({ }^{\text {p635 }}\) content attributes. \\
\hline webgl \({ }^{\text {p636 }}\) or webgl2 \({ }^{\text {p636 }}\) & Follow the behavior defined in the WebGL specifications. [WEBGL] \({ }^{\text {p1292 }}\) \\
\hline bitmaprenderer \({ }^{\text {p636 }}\) & If the context's bitmap mode \({ }^{\text {p688 }}\) is set to blank \({ }^{\text {p688 }}\), run the steps to set an ImageBitmapRenderingContext's output bitmap \({ }^{\text {p688 }}\), passing the canvas \({ }^{\text {p634 }}\) element's rendering context. \\
\hline placeholder \({ }^{\text {p636 }}\) & Do nothing. \\
\hline none \({ }^{\text {p636 }}\) & Do nothing. \\
\hline
\end{tabular}

The width and height IDL attributes must reflect \({ }^{\mathrm{p94}}\) the respective content attributes of the same name, with the same defaults.

\section*{For web developers (non-normative)}
context \(=\) canvas. getContext \({ }^{\text {p636 }}\) (contextId [, options ] )
Returns an object that exposes an API for drawing on the canvas. contextld specifies the desired API: " \(2 d^{\text {p636" }}\),
"bitmaprenderer \({ }^{\text {p637", "webgl }}{ }^{\text {p637" }}\), or "webgl2 \({ }^{\text {p637". }}\). options is handled by that API.
This specification defines the " \(2 d^{p 636 "}\) "and "bitmaprenderer \(r^{\text {p637" }}\) contexts below. The WebGL specifications define the "webgl \({ }^{\text {p637" }}\) " and "webgl2 \({ }^{\text {p637" } " ~ c o n t e x t s . ~[W E B G L] ~}{ }^{\text {p1292 }}\)
Returns null if contextld is not supported, or if the canvas has already been initialized with another context type (e.g., trying to get a " \(2 d^{\text {p636" }}\) context after getting a "webgl \({ }^{\text {p637" }}\) context).

The getContext(contextId, options) method of the canvas \({ }^{\text {p634 }}\) element, when invoked, must run these steps:
1. If options is not an object, then set options to null.
2. Set options to the result of converting options to a JavaScript value.
3. Run the steps in the cell of the following table whose column header matches this canvas \({ }^{\text {p634 }}\) element's canvas context mode \({ }^{\text {p636 }}\) and whose row header matches contextld:
\begin{tabular}{|c|c|c|c|c|c|}
\hline & none \({ }^{\text {p636 }}\) & \(2 \mathrm{~d}^{\text {p636 }}\) & bitmaprenderer \({ }^{\text {p636 }}\) & \[
\begin{array}{|l}
\text { webgl| }{ }^{\text {p636 }} \text { or } \\
\text { webgl2 }^{\text {p636 }}
\end{array}
\] & placeholder \({ }^{\text {p636 }}\) \\
\hline "2d" & Follow the 2D context creation algorithm \({ }^{\text {p644 }}\) defined & Return the same object & Return null. & Return null. & Throw an "InvalidStateError" \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|c|}
\hline & none \({ }^{\text {p636 }}\) & \(\underline{2 d}{ }^{\text {p636 }}\) & bitmaprenderer \({ }^{\text {p636 }}\) & webgl \({ }^{\text {p636 }}\) or webgl2 \({ }^{\text {p636 }}\) & placeholder \({ }^{\text {p636 }}\) \\
\hline & in the section below, passing it this canvas \({ }^{\text {p634 }}\) element and options, to obtain a CanvasRenderingContext2D \({ }^{p 638}\) object; if this does not throw an exception, then set this canvas \({ }^{\text {p634 }}\) element's context mode \({ }^{\text {p636 }}\) to \(\underline{2 d^{p 636}}\), and return the CanvasRenderingContext2D \({ }^{\text {p638 }}\) object. & as was returned the last time the method was invoked with this same first argument. & & & DOMException. \\
\hline "bitmaprenderer" & Follow the ImageBitmapRenderingContext creation algorithm \({ }^{\text {p689 }}\) defined in the section below, passing it this canvas \({ }^{\text {p634 }}\) element and options, to obtain an ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object; then set this canvas \({ }^{\text {p634 }}\) element's context mode \({ }^{\text {p636 }}\) to bitmaprenderer \({ }^{\text {p636 }}\), and return the ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object. & Return null. & Return the same object as was returned the last time the method was invoked with this same first argument. & Return null. & Throw an "InvalidStateError" DOMException. \\
\hline "webgl" or "webgl2", if the user agent supports the WebGL feature in its current configuration & Follow the instructions given in the WebGL specifications' Context Creation sections to obtain a WebGLRenderingContext, WebGL2RenderingContext, or null; if the returned value is null, then return null; otherwise, set this canvas \({ }^{\text {p634 }}\) element's context mode \({ }^{\text {p636 }}\) to webg| \({ }^{\text {p636 }}\) or webgl2 \({ }^{\text {p636 }}\), and return the WebGLRenderingContext or WebGL2RenderingContext object. [WEBGL] \({ }^{\text {p1292 }}\) & Return null. & Return null. & Return the same object as was returned the last time the method was invoked with this same first argument. & Throw an "InvalidStateError" DOMException. \\
\hline An unsupported value* & Return null. & Return null. & Return null. & Return null. & Throw an "InvalidStateError" DOMException. \\
\hline
\end{tabular}
* For example, the "webgl \({ }^{\text {p637" }}\) or "webgl2 \({ }^{\text {p637" }}\) value in the case of a user agent having exhausted the graphics hardware's abilities and having no software fallback implementation.

\section*{For web developers (non-normative)}

\section*{url = canvas . toDataURL \({ }^{\text {p637 }}\) ( [ type [, quality ] ])}

Returns a data: URL for the image in the canvas.
The first argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "image/png \({ }^{\text {p1283 " }}\); that type is also used if the given type isn't supported. The second argument applies if the type is an image format that supports variable quality (such as "image/jpeg \({ }^{\text {p1283" }}\) ), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.
When trying to use types other than "image/png \({ }^{\text {p1283" }}\), authors can check if the image was really returned in the requested format by checking to see if the returned string starts with one of the exact strings "data:image/png," or "data:image/png;". If it does, the image is PNG, and thus the requested type was not supported. (The one exception to this is if the canvas has either no height or no width, in which case the result might simply be "data: , ".)
canvas . toBlob \({ }^{\text {p638 }}\) (callback [, type [, quality ] ])
Creates a Blob object representing a file containing the image in the canvas, and invokes a callback with a handle to that object.
The second argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "image/ png \({ }^{\text {p1283 }}\) "; that type is also used if the given type isn't supported. The third argument applies if the type is an image format that supports variable quality (such as "image/jpeg \({ }^{p 1283 "}\) "), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.
canvas. transferControlToOffscreen \({ }^{\text {p638 }}\) ()
Returns a newly created 0 ffscreenCanvas \({ }^{\text {p689 }}\) object that uses the canvas \({ }^{p 634}\) element as a placeholder. Once the canvas \({ }^{\text {p634 }}\) element has become a placeholder for an offscreenCanvas \({ }^{\text {p689 }}\) object, its intrinsic size can no longer be changed, and it cannot have a rendering context. The content of the placeholder canvas is updated by calling the commit () \({ }^{\text {p690 }}\) method of the offscreenCanvas \({ }^{\text {p689 }}\) object's rendering context.

The toDataURL(type, quality) method, when invoked, must run these steps:
1. If this canvas \({ }^{\text {p634 }}\) element's bitmap's origin-clean \({ }^{\text {p635 }}\) flag is set to false, then throw a "SecurityError" DOMException.
2. If this canvas \({ }^{p 634}\) element's bitmap has no pixels (i.e. either its horizontal dimension or its vertical dimension is zero) then return the string "data: , ". (This is the shortest data: URL; it represents the empty string in a text/plain resource.)
3. Let file be a serialization of this canvas element's bitmap as a file \({ }^{\mathrm{p695}}\), passing type and quality if given.
4. If file is null then return "data: , ".
5. Return a data: URL representing file. [RFC2397] \({ }^{\text {p1290 }}\)

The toBlob(callback, type, quality) method, when invoked, must run these steps:
1. If this canvas \({ }^{\text {p634 }}\) element's bitmap's origin-clean \({ }^{\text {p635 }}\) flag is set to false, then throw a "SecurityError" DOMException.
2. Let result be null.
3. If this canvas \({ }^{p 634}\) element's bitmap has pixels (i.e., neither its horizontal dimension nor its vertical dimension is zero), then set result to a copy of this canvas \({ }^{\text {p634 }}\) element's bitmap.
4. Run these steps in parallel \({ }^{p 42}\) :
1. If result is non-null, then set result to a serialization of result as a file \({ }^{\mathrm{p} 695}\) with type and quality if given.
2. Queue an element task \({ }^{\text {p946 }}\) on the canvas blob serialization task source given the canvas \({ }^{\text {p634 }}\) element to run these steps:
1. If result is non-null, then set result to a new Blob object, created in the relevant Realm \({ }^{\text {p924 }}\) of this canvas \({ }^{\text {p634 }}\) element, representing result. [FILEAPI] \({ }^{\text {p1287 }}\)
2. Invoke callback with «result».

The transferControlToOffscreen() method, when invoked, must run these steps:
1. If this canvas \({ }^{p 634}\) element's context mode \({ }^{\text {p636 }}\) is not set to none \({ }^{\text {p636 }}\), throw an "InvalidStateError" DOMException.
2. Let offscreenCanvas be a new OffscreenCanvas \({ }^{\text {p689 }}\) object with its width and height equal to the values of the width \({ }^{\text {p635 }}\) and height \({ }^{\text {p635 }}\) content attributes of this canvas \({ }^{\text {p634 }}\) element.
3. Set the placeholder canvas element \({ }^{\mathrm{p} 690}\) of offscreenCanvas to be a weak reference to this canvas \({ }^{\text {p634 }}\) element.
4. Set this canvas \({ }^{\text {p634 }}\) element's context mode \({ }^{\text {p636 }}\) to placeholder \({ }^{p 636}\).
5. Return offscreenCanvas.

```

Note
To maintain compatibility with existing web content, user agents need to enumerate methods defined in CanvasUserInterface \({ }^{\text {p640 }}\) immediately after the stroke( ( \({ }^{\text {p670 }}\) method on CanvasRenderingContext2D \({ }^{\text {p638 }}\) objects.
```
context = canvas . getContext [636('2d' [, { [ alpha p644 : true ] [, desynchronized p644: false ] } ] )
```

Returns a CanvasRenderingContext2D \({ }^{\text {p638 }}\) object that is permanently bound to a particular canvas \({ }^{\text {p634 }}\) element. If the alpha \({ }^{\text {p644 }}\) member is false, then the context is forced to always be opaque.

If the desynchronized \({ }^{p 644}\) member is true, then the context might be desynchronized \({ }^{\mathrm{p} 643}\).

\section*{context . canvas \({ }^{\text {p644 }}\)}

Returns the canvas \({ }^{p 634}\) element.
attributes \(=\) canvas . getContextAttributes \({ }^{\text {p643 }}\) ()
Returns an object whose:
- alpha \({ }^{p 643}\) member is true if the context has an alpha channel, or false if it was forced to be opaque.
- desynchronized \({ }^{\text {p644 }}\) member is true if the context can be desynchronized \({ }^{\text {p643 }}\).

\section*{A CanvasRenderingContext2D \({ }^{\text {p638 }}\) object has an output bitmap that is initialized when the object is created.}

The output bitmap \({ }^{\text {p643 }}\) has an origin-clean \({ }^{\text {p635 }}\) flag, which can be set to true or false. Initially, when one of these bitmaps is created, its origin-clean \({ }^{\text {p635 }}\) flag must be set to true.

The CanvasRenderingContext2D \({ }^{p 638}\) object also has an alpha boolean. When a CanvasRenderingContext2D \({ }^{p 638}\) object's alpha \({ }^{\text {p643 }}\) is false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

Note
Thus, the bitmap of such a context starts off as opaque black instead of transparent black; clearRect () \({ }^{\text {p666 }}\) always results in opaque black pixels, every fourth byte from getImageData() \({ }^{\text {p676 }}\) is always 255 , the putImageData() \({ }^{\text {p677 }}\) method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the output bitmap \({ }^{p 643}\) 's alpha channel; for instance, drawing a 50\% transparent white square on a freshly created output bitmap \({ }^{p 643}\) with its alpha \({ }^{p 643}\) set to false will result in a fully-opaque gray square.

The CanvasRenderingContext2 \(\mathrm{D}^{\mathrm{p638}}\) object also has a desynchronized boolean. When a CanvasRenderingContext2D \({ }^{\text {p638 }}\) object's desynchronized \({ }^{p 643}\) is true, then the user agent may optimize the rendering of the canvas to reduce the latency, as measured from input events to rasterization, by desynchronizing the canvas paint cycle from the event loop, bypassing the ordinary user agent rendering algorithm, or both. Insofar as this mode involves bypassing the usual paint mechanisms, rasterization, or both, it might introduce visible tearing artifacts.

\section*{Note}

The user agent usually renders on a buffer which is not being displayed, quickly swapping it and the one being scanned out for presentation; the former buffer is called back buffer and the latter front buffer. A popular technique for reducing latency is called front buffer rendering, also known as single buffer rendering, where rendering happens in parallel and racily with the scanning out process. This technique reduces the latency at the price of potentially introducing tearing artifacts and can be used to implement in total or part of the desynchronized \({ }^{\text {p643 }}\) boolean. [MULTIPLEBUFFERING] \({ }^{\text {p1289 }}\)

\section*{Note}

The desynchronized \({ }^{p 643}\) boolean can be useful when implementing certain kinds of applications, such as drawing applications, where the latency between input and rasterization is critical.

The getContextAttributes() method, when invoked, must return a CanvasRenderingContext2DSettings \({ }^{\text {p638 }}\) dictionary containing the following members:
- alpha \({ }^{\text {p643 }}\), set to this context's alpha \({ }^{\text {p643 }}\).
- desynchronized \({ }^{\text {p643 }}\), set to this context's desynchronized \({ }^{\text {p643 }}\).

The CanvasRenderingContext2D \({ }^{\text {p638 }} 2 \mathrm{D}\) rendering context represents a flat linear Cartesian surface whose origin \((0,0)\) is at the top left corner, with the coordinate space having \(x\) values increasing when going right, and \(y\) values increasing when going down. The \(x\)-coordinate of the right-most edge is equal to the width of the rendering context's output bitmap \({ }^{\text {p643 }}\) in CSS pixels; similarly, the
\(y\)-coordinate of the bottom-most edge is equal to the height of the rendering context's output bitmap \({ }^{\text {p643 }}\) in CSS pixels.
The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

\section*{Example}

Using CSS pixels to describe the size of a rendering context's output bitmap \({ }^{\text {p643 }}\) does not mean that when rendered the canvas will cover an equivalent area in CSS pixels. CSS pixels are reused for ease of integration with CSS features, such as text layout.

In other words, the canvas \({ }^{\text {p634 }}\) element below's rendering context has a \(200 \times 200\) output bitmap \({ }^{\text {p643 }}\) (which internally uses CSS pixels as a unit for ease of integration with CSS) and is rendered as \(100 \times 100\) CSS pixels:
```
<canvas width=200 height=200 style=width:100px;height:100px>
```

The 2D context creation algorithm, which is passed a target (a canvas \({ }^{\text {p634 }}\) element) and options, consists of running these steps:
1. Let settings be the result of converting options to the dictionary type CanvasRenderingContext2DSettings \({ }^{\text {p638 }}\). (This can throw an exception.).
2. Let context be a new CanvasRenderingContext2D \({ }^{\text {p638 }}\) object.
3. Initialize context's canvas \({ }^{p 644}\) attribute to point to target.
4. Set context's output bitmap \({ }^{\text {p643 }}\) to the same bitmap as target's bitmap (so that they are shared).
5. Set bitmap dimensions \({ }^{\mathrm{p} 644}\) to the numeric values \({ }^{\mathrm{p} 635}\) of target's width \({ }^{\mathrm{p} 635}\) and height \({ }^{\mathrm{p} 635}\) content attributes.
6. Set context's alpha \({ }^{\text {p643 }}\) to settings's alpha.
7. Set context's desynchronized \({ }^{\text {p643 }}\) to settings's desynchronized.
8. Return context.

When the user agent is to set bitmap dimensions to width and height, it must run these steps:
1. Reset the rendering context to its default state \({ }^{\mathrm{p} 646}\).
2. Resize the output bitmap \({ }^{\text {p643 }}\) to the new width and height and clear it to transparent black.
3. Let canvas be the canvas \({ }^{\rho 634}\) element to which the rendering context's canvas \({ }^{\rho 644}\) attribute was initialized.
4. If the numeric value \({ }^{\text {p635 }}\) of canvas's width \({ }^{p 635}\) content attribute differs from width, then set canvas's width \({ }^{p 635}\) content attribute to the shortest possible string representing width as a valid non-negative integer \({ }^{\mathrm{p} 69}\).
5. If the numeric value \({ }^{\text {p635 }}\) of canvas's height \({ }^{\text {p635 }}\) content attribute differs from height, then set canvas's height \({ }^{\text {p635 }}\) content attribute to the shortest possible string representing height as a valid non-negative integer \({ }^{\text {p69 }}\).

\section*{Example}

Only one square appears to be drawn in the following example:
```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0,0,50,50);
canvas.setAttribute('width', '300'); // clears the canvas
context.fillRect(0,100,50,50);
canvas.width = canvas.width; // clears the canvas
context.fillRect(100,0,50,50); // only this square remains
```

The canvas attribute must return the value it was initialized to when the object was created.

The CanvasFillRule \({ }^{\text {p638 }}\) enumeration is used to select the fill rule algorithm by which to determine if a point is inside or outside a path.

The value "nonzero" value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path going in one direction is equal to the number of times it crosses the path going in the other direction.

The "evenodd" value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a halfinfinite straight line drawn from that point crosses the shape's path is even.

If a point is not outside a shape, it is inside the shape.

The ImageSmoothingQuality \({ }^{p 638}\) enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The "low" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "medium" value indicates a preference for a medium level of image interpolation quality.
The "high" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

\section*{Note}

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-smoothing algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used.

\subsection*{4.12.5.1.1 Implementation notes \(\S^{p 64}\)}

This section is non-normative.

The output bitmap \({ }^{\text {p643 }}\), when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap's actual data is needed (for example because of a call to drawImage() \({ }^{\text {p673 }}\), or the createImageBitmap() \({ }^{\text {p992 }}\) factory method). In many cases, this will be more memory efficient.

The bitmap of a canvas \({ }^{\text {p634 }}\) element is the one bitmap that's pretty much always going to be needed in practice. The output bitmap \({ }^{\text {p643 }}\) of a rendering context, when it has one, is always just an alias to a canvas \({ }^{\text {p634 }}\) element's bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its intrinsic size, or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

\subsection*{4.12.5.1.2 The canvas state \(\S^{p 64}\)}

Objects that implement the CanvasState \({ }^{\text {p639 }}\) interface maintain a stack of drawing states. Drawing states consist of:
- The current transformation matrix \({ }^{\text {p659 }}\)
- The current clipping region \({ }^{\text {p670 }}\).
- The current values of the following attributes: strokeStyle \({ }^{\text {p663 }}, f i l l\) Style \({ }^{\text {p663 }}\), globalAlpha \({ }^{\text {p679 }}\), lineWidth \({ }^{p 647}\), lineCap \({ }^{\text {p647 }}\) lineJoin \({ }^{\text {p647 }}\), miterLimit \(t^{p 647}\), lineDash0ffset \({ }^{\text {p647 }}\), shadowOffsetX \({ }^{\text {p688 }}\), shadowOffsetY \({ }^{\text {p680 }}\), shadowBlur \({ }^{\text {p688 }}\), shadowColor \({ }^{\text {p688 }}\),
 imageSmoothingEnabled \({ }^{\text {p680 }}\), imageSmoothingQuality \({ }^{\text {p680 }}\).
- The current dash list \({ }^{\text {p647 }}\).

\section*{Note}

The current default path \({ }^{p 669}\) and the rendering context's bitmaps are not part of the drawing state. The current default path \({ }^{p 669}\) is persistent, and can only be reset using the beginPath ( ) \({ }^{\text {p670 }}\) method. The bitmaps depend on whether and how the rendering

\section*{For web developers (non-normative)}
context. save \({ }^{\text {p646 }}\) ()
Pushes the current state onto the stack.
context . restore \({ }^{\text {p646 }}\) ()
Pops the top state on the stack, restoring the context to that state.

The save() method, when invoked, must push a copy of the current drawing state onto the drawing state stack.
The restore() method, when invoked, must pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

When the user agent is to reset the rendering context to its default state, it must clear the drawing state stack and everything that drawing state \({ }^{\mathrm{p} 645}\) consists of to initial values.

\subsection*{4.12.5.1.3 Line styles \(\S^{p 64}\)}

\section*{For web developers (non-normative)}
context . lineWidth \({ }^{\text {p647 }}\) [ = value ]
styles. lineWidth \({ }^{\text {p647 }}\) [ = value ]
Returns the current line width.
Can be set, to change the line width. Values that are not finite values greater than zero are ignored.
context. lineCap \({ }^{\text {p647 }}\) [ = value ]
styles. lineCap \({ }^{\text {p647 }}\) [ = value ]
Returns the current line cap style.
Can be set, to change the line cap style.
The possible line cap styles are "butt", "round", and "square". Other values are ignored.
context . lineJoin \({ }^{\text {p647 }}\) [ = value ]
styles. lineJoin \({ }^{\text {p647 }}\) [ = value]
Returns the current line join style.
Can be set, to change the line join style.
The possible line join styles are "bevel", "round", and "miter". Other values are ignored.
context . miterLimit \({ }^{\text {p647 }}\) [ = value \(]\)
styles. miterLimit \({ }^{\text {p647 }}\) [ = value ]
Returns the current miter limit ratio.
Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.
context . setLineDash \({ }^{\text {p647 }}\) (segments)
styles. setLineDash \({ }^{\text {p647 }}\) (segments)
Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.
segments \(=\) context \(\cdot\) getLineDash \({ }^{\mathrm{p} 647}()\)
segments \(=\) styles \(\cdot\) getLineDash \({ }^{\text {p647 }}\) ()
Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).
context. lineDash0ffset \({ }^{\text {p647 }}\)
styles. lineDashOffset \({ }^{\text {p647 }}\)
Returns the phase offset (in the same units as the line dash pattern).
Can be set, to change the phase offset. Values that are not finite values are ignored.

Objects that implement the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface have attributes and methods (defined in this section) that control how lines are treated by the object.

The lineWidth attribute gives the width of lines, in coordinate space units. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface is created, the lineWidth \({ }^{\text {p647 }}\) attribute must initially have the value 1.0.

The lineCap attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "butt", "round", and "square".

On getting, it must return the current value. On setting, the current value must be changed to the new value.
When the object implementing the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface is created, the lineCap \({ }^{\text {p647 }}\) attribute must initially have the value "butt".

The lineJoin attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "bevel",
"round", and "miter".
On getting, it must return the current value. On setting, the current value must be changed to the new value.
When the object implementing the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface is created, the lineJoin \({ }^{\text {p647 }}\) attribute must initially have the value "miter".

When the lineJoin \({ }^{p 647}\) attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the miterLimit attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface is created, the miterLimit \({ }^{\text {p647 }}\) attribute must initially have the value 10.0.

Each CanvasPathDrawingStyles \({ }^{\text {p641 }}\) object has a dash list, which is either empty or consists of an even number of non-negative numbers. Initially, the dash list \({ }^{\text {p647 }}\) must be empty.

The setLineDash() method, when invoked, must run these steps:
1. Let \(a\) be the argument.
2. If any value in a is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).
3. If the number of elements in \(a\) is odd, then let \(a\) be the concatenation of two copies of \(a\).
4. Let the object's dash list \({ }^{\text {p647 }}\) be \(a\).

When the getLineDash() method is invoked, it must return a sequence whose values are the values of the object's dash list \({ }^{\text {p647 }}\), in the same order.

It is sometimes useful to change the "phase" of the dash pattern, e.g. to achieve a "marching ants" effect. The phase can be set using the lineDashOffset attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface is created, the lineDash0ffset \({ }^{\text {p647 }}\) attribute must initially have the value 0.0.

When a user agent is to trace a path, given an object style that implements the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface, it must run the following algorithm. This algorithm returns a new path \({ }^{\mathrm{p} 654}\).
1. Let path be a copy of the path being traced.
2. Prune all zero-length line segments \({ }^{\text {p654 }}\) from path.
3. Remove from path any subpaths containing no lines (i.e. subpaths with just one point).
4. Replace each point in each subpath of path other than the first point and the last point of each subpath by a join that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.
5. Add a straight closing line to each closed subpath in path connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).
6. If style's dash list \({ }^{\text {p647 }}\) is empty, then jump to the step labeled convert.
7. Let pattern width be the concatenation of all the entries of style's dash list \({ }^{\mathrm{p} 647}\), in coordinate space units.
8. For each subpath subpath in path, run the following substeps. These substeps mutate the subpaths in path in vivo.
1. Let subpath width be the length of all the lines of subpath, in coordinate space units.
2. Let offset be the value of style's lineDash0ffset \({ }^{\text {p647 }}\), in coordinate space units.
3. While offset is greater than pattern width, decrement it by pattern width.

While offset is less than zero, increment it by pattern width.
4. Define \(L\) to be a linear coordinate line defined along all lines in subpath, such that the start of the first line in the subpath is defined as coordinate 0 , and the end of the last line in the subpath is defined as coordinate subpath width.
5. Let position be zero minus offset.
6. Let index be 0 .
7. Let current state be off (the other states being on and zero-on).
8. Dash on: Let segment length be the value of style's dash list \({ }^{\text {p647 's } s \text { indexth entry. }}\)
9. Increment position by segment length.
10. If position is greater than subpath width, then end these substeps for this subpath and start them again for the next subpath; if there are no more subpaths, then jump to the step labeled convert instead.
11. If segment length is nonzero, then let current state be on.
12. Increment index by one.
13. Dash off: Let segment length be the value of style's dash list \({ }^{p 647}\) 's indexth entry.
14. Let start be the offset position on \(L\).
15. Increment position by segment length.
16. If position is less than zero, then jump to the step labeled post-cut.
17. If start is less than zero, then let start be zero.
18. If position is greater than subpath width, then let end be the offset subpath width on L. Otherwise, let end be the offset position on \(L\).
19. Jump to the first appropriate step:
\(\rightarrow\) If segment length is zero and current state is off
Do nothing, just continue to the next step.
\(\rightarrow\) If current state is off
Cut the line on which end finds itself short at end and place a point there, cutting in two the subpath that it
was in; remove all line segments, joins, points, and subpaths that are between start and end; and finally place a single point at start with no lines connecting to it.

The point has a directionality for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when \(L\) was defined above).
\(\leftrightarrow\) Otherwise
Cut the line on which start finds itself into two at start and place a point there, cutting in two the subpath that it was in, and similarly cut the line on which end finds itself short at end and place a point there, cutting in two the subpath that it was in, and then remove all line segments, joins, points, and subpaths that are between start and end.

If start and end are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed, unless a join also happens to be at that point, in which case the join must be removed.
20. Post-cut: If position is greater than subpath width, then jump to the step labeled convert.
21. If segment length is greater than zero, then let positioned-at-on-dash be false.
22. Increment index by one. If it is equal to the number of entries in style's dash list \({ }^{\mathrm{p} 647}\), then let index be 0 .
23. Return to the step labeled dash on.
9. Convert: This is the step that converts the path to a new path that represents its stroke.

Create a new path \({ }^{\text {p654 }}\) that describes the edge of the areas that would be covered if a straight line of length equal to style's lineWidth \({ }^{\text {p647 }}\) was swept along each subpath in path while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy style's lineCap \({ }^{\text {p647 }}\) attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy style's lineJoin \({ }^{\text {p647 }}\) type, as defined below.

Caps: Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of style's lineCap \({ }^{p 647}\). The "butt" value means that no additional line cap is added. The "round" value means that a semi-circle with the diameter equal to style's lineWidth \({ }^{p 647}\) width must additionally be placed on to the line coming out of each point. The "square" value means that a rectangle with the length of style's lineWidth \({ }^{\text {p647 }}\) width and the width of half style's lineWidth \({ }^{\text {p647 }}\) width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point's directionality (as defined above).

Joins: In addition to the point where a join occurs, two additional points are relevant to each join, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all joins. The lineJoin \({ }^{p 647}\) attribute controls whether anything else is rendered. The three aforementioned values have the following meanings:

The "bevel" value means that this is all that is rendered at joins.
The "round" value means that an arc connecting the two aforementioned corners of the join, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the join, must be added at joins.

The "miter" value means that a second triangle must (if it can given the miter length) be added at the join, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length.

The miter length is the distance from the point where the join occurs to the intersection of the line edges on the outside of the join. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by style's miterLimit \({ }^{p 647}\) attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a subpath is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a subpath going in one direction is equal to the number of times it crosses a subpath going in the
other direction.
10. Return the newly created path.

\subsection*{4.12.5.1.4 Text styles \(\S^{\text {p65 }}\)}

For web developers (non-normative)
context . font \({ }^{\text {p651 }}\) [ = value ]
styles. font \({ }^{\text {p651 }}\) [ = value ]
Returns the current font settings.
Can be set, to change the font. The syntax is the same as for the CSS 'font' property; values that cannot be parsed as CSS font values are ignored.

Relative keywords and lengths are computed relative to the font of the canvas \({ }^{\text {p634 }}\) element.
context . textAlign \({ }^{\text {p652 }}\) [ = value \(]\)
styles. textAlign \({ }^{\text {p652 }}\) [ = value ]
Returns the current text alignment settings.
Can be set, to change the alignment. The possible values are and their meanings are given below. Other values are ignored. The default is "start".
context \(\cdot\) textBaseline \({ }^{\text {p652 }}\) [ = value ]
styles. textBaseline \({ }^{\text {p652 }}\) [ = value ]
Returns the current baseline alignment settings.
Can be set, to change the baseline alignment. The possible values and their meanings are given below. Other values are ignored. The default is "alphabetic \({ }^{\text {p653". }}\).
context . direction \({ }^{\text {p652 }}\) [ = value \(]\)
styles \(\cdot\) direction \({ }^{\text {p652 }}\) [ = value ]
Returns the current directionality.
Can be set, to change the directionality. The possible values and their meanings are given below. Other values are ignored. The default is "inherit \({ }^{\text {p653" }}\).

Objects that implement the CanvasTextDrawingStyles \({ }^{\text {p641 }}\) interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a font style source object. For CanvasRenderingContext2D \({ }^{\text {p638 }}\) objects, this is the canvas \({ }^{\text {p634 }}\) element given by the value of the context's canvas \({ }^{\text {p644 }}\) attribute. For OffscreenCanvasRenderingContext2D \({ }^{\text {p693 }}\) objects, this is the associated OffscreenCanvas object \({ }^{\text {p693 }}\).

Font resolution for the font style source object \({ }^{\text {p650 }}\) requires a font source. This is determined for a given object implementing CanvasTextDrawingStyles \({ }^{\text {p641 }}\) by the following steps: [CSSFONTLOAD] \({ }^{\text {p1286 }}\)
1. If object's font style source object \({ }^{p 650}\) is a canvas \({ }^{\text {p634 }}\) element, return the element's node document.
2. Otherwise, object's font style source object \({ }^{p 650}\) is an 0 ffscreenCanvas \({ }^{\text {p689 }}\) object:
1. Let global be object's relevant global object \({ }^{\text {p924 }}\).
2. If global is a Window \({ }^{\text {p824 }}\) object, then return global's associated Document \({ }^{\text {p826 }}\).
3. Assert: global implements WorkerGlobalScope \({ }^{\text {p1044 }}\).
4. Return global.

\section*{Example}

This is an example of font resolution with a regular canvas \({ }^{\text {p634 }}\) element with ID c1.
```
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);
```
```
const context = document.getElementById("c1").getContext("2d");
document.fonts.ready.then(function() {
    context.font = "64px MyCanvasFont";
    context.fillText("hello", 0, 0);
});
```

In this example, the canvas will display text using mycanvasfont.ttf as its font.

\section*{Example}

This is an example of how font resolution can happen using offscreenCanvas \({ }^{\text {p689 }}\). Assuming a canvas \({ }^{\text {p634 }}\) element with ID c2 which is transferred to a worker like so:
```
const offscreenCanvas = document.getElementById("c2").transferControlToOffscreen();
worker.postMesage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker:
```
self.onmessage = function(ev) {
    const transferredCanvas = ev.data;
    const context = transferredCanvas.getContext("2d");
    const font = new FontFace("MyFont", "url(myfont.ttf)");
    self.fonts.add(font);
    self.fonts.ready.then(function() {
        context.font = "64px MyFont";
        context.fillText("hello", 0, 0);
    });
};
```

In this example, the canvas will display a text using myfont.ttf. Notice that the font is only loaded inside the worker, and not in the document context.

The font IDL attribute, on setting, must be parsed as a CSS <'font'> value (but without supporting property-independent style sheet syntax like 'inherit'), and the resulting font must be assigned to the context, with the 'line-height' component forced to 'normal', with the 'font-size' component converted to CSS pixels, and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [CSS] \({ }^{\text {p1285 }}\)

Font family names must be interpreted in the context of the font style source object \({ }^{\text {p650 }}\) when the font is to be used; any fonts embedded using @font - face or loaded using FontFace \({ }^{\text {p62 }}\) objects that are visible to the font style source object \({ }^{\text {p650 }}\) must therefore be available once they are loaded. (Each font style source object \({ }^{\text {p650 }}\) has a font source, which determines what fonts are available.) If a font is used before it is fully loaded, or if the font style source object \({ }^{\text {p650 }}\) does not have that font in scope at the time the font is to be used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications.
[CSSFONTS] \({ }^{\text {p1286 }}\) [CSSFONTLOAD] \({ }^{\text {p1286 }}\)
On getting, the font \({ }^{\text {p651 }}\) attribute must return the serialized form of the current font of the context (with no 'line-height' component). [CSSOM] \({ }^{\text {p1286 }}\)

\section*{Example}

For example, after the following statement:
```
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```
...the expression context. font would evaluate to the string "italic \(12 p x\) "Unknown Font", sans-serif". The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.

When the object implementing the CanvasTextDrawingStyles \({ }^{\text {p641 }}\) interface is created, the font of the context must be set to 10 px sans-serif. When the 'font-size' component is set to lengths using percentages, 'em' or 'ex' units, or the 'larger' or 'smaller' keywords, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object \({ }^{\mathrm{p} 650}\) at the time that
the attribute is set, if it is an element. When the 'font-weight' component is set to the relative values 'bolder' and 'lighter', these must be interpreted relative to the computed value of the 'font-weight' property of the font style source object \({ }^{\text {p650 }}\) at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object \(^{\text {p650 }}\) is not an element or is not being rendered \({ }^{\text {p1192 }}\) ), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The textAlign IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles \({ }^{\text {p641 }}\) interface is created, the textAlign \({ }^{\text {p652 }}\) attribute must initially have the value start \({ }^{p 652}\).

The textBaseline IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles \({ }^{\text {p641 }}\) interface is created, the textBaseline \({ }^{\text {p652 }}\) attribute must initially have the value alphabetic \({ }^{\text {p653 }}\).

The direction IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles \({ }^{p 641}\) interface is created, the direction \({ }^{\text {p652 }}\) attribute must initially have the value "inherit \({ }^{\text {p653" }}\).

The textAlign \({ }^{p 652}\) attribute's allowed keywords are as follows:
start
Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).
end
Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).
left
Align to the left.
right
Align to the right.
center
Align to the center.
The textBaseline \({ }^{\text {p652 }}\) attribute's allowed keywords correspond to alignment points in the font:

The keywords map to these alignment points as follows:
top
The top of the em square
```
hanging
```

The hanging baseline
middle
The middle of the em square
```
alphabetic
```

The alphabetic baseline
ideographic
The ideographic-under baseline
bottom
The bottom of the em square
The direction \({ }^{p 652}\) attribute's allowed keywords are as follows:
ltr
Treat input to the text preparation algorithm \({ }^{\text {p653 }}\) as left-to-right text.
rtl
Treat input to the text preparation algorithm \({ }^{\text {p653 }}\) as right-to-left text.
inherit
Default to the directionality of the canvas \({ }^{\text {p634 }}\) element or Document \({ }^{\text {p114 }}\) as appropriate.
The text preparation algorithm is as follows. It takes as input a string text, a CanvasTextDrawingStyles \({ }^{\text {p641 }}\) object target, and an optional length maxWidth. It returns an array of glyph shapes, each positioned on a common coordinate space, a physical alignment whose value is one of left, right, and center, and an inline box. (Most callers of this algorithm ignore the physical alignment and the inline box.)
1. If maxWidth was provided but is less than or equal to zero or equal to NaN , then return an empty array.
2. Replace all ASCII whitespace in text with U+0020 SPACE characters.
3. Let font be the current font of target, as given by that object's font \({ }^{\mathrm{p} 651}\) attribute.
4. Apply the appropriate step from the following list to determine the value of direction:
\(\rightarrow\) If the target object's direction \({ }^{p 652}\) attribute has the value " \(\mathrm{ttr} \mathrm{r}^{\mathrm{p} 63 \mathrm{u}}\) " Let direction be ' \(\mathrm{Itr}^{\mathrm{p} 142 \mathrm{I}}\).
\(\rightarrow\) If the target object's direction \({ }^{p 652}\) attribute has the value "rtlu \({ }^{p 653 "}\) Let direction be 'rt| \({ }^{\mathrm{pl42}}\) '.
\(\rightarrow\) If the target object's font style source object \({ }^{\text {p650 }}\) is an element Let direction be the directionality \({ }^{\text {p142 }}\) of the target object's font style source object \({ }^{\text {p650 }}\).
\(\rightarrow\) If the target object's font style source object \({ }^{\text {p650 }}\) is a Document \({ }^{\text {p114 }}\) with a non-null document element Let direction be the directionality \({ }^{p 142}\) of the target object's font style source object \({ }^{p 650}\) 's document element.
\(\rightarrow\) Otherwise
Let direction be ' \({ }^{1 t r^{p 142}{ }^{14} \text {. }}\)
5. Form a hypothetical infinitely-wide CSS line box containing a single inline box containing the text text, with all the properties at their initial values except the 'font' property of the inline box set to font, the 'direction' property of the inline box set to direction, and the 'white-space' property set to 'pre'. [CSS] \({ }^{p 1285}\)
6. If maxWidth was provided and the hypothetical width of the inline box in the hypothetical line box is greater than maxWidth CSS pixels, then change font to have a more condensed font (if one is available or if a reasonably readable one can be synthesized by applying a horizontal scale factor to the font) or a smaller font, and return to the previous step.
7. The anchor point is a point on the inline box, and the physical alignment is one of the values left, right, and center. These variables are determined by the textAlign \({ }^{p 652}\) and textBaseline \({ }^{p 652}\) values as follows:

Horizontal position:

\section*{If textAlign \({ }^{\text {p652 }}\) is left \(^{\text {p652 }}\)}

If textAlign \({ }^{p 652}\) is start \({ }^{p 652}\) and direction is 'Itr'
If textAlign \({ }^{\text {p652 }}\) is end \({ }^{\text {p652 }}\) and direction is 'rtl'
Let the anchor point's horizontal position be the left edge of the inline box, and let physical alignment be left.

\section*{If textAlign \({ }^{p 652}\) is right \({ }^{\text {p652 }}\)}

If textAlign \({ }^{p 652}\) is end \({ }^{p 652}\) and direction is 'Itr'
If textAlign \({ }^{p 652}\) is start \({ }^{p 652}\) and direction is 'rtl'
Let the anchor point's horizontal position be the right edge of the inline box, and let physical alignment be right.

\section*{If textAlign \({ }^{p 652}\) is center \({ }^{\text {p652 }}\)}

Let the anchor point's horizontal position be half way between the left and right edges of the inline box, and let physical alignment be center.

Vertical position:

\section*{If textBaseline \({ }^{p 652}\) is top \({ }^{p 652}\)}

Let the anchor point's vertical position be the top of the em box of the first available font of the inline box.

\section*{If textBaseline \({ }^{\text {p652 }}\) is hanging \({ }^{\text {p653 }}\)}

Let the anchor point's vertical position be the hanging baseline of the first available font of the inline box.

\section*{If textBaseline \({ }^{p 652}\) is middle \({ }^{p 653}\)}

Let the anchor point's vertical position be half way between the bottom and the top of the em box of the first available font of the inline box.

\section*{If textBaseline \({ }^{\text {p652 }}\) is alphabetic \({ }^{\text {p653 }}\)}

Let the anchor point's vertical position be the alphabetic baseline of the first available font of the inline box.

\section*{If textBaseline \({ }^{\text {p652 }}\) is ideographic \({ }^{\text {p653 }}\)}

Let the anchor point's vertical position be the ideographic-under baseline of the first available font of the inline box.
If textBaseline \({ }^{\text {p652 }}\) is bottom \({ }^{\text {p653 }}\)
Let the anchor point's vertical position be the bottom of the em box of the first available font of the inline box.
8. Let result be an array constructed by iterating over each glyph in the inline box from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the inline box, positioned on a coordinate space using CSS pixels with its origin is at the anchor point.
9. Return result, physical alignment, and the inline box.

\subsection*{4.12.5.1.5 Building paths \(\S^{p 65}\)}

Objects that implement the CanvasPath \({ }^{p 641}\) interface have a path \({ }^{p 654}\). A path has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved line segments, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

Paths \({ }^{\text {p654 }}\) have a need new subpath flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a path \({ }^{\text {p654 }}\) is created, its need new subpath \({ }^{\text {p654 }}\) flag must be set.

When an object implementing the CanvasPath \({ }^{p 641}\) interface is created, its path \({ }^{p 654}\) must be initialized to zero subpaths.

\section*{For web developers (non-normative)}
context . moveTo \({ }^{\text {p657 }}(x, y)\)
path . moveTo \({ }^{\text {p657 }}(x, y)\)
Creates a new subpath with the given point.
context . closePath \({ }^{\text {p657 () }}\)
path . closePath \({ }^{\text {p657 }}\) ()
Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.
context. lineTo \({ }^{p 657}(x, y)\)
path. lineTo \({ }^{\text {p657 }}(x, y)\)
Adds the given point to the current subpath, connected to the previous one by a straight line.
context . quadraticCurveTo \({ }^{\text {p657 }}\) (cpx, cpy, \(x, y\) )
path . quadraticCurveTo \({ }^{\text {p657 }}\) (cpx, cpy, \(x, y\) )
Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.
context . bezierCurveTo \({ }^{\text {p657 }}\) (cp1x, cp1y, cp2x, cp2y, \(x, y\) )
path . bezierCurveTo \({ }^{\text {p657 }}\) (cp1x, cp1y, cp2x, cp2y, \(x, y\) )
Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.
context \(\cdot \operatorname{arcTo}^{\text {p657 }}(x 1, y 1, x 2, y 2\), radius \()\)
path . \(\operatorname{arcTo}^{\text {p657 }}(x 1, y 1, x 2, y 2\), radius \()\)
Adds an arc with the given control points and radius to the current subpath, connected to the previous point by a straight line. Throws an "IndexSizeError" DOMException if the given radius is negative.

context \(\cdot \operatorname{arc}^{p 658}(x, y\), radius, startAngle, endAngle [, anticlockwise ] ) path . \(\operatorname{arc}^{\mathrm{p} 658}(x, y\), radius, startAngle, endAngle [, anticlockwise ] )

Adds points to the subpath such that the arc described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.
Throws an "IndexSizeError" DOMException if the given radius is negative.

// the thick line corresponds to: context.move \(\mathrm{To}\left(\mathrm{x}_{0}, \mathrm{y}_{0}\right)\) context.arc( \(x, y\), radius, \(\alpha, \beta\) ) context.stroke()
context . ellipse \({ }^{\text {p658 }}(x, y\), radiusX, radius \(Y\), rotation, startAngle, endAngle [, anticlockwise] ) path . ellipse \({ }^{\text {p658 }}(x, y\), radius \(X\), radius \(Y\), rotation, startAngle, endAngle [, anticlockwise] )

Adds points to the subpath such that the arc described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.
Throws an "IndexSizeError" DOMException if the given radius is negative.
context . \(\operatorname{rect}^{p 658}(x, y, w, h)\)
path. rect \(^{\text {p658 }}(x, y, w, h)\)
Adds a new closed subpath to the path, representing the given rectangle.

The following methods allow authors to manipulate the paths \({ }^{\text {p654 }}\) of objects implementing the CanvasPath \({ }^{\text {p641 }}\) interface.
For objects implementing the CanvasDrawPath \(h^{\text {p640 }}\) and CanvasTransform \({ }^{\text {p639 }}\) interfaces, the points passed to the methods, and the resulting lines added to current default path \({ }^{\text {p669 }}\) by these methods, must be transformed according to the current transformation
matrix \({ }^{\text {p659 }}\) before being added to the path.
The moveTo \((x, y)\) method, when invoked, must run these steps:
1. If either of the arguments are infinite or NaN , then return.
2. Create a new subpath with the specified point as its first (and only) point.

When the user agent is to ensure there is a subpath for a coordinate \((x, y)\) on a path \({ }^{\text {p654 }}\), the user agent must check to see if the path \({ }^{\text {p654 }}\) has its need new subpath \({ }^{\mathrm{p} 654}\) flag set. If it does, then the user agent must create a new subpath with the point ( \(x, y\) ) as its first (and only) point, as if the moveTo ( \()^{\text {p657 }}\) method had been called, and must then unset the path \({ }^{\text {p654's }}\) need new subpath \({ }^{\text {p654 }}\) flag.

The closePath() method, when invoked, must do nothing if the object's path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath's first point, and finally add this new subpath to the path.

\section*{Note}

If the last subpath had more than one point in its list of points, then this is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus "closing" the subpath.

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object's path.

The lineTo \((x, y)\) method, when invoked, must run these steps:
1. If either of the arguments are infinite or NaN , then return.
2. If the object's path has no subpaths, then ensure there is a subpath \({ }^{\mathrm{p657}}\) for \((x, y)\).
3. Otherwise, connect the last point in the subpath to the given point \((x, y)\) using a straight line, and then add the given point \((x, y)\) to the subpath.

The quadraticCurveTo( \(c p x, c p y, x, y\) ) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Ensure there is a subpath \({ }^{\text {p657 }}\) for ( \(c p x, c p y\) )
3. Connect the last point in the subpath to the given point ( \(x, y\) ) using a quadratic Bézier curve with control point (cpx, cpy). [BEZIER] \({ }^{\text {p1285 }}\)
4. Add the given point \((x, y)\) to the subpath.

The bezierCurveTo(cp1x, cp1y, cp2x, cp2y, \(x, y\) ) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Ensure there is a subpath \({ }^{\mathrm{p} 657}\) for ( \(c p 1 x, c p 1 y\) ).
3. Connect the last point in the subpath to the given point ( \(x, y\) ) using a cubic Bézier curve with control points ( \(c p 1 x, c p 1 y\) ) and (cp2x, cp2y). [BEZIER] \({ }^{p 1285}\)
4. Add the point \((x, y)\) to the subpath.

The \(\operatorname{arcTo}(x 1, y 1, x 2, y 2, r a d i u s)\) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Ensure there is a subpath \({ }^{\mathrm{p} 657}\) for \((x 1, y 1)\).
3. If radius is negative, then throw an "IndexSizeError" DOMException.
4. Let the point \((x 0, y 0)\) be the last point in the subpath, transformed by the inverse of the current transformation matrix \({ }^{\text {p659 }}\) (so that it is in the same coordinate system as the points passed to the method).
5. If the point \((x 0, y 0)\) is equal to the point \((x 1, y 1)\), or if the point \((x 1, y 1)\) is equal to the point \((x 2, y 2)\), or if radius is zero, then add the point \((x 1, y 1)\) to the subpath, and connect that point to the previous point \((x 0, y 0)\) by a straight line.
6. Otherwise, if the points \((x 0, y 0),(x 1, y 1)\), and \((x 2, y 2)\) all lie on a single straight line, then add the point \((x 1, y 1)\) to the subpath, and connect that point to the previous point \((x 0, y 0)\) by a straight line.
7. Otherwise, let The Arc be the shortest arc given by circumference of the circle that has radius radius, and that has one point tangent to the half-infinite line that crosses the point ( \(x 0, y 0\) ) and ends at the point ( \(x 1, y 1\) ), and that has a different point tangent to the half-infinite line that ends at the point \((x 1, y 1)\) and crosses the point \((x 2, y 2)\). The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point ( \(x 0, y 0\) ) to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by The Arc, adding the end tangent point to the subpath.

The \(\operatorname{arc}\left(x, y\right.\), radius, startAngle, endAngle, anticlockwise) method, when invoked, must run the ellipse method steps \({ }^{\text {p658 }}\) with this, \(x, y\), radius, radius, 0 , startAngle, endAngle, and anticlockwise.

\section*{Note}

This makes it equivalent to ellipse( () \({ }^{\text {p658 }}\) except that both radii are equal and rotation is 0 .

The ellipse( \(x, y\), radiusX, radiusY, rotation, startAngle, endAngle, anticlockwise) method, when invoked, must run the ellipse method steps \({ }^{\text {p658 }}\) with this, \(x, y\), radius \(X\), radius \(Y\), rotation, startAngle, endAngle, and anticlockwise.

The ellipse method steps, given canvasPath, \(x, y\), radius \(X\), radius \(Y\), rotation, startAngle, endAngle, and anticlockwise, are:
1. If any of the arguments are infinite or NaN , then return.
2. If either radius \(X\) or radius \(Y\) are negative, then throw an "IndexSizeError" DOMException.
3. If canvasPath's path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.
4. Add the start and end points of the arc to the subpath, and connect them with an arc. The arc and its start and end points are defined as follows:

Consider an ellipse that has its origin at ( \(x, y\) ), that has a major-axis radius radius \(X\) and a minor-axis radius radius \(Y\), and that is rotated about its origin such that its semi-major axis is inclined rotation radians clockwise from the \(x\)-axis.

If anticlockwise is false and endAngle-startAngle is equal to or greater than \(2 \pi\), or, if anticlockwise is true and startAngle-endAngle is equal to or greater than \(2 \pi\), then the arc is the whole circumference of this ellipse, and the point at startAngle along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, acts as both the start point and the end point.

Otherwise, the points at startAngle and endAngle along this circle's circumference, measured in radians clockwise from the ellipse's semi-major axis, are the start and end points respectively, and the arc is the path along the circumference of this ellipse from the start point to the end point, going anti-clockwise if anticlockwise is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than \(2 \pi\) radians.

Note
Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the closePath() \({ }^{\text {p657 }}\) method is appropriately invoked.

The rect \((x, y, w, h)\) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Create a new subpath containing just the four points \((x, y),(x+w, y),(x+w, y+h),(x, y+h)\), in that order, with those four points connected by straight lines.
3. Mark the subpath as closed.
4. Create a new subpath with the point \((x, y)\) as the only point in the subpath.

\subsection*{4.12.5.1.6 Path \(2 D^{p 642}\) objects \(\S^{p 65}\)}

Path2D \({ }^{\text {p642 }}\) objects can be used to declare paths that are then later used on objects implementing the CanvasDrawPath \({ }^{\text {p640 }}\) interface. In addition to many of the APIs described in earlier sections, Path2D \({ }^{\text {p642 }}\) objects have methods to combine paths, and to add text to paths.

\section*{For web developers (non-normative)}

\section*{path \(=\) new Path2D \({ }^{\text {p659 }}\) ()}

Creates a new empty Path2D \({ }^{\text {p642 }}\) object.
path \(=\) new Path2D \({ }^{\text {p659 }}\) (path)
When path is a Path2D \({ }^{\text {p642 }}\) object, returns a copy.
When path is a string, creates the path described by the argument, interpreted as SVG path data. [SVG] \({ }^{\text {p1291 }}\)
path . addPath \({ }^{\text {p659 }}\) (path [, transform ])
Adds to the path the path given by the argument.

The Path2D (path) constructor, when invoked, must run these steps:
1. Let output be a new Path2D \({ }^{\text {p642 }}\) object.
2. If path is not given, then return output.
3. If path is a Path2D \({ }^{\text {p642 }}\) object, then add all subpaths of path to output and return output. (In other words, it returns a copy of the argument.)
4. Let svgPath be the result of parsing and interpreting path according to SVG 2 's rules for path data. [SVG] \({ }^{1291}\)

\section*{Note}

The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.
5. Let \((x, y)\) be the last point in svgPath.
6. Add all the subpaths, if any, from svgPath to output.
7. Create a new subpath in output with \((x, y)\) as the only point in the subpath.
8. Return output.

The addPath ( \(b\), transform) method, when invoked on a Path2D \({ }^{p 642}\) object \(a\), must run these steps:
1. If the Path \(2 D^{p 642}\) object \(b\) has no subpaths, then return.
2. Let matrix be the result of creating a DOMMatrix from the 2D dictionary transform.
3. If one or more of matrix's m 11 element, m 12 element, m 21 element, m 22 element, m 41 element, or m 42 element are infinite or NaN , then return.
4. Create a copy of all the subpaths in \(b\). Let this copy be known as \(c\).
5. Transform all the coordinates and lines in \(c\) by the transform matrix matrix.
6. Let \((x, y)\) be the last point in the last subpath of \(c\).
7. Add all the subpaths in \(c\) to \(a\).
8. Create a new subpath in a with \((x, y)\) as the only point in the subpath.

\subsection*{4.12.5.1.7 Transformations \(\S^{p 65}\)}

Objects that implement the CanvasTransform \({ }^{\text {p639 }}\) interface have a current transformation matrix, as well as methods (described in this section) to manipulate it. When an object implementing the CanvasTransform \({ }^{\text {p639 }}\) interface is created, its transformation matrix must be initialized to the identity matrix.

The current transformation matrix \({ }^{\text {p659}}\) is applied to coordinates when creating the current default path \({ }^{\text {p669 }}\), and when painting text,
shapes, and Path2D \({ }^{\text {p642 }}\) objects, on objects implementing the CanvasTransform \({ }^{\text {p639 }}\) interface.
The transformations must be performed in reverse order.

\section*{Note}

For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.

\section*{For web developers (non-normative)}

\section*{context . scale \({ }^{\text {p660 }}(\boldsymbol{x}, \boldsymbol{y})\)}

Changes the current transformation matrix \({ }^{\text {p659 }}\) to apply a scaling transformation with the given characteristics.
context . rotate \({ }^{\text {p660 }}\) (angle)
Changes the current transformation matrix \({ }^{\text {p659 }}\) to apply a rotation transformation with the given characteristics. The angle is in radians.

\section*{context . translate \({ }^{\text {p660 }}(x, y)\)}

Changes the current transformation matrix \({ }^{\text {p659 }}\) to apply a translation transformation with the given characteristics.
context . transform \({ }^{p 660}(a, b, c, d, e, f)\)
Changes the current transformation matrix \({ }^{\text {p659 }}\) to apply the matrix given by the arguments as described below.
matrix \(=\) context . getTransform \({ }^{\text {p661 }}()\)
Returns a copy of the current transformation matrix \({ }^{\text {p659 }}\), as a newly created DOMMatrix object.
context . setTransform \({ }^{\text {p661 }}(\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}, \boldsymbol{d}, \mathbf{e}, \boldsymbol{f})\)
Changes the current transformation matrix \({ }^{\text {p659 }}\) to the matrix given by the arguments as described below.
context . setTransform \({ }^{\text {p661 }}\) (transform)
Changes the current transformation matrix \({ }^{\text {p659 }}\) to the matrix represented by the passed D0MMatrix2DInit dictionary.
context . resetTransform \({ }^{\text {p661 }}\) ()
Changes the current transformation matrix \({ }^{\text {p659 }}\) to the identity matrix.

The scale \((x, y)\) method, when invoked, must run these steps:
1. If either of the arguments are infinite or NaN , then return.
2. Add the scaling transformation described by the arguments to the current transformation matrix \({ }^{\text {p659. }}\). The \(x\) argument represents the scale factor in the horizontal direction and the \(y\) argument represents the scale factor in the vertical direction. The factors are multiples.

The rotate(angle) method, when invoked, must run these steps:
1. If angle is infinite or NaN , then return.
2. Add the rotation transformation described by the argument to the current transformation matrix \({ }^{\text {p659 }}\). The angle argument represents a clockwise rotation angle expressed in radians.

The translate \((x, y)\) method, when invoked, must run these steps:
1. If either of the arguments are infinite or NaN , then return.
2. Add the translation transformation described by the arguments to the current transformation matrix \({ }^{\text {p659 }}\). The \(x\) argument represents the translation distance in the horizontal direction and the \(y\) argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

The transform( \(a, b, c, d, e, f)\) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Replace the current transformation matrix \({ }^{\text {p659 }}\) with the result of multiplying the current transformation matrix with the matrix described by:
\[
\begin{aligned}
& a c e \\
& b d f
\end{aligned}
\]
\[
001
\]
```
Note
The arguments \(\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}, \mathrm{e}\), and f are sometimes called \(\mathrm{m} 11, \mathrm{~m} 12, \mathrm{~m} 21, \mathrm{~m} 22, \mathrm{dx}\), and dy or \(\mathrm{m} 11, \mathrm{~m} 21, \mathrm{~m} 12, \mathrm{~m} 22, \mathrm{dx}\), and dy . Care ought to be taken in particular with the order of the second and third arguments (b and c) as their order varies from API to API and APIs sometimes use the notation \(\mathrm{m} 12 / \mathrm{m} 21\) and sometimes \(\mathrm{m} 21 / \mathrm{m} 12\) for those positions.
```

The getTransform() method, when invoked, must return a newly created DOMMatrix representing a copy of the current transformation matrix \({ }^{\text {p659 }}\) matrix of the context.

\section*{Note}

This returned object is not live, so updating it will not affect the current transformation matrix \({ }^{\text {p659 }}\), and updating the current transformation matrix \({ }^{\text {p659 }}\) will not affect an already returned D0MMatrix.

The setTransform( \(a, b, c, d, e, f)\) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN, then return.
2. Reset the current transformation matrix \({ }^{\text {p659 }}\) to the identity matrix.
3. Invoke the transform \({ }^{\mathrm{p66} \mathrm{\theta}}(a, b, c, d, e, f)\) method with the same arguments.

The setTransform(transform) method, when invoked, must run these steps:
1. Let matrix be the result of creating a DOMMatrix from the 2D dictionary transform.
2. If one or more of matrix's \(\underline{m 11}\) element, \(\underline{m} 12\) element, \(\underline{m} 21\) element, \(\underline{m} 22\) element, \(\underline{m} 41\) element, or \(\underline{m} 42\) element are infinite or NaN , then return.
3. Reset the current transformation matrix \({ }^{\text {p659 }}\) to matrix.

The resetTransform () method, when invoked, must reset the current transformation matrix \({ }^{\text {p659 }}\) to the identity matrix.

\section*{Note}

Given a matrix of the form created by the transform( ) \({ }^{\text {p660 }}\) and setTransform( ( \({ }^{\mathrm{p} 661}\) methods, i.e.,
ace
b d f
001
the resulting transformed coordinates after transform matrix multiplication will be
```
xnew }=ax+cy+
Ynew = b x + d y +f
```

\subsection*{4.12.5.1.8 Image sources for 2 D rendering contexts \(\S_{1}^{\text {p66 }}\)}

Some methods on the CanvasDrawImage \({ }^{\text {p640 }}\) and CanvasFillStrokeStyles \({ }^{\text {p639 }}\) interfaces take the union type CanvasImageSource \({ }^{\text {p638 }}\) as an argument.

This union type allows objects implementing any of the following interfaces to be used as image sources:
- HTMLOrSVGImageElement \({ }^{\text {p638 }}\) (img \({ }^{\text {p320 }}\) or SVG image elements)
- HTMLVideoElement \({ }^{\text {p380 }}\) (video \({ }^{\text {p380 }}\) elements)
- HTMLCanvasElement \({ }^{\text {p634 }}\) (canvas \({ }^{\text {p634 }}\) elements)
- ImageBitmapp \({ }^{\text {p990 }}\)

Although not formally specified as such, SVG image elements are expected to be implemented nearly identical to img \({ }^{\text {p320 }}\) elements. That is, SVG image elements share the fundamental concepts and features of img \({ }^{\text {p320 }}\) elements.

Note
The ImageBitmap \({ }^{\text {p990 }}\) interface can be created from a number of other image-representing types, including ImageData \({ }^{\text {p642 }}\).

To check the usability of the image argument, where image is a CanvasImageSource \({ }^{\text {p638 }}\) object, run these steps:
1. Switch on image:
\(\rightarrow\) HTMLOrSVGImageElement \({ }^{\text {p638 }}\)
If image's current request \({ }^{\mathrm{p} 336}\) 's state \({ }^{\mathrm{p} 336}\) is broken \({ }^{\text {p336 }}\), then throw an "InvalidStateError" DOMException.
If image is not fully decodable \({ }^{\text {p336 }}\), then return bad.
If image has an intrinsic width or intrinsic height (or both) equal to zero, then return bad.
\(\hookrightarrow\) HTMLVideoElement \({ }^{\text {p380 }}\)
If image's readyState \({ }^{\text {p487 }}\) attribute is either HAVE NOTHING \({ }^{\text {p405 }}\) or HAVE METADATA \({ }^{\text {p405 }}\), then return bad.
\(\rightarrow\) HTMLCanvasElement \({ }^{\text {p634 }}\)
\(\rightarrow\) OffscreenCanvas \({ }^{\text {p689 }}\)
If image has either a horizontal dimension or a vertical dimension equal to zero, then throw an "InvalidStateError" DOMException.
\(\rightarrow\) ImageBitmap \({ }^{\text {p990 }}\)
If image's [[Detached]] p104 internal slot value is set to true, then throw an "InvalidStateError" DOMException.
2. Return good.

When a CanvasImageSource \({ }^{\text {p638 }}\) object represents an HTMLOrSVGImageElement \({ }^{\text {p638 }}\), the element's image must be used as the source image.

Specifically, when a CanvasImageSource \({ }^{\text {p638 }}\) object represents an animated image in an HTMLOrSVGImageElement \({ }^{\text {p638 }}\), the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for CanvasRenderingContext \(2 \mathrm{D}^{\text {p638 }}\) APIs.

When a CanvasImageSource \({ }^{\text {p638 }}\) object represents an HTMLVideoElement \({ }^{p 38 \theta}\), then the frame at the current playback position \({ }^{\text {p404 }}\) when the method with the argument is invoked must be used as the source image when rendering the image for CanvasRenderingContext2D \({ }^{\text {p638 }}\) APIs, and the source image's dimensions must be the intrinsic width \({ }^{\text {p382 }}\) and intrinsic height \({ }^{\text {p382 }}\) of the media resource \({ }^{\text {p389 }}\) (i.e. after any aspect-ratio correction has been applied).

When a CanvasImageSource \({ }^{\text {p638 }}\) object represents an HTMLCanvasElement \({ }^{\text {p634 }}\), the element's bitmap must be used as the source image.
When a CanvasImageSource \({ }^{\text {p638 }}\) object represents an element that is being rendered \({ }^{\text {p1192 }}\) and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. width \({ }^{\mathrm{p} 449}\) and height \({ }^{\text {p449 }}\) attributes on the source element have no effect on how the object is interpreted when rendering the image for CanvasRenderingContext2D \({ }^{\text {p638 }}\) APIs).

When a CanvasImageSource \({ }^{\text {p638 }}\) object represents an ImageBitmap \({ }^{\text {p996 }}\), the object's bitmap image data must be used as the source image.

An object image is not origin-clean if, switching on image:
```
HTMLOrSVGImageElement }\mp@subsup{}{}{p638
HTMLVideoElement }\mp@subsup{}{}{p380
        image's origin }\mp@subsup{}{}{p837}\mathrm{ is not same origin }\mp@subsup{}{}{p838}\mathrm{ with entry settings object }\mp@subsup{}{}{\mathrm{ p921 's origin }
HTMLCanvasElement }\mp@subsup{}{}{\mathrm{ p634}
| ImageBitMap }\mp@subsup{}{}{\mathrm{ p990}
        image's bitmap's origin-clean}\mp@subsup{}{}{p635}\mathrm{ flag is false.

\subsection*{4.12.5.1.9 Fill and stroke styles §}

\section*{For web developers (non-normative)}
context . fillStyle \({ }^{\text {p663 }}\) [ = value ]
Returns the current style used for filling shapes.
Can be set, to change the fill style.
The style can be either a string containing a CSS color, or a CanvasGradient \({ }^{\text {p642 }}\) or CanvasPattern \({ }^{\text {p642 }}\) object. Invalid values are ignored.
context. strokeStyle \({ }^{\text {p663 }}\) [ = value]
Returns the current style used for stroking shapes.
Can be set, to change the stroke style.
The style can be either a string containing a CSS color, or a CanvasGradient \({ }^{\text {p642 }}\) or CanvasPattern \({ }^{\text {p642 }}\) object. Invalid values are ignored.

Objects that implement the CanvasFillStrokeStyles \({ }^{\text {p639 }}\) interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

The fillStyle attribute represents the color or style to use inside shapes, and the strokeStyle attribute represents the color or style to use for the lines around the shapes.

Both attributes can be either strings, CanvasGradient \({ }^{p 642} \mathrm{~s}\), or CanvasPattern \({ }^{\mathrm{p} 642}\) s. On setting, strings must be parsed \({ }^{\mathrm{p} 58}\) with this canvas \({ }^{\text {p634 }}\) element and the color assigned, and CanvasGradient \({ }^{\text {p642 }}\) and CanvasPattern \({ }^{\text {p642 }}\) objects must be assigned themselves. If parsing the value results in failure, then it must be ignored, and the attribute must retain its previous value. If the new value is a CanvasPattern \({ }^{\text {p642 }}\) object that is marked as not origin-clean \({ }^{\text {p665 }}\), then the CanvasRenderingContext \(2 D^{p 638}\) 's origin-clean \({ }^{\text {p635 }}\) flag must be set to false.

When set to a CanvasPattern \({ }^{\text {p642 }}\) or CanvasGradient \({ }^{\text {p642 }}\) object, the assignment is live \({ }^{\text {p45 }}\), meaning that changes made to the object after the assignment do affect subsequent stroking or filling of shapes.

On getting, if the value is a color, then the serialization of the color \({ }^{p 663}\) must be returned. Otherwise, if it is not a color but a CanvasGradient \({ }^{\mathrm{p} 642}\) or CanvasPattern \({ }^{\mathrm{p642}}\), then the respective object must be returned. (Such objects are opaque and therefore only useful for assigning to other attributes or for comparison to other gradients or patterns.)

The serialization of a color for a color value is a string, computed as follows: if it has alpha equal to 1.0 , then the string is a lowercase six-digit hex value, prefixed with a "\#" character ( \(U+0023\) NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits being ASCII lower hex digits. Otherwise, the color value has alpha less than 1.0, and the string is the color value in the CSS rgba() functional-notation format: the literal string "rgba" (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESIS, a base-ten integer in the range 0-255 representing the red component (using ASCII digits in the shortest form possible), a literal U+002C COMMA and U+0020 SPACE, an integer for the green component, a comma and a space, an integer for the blue component, another comma and space, a U+0030 DIGIT ZERO, if the alpha value is greater than zero then a U+002E FULL STOP (representing the decimal point), if the alpha value is greater than zero then one or more ASCII digits representing the fractional part of the alpha, and finally a U+0029 RIGHT PARENTHESIS. User agents must express the fractional part of the alpha value, if any, with the level of precision necessary for the alpha value, when reparsed, to be interpreted as the same alpha value.

When the context is created, the fillStyle \({ }^{p 663}\) and strokeStyle \({ }^{p 663}\) attributes must initially have the string value \#000000.
When the value is a color, it must not be affected by the transformation matrix when used to draw on bitmaps.

There are two types of gradients, linear gradients and radial gradients, both represented by objects implementing the opaque CanvasGradient \({ }^{\text {p642 }}\) interface.

Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is transparent black.

\section*{gradient . addColorStop \({ }^{\text {p664 }}\) (offset, color)}

Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.

Throws an "IndexSizeError" DOMException if the offset is out of range. Throws a "SyntaxError" DOMException if the color cannot be parsed.
gradient \(=\) context \(\cdot \boldsymbol{c r e a t e L i n e a r G r a d i e n t ~}{ }^{\text {p664 }}(\mathbf{x 0}, y 0, x 1, y 1)\)
Returns a CanvasGradient \({ }^{p 642}\) object that represents a linear gradient that paints along the line given by the coordinates represented by the arguments.
gradient \(=\) context. createRadialGradient \({ }^{\mathrm{p} 664}(x 0, y 0, r 0, x 1, y 1, r 1)\)
Returns a CanvasGradient \({ }^{p 642}\) object that represents a radial gradient that paints along the cone given by the circles represented by the arguments.
If either of the radii are negative, throws an "IndexSizeError" DOMException exception.

The addColorStop(offset, color) method on the CanvasGradient \({ }^{p 642}\), when invoked, must run these steps:
1. If the offset is less than 0 or greater than 1 , then throw an "IndexSizeError" DOMException.
2. Let parsed color be the result of parsing \({ }^{\mathrm{p} 58}\) color.

\section*{Note}

No element is passed to the parser because CanvasGradient \({ }^{\text {p642 }}\) objects are canvas \({ }^{p 634}\)-neutral - a CanvasGradient \({ }^{\text {p642 }}\) object created by one canvas \({ }^{\text {p634 }}\) can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.
3. If parsed color is failure, throw a "SyntaxError" DOMException.
4. Place a new stop on the gradient, at offset offset relative to the whole gradient, and with the color parsed color.

If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

The createLinearGradient \((x 0, y 0, x 1, y 1)\) method takes four arguments that represent the start point ( \(x 0, y 0\) ) and end point ( \(x 1\), \(y 1)\) of the gradient. The method, when invoked, must return a linear CanvasGradient \({ }^{p 642}\) initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the interpolation and extrapolation \({ }^{\text {p663 }}\) described above). The points in the linear gradient must be transformed as described by the current transformation matrix \({ }^{\text {p659 }}\) when rendering.

If \(x 0=x 1\) and \(y 0=y 1\), then the linear gradient must paint nothing.
The createRadialGradient \((x 0, y 0, r 0, x 1, y 1, r 1)\) method takes six arguments, the first three representing the start circle with origin \((x 0, y 0)\) and radius \(r 0\), and the last three representing the end circle with origin ( \(x 1, y 1\) ) and radius \(r 1\). The values are in coordinate space units. If either of rO or r1 are negative, then an "IndexSizeError" DOMException must be thrown. Otherwise, the method, when invoked, must return a radial CanvasGradient \({ }^{p 642}\) initialized with the two specified circles.

Radial gradients must be rendered by following these steps:
1. If \(x_{0}=x_{1}\) and \(y_{0}=y_{1}\) and \(r_{0}=r_{1}\), then the radial gradient must paint nothing. Return.
2. Let \(x(\omega)=\left(x_{1}-x_{0}\right) \omega+x_{0}\)

Let \(\mathrm{y}(\omega)=\left(y_{1}-y_{0}\right) \omega+y_{0}\)
Let \(r(\omega)=\left(r_{1}-r_{0}\right) \omega+r_{0}\)
Let the color at \(\omega\) be the color at that position on the gradient (with the colors coming from the interpolation and extrapolation \({ }^{\text {p663 }}\) described above).
3. For all values of \(\omega\) where \(r(\omega)>0\), starting with the value of \(\omega\) nearest to positive infinity and ending with the value of \(\omega\) nearest to negative infinity, draw the circumference of the circle with radius \(r(\omega)\) at position \((x(\omega)\), \(y(\omega))\), with the color at \(\omega\), but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering

> of the gradient.

\section*{Note}

This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle (0.0) using the color of the first offset, the part of the cone after the end circle (1.0) using the color of the last offset, and areas outside the cone untouched by the gradient (transparent black).

The resulting radial gradient must then be transformed as described by the current transformation matrix \({ }^{\text {p659 }}\) when rendering.
Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque CanvasPattern \({ }^{p 642}\) interface.

\section*{For web developers (non-normative)}
pattern = context. createPattern \({ }^{\text {p665 }}\) (image, repetition)
Returns a CanvasPattern \({ }^{p 642}\) object that uses the given image and repeats in the direction(s) given by the repetition argument. The allowed values for repetition are repeat (both directions), repeat-x (horizontal only), repeat-y (vertical only), and norepeat (neither). If the repetition argument is empty, the value repeat is used.

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an "InvalidStateError" DOMException.
pattern. setTransform \({ }^{\mathrm{p} 665}\) (transform)
Sets the transformation matrix that will be used when rendering the pattern during a fill or stroke painting operation.

The createPattern(image, repetition) method, when invoked, must run these steps:
1. Let usability be the result of checking the usability of \({ }^{\mathrm{p} 662}\) image.
2. If result is bad, then return null.
3. Assert: result is good.
4. If repetition is the empty string, then set it to "repeat".
5. If repetition is not identical to one of "repeat", "repeat-x", "repeat-y", or "no-repeat", then throw a "SyntaxError" DOMException.
6. Let pattern be a new CanvasPattern \({ }^{\mathrm{p} 642}\) object with the image image and the repetition behavior given by repetition.
7. If image is not origin-clean \({ }^{\text {p662 }}\), then mark pattern as not origin-clean.
8. Return pattern.

Modifying the image used when creating a CanvasPattern \({ }^{p 642}\) object after calling the createPattern() \({ }^{\text {p665 }}\) method must not affect the pattern(s) rendered by the CanvasPattern \({ }^{\text {p642 }}\) object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern's transformation matrix must be the identity matrix.

The setTransform(transform) method, when invoked, must run these steps:
1. Let matrix be the result of creating a DOMMatrix from the 2D dictionary transform.
2. If one or more of matrix's m 11 element, m 12 element, m 21 element, m 22 element, m 41 element, or m 42 element are infinite or NaN , then return.
3. Reset the pattern's transformation matrix to matrix.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:
1. Create an infinite transparent black bitmap.
2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per CSS pixel of the image, then place repeated copies of this image horizontally to the left and
right, if the repetition behavior is "repeat-x", or vertically up and down, if the repetition behavior is "repeat-y", or in all four directions all over the bitmap, if the repetition behavior is "repeat".

If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the imageSmoothingEnabled \({ }^{\text {p680 }}\) attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the imageSmoothingQuality \({ }^{\text {p680 }}\) attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel's coordinates to the original image's dimensions. (That is, the filter uses 'repeat' behavior, regardless of the value of the pattern's repetition behavior.)
3. Transform the resulting bitmap according to the pattern's transformation matrix.
4. Transform the resulting bitmap again, this time according to the current transformation matrix \({ }^{\mathrm{p} 659}\).
5. Replace any part of the image outside the area in which the pattern is to be rendered with transparent black.
6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be transparent black (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

\subsection*{4.12.5.1.10 Drawing rectangles to the bitmap \(\S^{p 66}\)}

Objects that implement the CanvasRect \({ }^{\text {p640 }}\) interface provide the following methods for immediately drawing rectangles to the bitmap. The methods each take four arguments; the first two give the \(x\) and \(y\) coordinates of the top left of the rectangle, and the second two give the width \(w\) and height \(h\) of the rectangle, respectively.

The current transformation matrix \({ }^{p 659}\) must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: \((x, y),(x+w, y),(x+w, y+h),(x, y+h)\).

Shapes are painted without affecting the current default path \({ }^{\text {p669 }}\), and are subject to the clipping region \({ }^{\text {p670 }}\), and, with the exception of clearRect () \({ }^{\text {p666 }}\), also shadow effects \({ }^{\text {p680 }}\), global alpha \({ }^{\text {p679 }}\), and global composition operators \({ }^{\text {p679 }}\).

\section*{For web developers (non-normative)}
context . clearRect \({ }^{\text {p666 }}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{w}, \boldsymbol{h})\)
Clears all pixels on the bitmap in the given rectangle to transparent black.
context. fillRect \({ }^{\text {p666 }}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{w}, \boldsymbol{h})\)
Paints the given rectangle onto the bitmap, using the current fill style.
context . strokeRect \({ }^{\text {p667 }}(x, y, w, h)\)
Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.

The clearRect ( \(x, y, w, h\) ) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Let pixels be the set of pixels in the specified rectangle that also intersect the current clipping region \({ }^{\text {p670 }}\).
3. Clear the pixels in pixels to a transparent black, erasing any previous image.

\section*{Note}

If either height or width are zero, this method has no effect, since the set of pixels would be empty.

The fillRect (x, \(y, w, h)\) method, when invoked, must must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. If either \(w\) or \(h\) are zero, then return.
3. Paint the specified rectangular area using the fillStyle \({ }^{\text {p663 }}\).

The strokeRect \((x, y, w, h)\) method, when invoked, must run these steps:
1. If any of the arguments are infinite or NaN, then return.
2. Take the result of tracing the path \({ }^{\mathrm{p647}}\) described below, using the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface's line styles, and fill it with the strokeStyle \({ }^{p 663}\).

If both \(w\) and \(h\) are zero, the path has a single subpath with just one point ( \(x, y\) ), and no lines, and this method thus has no effect (the trace a path \({ }^{\text {p647 }}\) algorithm returns an empty path in that case).

If just one of either \(w\) or \(h\) is zero, then the path has a single subpath consisting of two points, with coordinates \((x, y)\) and \((x+w, y+h)\), in that order, connected by a single straight line.

Otherwise, the path has a single subpath consisting of four points, with coordinates \((x, y),(x+w, y),(x+w, y+h)\), and \((x, y+h)\), connected to each other in that order by straight lines.

\section*{}
```
For web developers (non-normative)
    context . fillText }\mp@subsup{}{}{\mathrm{ p667}}(text, x, y [, maxWidth ] )
    context . strokeText }\mp@subsup{}{}{\mathrm{ p667}}(\mathrm{ (text, x, y [, maxWidth ])
        Fills or strokes (respectively) the given text at the given position. If a maximum width is provided, the text will be scaled to fit
        that width if necessary.
    metrics = context . measureText }\mp@subsup{}{}{\mathrm{ p668}}\mathrm{ (text)

    metrics. fontBoundingBoxDescent }\mp@subsup{}{}{\mathrm{ p668}
    metrics . actualBoundingBoxAscent }\mp@subsup{}{}{\mathrm{ p668}
    metrics. actualBoundingBoxDescent }\mp@subsup{}{}{p668
    metrics. emHeightAscent }\mp@subsup{}{}{p668
    metrics . emHeightDescent }\mp@subsup{}{}{p669
    metrics . hangingBaseline }\mp@subsup{}{}{\mathrm{ p669}
    metrics. alphabeticBaseline }\mp@subsup{}{}{\mathrm{ p669}
    metrics . ideographicBaseline }\mp@subsup{}{}{\mathrm{ p669}
    Returns the measurement described below.
```

Objects that implement the CanvasText \({ }^{\text {p640 }}\) interface provide the following methods for rendering text.
The fillText() and strokeText() methods take three or four arguments, text, \(x, y\), and optionally maxWidth, and render the given text at the given \((x, y)\) coordinates ensuring that the text isn't wider than maxWidth if specified, using the current font \({ }^{p 651}\),
textAlign \({ }^{\text {p652 }}\), and textBaseline \({ }^{p 652}\) values. Specifically, when the methods are invoked, the user agent must run these steps:
1. If any of the arguments are infinite or NaN, then return.
2. Run the text preparation algorithm \({ }^{\text {p653 }}\), passing it text, the object implementing the CanvasText \({ }^{\text {p640 }}\) interface, and, if the maxWidth argument was provided, that argument. Let glyphs be the result.
3. Move all the shapes in glyphs to the right by \(x\) CSS pixels and down by CSS pixels.
4. Paint the shapes given in glyphs, as transformed by the current transformation matrix \({ }^{\text {p659 }}\), with each CSS pixel in the coordinate space of glyphs mapped to one coordinate space unit.

For fillText() \()^{\text {p667 }}\), fillStyle \({ }^{\text {p663 }}\) must be applied to the shapes and strokeStyle \({ }^{\text {p663 }}\) must be ignored. For
strokeText () \({ }^{\text {p667 }}\), the reverse holds: strokeStyle \({ }^{\text {p663 }}\) must be applied to the result of tracing \({ }^{\text {p647 }}\) the shapes using the object implementing the CanvasText \({ }^{p 640}\) interface for the line styles, and fillstyle \({ }^{p 663}\) must be ignored.

These shapes are painted without affecting the current path, and are subject to shadow effects \({ }^{\text {p680 }}\), global alpha \({ }^{\text {p679 }}\), the clipping region \({ }^{\text {p670 }}\), and global composition operators \({ }^{\text {p679 }}\).

The measureText ( ) method takes one argument, text. When the method is invoked, the user agent must run the text preparation algorithm \({ }^{\text {p653 }}\), passing it text and the object implementing the CanvasText \({ }^{\text {p640 }}\) interface, and then using the returned inline box must return a new TextMetrics \({ }^{p 642}\) object with members behaving as described in the following list: [CSS] \({ }^{\text {p1285 }}\)

\section*{width attribute}

The width of that inline box, in CSS pixels. (The text's advance width.)

\section*{actualBoundingBoxLeft attribute}

The distance parallel to the baseline from the alignment point given by the textAlign \({ }^{p 652}\) attribute to the left side of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going left from the given alignment point.

\section*{Note}

The sum of this value and the next (actualBoundingBoxRight \({ }^{p 668}\) ) can be wider than the width of the inline box (width \({ }^{\text {p668 }}\) ), in particular with slanted fonts where characters overhang their advance width.

\section*{actualBoundingBoxRight attribute}

The distance parallel to the baseline from the alignment point given by the textAlign \({ }^{p 652}\) attribute to the right side of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going right from the given alignment point.

\section*{fontBoundingBoxAscent attribute}

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the ascent metric of the first available font, in CSS pixels; positive numbers indicating a distance going up from the given baseline.

\section*{Note}

This value and the next are useful when rendering a background that have to have a consistent height even if the exact text being rendered changes. The actualBoundingBoxAscent \({ }^{p 668}\) attribute (and its corresponding attribute for the descent) are useful when drawing a bounding box around specific text.

\section*{fontBoundingBoxDescent attribute}

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the descent metric of the first available font, in CSS pixels; positive numbers indicating a distance going down from the given baseline.
actualBoundingBoxAscent attribute
The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the top of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going up from the given baseline.

\section*{Note}

This number can vary greatly based on the input text, even if the first font specified covers all the characters in the input. For example, the actualBoundingBoxAscent \({ }^{\text {p668 }}\) of a lowercase "o" from an alphabetic baseline would be less than that of an uppercase "F". The value can easily be negative; for example, the distance from the top of the em box (textBaseline \({ }^{\text {p652 }}\) value "top \({ }^{p 652 "}\) ") to the top of the bounding rectangle when the given text is just a single comma " ," would likely (unless the font is quite unusual) be negative.

\section*{actualBoundingBoxDescent attribute}

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the bottom of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going down from the given baseline.

\section*{emHeightAscent attribute}

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the highest top of the em squares in the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the top of that em square (so this value will usually be positive). Zero if the given baseline is the top of that em square; half the font size if the given baseline is the middle of that em square.
```
emHeightDescent attribute
```

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the lowest bottom of the em squares in the inline box, in CSS pixels; positive numbers indicating that the given baseline is above the bottom of that em square. (Zero if the given baseline is the bottom of that em square.)

\section*{hangingBaseline attribute}

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the hanging baseline of the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the hanging baseline. (Zero if the given baseline is the hanging baseline.)
alphabeticBaseline attribute
The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the alphabetic baseline of the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the alphabetic baseline. (Zero if the given baseline is the alphabetic baseline.)

\section*{ideographicBaseline attribute}

The distance from the horizontal line indicated by the textBaseline \({ }^{p 652}\) attribute to the ideographic-under baseline of the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the ideographic-under baseline. (Zero if the given baseline is the ideographic-under baseline.)
```
Note
    Glyphs rendered using fillText() (}\mp@subsup{}{}{\textrm{p}677}\mathrm{ and strokeText() (}\mp@subsup{}{}{\textrm{p}677}\mathrm{ can spill out of the box given by the font size (the em square size)
    and the width returned by measureText() (}\mp@subsup{}{}{\mathrm{ p68 }}\mathrm{ (the text width). Authors are encouraged to use the bounding box values described
    above if this is an issue.
```

\section*{Note}

A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated way of doing multiline layout.

\subsection*{4.12.5.1.12 Drawing paths to the canvas \(\S^{p 66}\)}

Objects that implement the CanvasDrawPath \({ }^{\text {p64e }}\) interface have a current default path. There is only one current default path \({ }^{\text {p669 }}\), it is not part of the drawing state \({ }^{\text {p645 }}\). The current default path \({ }^{\text {p669 }}\) is a path \({ }^{\text {p654 }}\), as described above.

\section*{For web developers (non-normative)}
context . beginPath \({ }^{\text {p670 }}\) ()
Resets the current default path \({ }^{\text {p669 }}\).
context . fill \({ }^{\text {p679 }}\) ( [ fillRule ])
context . fill \({ }^{\text {p670 }}\) (path [, fillRule ])
Fills the subpaths of the current default path \({ }^{\text {p669 }}\) or the given path with the current fill style, obeying the given fill rule.
context. stroke \({ }^{\text {p670 }}\) ()
context. stroke \({ }^{\text {p670 }}\) (path)
Strokes the subpaths of the current default path \({ }^{\text {p669 }}\) or the given path with the current stroke style.
context . clip \({ }^{\text {p670 }}\) ([fillRule ])
context . clip \({ }^{\text {p679 }}\) (path [, fillRule ])
Further constrains the clipping region to the current default path \({ }^{\text {p669 }}\) or the given path, using the given fill rule to determine what points are in the path.
context. isPointInPath \({ }^{\text {p678 }}(x, y[\), fillRule ] )
context . isPointInPath \({ }^{\text {p679 }}\) (path, \(x, y[\), fillRule ])
Returns true if the given point is in the current default path \({ }^{\text {p669 }}\) or the given path, using the given fill rule to determine what points are in the path.
```
context. isPointInStroke }\mp@subsup{}{}{p679}(x,y
context . isPointInStroke }\mp@subsup{}{}{\mathrm{ p670}}(path, x, y
```

Returns true if the given point would be in the region covered by the stroke of the current default path \({ }^{\text {p669 }}\) or the given path, given the current stroke style.

The beginPath () method, when invoked, must empty the list of subpaths in the context's current default path \({ }^{\text {p669 }}\) so that the it once again has zero subpaths.

Where the following method definitions use the term intended path, it means the Path2D \({ }^{\text {p642 }}\) argument, if one was provided, or the current default path \({ }^{\text {p669 }}\) otherwise.

When the intended path is a Path2D \({ }^{p 642}\) object, the coordinates and lines of its subpaths must be transformed according to the current transformation matrix \({ }^{\text {p659 }}\) on the object implementing the CanvasTransform \({ }^{\text {p639 }}\) interface when used by these methods (without affecting the Path2D \({ }^{\text {p642 }}\) object itself). When the intended path is the current default path \({ }^{\text {p669 }}\), it is not affected by the transform. (This is because transformations already affect the current default path \({ }^{\text {p669 }}\) when it is constructed, so applying it when it is painted as well would result in a double transformation.)

The fill() method, when invoked, must fill all the subpaths of the intended path, using fillStyle \({ }^{\text {p663 }}\), and using the fill rule \({ }^{\text {p645 }}\) indicated by the fillRule argument. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

The stroke() method, when invoked, must trace \({ }^{\text {p647 }}\) the intended path, using this CanvasPathDrawingStyles \({ }^{\text {p641 }}\) object for the line styles, and then fill the resulting path using the strokeStyle \({ }^{\text {p663 }}\) attribute, using the nonzero winding rule \({ }^{\text {p645 }}\).

\section*{Note}

As a result of how the algorithm to trace a path \({ }^{p 647}\) is defined, overlapping parts of the paths in one stroke operation are treated as if their union was what was painted.

\section*{Note}

The stroke style is affected by the transformation during painting, even if the intended path is the current default path \({ }^{p 669}\).

Paths, when filled or stroked, must be painted without affecting the current default path \({ }^{p 669}\) or any Path \(2 \mathrm{D}^{\text {p642 }}\) objects, and must be subject to shadow effects \({ }^{\text {p680 }}\), global alpha \({ }^{\text {p679 }}\), the clipping region \({ }^{\text {p670 }}\), and global composition operators \({ }^{\text {p679 }}\). (The effect of transformations is described above and varies based on which path is being used.)

The clip() method, when invoked, must create a new clipping region by calculating the intersection of the current clipping region and the area described by the intended path, using the fill rule \({ }^{\text {p645 }}\) indicated by the fillRule argument. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, the clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

The isPointInPath () method, when invoked, must return true if the point given by the \(x\) and \(y\) coordinates passed to the method, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the intended path as determined by the fill rule \({ }^{\mathrm{p} 645}\) indicated by the fillRule argument; and must return false otherwise. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside the path. If either of the arguments are infinite or NaN , then the method must return false.

The isPointInStroke() method, when invoked, must return true if the point given by the \(x\) and \(y\) coordinates passed to the method, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from tracing \({ }^{\mathrm{p} 647}\) the intended path, using the nonzero winding rule \({ }^{\text {p645 }}\), and using the CanvasPathDrawingStyles \({ }^{\text {p641 }}\) interface for the line styles; and must return false otherwise. Points on the resulting path must be considered to be inside the path. If either of the arguments are infinite or NaN , then the method must return false.

This canvas \({ }^{\rho 634}\) element has a couple of checkboxes. The path-related commands are highlighted:
```
<canvas height=400 width=750>
    <label><input type=checkbox id=showA> Show As</label>
    <label><input type=checkbox id=showB> Show Bs</label>
    <!-- ... -->
</canvas>
<script>
    function drawCheckbox(context, element, x, y, paint) {
        context.save();
        context.font = '10px sans-serif';
        context.textAlign = 'left';
        context.textBaseline = 'middle';
        var metrics = context.measureText(element.labels[0].textContent);
        if (paint) {
            context.beginPath();
            context.strokeStyle = 'black';
            context.rect(x-5, y-5, 10, 10);
            context.stroke();
            if (element.checked) {
                context.fillStyle = 'black';
                context.fill();
            }
            context.fillText(element.labels[0].textContent, x+5, y);
        }
        context.beginPath();
        context.rect(x-7, y-7, 12 + metrics.width+2, 14);
        context.drawFocusIfNeeded(element);
        context.restore();
}
    function drawBase() { /* ... */ }
    function drawAs() {/* ...*/ }
    function drawBs() { /* ...*/ }
    function redraw() {
        var canvas = document.getElementsByTagName('canvas')[0];
        var context = canvas.getContext('2d');
        context.clearRect(0, 0, canvas.width, canvas.height);
        drawCheckbox(context, document.getElementById('showA'), 20, 40, true);
        drawCheckbox(context, document.getElementById('showB'), 20, 60, true);
        drawBase();
        if (document.getElementById('showA').checked)
            drawAs();
        if (document.getElementById('showB').checked)

document.getElementsByTagName('canvas')[0].addEventListener('blur', redraw, true);
document.getElementsByTagName('canvas')[0].addEventListener('change', redraw, true);
document.getElementsByTagName('canvas')[0].addEventListener('click', processClick, false);
redraw();
</script>
```

\subsection*{4.12.5.1.13 Drawing focus rings and scrolling paths into view \(\underset{\S^{p 67}}{\substack{\text { d }}}\)}

\section*{For web developers (non-normative)}
context . drawFocusIfNeeded \({ }^{\text {p672 }}\) (element)
context . drawFocus IfNeeded \({ }^{\text {p672 }}\) (path, element)
If the given element is focused \({ }^{\text {p771 }}\), draws a focus ring around the current default path \({ }^{\text {p669 }}\) or the given path, following the platform conventions for focus rings.
context . scrollPathIntoView \({ }^{\text {p673 }}\) ()
context . scrollPathIntoView \({ }^{\text {p673 }}\) (path)
Scrolls the current default path \({ }^{\text {p669 }}\) or the given path into view. This is especially useful on devices with small screens, where the whole canvas might not be visible at once.

Objects that implement the CanvasUserInterface \({ }^{\text {p640 }}\) interface provide the following methods to control drawing focus rings and scrolling paths into view.

The drawFocusIfNeeded(element) method, when invoked, must run these steps:
1. If element is not focused \({ }^{\mathrm{p} 771}\) or is not a descendant of the element with whose context the method is associated, then return.
2. Draw a focus ring of the appropriate style along the intended path, following platform conventions.

\section*{Note}

Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don't draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the focus() \({ }^{\text {p782 }}\) method based on the kind of user interaction event from which the call was triggered (if any).

The focus ring should not be subject to the shadow effects \({ }^{\text {p680 }}\), the global alpha \({ }^{\text {p679 }}\), the global composition operators \({ }^{\text {p679 }}\), or any of the members in the CanvasFillStrokeStyles \({ }^{\text {p639 }}\), CanvasPathDrawingStyles \({ }^{\text {p641 }}\), CanvasTextDrawingStyles \({ }^{\text {p641 }}\) interfaces, but should be subject to the clipping region \({ }^{\text {p670 }}\). (The effect of transformations is described above and varies based on which path is being used.)
3. Inform the user \({ }^{p 673}\) that the focus is at the location given by the intended path. User agents may wait until the next time the event loop \({ }^{\text {p944 }}\) reaches its update the rendering \({ }^{\text {p947 }}\) step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

\section*{Note}

This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform's native conventions.

The scrollPathIntoView() method, when invoked, must run these steps:
1. Let specifiedRectangle be the rectangle of the bounding box of the intended path.
2. Let notionalChild be a hypothetical element that is a rendered child of the canvas \({ }^{\text {p634 }}\) element whose dimensions are those of specifiedRectangle.
3. Scroll notionalChild into view with behavior set to "auto", block set to "start", and inline set to "nearest".
4. Optionally, inform the user \({ }^{p 673}\) that the caret or selection (or both) cover specifiedRectangle of the canvas. The user agent may wait until the next time the event loop \({ }^{\text {p944 }}\) reaches its update the rendering \({ }^{\text {p947 }}\) step to optionally inform the user.
"Inform the user", as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as magnification tools so that the user's magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

\subsection*{4.12.5.1.14 Drawing images \(\S^{p 67}\)}

Objects that implement the CanvasDrawImage \({ }^{\text {p640 }}\) interface have the drawImage method to draw images.

This method can be invoked with three different sets of arguments:
- drawImage(image, \(d x, d y)\)
- drawImage(image, \(d x, d y, d w, d h)\)
- drawImage(image, sx, sy, sw, sh, \(d x, d y, d w, d h)\)

For web developers (non-normative)
context . drawImage \({ }^{\mathrm{p} 673}\) (image, \(d x, d y\) )
context . drawImage \({ }^{\mathrm{p} 673}\) (image, \(d x, d y, d w, d h\) )
context . drawImage \({ }^{\mathrm{p} 673}\) (image, sx, sy, sw, sh, dx, dy, dw, dh)
Draws the given image onto the canvas. The arguments are interpreted as follows:

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an "InvalidStateError" DOMException.

When the drawImage( ( \({ }^{\text {p673 }}\) method is invoked, the user agent must run these steps:
1. If any of the arguments are infinite or NaN , then return.
2. Let usability be the result of checking the usability of image \({ }^{\text {p662 }}\).
3. If usability is bad, then return (without drawing anything).
4. Establish the source and destination rectangles as follows:

If not specified, the \(d w\) and \(d h\) arguments must default to the values of \(s w\) and \(s h\), interpreted such that one CSS pixel in the image is treated as one unit in the output bitmap \({ }^{p 643}\) 's coordinate space. If the \(s x, s y, s w\), and \(s h\) arguments are omitted, then they must default to 0,0 , the image's intrinsic width in image pixels, and the image's intrinsic height in image pixels, respectively. If the image has no intrinsic dimensions, then the concrete object size must be used instead, as determined using the CSS "Concrete Object Size Resolution" algorithm, with the specified size having neither a definite width nor height, nor any additional constraints, the object's intrinsic properties being those of the image argument, and the default object size being the size of the output bitmap \({ }^{\text {p643 }}\). [CSSIMAGES] \({ }^{\text {p1286 }}\)

The source rectangle is the rectangle whose corners are the four points ( \(s x, s y\) ), ( \(s x+s w, s y\) ), \((s x+s w, s y+s h),(s x, s y+s h)\).
The destination rectangle is the rectangle whose corners are the four points ( \(d x, d y\) ), ( \(d x+d w, d y),(d x+d w, d y+d h),(d x\), \(d y+d h)\).

When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

\section*{Note}

When the destination rectangle is outside the destination image (the output bitmap \({ }^{p 643}\) ), the pixels that land outside the output bitmap \({ }^{\text {p643 }}\) are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the output bitmap \({ }^{\text {p643 }}\).
5. If one of the \(s w\) or sh arguments is zero, then return. Nothing is painted.
6. Paint the region of the image argument specified by the source rectangle on the region of the rendering context's output bitmap \({ }^{\text {p643 }}\) specified by the destination rectangle, after applying the current transformation matrix \({ }^{\text {p659 }}\) to the destination rectangle.

The image data must be processed in the original direction, even if the dimensions given are negative.
When scaling up, if the imageSmoothingEnabled \({ }^{\text {p680 }}\) attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the imageSmoothingQuality \({ }^{\text {p680 }}\) attribute to guide the choice of filtering algorithm when the imageSmoothingEnabled \({ }^{\text {p680 }}\) attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

\section*{Note}

This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the imageSmoothingEnabled \({ }^{\text {p680 }}\) attribute is set to true.

\section*{Note}

When a canvas \({ }^{p 634}\) element is drawn onto itself, the drawing model \({ }^{p 682}\) requires the source to be copied before the image is drawn, so it is possible to copy parts of a canvas \({ }^{\text {p634 }}\) element onto overlapping parts of itself.

If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses 'clamp-to-edge' behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

\section*{Note}

Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of transparent black, or by copying sprites to be scaled into temporary canvas \({ }^{\text {p634 }}\) elements and drawing the scaled sprites from there.

Images are painted without affecting the current path, and are subject to shadow effects \({ }^{\text {p680 }}\), global alpha \({ }^{\text {p679 }}\), the clipping region \({ }^{\text {p670 }}\), and global composition operators \({ }^{\text {p679 }}\).
7. If image is not origin-clean \({ }^{\text {p662 }}\), then set the CanvasRenderingContext \(2 D^{p 638}\) 's origin-clean \({ }^{\text {p635 }}\) flag to false.

\subsection*{4.12.5.1.15 Pixel manipulation \(\S_{5}^{867}\)}

\section*{For web developers (non-normative)}
imagedata \(=\) new ImageData \({ }^{\text {p675 }}\) (sw, sh)
imagedata \(=\) context . createImageData \({ }^{p 675}(s w, s h)\)
Returns an ImageData \({ }^{\text {p642 }}\) object with the given dimensions. All the pixels in the returned object are transparent black.
Throws an "IndexSizeError" DOMException if either of the width or height arguments are zero.
imagedata \(=\) context. createImageData \({ }^{\text {p675 }}\) (imagedata)
Returns an ImageData \({ }^{\text {p642 }}\) object with the same dimensions as the argument. All the pixels in the returned object are transparent black.
imagedata \(=\) new \(\underline{\text { ImageData }}{ }^{\text {p675 }}\) (data, sw [, sh ])
Returns an ImageData \({ }^{\text {p642 }}\) object using the data provided in the Uint8ClampedArray argument, interpreted using the given dimensions.

As each pixel in the data is represented by four numbers, the length of the data needs to be a multiple of four times the given width. If the height is provided as well, then the length needs to be exactly the width times the height times 4.

Throws an "IndexSizeError" DOMException if the given data and dimensions can't be interpreted consistently, or if either dimension is zero.
imagedata \(=\) context \(\cdot\) getImageData \({ }^{\text {p676 }}(s x, s y, s w, s h)\)
Returns an ImageData \({ }^{\mathrm{p} 642}\) object containing the image data for the given rectangle of the bitmap.
Throws an "IndexSizeError" DOMException if the either of the width or height arguments are zero.
imagedata . width \({ }^{\text {p676 }}\)
imagedata . height \({ }^{\text {p676 }}\)
Returns the actual dimensions of the data in the ImageData \({ }^{\text {p642 }}\) object, in pixels.
imagedata . data \({ }^{\text {p676 }}\)
Returns the one-dimensional array containing the data in RGBA order, as integers in the range 0 to 255.

Paints the data from the given ImageData \({ }^{\text {p642 }}\) object onto the bitmap. If a dirty rectangle is provided, only the pixels from that rectangle are painted.
The globalAlpha \({ }^{\text {p679 }}\) and globalCompositeOperation \({ }^{\text {p679 }}\) attributes, as well as the shadow attributes, are ignored for the purposes of this method call; pixels in the canvas are replaced wholesale, with no composition, alpha blending, no shadows, etc.
Throws an "InvalidStateError" DOMException if the imagedata object's data \({ }^{\text {p676 }}\) attribute value's [[ViewedArrayBuffer]] internal slot is detached.

Objects that implement the CanvasImageData \({ }^{\text {p641 }}\) interface provide the following methods for reading and writing pixel data to the bitmap.

The ImageData() constructors and the createImageData() methods are used to instantiate new ImageData \({ }^{\text {p642 }}\) objects.
When the ImageData ( ) \({ }^{\mathrm{p} 675}\) constructor is invoked with two numeric arguments \(s w\) and \(s h\), it must run these steps:
1. If one or both of \(s w\) and sh are zero, then throw an "IndexSizeError" DOMException.
2. Create an ImageData object \({ }^{\text {p676 }}\) with parameter pixelsPerRow set to \(s w\), and rows set to \(s h\).
3. Initialize the image data of the newly created ImageData \({ }^{\mathrm{p} 642}\) object to transparent black.
4. Return the newly created ImageData \({ }^{\text {p642 }}\) object.

When the ImageData( ( \({ }^{\text {p675 }}\) constructor is invoked with its first argument being an Uint8ClampedArray source and its second and optional third arguments being numeric arguments \(s w\) and \(s h\), it must run these steps:
1. Let length be the number of bytes in source.
2. If length is not a nonzero integral multiple of four, then throw an "InvalidStateError" DOMException.
3. Let length be length divided by four.
4. If length is not an integral multiple of \(s w\), then throw an "IndexSizeError" DOMException.

\section*{Note}

At this step, the length is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if sw is zero, this step will throw the exception and return.
5. Let height be length divided by sw.
6. If the sh argument was not omitted, and its value is not equal to height, then throw an "IndexSizeError" DOMException.
7. Create an ImageData object \({ }^{\text {p676 }}\), with parameter pixelsPerRow set to sw, rows set to sh, and using source. Return the newly created ImageData \({ }^{\text {p642 }}\) object.

\section*{Note}

The resulting object's data is not a copy of source, it's the actual Uint8ClampedArray object passed as the first argument to the constructor.

When the createImageData( \()^{\text {p675 }}\) method is invoked with two numeric arguments \(s w\) and \(s h\), it must create an ImageData object \({ }^{\text {p676 }}\), with parameter pixelsPerRow set to the absolute magnitude of \(s w\), and parameter rows set to the absolute magnitude of sh. Initialize the image data of the new ImageData \({ }^{p 642}\) object to transparent black. If both \(s w\) and sh are nonzero, then return the new ImageData \({ }^{\text {p642 }}\) object. If one or both of \(s w\) and sh are zero, then throw an "IndexSizeError" DOMException instead.

When the createImageData( \()^{\text {p675 }}\) method is invoked with a single imagedata argument, it must create an ImageData object \({ }^{\text {p676 }}\), with parameter pixelsPerRow set to the value of the width \({ }^{\text {p676 }}\) attribute of the ImageData \({ }^{\text {p642 }}\) object passed as the argument, and the rows parameter set to the value of the height \({ }^{p 676}\) attribute. Initialize the image data of the new ImageData \({ }^{p 642}\) object to transparent black. Return the newly created ImageData \({ }^{p 642}\) object.

The getImageData(sx, sy, sw, sh) method, when invoked, must, if either the sw or sh arguments are zero, throw an "IndexSizeError" DOMException; otherwise, if the CanvasRenderingContext2D \({ }^{\text {p638 }}\) 's origin-clean \({ }^{\text {p635 }}\) flag is set to false, it must throw a "SecurityError" DOMException; otherwise, it must create an ImageData object \({ }^{\text {p676 }}\), with parameter pixelsPerRow set to sw, and parameter rows set to \(s h\). Set the pixel values of the image data of the newly created ImageData \({ }^{\text {p642 }}\) object to represent the output \(b_{\text {bitmap }}{ }^{\text {p643 }}\) for the area of that bitmap denoted by the rectangle whose corners are the four points ( \(s x, s y\) ), ( \(s x+s w, s y\) ), ( \(s x+s w\), \(s y+s h)\), \((s x, s y+s h)\), in the bitmap's coordinate space units. Pixels outside the output bitmap \({ }^{\text {p643 }}\) must be set to transparent black. Pixel values must not be premultiplied by alpha.

When the user agent is required to create an ImageData object, given a positive integer number of rows rows, a positive integer number of pixels per row pixelsPerRow, and an optional Uint8ClampedArray source, it must run these steps:
1. Let imageData be a new uninitialized ImageData \({ }^{\text {p642 }}\) object.
2. If source is specified, then assign the data attribute of imageData to source.
3. If source is not specified, then initialize the data \({ }^{\text {p676 }}\) attribute of imageData to a new Uint8ClampedArray object. The Uint8ClampedArray object must use a new Canvas Pixel ArrayBuffer \({ }^{\text {p677 }}\) for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The Canvas Pixel ArrayBuffer \({ }^{\text {p677 }}\) must have the correct size to store rows \(\times\) pixelsPerRow pixels.

If the Canvas Pixel ArrayBuffer \({ }^{\text {p677 }}\) cannot be allocated, then rethrow the RangeError thrown by JavaScript, and return.
4. Initialize the width attribute of imageData to pixelsPerRow.
5. Initialize the height attribute of imageData to rows.
6. Return imageData.

ImageData \({ }^{\mathrm{p} 642}\) objects are serializable objects \({ }^{\text {p102 }}\). Their serialization steps \({ }^{\text {p102 }}\), given value and serialized, are:
1. Set serialized.[[Data]] to the sub-serialization \({ }^{\text {p107 }}\) of the value of value's data \({ }^{\text {p676 }}\) attribute.
2. Set serialized.[[Width]] to the value of value's width \({ }^{p 676}\) attribute.
3. Set serialized.[[Height]] to the value of value's height \({ }^{\text {p676 }}\) attribute.

Their deserialization steps \({ }^{\text {p103 }}\), given serialized and value, are:
1. Initialize value's data \({ }^{\text {p676 }}\) attribute to the sub-deserialization \({ }^{\text {p110 }}\) of serialized.[[Data]].
2. Initialize value's width \(^{\mathrm{p} 676}\) attribute to serialized.[[Width]].
3. Initialize value's height \({ }^{\text {p676 }}\) attribute to serialized.[[Height]].

A Canvas Pixel ArrayBuffer is an ArrayBuffer whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel's red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range \(0 . .255\), representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel's red component.

The putImageData() method writes data from ImageData \({ }^{\text {p642 }}\) structures back to the rendering context's output bitmap \({ }^{\text {p643 }}\). Its arguments are: imagedata, \(d x, d y, \operatorname{dirty} X\), dirty \(Y\), dirtyWidth, and dirtyHeight.

When the last four arguments to this method are omitted, they must be assumed to have the values 0,0 , the width \({ }^{\mathrm{p676}}\) member of the imagedata structure, and the height \({ }^{\text {p676 }}\) member of the imagedata structure, respectively.

The method, when invoked, must act as follows:
1. Let buffer be imagedata's data \({ }^{p 676}\) attribute value's [[ViewedArrayBuffer]] internal slot.
2. If IsDetachedBuffer(buffer) is true, then throw an "InvalidStateError" DOMException.
3. If dirtyWidth is negative, then let dirty \(X\) be dirty \(X+\) dirtyWidth, and let dirtyWidth be equal to the absolute magnitude of dirtyWidth.

If dirtyHeight is negative, then let dirty \(Y\) be dirty \(Y\) +dirtyHeight, and let dirtyHeight be equal to the absolute magnitude of dirtyHeight.
4. If dirty \(X\) is negative, then let dirtyWidth be dirtyWidth+dirty \(X\), and let dirty \(X\) be zero.

If dirtyY is negative, then let dirtyHeight be dirtyHeight+dirtyY, and let dirtyY be zero.
5. If dirty \(X+\) dirtyWidth is greater than the width \({ }^{p 676}\) attribute of the imagedata argument, then let dirtyWidth be the value of that width \({ }^{p 676}\) attribute, minus the value of dirty \(X\).

If dirty \(Y+\) dirtyHeight is greater than the height \({ }^{\text {p676 }}\) attribute of the imagedata argument, then let dirtyHeight be the value of that height \({ }^{\text {p676 }}\) attribute, minus the value of dirty \(Y\).
6. If, after those changes, either dirtyWidth or dirtyHeight are negative or zero, then return without affecting any bitmaps.
7. For all integer values of \(x\) and \(y\) where dirty \(X \leq x<\operatorname{dirty} X+d i r t y W i d t h\) and dirty \(Y \leq y<d i r t y Y+d i r t y H e i g h t, ~ c o p y ~ t h e ~ f o u r ~\) channels of the pixel with coordinate ( \(x, y\) ) in the imagedata data structure's Canvas Pixel ArrayBuffer \({ }^{\text {p677 }}\) to the pixel with coordinate \((d x+x, d y+y)\) in the rendering context's output bitmap \({ }^{\text {p643 }}\).

\section*{Note}

Due to the lossy nature of converting to and from premultiplied alpha color values, pixels that have just been set using putImageData() \()^{\text {p677 }}\) might be returned to an equivalent getImageData() \()^{\text {p676 }}\) as different values.

The current path, transformation matrix \({ }^{\text {p659 }}\), shadow attributes \({ }^{\text {p680 }}\), global alpha \({ }^{\text {p679 }}\), the clipping region \({ }^{\text {p670 }}\), and global composition operator \({ }^{\mathrm{p679}}\) must not affect the methods described in this section.

\section*{Example}

In the following example, the script generates an ImageData \({ }^{\text {p642 }}\) object so that it can draw onto it.
```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);
```
```
// create some plasma
FillPlasma(data, 'green'); // green plasma
// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle
// paint the plasma+cloud on the canvas
context.putImageData(data, 0, 0);
// support methods
function FillPlasma(data, color) { ... }
function AddCloud(data, x, y) { ... }
```

\section*{Example}

Here is an example of using getImageData( \()^{\text {p676 }}\) and putImageData( \()^{\text {p677 }}\) to implement an edge detection filter.
```
<!DOCTYPE HTML>
<html lang="en">
    <head>
    <title>Edge detection demo</title>
    <script>
        var image = new Image();
        function init() {
            image.onload = demo;
            image.src = "image.jpeg";
        }
        function demo() {
            var canvas = document.getElementsByTagName('canvas')[0];
            var context = canvas.getContext('2d');
            // draw the image onto the canvas
            context.drawImage(image, 0, 0);
            // get the image data to manipulate
            var input = context.getImageData(0, 0, canvas.width, canvas.height);
            // get an empty slate to put the data into
            var output = context.createImageData(canvas.width, canvas.height);
            // alias some variables for convenience
            // In this case input.width and input.height
            // match canvas.width and canvas.height
            // but we'll use the former to keep the code generic.
            var w = input.width, h = input.height;
            var inputData = input.data;
            var outputData = output.data;
            // edge detection
            for (var y = 1; y < h-1; y += 1) {
                for (var x = 1; x < w-1; x += 1) {
                    for (var c = 0; c < 3; c += 1) {
                        var i = (y*w + x)*4 + c;
                        outputData[i] = 127 + -inputData[i - w*4 - 4] - inputData[i - w*4] - inputData[i -
w*4 + 4] +
                                    -inputData[i - 4] + 8*inputData[i] - inputData[i + 4]
+
                        inputData[i + w*4 - 4] - inputData[i + w*4] - inputData[i +
w*4 + 4];
            }
```
```
            outputData[(y*w + x)*4 + 3] = 255; // alpha
            }
        }
        // put the image data back after manipulation
        context.putImageData(output, 0, 0);
        }
    </script>
    </head>
    <body onload="init()">
    <canvas></canvas>
    </body>
</html>
```

\subsection*{4.12.5.1.16 Compositing \({ }_{9}^{\text {§ }}\) 97}

\section*{For web developers (non-normative)}

\section*{context . globalAlpha \({ }^{\text {p679 }}\) [ = value ]}

Returns the current alpha value applied to rendering operations.
Can be set, to change the alpha value. Values outside of the range 0.0 .. 1.0 are ignored.
context . globalCompositeOperation \({ }^{\text {p679 }}\) [ = value]
Returns the current composition operation, from the values defined in Compositing and Blending. [COMPOSITE] \({ }^{\text {p1285 }}\).
Can be set, to change the composition operation. Unknown values are ignored.

All drawing operations on an object which implements the CanvasCompositing \({ }^{\text {p639 }}\) interface are affected by the global compositing attributes, globalAlpha \({ }^{\text {p679 }}\) and globalCompositeOperation \({ }^{\text {p679 }}\).

The globalAlpha attribute gives an alpha value that is applied to shapes and images before they are composited onto the output bitmap \({ }^{\text {p643 }}\). The value must be in the range from 0.0 (fully transparent) to 1.0 (no additional transparency). If an attempt is made to set the attribute to a value outside this range, including Infinity and Not-a-Number ( NaN ) values, then the attribute must retain its previous value. When the context is created, the globalAlpha \({ }^{\text {p679 }}\) attribute must initially have the value 1.0 .

The globalComposite0peration attribute sets the current composition operator, which controls how shapes and images are drawn onto the output bitmap \({ }^{p 643}\), once they have had globalAlpha \({ }^{\text {p679 }}\) and the current transformation matrix applied. The possible values are those defined in Compositing and Blending, and include the values source-over and copy. [COMPOSITE] \({ }^{\text {p1285 }}\)

These values are all case-sensitive - they must be used exactly as defined. User agents must not recognize values that are not identical to one of the values given in Compositing and Blending. [COMPOSITE] \({ }^{\text {p1285 }}\)

On setting, if the user agent does not recognize the specified value, it must be ignored, leaving the value of globalCompositeOperation \({ }^{\text {p679 }}\) unaffected. Otherwise, the attribute must be set to the given new value.

When the context is created, the globalComposite0peration \({ }^{\text {p679 }}\) attribute must initially have the value source-over \({ }^{\text {p679 }}\).

\subsection*{4.12.5.1.17 Image smoothing \(\S^{p 67}\) \\ 9}

For web developers (non-normative)
context . imageSmoothingEnabled \(^{\text {p688 }}\) [ = value ]
Returns whether pattern fills and the drawImage( ) \({ }^{\text {p673 }}\) method will attempt to smooth images if their pixels don't line up exactly with the display, when scaling images up.
Can be set, to change whether images are smoothed (true) or not (false).

\section*{context . imageSmoothingQuality \({ }^{\text {p688 }}\) [ = value]}

Returns the current image-smoothing-quality preference.
Can be set, to change the preferred quality of image smoothing. The possible values are "low \({ }^{\mathrm{p} 645}\) ", "medium \({ }^{\mathrm{p} 645 \text { " }}\) and "high \({ }^{\mathrm{p} 645 \mathrm{n}}\) ". Unknown values are ignored.

Objects that implement the CanvasImageSmoothing \({ }^{\text {p639 }}\) interface have attributes that control how image smoothing is performed.
The imageSmoothingEnabled attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the CanvasImageSmoothing \({ }^{\text {p639 }}\) interface is created, the attribute must be set to true.

The imageSmoothingQuality attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the CanvasImageSmoothing \({ }^{\text {p639 }}\) interface is created, the attribute must be set to "low \({ }^{\mathrm{p} 645 \text { ". }}\).

\subsection*{4.12.5.1.18 Shadows \(\S^{p 68}\)}

All drawing operations on an object which implements the CanvasShadowStyles \({ }^{\text {p640 }}\) interface are affected by the four global shadow attributes.

\section*{For web developers (non-normative)}
context . shadowColor \({ }^{\text {p688 }}\) [ = value]
Returns the current shadow color.
Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.
context . shadowOffset \({ }^{\text {p688 }}\) [ = value ]
context . shadowOffset \({ }^{\text {p688 }}\) [ = value ]
Returns the current shadow offset.
Can be set, to change the shadow offset. Values that are not finite numbers are ignored.
context . shadowBlur \({ }^{\text {p680 }}\) [ = value ]
Returns the current level of blur applied to shadows.
Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.

The shadowColor attribute sets the color of the shadow.
When the context is created, the shadowColor \({ }^{p 680}\) attribute initially must be transparent black.
On getting, the serialization of the color \({ }^{\mathrm{p} 663}\) must be returned.
On setting, the new value must be parsed \({ }^{p 58}\) with this canvas \({ }^{p 634}\) element and the color assigned. If parsing the value results in failure then it must be ignored, and the attribute must retain its previous value. [CSSCOLOR] \({ }^{\text {p1286 }}\)

The shadow0ffsetX and shadow0ffsetY attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0 .
On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN , in which case the new value must be ignored.

The shadowBlur attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not affected by the current transformation matrix.)

When the context is created, the shadowBlur \({ }^{p 680}\) attribute must initially have the value 0 .
On getting, the attribute must return its current value. On setting the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

Shadows are only drawn if the opacity component of the alpha component of the color of shadowColor \({ }^{\text {p688 }}\) is nonzero and either the shadowBlur \({ }^{\text {p680 }}\) is nonzero, or the shadowOffset \(X^{p 680}\) is nonzero, or the shadow \(0 f f f^{\text {set }}{ }^{p 680}\) is nonzero.

When shadows are drawn \({ }^{\text {p681 }}\), they must be rendered as follows:
1. Let \(A\) be an infinite transparent black bitmap on which the source image for which a shadow is being created has been rendered.
2. Let \(B\) be an infinite transparent black bitmap, with a coordinate space and an origin identical to \(A\).
3. Copy the alpha channel of \(A\) to \(B\), offset by shadow \(0 f f\) set \(X^{p 680}\) in the positive \(x\) direction, and shadow \(0 f f f^{5} Y^{p 688}\) in the positive \(y\) direction.
4. If shadowBlur \({ }^{p 680}\) is greater than 0 :
1. Let \(\sigma\) be half the value of shadowBlur \({ }^{p 688}\).
2. Perform a 2D Gaussian Blur on \(B\), using \(\sigma\) as the standard deviation.

User agents may limit values of \(\sigma\) to an implementation-specific maximum value to avoid exceeding hardware limitations during the Gaussian blur operation.
5. Set the red, green, and blue components of every pixel in \(B\) to the red, green, and blue components (respectively) of the color of shadowColor \({ }^{\text {p680 }}\).
6. Multiply the alpha component of every pixel in \(B\) by the alpha component of the color of shadowColor \({ }^{\text {p688 }}\).
7. The shadow is in the bitmap \(B\), and is rendered as part of the drawing model \({ }^{p 682}\) described below.

If the current composition operation is copy \({ }^{\text {p679 }}\), then shadows effectively won't render (since the shape will overwrite the shadow).

\subsection*{4.12.5.1.19 Filters \(\S^{p 68}\)}

All drawing operations on an object which implements the CanvasFilters \({ }^{\text {p640 }}\) interface are affected by the global filter attribute.

\section*{For web developers (non-normative)}

\section*{context \(\cdot\) filter \(^{\text {p681 }}\) [ = value ]}

Returns the current filter.
Can be set, to change the filter. Values that cannot be parsed as a <filter-function-list> value are ignored.

The filter \({ }^{p 681}\) attribute, on getting, must return the last value it was successfully set to. The value must not be re-serialized. On setting, if the new value is 'none' (not the empty string, null, or undefined), filters must be disabled for the context. Otherwise, the value must be parsed as a <filter-function-list> value. If the value cannot be parsed as a <filter-function-list> value, where using property-independent style sheet syntax like 'inherit' or 'initial' is considered an invalid value, then it must be ignored, and the attribute must retain its previous value. When creating the object implementing the CanvasFilters \({ }^{\text {p640 }}\) interface, the attribute must be set to 'none'.

A <filter-function-list> value consists of a sequence of one or more filter functions or references to SVG filters. The input to the filter is used as the input to the first item in the list. Subsequent items take the output of the previous item as their input. [FILTERS] \({ }^{\text {p1287 }}\)

Coordinates used in the value of the filter \(r^{p 681}\) attribute are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the current transformation matrix \({ }^{\text {p659. }}\). The current transformation matrix affects only the input to the filter. Filters are applied in the output bitmap \({ }^{\text {p643' }} \mathrm{s}\) coordinate space.

When the value of the filter \({ }^{p 681}\) attribute defines lengths using percentages or using 'em' or 'ex' units, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object \({ }^{\text {p650 }}\) at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object \({ }^{\text {p650 }}\) is not an element or is not being rendered \({ }^{\text {p1192 }}\) ), then the relative keywords must be interpreted relative to the default value of the font \({ }^{\text {p651 }}\) attribute. The 'larger' and 'smaller' keywords are not supported.

If the value of the filter \({ }^{\text {p681 }}\) attribute refers to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the \(£\) filter \({ }^{\text {p681 }}\) attribute refers to an SVG filter in an external resource document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

\subsection*{4.12.5.1.20 Working with externally-defined SVG filters \(\frac{\varsigma}{2}_{26 \mathrm{~d}}^{2}\)}

This section is non-normative.
Since drawing is performed using filter value 'none' until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a load event (for example, an SVG use element), and wait for the load event to be dispatched.

\subsection*{4.12.5.1.21 Drawing model \({ }^{\text {§ }}{ }^{688}\)}

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):
1. Render the shape or image onto an infinite transparent black bitmap, creating image \(A\), as described in the previous sections. For shapes, the current fill, stroke, and line styles must be honored, and the stroke must itself also be subjected to the current transformation matrix.
2. When the filter attribute is set to a value other than 'none' and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image \(A\) as the input to the \(f i l t e r r^{\text {p681 }}\), creating image \(B\). Otherwise, let \(B\) be an alias for \(A\).
3. When shadows are drawn \({ }^{\text {p681 }}\), render the shadow from image \(B\), using the current shadow styles, creating image \(C\).
4. When shadows are drawn \({ }^{\text {p681 }}\), multiply the alpha component of every pixel in \(C\) by globalalphap \({ }^{\text {p679 }}\).
5. When shadows are drawn \({ }^{\text {p681 }}\), composite \(C\) within the clipping region \({ }^{\text {p670 }}\) over the current output bitmap \({ }^{p 643}\) using the current composition operator \({ }^{\text {p679 }}\).
6. Multiply the alpha component of every pixel in \(B\) by globalAlpha \({ }^{\text {p679 }}\).
7. Composite \(B\) within the clipping region \({ }^{p 670}\) over the current output bitmap \({ }^{p 643}\) using the current composition operator \({ }^{p 679}\).

When compositing onto the output bitmap \({ }^{\text {p643 }}\), pixels that would fall outside of the output bitmap \({ }^{p 643}\) must be discarded.

\subsection*{4.12.5.1.22 Best practices \(\mathbb{\S}^{p 68}\)}

When a canvas is interactive, authors should include focusable \({ }^{\text {p772 }}\) elements in the element's fallback content corresponding to each focusable \({ }^{\mathrm{p} 772}\) part of the canvas, as in the example above \({ }^{\mathrm{p} 670}\).

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the drawFocusIfNeeded () \({ }^{\text {p672 }}\) method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is focused \({ }^{\text {p771 }}\), so that it can simply be called whenever drawing the element, without checking whether the element is focused or not first.

In addition to drawing focus rings, authors should use the scrollPathIntoView() \({ }^{\text {p673 }}\) method when an element in the canvas is focused, to make sure it is visible on the screen (if applicable).

Authors should avoid implementing text editing controls using the canvas \({ }^{p 634}\) element. Doing so has a large number of disadvantages:
- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
- Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
- Native features such as copy-and-paste have to be reimplemented.
- Native features such as spell-checking have to be reimplemented.
- Native features such as drag-and-drop have to be reimplemented.
- Native features such as page-wide text search have to be reimplemented.
- Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
- Bidirectional text editing has to be reimplemented.
- For multiline text editing, line wrapping has to be implemented for all relevant languages.
- Text selection has to be reimplemented.
- Dragging of bidirectional text selections has to be reimplemented.
- Platform-native keyboard shortcuts have to be reimplemented.
- Platform-native input method editors (IMEs) have to be reimplemented.
- Undo and redo functionality has to be reimplemented.
- Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the input \({ }^{\text {p493 }}\) element, the textarea \({ }^{\text {p548 }}\) element, or the contenteditable \({ }^{\text {p787 }}\) attribute.

\subsection*{4.12.5.1.23 Examples \(\S^{p 68}\)}

This section is non-normative.

\section*{Example}

Here is an example of a script that uses canvas to draw pretty glowing lines.
```
<canvas width="800" height="450"></canvas>
<script>
var context = document.getElementsByTagName('canvas')[0].getContext('2d');
var lastX = context.canvas.width * Math.random();
var lastY = context.canvas.height * Math.random();
var hue = 0;
function line() {
    context.save();
    context.translate(context.canvas.width/2, context.canvas.height/2);
    context.scale(0.9, 0.9);
    context.translate(-context.canvas.width/2, -context.canvas.height/2);
    context.beginPath();
    context.lineWidth = 5 + Math.random() * 10;
    context.moveTo(lastX, lastY);
    lastX = context.canvas.width * Math.random();
    lastY = context.canvas.height * Math.random();
    context.bezierCurveTo(context.canvas.width * Math.random(),
                    context.canvas.height * Math.random(),
                    context.canvas.width * Math.random(),
                    context.canvas.height * Math.random(),
                    lastX, lastY);
        hue = hue + 10 * Math.random();
    context.strokeStyle = 'hsl(' + hue + ', 50%, 50%)'
    context.shadowColor = 'white';
    context.shadowBlur = 10
    context.stroke();
    context.restore();
```
```
}
setInterval(line, 50);
function blank() {
    context.fillStyle = 'rgba(0,0,0,0.1)';
    context.fillRect(0, 0, context.canvas.width, context.canvas.height);
}
setInterval(blank, 40);
</script>
```

\section*{Example}

The 2D rendering context for canvas \({ }^{\text {p634 }}\) is often used for sprite-based games. The following example demonstrates this:

\subsection*{4.12.5.2 The ImageBitmap \(^{\text {p990 }}\) rendering context \({\underset{7}{\delta^{p 68}}}^{\text {pen }}\)}

\subsection*{4.12.5.2.1 Introduction \(\S^{p 68}\)}

ImageBitmapRenderingContext \({ }^{\text {p687 }}\) is a performance-oriented interface that provides a low overhead method for displaying the contents of ImageBitmap \({ }^{\text {p998 }}\) objects. It uses transfer semantics to reduce overall memory consumption. It also streamlines performance by avoiding intermediate compositing, unlike the drawImage( \()^{\text {p673 }}\) method of CanvasRenderingContext2D \({ }^{\text {p638 }}\).

Using an \(\underline{i m g}{ }^{p 32 \theta}\) element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the img \({ }^{\text {p320 }}\) element's copy, and the one in the canvas's backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using ImageBitmapRenderingContext \({ }^{\text {p687 }}\).

\section*{Example}

Using ImageBitmapRenderingContext \({ }^{\text {p687 }}\), here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:
```
createImageBitmap(inputImageBlob).then(image => {
    const canvas = document.createElement('canvas');
    const context = canvas.getContext('bitmaprenderer');
    context.transferFromImageBitmap(image) ;
    canvas.toBlob(outputJPEGBlob => {
            // Do something with outputJPEGBlob.
    }, 'image/jpeg');
});
```
4.12.5.2.2 The ImageBitmapRenderingContext \({ }^{\text {p687 }}\) interface \(\underset{7}{\S^{p 68}}\)
```
[Exposed=(Window,Worker)]
interface ImageBitmapRenderingContext {
    readonly attribute (HTMLCanvasElement or OffscreenCanvas) canvas;
    undefined transferFromImageBitmap(ImageBitmap? bitmap);
};
```
```
dictionary ImageBitmapRenderingContextSettings {
    boolean alpha = true;
};
```

\section*{For web developers (non-normative)}

\section*{context = canvas . getContext \({ }^{\text {p636 }}\) ('bitmaprenderer' [, \{ [ alpha \({ }^{\text {p689 }}\) : false ] \} ] )}

Returns an ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object that is permanently bound to a particular canvas \({ }^{\text {p634 }}\) element.
If the alpha \({ }^{\text {p689 }}\) setting is provided and set to false, then the canvas is forced to always be opaque.
context . canvas \({ }^{\text {p688 }}\)
Returns the canvas \({ }^{\text {p634 }}\) element that the context is bound to.
context . transferFromImageBitmap \({ }^{\text {p689 }}\) (imageBitmap)
Transfers the underlying bitmap data \({ }^{\text {p991 }}\) from imageBitmap to context, and the bitmap becomes the contents of the canvas \({ }^{\text {p634 }}\) element to which context is bound.
context . transferFromImageBitmap \({ }^{\text {p689 }}\) (null)
Replaces contents of the canvas \({ }^{\text {p634 }}\) element to which context is bound with a transparent black bitmap whose size corresponds to the width \({ }^{\text {p635 }}\) and height \({ }^{\text {p635 }}\) content attributes of the canvas \({ }^{\text {p634 }}\) element.

The canvas attribute must return the value it was initialized to when the object was created.
An ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object has an output bitmap, which is a reference to bitmap data \({ }^{\text {p991 }}\).
An ImageBitmapRenderingContext \({ }^{p 687}\) object has a bitmap mode, which can be set to valid or blank. A value of valid \({ }^{p 688}\) indicates that the context's output bitmap \({ }^{\text {p688 }}\) refers to bitmap data \({ }^{\text {p991 }}\) that was acquired via transferFromImageBitmap () \({ }^{\text {p689. }}\). A value blank \({ }^{\text {p688 }}\) indicates that the context's output bitmap \({ }^{\text {p688 }}\) is a default transparent bitmap.

An ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object also has an alpha flag, which can be set to true or false. When an ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object has its alpha \({ }^{\text {p688 }}\) flag set to false, the contents of the canvas \({ }^{\text {p634 }}\) element to which the context is bound are obtained by compositing the context's output bitmap \({ }^{\text {p688 }}\) onto an opaque black bitmap of the same size using the source-over composite operation. If the alpha \({ }^{p 688}\) flag is set to true, then the output bitmap \({ }^{p 688}\) is used as the contents of the canvas \({ }^{\text {p634 }}\) element to which the context is bound. [COMPOSITE] \({ }^{\text {p1285 }}\)

\section*{Note}

The step of compositing over an opaque black bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.

When a user agent is required to set an ImageBitmapRenderingContext's output bitmap, with a context argument that is an ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object and an optional argument bitmap that refers to bitmap data \({ }^{\text {p991 }}\), it must run these steps:
1. If a bitmap argument was not provided, then:
1. Set context's bitmap mode \({ }^{\text {p688 }}\) to blank \({ }^{\text {p688 }}\).
2. Let canvas be the canvas \({ }^{\text {p634 }}\) element to which context is bound.
3. Set context's output bitmap \({ }^{\text {p688 }}\) to be transparent black with an intrinsic width equal to the numeric value \({ }^{\text {p635 }}\) of canvas's width \({ }^{p 635}\) attribute and an intrinsic height equal to the numeric value \({ }^{\text {p635 }}\) of canvas's height \({ }^{p 635}\) attribute, those values being interpreted in CSS pixels.
4. Set the output bitmap \({ }^{\text {p688' }} \mathrm{s}\) origin-clean \({ }^{\text {p635 }}\) flag to true.
2. If a bitmap argument was provided, then:
1. Set context's bitmap mode \({ }^{\text {p688 }}\) to valid \({ }^{\text {p688 }}\).
2. Set context's output bitmap \({ }^{\text {p688 }}\) to refer to the same underlying bitmap data as bitmap, without making a copy.

\section*{Note}

The origin-clean \({ }^{\text {p635 }}\) flag of bitmap is included in the bitmap data to be referenced by context's output
```
bitmap }\mp@subsup{}{}{p688}
```

The ImageBitmapRenderingContext creation algorithm, which is passed a target and options, consists of running these steps:
1. Let settings be the result of converting options to the dictionary type ImageBitmapRenderingContextSettings \({ }^{\text {p688 }}\). (This can throw an exception.)
2. Let context be a new ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object.
3. Initialize context's canvas \({ }^{p 644}\) attribute to point to target.
4. Set context's output bitmap \({ }^{p 688}\) to the same bitmap as target's bitmap (so that they are shared).
5. Run the steps to set an ImageBitmapRenderingContext's output bitmap \({ }^{\text {p688 }}\) with context.
6. Initialize context's alpha \({ }^{\text {p688 }}\) flag to true.
7. Process each of the members of settings as follows:
alpha
If false, then set context's alpha \({ }^{\text {p688 }}\) flag to false.
8. Return context.

The transferFromImageBitmap(imageBitmap) method, when invoked, must run these steps:
1. Let bitmapContext be the ImageBitmapRenderingContext \({ }^{\text {p687 }}\) object on which the transferFromImageBitmap() \({ }^{\text {p689 }}\) method was called.
2. If imageBitmap is null, then run the steps to set an ImageBitmapRenderingContext's output bitmap \({ }^{\text {p688 }}\), with bitmapContext as the context argument and no bitmap argument, then return.
3. If the value of imageBitmap's [[Detached]] \({ }^{\text {p104 }}\) internal slot is set to true, then throw an "InvalidStateError" DOMException.
4. Run the steps to set an ImageBitmapRenderingContext's output bitmap \({ }^{\text {p688 }}\), with the context argument equal to bitmapContext, and the bitmap argument referring to imageBitmap's underlying bitmap data \({ }^{\text {p991 }}\).
5. Set the value of imageBitmap's [[Detached]] \({ }^{\text {p104 }}\) internal slot to true.
6. Unset imageBitmap's bitmap data \({ }^{\text {p991 }}\).

\subsection*{4.12.5.3 The OffscreenCanvas \({ }^{\text {p689 }}\) interface \({ }_{\delta^{p 68}}\)}

IDL
```
typedef (OffscreenCanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext) OffscreenRenderingContext;
dictionary ImageEncodeOptions {
    DOMString type = "image/png";
    unrestricted double quality;
};
enum OffscreenRenderingContextId { "2d", "\underline{bitmaprenderer", "webgl", "webgl2" };}
[Exposed=(Window,Worker), Transferable]
interface OffscreenCanvas : EventTarget {
    constructor([EnforceRange] unsigned long long width, [EnforceRange] unsigned long long height);
    attribute [EnforceRange] unsigned long long width;
    attribute [EnforceRange] unsigned long long height;
```
```
OffscreenRenderingContext? getContext(OffscreenRenderingContextId contextId, optional any options =
null);
    ImageBitmap transferToImageBitmap();
    Promise<Blob> convertToBlob(optional ImageEncodeOptions options = {});
};
```
```
Note
    OffscreenCanvas }\mp@subsup{}{}{p689}\mathrm{ is an EventTarget so that WebGL can fire webglcontextlost and webglcontextrestored events at it.
    [WEBGL] p1292
```

OffscreenCanvas \({ }^{\text {p689 }}\) objects are used to create rendering contexts, much like an HTMLCanvasElement \({ }^{\text {p634 }}\), but with no connection to the DOM. This makes it possible to use canvas rendering contexts in workers \({ }^{\text {p1028 }}\).

An OffscreenCanvas \({ }^{\text {p689 }}\) object may hold a weak reference to a placeholder canvas element, which is typically in the DOM, whose embedded content is provided by the OffscreenCanvas \({ }^{\text {p689}}\) object. The bitmap of the 0 ffscreenCanvas \({ }^{\text {p689 }}\) object is pushed to the placeholder canvas element \({ }^{\text {p690 }}\) by calling the commit () method of the offscreenCanvas \({ }^{\text {p689 }}\) object's rendering context. All rendering context types that can be created by an OffscreenCanvas \({ }^{\text {p689 }}\) object must implement a commit () \({ }^{\text {p690 }}\) method. The exact behavior of the commit method (e.g. whether it copies or transfers bitmaps) may vary, as defined by the rendering contexts' respective specifications. Only the 2D context for offscreen canvases \({ }^{\text {p693 }}\) is defined in this specification.

\section*{For web developers (non-normative)}

\section*{offscreenCanvas \(=\) new \(\underline{\text { OffscreenCanvas }}{ }^{\text {p699 }}\) (width, height)}

Returns a new OffscreenCanvas \({ }^{\text {p689 }}\) object that is not linked to a placeholder canvas element \({ }^{\text {p690 }}\), and whose bitmap's size is determined by the width and height arguments.

\section*{context \(=\) offscreenCanvas. getContext \({ }^{\text {p691 }}\) (contextld [, options ] )}

Returns an object that exposes an API for drawing on the OffscreenCanvas \({ }^{\text {p689 }}\) object. contextld specifies the desired API:

This specification defines the " \(2 \mathrm{~d}^{\mathrm{p} 636}\) " context below, which is similar but distinct from the " \(2 \mathrm{~d}^{\mathrm{p691}}\) " context that is created from a canvas \({ }^{\text {p634 }}\) element. The WebGL specifications define the "webgl \({ }^{\text {p691" }}\) and "webgl2 \({ }^{\text {p691 " }}\) contexts. [WEBGL] \({ }^{\text {p1292 }}\)

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a " \(2 d^{\text {p691" }}\) context after getting a "webgl \({ }^{\text {p691" }}\) context).

An OffscreenCanvas \({ }^{\text {p689 }}\) object has an internal bitmap that is initialized when the object is created. The width and height of the \(\underline{\text { bitmap }}{ }^{\text {p690 }}\) are equal to the values of the width \({ }^{\text {p691 }}\) and height \({ }^{\text {p691 }}\) attributes of the \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object. Initially, all the bitmap's pixels are transparent black.

An 0 ffscreenCanvas \({ }^{\text {p689 }}\) object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an 0ffscreenCanvas \({ }^{\text {p689 }}\) object also has a context mode, which is initially none but can be changed to either 2d, bitmaprenderer, webgl, webgl2, or detached by algorithms defined in this specification.

The constructor OffscreenCanvas (width, height), when invoked, must create a new \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object with its bitmap \({ }^{\text {p690 }}\) initialized to a rectangular array of transparent black pixels of the dimensions specified by width and height; and its width \({ }^{\text {p691 }}\) and height \({ }^{\text {p691 }}\) attributes initialized to width and height respectively.

OffscreenCanvas \({ }^{\text {p689 }}\) objects are transferable \({ }^{\text {p103 }}\). Their transfer steps \({ }^{\text {p104 }}\), given value and dataHolder, are as follows:
1. If value's context mode \({ }^{\text {p690 }}\) is not equal to none \({ }^{\text {p690 }}\), then throw an "InvalidStateError" DOMException.
2. Set value's context mode \({ }^{\text {p690 }}\) to detached \({ }^{\text {p690 }}\).
3. Let width and height be the dimensions of value's bitmap \({ }^{\text {p690 }}\).
4. Unset value's bitmap \({ }^{\text {p690 }}\).
5. Set dataHolder.[[Width]] to width and dataHolder.[[Height]] to height.
6. Set dataHolder.[[PlaceholderCanvas]] to be a weak reference to value's placeholder canvas element \({ }^{\text {p690 }}\), if value has one, or null if it does not.

Their transfer-receiving steps \({ }^{\text {p104 }}\), given dataHolder and value, are:
1. Initialize value's \(\underline{\text { bitmap }^{\text {p690 }}}\) to a rectangular array of transparent black pixels with width given by dataHolder.[[Width]] and height given by dataHolder.[[Height]].
2. If dataHolder.[[PlaceholderCanvas]] is not null, set value's placeholder canvas element \({ }^{\text {p690 }}\) to dataHolder.[[PlaceholderCanvas]] (while maintaining the weak reference semantics).

The getContext (contextId, options) method of an OffscreenCanvas \({ }^{\text {p689 }}\) object, when invoked, must run these steps:
1. If options is not an object, then set options to null.
2. Set options to the result of converting options to a JavaScript value.
3. Run the steps in the cell of the following table whose column header matches this 0 ffscreenCanvas \({ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) and whose row header matches contextld:
\begin{tabular}{|c|c|c|c|c|c|}
\hline & none \({ }^{\text {p690 }}\) & \(2 d^{\text {p690 }}\) & bitmaprenderer \({ }^{\text {p690 }}\) & webgl \({ }^{\text {p690 }}\) or webgl2 \({ }^{\text {p690 }}\) & detached \({ }^{\text {p690 }}\) \\
\hline "2d" & Follow the offscreen 2D context creation algorithm \({ }^{\text {p693 }}\) defined in the section below, passing it this 0 ffscreenCanvas \({ }^{\text {p689 }}\) object and options, to obtain an OffscreenCanvasRenderingContext2D \({ }^{\text {p693 }}\) object; if this does not throw an exception, then set this OffscreenCanvas \({ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) to \(2 \mathrm{~d}^{\mathrm{p} 690}\), and return the new OffscreenCanvasRenderingContext2D \({ }^{\text {p693 }}\) object. & Return the same object as was returned the last time the method was invoked with this same first argument. & Return null. & Return null. & Throw an "InvalidStateError" DOMException. \\
\hline "bitmaprenderer" & Follow the ImageBitmapRenderingContext creation algorithm \({ }^{\text {p689 }}\) defined in the section above, passing it this OffscreenCanvas \({ }^{\text {p689 }}\) object and options, to obtain an ImageBitmapRenderingcontext \({ }^{\text {p687 }}\) object; if this does not throw an exception, then set this OffscreenCanvas \({ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) to bitmaprenderer \({ }^{p 690}\), and return the new ImageBitmapRenderingcontext \({ }^{\text {p687 }}\) object. & Return null. & Return the same object as was returned the last time the method was invoked with this same first argument. & Return null. & Throw an "InvalidStateError" DOMException. \\
\hline \begin{tabular}{l}
"webgl" or \\
"webgl2"
\end{tabular} & \begin{tabular}{l}
Follow the instructions given in the WebGL specifications' Context Creation sections to obtain either a WebGLRenderingContext, \\
WebGL2RenderingContext, or null; if the returned value is null, then return null; otherwise, set this OffscreenCanvas \({ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) to webgl \({ }^{\text {p690 }}\) or webgl2 \({ }^{\text {p690 }}\), and return the WebGLRenderingContext or WebGL2RenderingContext object. [WEBGL] \({ }^{\text {p1292 }}\)
\end{tabular} & Return null. & Return null. & Return the same value as was returned the last time the method was invoked with this same first argument. & Throw an "InvalidStateError" DOMException. \\
\hline
\end{tabular}

\section*{For web developers (non-normative)}
offscreenCanvas . width \({ }^{\text {p691 }}\) [ = value ]
offscreenCanvas \(\cdot\) height \({ }^{\text {p691 }}\) [ = value ]
These attributes return the dimensions of the OffscreenCanvas \({ }^{\text {p689 }}\) object's bitmap \({ }^{\text {p690 }}\).
They can be set, to replace the bitmap \({ }^{\text {p690 }}\) with a new, transparent black bitmap of the specified dimensions (effectively resizing it).

If either the width or height attributes of an 0ffscreenCanvas \({ }^{\text {p689 }}\) object are set (to a new value or to the same value as before) and the \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) is \(\underline{2 d^{p 690}}\), then replace the \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object's bitmap \({ }^{\text {p690 }}\) with a new transparent black bitmap and reset the rendering context to its default state \({ }^{\text {p646 }}\). The new bitmap's dimensions are equal to the new values of the width \({ }^{\text {p691 }}\) and height \({ }^{\text {p691 }}\) attributes.

The resizing behavior for "webgr \({ }^{\text {p691" }}\) and "webgl2 \({ }^{\text {p691" }}\) contexts is defined in the WebGL specifications. [WEBGL] \({ }^{p 1292}\)
canvas element \({ }^{\text {p690 }}\) 's intrinsic size will only be updated via the commit ( ) \({ }^{\text {p690 }}\) method of the 0 ffscreenCanvas \({ }^{\text {p689 }}\) object's rendering context.

\section*{For web developers (non-normative)}

\section*{promise \(=\) offscreenCanvas . convertToBlob \({ }^{\text {p692 }}\) ([options] )}

Returns a promise that will fulfill with a new Blob object representing a file containing the image in the OffscreenCanvas \({ }^{\text {p689 }}\) object.

The argument, if provided, is a dictionary that controls the encoding options of the image file to be created. The type \({ }^{\text {p692 }}\) field specifies the file format and has a default value of "image/png \({ }^{\text {p1283" }}\); that type is also used if the requested type isn't supported. If the image format supports variable quality (such as "image/jpeg \({ }^{\text {p1283" }}\) ), then the quality \({ }^{\text {p692 }}\) field is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.
canvas . transferToImageBitmap \({ }^{\text {p692 }}\) ()
Returns a newly created ImageBitmap \({ }^{\text {p990 }}\) object with the image in the 0ffscreenCanvas \({ }^{\text {p689 }}\) object. The image in the OffscreenCanvas \({ }^{\text {p689 }}\) object is replaced with a new blank image.

The convertToBlob(options) method, when invoked, must run following steps:
1. If the value of this 0 ffscreenCanvas \({ }^{\text {p689 }}\) object's [[Detached]] \({ }^{\text {p104 }}\) internal slot is set to true, then return a promise rejected with an "InvalidStateError" DOMException.
2. If this OffscreenCanvas \({ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) is \(\underline{2 d^{p 690}}\) and the rendering context's bitmap \({ }^{\text {p693' }}\) s origin-clean \({ }^{\text {p693 }}\) flag is set to false, then return a promise rejected with a "SecurityError" DOMException.
3. If this OffscreenCanvas \({ }^{p 689}\) object's bitmap \({ }^{p 690}\) has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return a promise rejected with an "IndexSizeError" DOMException.
4. Let bitmap be a copy of this OffscreenCanvas \({ }^{\text {p689 }}\) object's bitmap \({ }^{\text {p690 }}\).
5. Let result be a new promise object.
6. Run these steps in parallel \({ }^{\mathrm{p} 42}\) :
1. Let file be a serialization of bitmap as a file \({ }^{\text {p695 }}\), with options's type and quality if present.
2. Queue an element task \({ }^{\text {p946 }}\) on the canvas blob serialization task source \({ }^{\text {p638 }}\) given the canvas \({ }^{\text {p634 }}\) element to run these steps:
1. If file is null, then reject result with an "EncodingError" DOMException.
2. Otherwise, resolve result with a new Blob object, created in the relevant Realm \({ }^{\text {p924 }}\) of this OffscreenCanvas \({ }^{\text {p689 }}\) object, representing file. [FILEAPI] \({ }^{\text {p1287 }}\)
7. Return result.

The transferToImageBitmap() method, when invoked, must run the following steps:
1. If the value of this \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object's [[Detached] \(]^{p 104}\) internal slot is set to true, then throw an "InvalidStateError" DOMException.
2. If this OffscreenCanvas \({ }^{\text {p689 }}\) object's context mode \({ }^{\text {p690 }}\) is set to none \({ }^{\text {p690 }}\), then throw an "InvalidStateError" DOMException.
3. Let image be a newly created ImageBitmap \({ }^{\text {p999 }}\) object that references the same underlying bitmap data as this OffscreenCanvas \({ }^{\text {p689 }}\) object's bitmap \({ }^{\text {p690 }}\).
4. Set this OffscreenCanvas \({ }^{p 689}\) object's bitmap \({ }^{\text {p690 }}\) to reference a newly created bitmap of the same dimensions as the previous bitmap, and with its pixels initialized to transparent black, or opaque black if the rendering context's alpha \({ }^{\text {p693 }}\) flag is set to false.

Note
This means that if the rendering context of this OffscreenCanvas \({ }^{\text {p689 }}\) is a WebGLRenderingContext, the value of preserveDrawingBuffer will have no effect. [WEBGL] \({ }^{\text {p1292 }}\)
5. Return image.
```
[Exposed=(Window,Worker)]
interface OffscreenCanvasRenderingContext2D {
    undefined commit();
    readonly attribute OffscreenCanvas canvas;
};
OffscreenCanvasRenderingContext2D includes CanvasState;
OffscreenCanvasRenderingContext2D includes CanvasTransform;
OffscreenCanvasRenderingContext2D includes CanvasCompositing;
OffscreenCanvasRenderingContext2D includes CanvasImageSmoothing;
OffscreenCanvasRenderingContext2D includes CanvasFillStrokeStyles;
OffscreenCanvasRenderingContext2D includes CanvasShadowStyles;
OffscreenCanvasRenderingContext2D includes CanvasFilters;
OffscreenCanvasRenderingContext2D includes CanvasRect;
OffscreenCanvasRenderingContext2D includes CanvasDrawPath;
OffscreenCanvasRenderingContext2D includes CanvasText;
OffscreenCanvasRenderingContext2D includes CanvasDrawImage;
OffscreenCanvasRenderingContext2D includes CanvasImageData;
OffscreenCanvasRenderingContext2D includes CanvasPathDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasTextDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasPath;
```

The OffscreenCanvasRenderingContext \(2 D^{p 693}\) object is a rendering context for drawing to the bitmap \({ }^{\text {p690 }}\) of an 0 ffscreenCanvas \({ }^{\text {p689 }}\) object. It is similar to the CanvasRenderingContext2D \({ }^{\text {p638 }}\) object, with the following differences:
- there is no support for user interface \({ }^{p 640}\) features;
- its canvas \({ }^{\text {p694 }}\) attribute refers to an \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object rather than a canvas \({ }^{\text {p634 }}\) element;
- it has a commit ( ) \({ }^{\text {p694 }}\) method for pushing the rendered image to the context's \(\underline{0 f f s c r e e n C a n v a s ~}{ }^{\text {p689 }}\) object's placeholder canvas element \({ }^{\text {p690 }}\).

An 0 ffscreenCanvasRenderingContext \(2 \mathrm{D}^{\mathrm{p} 693}\) object has a bitmap that is initialized when the object is created.
The bitmap \({ }^{\text {p693 }}\) has an origin-clean flag, which can be set to true or false. Initially, when one of these bitmaps is created, its originclean \({ }^{\text {p693 }}\) flag must be set to true.

An OffscreenCanvasRenderingContext2D \({ }^{p 693}\) object also has an alpha flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When an 0 ffscreenCanvasRenderingContext \(2 D^{\text {p693 }}\) object has its alpha \({ }^{\text {p693 }}\) flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An OffscreenCanvasRenderingContext \(2 D^{p 693}\) object has an associated OffscreenCanvas object, which is the \(0 f f s c r e e n C a n v a s ~{ }^{\text {p689 }}\) object from which the 0 ffscreenCanvasRenderingContext \(2 D^{\text {p693 }}\) object was created.

\section*{For web developers (non-normative)}
offscreenCanvasRenderingContext2D . commit \({ }^{\text {p694 }}\) ()
Copies the rendering context's bitmap \({ }^{\text {p693 }}\) to the bitmap of the placeholder canvas element \({ }^{\text {p690 }}\) of the associated offscreenCanvas object \({ }^{\text {p693 }}\). The copy operation is synchronous. Calling this method is not needed for the transfer, since it happens automatically during the event loop \({ }^{\text {p944 }}\) execution.
offscreenCanvas \(=\) offscreenCanvasRenderingContext2D \(\cdot \underline{\text { canvas }{ }^{\text {p694 }}}\)
Returns the associated OffscreenCanvas object \({ }^{\text {p693 }}\).

The offscreen 2D context creation algorithm, which is passed a target (an offscreenCanvas \({ }^{\text {p689 }}\) object) and optionally some arguments, consists of running the following steps:
1. If the algorithm was passed some arguments, let arg be the first such argument. Otherwise, let arg be undefined.
2. Let settings be the result of converting options to the dictionary type CanvasRenderingContext2DSettings \({ }^{\text {p638 }}\). (This can throw an exception.).
3. Let context be a new \(\underline{0 f f s c r e e n C a n v a s R e n d e r i n g C o n t e x t 2 D^{p 693}}\) object.
4. Set context's associated OffscreenCanvas object \({ }^{\text {p693 }}\) to target.
5. Process each of the members of settings as follows:
alpha \({ }^{\text {p644 }}\)
If false, set context's alpha \({ }^{\text {p693 }}\) flag to false.
6. Set context's bitmap \({ }^{\text {p693 }}\) to a newly created bitmap with the dimensions specified by the width \({ }^{\text {p691 }}\) and height \({ }^{\text {p691 }}\) attributes of target, and set target's bitmap to the same bitmap (so that they are shared).
7. If context's alpha \({ }^{\text {p693 }}\) flag is set to true, initialize all the pixels of context's \(\underline{\text { bitmap }}^{\text {p693 }}\) to transparent black. Otherwise, initialize the pixels to opaque black.
8. Return context.

The commit () method, when invoked, must run the following steps:
1. If this \(\underline{0 f f s c r e e n C a n v a s R e n d e r i n g C o n t e x t ~} 2 D^{\text {p693 }}\) 's \(\underline{\text { associated } 0 f f s c r e e n C a n v a s ~ o b j e c t ~}{ }^{\text {p693 }}\) does not have a placeholder canvas element \({ }^{\text {p690 }}\), then return.
2. Let image be a copy of this \(\underline{0 f f s c r e e n C a n v a s R e n d e r i n g C o n t e x t ~} 2 D^{p 693}\) 's bitmap \({ }^{\text {p693 }}\), including the value of its origin-clean \({ }^{\text {p693 }}\) flag.
3. Queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the placeholder canvas element \({ }^{\text {p690 }}\) to set the placeholder canvas element \({ }^{\text {p690 ' }} \mathrm{s}\) output bitmap \({ }^{\text {p643 }}\) to be a reference to image.

\section*{Note}

If image has different dimensions than the bitmap previously referenced as the placeholder canvas element \({ }^{p 690}\) 's output bitmap \({ }^{p 643}\), then this task will result in a change in the placeholder canvas element \({ }^{p 690}\) 's intrinsic size, which can affect document layout.

\section*{Note}

> Implementations are encouraged to short-circuit the graphics update steps of the window event loop \({ }^{\text {p944 }}\) for the purposes of updating the contents of a placeholder canvas element p690 to the display. This could mean, for example, that the commit () \({ }^{\text {p694 }}\) method can copy the bitmap contents directly to a graphics buffer that is mapped to the physical display location of the placeholder canvas element \({ }^{p 690}\). This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the commit ( ) \({ }^{\text {p694 }}\) method is invoked from a worker event loop \({ }^{\text {p944 }}\) and the window event loop \({ }^{\text {p944 }}\) of the placeholder canvas element \({ }^{p 690}\) is busy. However, such shortcuts can not have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the placeholder canvas element \({ }^{p 690}\), in case the element is used as a CanvasImageSource \({ }^{\text {p638 }}\), as an ImageBitmapSource \({ }^{\text {p996 }}\), or in case toDataURL( () \({ }^{\text {p637 }}\) or toBlob() ( \({ }^{\text {p638 }}\) are called on it.

The canvas attribute, on getting, must return this \(\underline{0 f f s c r e e n C a n v a s R e n d e r i n g C o n t e x t 2 D^{p 693}}\) 's associated 0ffscreenCanvas object \({ }^{\text {p693 }}\).

\section*{}

The canvas \({ }^{\text {p634 }}\) APIs must perform color correction at only two points: when rendering images with their own gamma correction and color space information onto a bitmap, to convert the image to the color space used by the bitmaps (e.g. using the 2D Context's drawImage( ) \({ }^{\text {p673 }}\) method with an HTMLOrSVGImageElement \({ }^{\text {p638 }}\) object), and when rendering the actual canvas bitmap to the output device.

\section*{Note}

Thus, in the 2D context, colors used to draw shapes onto the canvas will exactly match colors obtained through the getImageData() \({ }^{\text {p676 }}\) method.

The toDataURL( ) \({ }^{\text {p637 }}\) method, when invoked, must not include color space information in the resources they return. Where the output format allows it, the color of pixels in resources created by toDataURL( ) \({ }^{\text {p637 }}\) must match those returned by the getImageData () \({ }^{\text {p676 }}\) method.

In user agents that support CSS, the color space used by a canvas \({ }^{\text {p634 }}\) element must match the color space used for processing any
colors for that element in CSS.

The gamma correction and color space information of images must be handled in such a way that an image rendered directly using an \(i^{\text {img }}{ }^{\mathrm{p} 32 \theta}\) element would use the same colors as one painted on a canvas \({ }^{p 634}\) element that is then itself rendered. Furthermore, the rendering of images that have no color correction information (such as those returned by the toDataURL() \({ }^{\text {p637 }}\) method) must be rendered with no color correction.

\section*{Note}

Thus, in the 2D context, calling the drawImage( () \({ }^{\mathrm{p} 673}\) method to render the output of the toDataURL( ) \({ }^{\mathrm{p637}}\) method to the canvas, given the appropriate dimensions, has no visible effect.

\subsection*{4.12.5.5 Serializing bitmaps to a file \(\S_{5}^{p 69}\)}

When a user agent is to create a serialization of the bitmap as a file, given a type and an optional quality, it must create an image file in the format given by type. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [PNG] \({ }^{\text {p1290 }}\)

The image file's pixel data must be the bitmap's pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per CSS pixel).

If type is supplied, then it must be interpreted as a MIME type giving the format to use. If the type has any parameters, then it must be treated as not supported.

\section*{Example}

For example, the value "image/png \({ }^{\text {p1283" }}\) "would mean to generate a PNG image, the value "image/jpeg \({ }^{\text {p1283" " would mean to }}\) generate a JPEG image, and the value "image/svg \(+x\) l \(^{\text {p1283" }}\) would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("image/png \({ }^{p 1283 "}\) "). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [PNG] \({ }^{\text {p1290 }}\)

User agents must convert the provided type to ASCII lowercase before establishing if they support that type.
For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an opaque black background using the source-over operator.

If type is an image format that supports variable quality (such as "image/jpeg \({ }^{\text {p1283" }}\) ), quality is given, and type is not "image/png \({ }^{\text {p1283" }}\), then, if Type(quality) is Number, and quality is in the range 0.0 to 1.0 inclusive, the user agent must treat quality as the desired quality level. Otherwise, the user agent must use its default quality value, as if the quality argument had not been given.

\section*{Note}

The use of type-testing here, instead of simply declaring quality as a Web IDL double, is a historical artifact.

\section*{Note}

Different implementations can have slightly different interpretations of "quality". When the quality is not specified, an implementation-specific default is used that represents a reasonable compromise between compression ratio, image quality, and encoding time.

\subsection*{4.12.5.6 Security with canvas \({ }^{\text {p634 }}\) elements \({ }^{\text {§ }}{ }_{5}^{\text {p6 }}\)}

This section is non-normative.
Information leakage can occur if scripts from one origin \({ }^{\text {p837 }}\) can access information (e.g. read pixels) from images from another origin (one that isn't the same \({ }^{\text {p838 }}\) ).

To mitigate this, bitmaps used with canvas \({ }^{\text {p634 }}\) elements and ImageBitmap \({ }^{\text {p996 }}\) objects are defined to have a flag indicating whether they are origin-clean \({ }^{\text {p635 }}\). All bitmaps start with their origin-clean \({ }^{\text {p635 }}\) set to true. The flag is set to false when cross-origin images are
used.

The toDataURL( ) \({ }^{\text {p637 }}\), \(\underline{\operatorname{toBlob}()^{p 638}}\), and getImageData( () \({ }^{\text {p676 }}\) methods check the flag and will throw a "SecurityError" DOMException rather than leak cross-origin data.

The value of the origin-clean \({ }^{\text {p635 }}\) flag is propagated from a source canvas \({ }^{\text {p634 }}\) element's bitmap to a new ImageBitmap \({ }^{\text {p999 }}\) object by createImageBitmap ( ) \({ }^{\text {p9922 }}\). Conversely, a destination canvas \({ }^{\text {p634 }}\) element's bitmap will have its origin-clean \({ }^{\text {p635 }}\) flags set to false by drawImage \({ }^{\text {p673 }}\) if the source image is an ImageBitmap \({ }^{p 996}\) object whose bitmap has its origin-clean \({ }^{\text {p635 }}\) flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the width \({ }^{p 635}\) or the height \({ }^{p 635}\) content attribute of the canvas \({ }^{\text {p634 }}\) element to which a CanvasRenderingContext2D \({ }^{\text {p638 }}\) is bound, the bitmap is cleared and its origin-clean \({ }^{\text {p635 }}\) flag is reset.

When using an ImageBitmapRenderingContext \({ }^{\text {p687 }}\), the value of the origin-clean \({ }^{\text {p635 }}\) flag is propagated from ImageBitmap \({ }^{\text {p99日 }}\) objects when they are transferred to the canvas \({ }^{\text {p634 }}\) via transferFromImageBitmap() \({ }^{\text {p689 }}\).

\subsection*{4.13 Custom elements \(\S^{p 69}\)}

\subsection*{4.13.1 Introduction \(\S^{p 69}\)}

This section is non-normative.
Custom elements \({ }^{\mathrm{p} 703}\) provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By defining \({ }^{\text {p706 }}\) a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements-both functionally and semantically-that prevent them from fully explaining the behaviors of HTML's existing elements, we hope to shrink this gap over time.

\subsection*{4.13.1.1 Creating an autonomous custom element \(\S^{p 69}\)}

This section is non-normative.
For the purposes of illustrating how to create an autonomous custom element \({ }^{\text {p703 }}\), let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:
```
<flag-icon country="nl"></flag-icon>
```

To do this, we first declare a class for the custom element, extending HTMLElement \({ }^{\text {p124 }}\) :
```
class FlagIcon extends HTMLElement {
    constructor() {
        super();
        this._countryCode = null;
    }
    static get observedAttributes() { return ["country"]; }
    attributeChangedCallback(name, oldValue, newValue) {
        // name will always be "country" due to observedAttributes
        this._countryCode = newValue;
        this._updateRendering();
    }
    connectedCallback() {
```
```
            this. updateRendering();
    }
    get country() {
        return this._countryCode;
    }
    set country(v) {
        this.setAttribute("country", v);
    }
    _updateRendering() {
        // Left as an exercise for the reader. But, you'll probably want to
        // check this.ownerDocument.defaultView to see if we've been
        // inserted into a document with a browsing context, and avoid
        // doing any work if not.
    }
}
```

We then need to use this class to define the element:
```
customElements.define("flag-icon", FlagIcon);
```

At this point, our above code will work! The parser, whenever it sees the flag-icon tag, will construct a new instance of our FlagIcon class, and tell our code about its new country attribute, which we then use to set the element's internal state and update its rendering (when appropriate).

You can also create flag-icon elements using the DOM API:
```
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

Finally, we can also use the custom element constructor \({ }^{p 703}\) itself. That is, the above code is equivalent to:
```
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

\subsection*{4.13.1.2 Creating a form-associated custom element \(\S^{\text {p69 }}\)}

This section is non-normative.
Adding a static formAssociated property, with a true value, makes an autonomous custom element \({ }^{\text {p703 }}\) a form-associated custom element \({ }^{\mathrm{p704}}\). The ElementInternals \({ }^{\mathrm{p} 714}\) interface helps you to implement functions and properties common to form control elements.
```
class MyCheckbox extends HTMLElement {
    static get formAssociated() { return true; }
    constructor() {
        super();
        this._internals = this.attachInternals();
        this._checked = false;
        this.addEventListener('click', this._onClick.bind(this));
    }
    get form() { return this._internals.form; }
    get name() { return this.getAttribute('name'); }
    get type() { return this.localName; }
```
```
    get checked() { return this._checked; }
    set checked(flag) {
        this._checked = !!flag;
        this._internals.setFormValue(this._checked ? 'on' : null);
    }
    _onClick(event) {
        this.checked = !this._checked;
    }
}
customElements.define('my-checkbox', MyCheckbox);
```

You can use the custom element my - checkbox like a built-in form-associated element. For example, putting it in form \({ }^{\text {p486 }}\) or labet \({ }^{\text {p490 }}\) associates the my-checkbox element with them, and submitting the form \({ }^{\text {p486 }}\) will send data provided by my-checkbox implementation.
```
<form action="..." method="...">
    <label><my-checkbox name="agreed"></my-checkbox> I read the agreement.</label>
    <input type="submit">
</form>
```

\subsection*{4.13.1.3 Creating a customized built-in element \(\S^{p 69}\)}

This section is non-normative.
Customized built-in elements \({ }^{\mathrm{p} 703}\) are a distinct kind of custom element \({ }^{\mathrm{p703}}\), which are defined slightly differently and used very differently compared to autonomous custom elements \({ }^{\mathrm{p} 703}\). They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely autonomous custom elements \({ }^{\mathrm{p} 703}\). Instead, customized built-in elements \({ }^{\mathrm{p} 703}\) allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially "mixing in" these capabilities on top of the already-existing element.

Customized built-in elements \({ }^{\mathrm{p} 703}\) require a distinct syntax from autonomous custom elements \({ }^{\mathrm{p} 703}\) because user agents and other software key off an element's local name in order to identify the element's semantics and behavior. That is, the concept of customized built-in elements \({ }^{\text {p703 }}\) building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we'll be creating a customized built-in element \({ }^{\text {p703 }}\) named plastic-button, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend HTMLButtonElement \({ }^{\text {p536 }}\) instead of HTMLElement \({ }^{\text {p124 }}\) :
```
class PlasticButton extends HTMLButtonElement {
    constructor() {
        super();
        this.addEventListener("click", () => {
            // Draw some fancy animation effects!
        });
    }
}
```

When defining our custom element, we have to also specify the extends option:
```
customElements.define("plastic-button", PlasticButton, { extends: "button" });
```

In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as \(q^{p 247}\) and blockquote \({ }^{\text {p217 }}\) both sharing HTMLQuoteElement \({ }^{p 218}\) ).

To construct our customized built-in element \({ }^{\text {p703 }}\) from parsed HTML source text, we use the is \({ }^{\text {p703 }}\) attribute on a button \({ }^{\text {p535 }}\) element:

Trying to use a customized built-in element \({ }^{\text {p703 }}\) as an autonomous custom element \({ }^{\text {p703 }}\) will not work; that is, <plastic-button>Click me? </plastic-button> will simply create an HTMLElement \({ }^{\text {p124 }}\) with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of createElement():
```
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!";
```

And as before, the constructor will also work:
```
const plasticButton2 = new PlasticButton();
console.log(plasticButton2.localName); // will output "button"
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLButtonElement);
```

Note that when creating a customized built-in element programmatically, the is \({ }^{\mathrm{p7} 73}\) attribute will not be present in the DOM, since it was not explicitly set. However, it will be added to the output when serializing \({ }^{\text {p1176 }}\) :
```
console.assert(!plasticButton.hasAttribute("is"));
console.log(plasticButton.outerHTML); // will output '<button is="plastic-button"></button>'
```

Regardless of how it is created, all of the ways in which button \({ }^{p 535}\) is special apply to such "plastic buttons" as well: their focus behavior, ability to participate in form submission \({ }^{\mathrm{p596}}\), the disabled \({ }^{\mathrm{p} 576}\) attribute, and so on.

Customized built-in elements \({ }^{\text {p703 }}\) are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as bgsound \({ }^{p 1232}\), blink \({ }^{p 1233}\), isindex \({ }^{p 1232}\), keygen \({ }^{p 1232}\), multicol \(l^{p 1233}\), nextid \({ }^{p 1232}\), or spacer \({ }^{p 1233}\) that have been defined to use HTMLUnknownElement \({ }^{\text {p124 }}\) as their element interface.

One reason for this requirement is future-compatibility: if a customized built-in element \({ }^{\mathrm{p} 703}\) was defined that extended a currentlyunknown element, for example combobox, this would prevent this specification from defining a combobox element in the future, as consumers of the derived customized built-in element \({ }^{\mathrm{p703}}\) would have come to depend on their base element having no interesting user-agent-supplied behavior.

\subsection*{4.13.1.4 Drawbacks of autonomous custom elements \(\S^{p 69}\)}

This section is non-normative.

As specified below, and alluded to above, simply defining and using an element called taco-button does not mean that such elements represent \({ }^{\text {p123 }}\) buttons. That is, tools such as web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an autonomous custom element \({ }^{\text {p703 }}\), a number of techniques would need to be employed:
- The addition of the tabindex \({ }^{\mathrm{p} 773}\) attribute would make the taco-button focusable \({ }^{\mathrm{p} 772}\). Note that if the taco-button were to become logically disabled, the tabindex \({ }^{\mathrm{p} 773}\) attribute would need to be removed.
- The addition of various ARIA attributes helps convey semantics to accessibility technology. For example, setting the role \({ }^{\text {p63 }}\) attribute to "button" will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the aria-label attribute is necessary to give the button an accessible name, instead of having accessibility technology traverse its child text nodes and announce them. And setting aria-disabled to "true" when the button is logically disabled conveys to accessibility technology the button's disabled state.
- The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to web browser users. In this case, the most relevant event handler would be one that proxies appropriate keydown events to become click events, so that you can activate the button both with keyboard and by clicking.
- In addition to any default visual styling provided for taco-button elements, the visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for taco-button will also need to have rules for taco-button[disabled].

With these points in mind, a full-featured taco-button that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:
```
class TacoButton extends HTMLElement {
    static get observedAttributes() { return ["disabled"]; }
    constructor() {
        super();
        this.addEventListener("keydown", e => {
            if (e.keyCode === 32 || e.keyCode === 13) {
                this.dispatchEvent(new MouseEvent("click", {
                bubbles: true,
                cancelable: true
                }));
            }
        });
        this.addEventListener("click", e => {
            if (this.disabled) {
                e.preventDefault();
                e.stopPropagation();
            }
        });
        this._observer = new MutationObserver(() => {
            this.setAttribute("aria-label", this.textContent);
        }) ;
    }
    connectedCallback() {
        this.setAttribute("role", "button");
        this.setAttribute("tabindex", "0");
        this._observer.observe(this, {
            childList: true,
            characterData: true,
            subtree: true
        });
    }
    disconnectedCallback() {
        this._observer.disconnect();
    }
    get disabled() {
        return this.hasAttribute("disabled");
    }
    set disabled(v) {
        if (v) {
            this.setAttribute("disabled", "");
        } else {
        this.removeAttribute("disabled");
        }
    }
    attributeChangedCallback() {
```
```
    // only is called for the disabled attribute due to observedAttributes
    if (this.disabled) {
        this.removeAttribute("tabindex");
        this.setAttribute("aria-disabled", "true");
        } else {
        this.setAttribute("tabindex", "0");
        this.setAttribute("aria-disabled", "false");
        }
    }
}
```

Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually "sprouting" tabindex \({ }^{\mathrm{p} 773}\) and aria-*p63 attributes of its own volition. This is because as of now there is no way to specify default accessibility semantics or focus behavior for custom elements, forcing the use of these attributes to do so (even though they are usually reserved for allowing the consumer to override default behavior).

In contrast, a simple customized built-in element \({ }^{\text {p703 }}\), as shown in the previous section, would automatically inherit the semantics and behavior of the button \({ }^{\text {p535 }}\) element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, customized built-in elements \({ }^{\text {p703 }}\) will be easier to develop, maintain, and consume.

\subsection*{4.13.1.5 Upgrading elements after their creation \(\S^{\text {p70 }}\)}

This section is non-normative.

Because element definition \({ }^{\text {p706 }}\) can occur at any time, a non-custom element could be created, and then later become a custom element \({ }^{\text {p703 }}\) after an appropriate definition \({ }^{\text {p705 }}\) is registered. We call this process "upgrading" the element, from a normal element into a custom element.

Upgrades \({ }^{\mathrm{p} 709}\) enable scenarios where it may be preferable for custom element definitions \({ }^{\mathrm{p} 705}\) to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following HTML document the element definition for img-viewer is loaded asynchronously:
```
<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>
<img-viewer filter="Kelvin">
    <img src="images/tree.jpg" alt="A beautiful tree towering over an empty savannah">
</img-viewer>
<script src="js/elements/img-viewer.js" async></script>
```

The definition for the img-viewer element here is loaded using a script \({ }^{\text {p614 }}\) element marked with the async \({ }^{p 615}\) attribute, placed after the <img-viewer> tag in the markup. While the script is loading, the img-viewer element will be treated as an undefined element, similar to a span \({ }^{\text {p279 }}\). Once the script loads, it will define the img-viewer element, and the existing img-viewer element on the page will be upgraded, applying the custom element's definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image's visual appearance).

Note that upgrades \({ }^{\text {p709 }}\) only apply to elements in the document tree. (Formally, elements that are connected.) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:
```
<!DOCTYPE html>
<html lang="en">
<title>Upgrade edge-cases example</title>
<example-element></example-element>
<script>
```
```
    "use strict";
    const inDocument = document.querySelector("example-element");
    const outOfDocument = document.createElement("example-element");
    // Before the element definition, both are HTMLElement
    console.assert(inDocument instanceof HTMLElement);
    console.assert(outOfDocument instanceof HTMLElement);
    class ExampleElement extends HTMLElement {}
    customElements.define("example-element", ExampleElement);
    // After element definition, the in-document element was upgraded:
    console.assert(inDocument instanceof ExampleElement);
    console.assert(!(outOfDocument instanceof ExampleElement))
    document.body.appendChild(out0fDocument);
    // Now that we've moved the element into the document, it too was upgraded:
    console.assert(outOfDocument instanceof ExampleElement);
</script>
```

\subsection*{4.13.2 Requirements for custom element constructors and reactions \(\S_{2}^{\text {p70 }}\)}

When authoring custom element constructors \({ }^{\text {p703 }}\), authors are bound by the following conformance requirements:
- A parameter-less call to super () must be the first statement in the constructor body, to establish the correct prototype chain and this value before any further code is run.
- A return statement must not appear anywhere inside the constructor body, unless it is a simple early-return (return or return this).
- The constructor must not use the document. write() \({ }^{\text {p970 }}\) or document.open() \({ }^{\text {p969 }}\) methods.
- The element's attributes and children must not be inspected, as in the non-upgrade \({ }^{\text {p709 }}\) case none will be present, and relying on upgrades makes the element less usable.
- The element must not gain any attributes or children, as this violates the expectations of consumers who use the createElement or createElementNS methods.
- In general, work should be deferred to connectedCallback as much as possible-especially work involving fetching resources or rendering. However, note that connectedCallback can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.
- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a shadow root.

Several of these requirements are checked during element creation, either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructorinitiated microtask \({ }^{\text {p945 }}\), as a microtask checkpoint \({ }^{\text {p949 }}\) can occur immediately after construction.

When authoring custom element reactions \({ }^{\text {p711 }}\), authors should avoid manipulating the node tree as this can lead to unexpected results.

\section*{Example}

An element's connectedCallback can be queued before the element is disconnected, but as the callback queue is still processed, it results in a connectedCallback for an element that is no longer connected:
```
class CParent extends HTMLElement {
    connectedCallback() {
        this.firstChild.remove();
    }
```
```
}
customElements.define("c-parent", CParent);
class CChild extends HTMLElement {
    connectedCallback() {
        console.log("CChild connectedCallback: isConnected =", this.isConnected);
    }
}
customElements.define("c-child", CChild);
const parent = new CParent(),
            child = new CChild();
parent.append(child);
document.body.append(parent);
// Logs:
// CChild connectedCallback: isConnected = false
```

\subsection*{4.13.3 Core concepts \(\S^{p 70}\)}

A custom element is an element that is custom. Informally, this means that its constructor and prototype are defined by the author, instead of by the user agent. This author-supplied constructor function is called the custom element constructor.

Two distinct types of custom elements \({ }^{\text {p703 }}\) can be defined:
1. An autonomous custom element, which is defined with no extends option. These types of custom elements have a local name equal to their defined name \({ }^{\text {p705 }}\).
2. A customized built-in element, which is defined with an extends option. These types of custom elements have a local name equal to the value passed in their extends option, and their defined name \({ }^{p 705}\) is used as the value of the is attribute, which therefore must be a valid custom element name \({ }^{\text {p704 }}\).

After a custom element \({ }^{\mathrm{p} 703}\) is created, changing the value of the \(i s^{\mathrm{p} 703}\) attribute does not change the element's behavior, as it is saved on the element as its is value.

Autonomous custom elements \({ }^{\text {p703 }}\) have the following element definition:

\section*{Categories \({ }^{\text {p128 }}\) :}

Flow content \({ }^{p 131}\).
Phrasing content \({ }^{\text {p132 }}\).
Palpable content \({ }^{\mathrm{p} 133}\).
For form-associated custom elements \({ }^{\text {p704 }}\) : Listed \({ }^{\text {p486 }}\), labelable \({ }^{\text {p486 }}\), submittable \({ }^{\text {p486 }}\), and resettable \({ }^{\text {p486 }}\) form-associated element \({ }^{\text {p486 }}\).

Contexts in which this element can be used \({ }^{\text {p128 }}\) :
Where phrasing content \({ }^{\text {p132 }}\) is expected.
Content model \({ }^{\text {p128 }}\) :
Iransparent \({ }^{\mathrm{p} 133}\).
Content attributes \({ }^{\text {p128 }}\) :
Global attributes \({ }^{p 136}\), except the is \({ }^{p 703}\) attribute
form \({ }^{\text {p566 }}\), for form-associated custom elements \({ }^{\text {p704 }}\) - Associates the element with a form \({ }^{\text {p486 }}\) element disabled \({ }^{\text {p570 }}\), for form-associated custom elements \({ }^{\mathrm{p} 704}\) - Whether the form control is disabled readonly \({ }^{\text {p704 }}\), for form-associated custom elements \({ }^{\text {p704 }}\) - Affects willValidate \({ }^{\text {p593 }}\), plus any behavior added by the custom element author
name \({ }^{\mathrm{p568}}\), for form-associated custom elements \({ }^{\mathrm{p} 704}\) - Name of the element to use for form submission \({ }^{\text {p595 }}\) and in the form.elements \({ }^{\text {p488 }}\) API
Any other attribute that has no namespace (see prose).

\section*{Accessibility considerations \({ }^{\text {p129 }}\) :}

For form-associated custom elements \({ }^{\mathrm{p} 704}\) : for authors; for implementers.
Otherwise: for authors; for implementers.
DOM interface \({ }^{\text {p129 }}\) :
Supplied by the element's author (inherits from HTMLElement \({ }^{\text {p124 }}\) )
An autonomous custom element \({ }^{\mathrm{p} 703}\) does not have any special meaning: it represents \({ }^{\mathrm{p} 123}\) its children. A customized built-in element \({ }^{\mathrm{p} 703}\) inherits the semantics of the element that it extends.

Any namespace-less attribute that is relevant to the element's functioning, as determined by the element's author, may be specified on an autonomous custom element \({ }^{\text {p703 }}\), so long as the attribute name is XML-compatible \({ }^{\text {p44 }}\) and contains no ASCII upper alphas. The exception is the is \({ }^{\text {p703 }}\) attribute, which must not be specified on an autonomous custom element \({ }^{\text {p703 }}\) (and which will have no effect if it is).

Customized built-in elements \({ }^{\text {p703 }}\) follow the normal requirements for attributes, based on the elements they extend. To add custom attribute-based behavior, use data-*p145 attributes.

An autonomous custom element \({ }^{\mathrm{p} 703}\) is called a form-associated custom element if the element is associated with a custom element definition \({ }^{\text {p705 }}\) whose form-associated \({ }^{\text {p705 }}\) field is set to true.

The name \({ }^{\mathrm{p} 568}\) attribute represents the form-associated custom element \({ }^{\mathrm{p} 704}\) 's name. The disabled \({ }^{\mathrm{p} 570}\) attribute is used to make the formassociated custom element \({ }^{\text {p704 }}\) non-interactive and to prevent its submission value \({ }^{\text {p716 }}\) from being submitted. The form \({ }^{\text {p566 }}\) attribute is used to explicitly associate the form-associated custom element \({ }^{\text {p704 }}\) with its form owner \({ }^{\text {p566 }}\).

The readonly attribute of form-associated custom elements \({ }^{\mathrm{p} 704}\) specifies that the element is barred from constraint validation \({ }^{\mathrm{p} 590}\). User agents don't provide any other behavior for the attribute, but custom element authors should, where possible, use its presence to make their control non-editable in some appropriate fashion, similar to the behavior for the readonly \({ }^{\mathrm{p} 522}\) attribute on built-in form controls.

Constraint validation: If the readonly \({ }^{\text {p704 }}\) attribute is specified on a form-associated custom element \({ }^{\text {p704 }}\), the element is barred from constraint validation \({ }^{\text {p590 }}\).

The reset algorithm \({ }^{\mathrm{p} 604}\) for form-associated custom elements \({ }^{\mathrm{p} 704}\) is to enqueue a custom element callback reaction \({ }^{\mathrm{p} 713}\) with the element, callback name "formResetCallback", and an empty argument list.

A valid custom element name is a sequence of characters name that meets all of the following requirements:
- name must match the PotentialCustomElementName \({ }^{\text {p704 }}\) production:
```
PotentialCustomElementName ::=
    [a-z] (PCENCharrp704 )* '-' (PCENCharpp04 )*
PCENChar ::=
    "-" | "." | [0-9] | "_" | [a-z] | #xB7 | [#xC0-#xD6] | [#xD8-#xF6] | [#xF8-#x37D] | [#x37F-#x1FFF] |
    [#x200C-#x200D] | [#x203F-#x2040] | [#x2070-#x218F] | [#x2C00-#x2FEF] | [#x3001-#xD7FF] |
    [#xF900-#xFDCF] | [#xFDF0-#xFFFD] | [#x10000-#xEFFFF]
```

This uses the EBNF notation from the XML specification. [XML] \({ }^{\text {p1293 }}\)
- name must not be any of the following:
```
- annotation-xml
- color-profile
- font-face
- font-face-src
- font-face-uri
- font-face-format
- font-face-name
- missing-glyph
```

\section*{Note}

The list of names above is the summary of all hyphen-containing element names from the applicable specifications \({ }^{p 65}\), namely SVG 2 and MathML. [SVG] \({ }^{p 1291}\) [MATHML] \({ }^{p 1289}\)

These requirements ensure a number of goals for valid custom element names \({ }^{\text {p704 }}\) :
- They start with an ASCII lower alpha, ensuring that the HTML parser will treat them as tags instead of as text.
- They do not contain any ASCII upper alphas, ensuring that the user agent can always treat HTML elements ASCII-caseinsensitively.
- They contain a hyphen, used for namespacing and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).
- They can always be created with createElement () and createElementNS(), which have restrictions that go beyond the parser's.

Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like <math- \(\alpha>\) or <emotion-()>

A custom element definition describes a custom element \({ }^{\mathrm{p} 703}\) and consists of:

\section*{A name}

A valid custom element name \({ }^{\text {p704 }}\)

\section*{A local name}

A local name

\section*{A constructor}

A Web IDL CustomElementConstructor \({ }^{\text {p706 }}\) callback function type value wrapping the custom element constructor \({ }^{\text {p703 }}\)

\section*{A list of observed attributes}

A sequence<DOMString>

\section*{A collection of lifecycle callbacks}

A map, whose keys are the strings "connectedCallback", "disconnectedCallback", "adoptedCallback", "attributeChangedCallback", "formAssociatedCallback", "formDisabledCallback", "formResetCallback", and "formStateRestoreCallback". The corresponding values are either a Web IDL Function callback function type value, or null. By default the value of each entry is null.

\section*{A construction stack}

A list, initially empty, that is manipulated by the upgrade an element \({ }^{\text {p709 }}\) algorithm and the HTML element constructors \({ }^{\text {p125 }}\). Each entry in the list will be either an element or an already constructed marker.

\section*{A form-associated boolean}

If this is true, user agent treats elements associated to this custom element definition \({ }^{\text {p705 }}\) as form-associated custom elements \({ }^{\text {p704 }}\).

\section*{A disable internals boolean}

Controls attachInternals() \()^{\text {p716 }}\).

\section*{A disable shadow boolean}

Controls attachShadow().
To look up a custom element definition, given a document, namespace, localName, and is, perform the following steps. They will return either a custom element definition \({ }^{\text {p705 }}\) or null:
1. If namespace is not the HTML namespace, return null.

3. Let registry be document's relevant global object \({ }^{\text {p924 }}\) 's CustomElementRegistry \({ }^{\text {p706 }}\) object.
4. If there is custom element definition \({ }^{\text {p705 }}\) in registry with name \({ }^{\text {p705 }}\) and local name \({ }^{\text {p705 }}\) both equal to localName, return that custom element definition \({ }^{\text {p705 }}\).
5. If there is a custom element definition \({ }^{\text {p705 }}\) in registry with name \({ }^{\text {p705 }}\) equal to is and local name \({ }^{\text {p705 }}\) equal to localName, return that custom element definition \({ }^{\text {p705 }}\).
6. Return null.

\subsection*{4.13.4 The CustomElementRegistry \({ }^{\text {p706 }}\) interface \(\S^{p 70}\)}

Each Window \({ }^{\text {p824 }}\) object is associated with a unique instance of a CustomElementRegistry \({ }^{\text {p706 }}\) object, allocated when the Window \({ }^{\text {p824 }}\) object is created.

Note
Custom element registries are associated with Window \({ }^{\text {p824 }}\) objects, instead of Document \({ }^{p 114}\) objects, since each custom element constructor \({ }^{\text {p703 }}\) inherits from the \(\underline{H T M L E l e m e n t ~}{ }^{\text {p124 }}\) interface, and there is exactly one HTMLElement \({ }^{\text {p124 }}\) interface per Window \({ }^{\text {p824 }}\) object.

The customElements attribute of the Window \({ }^{\mathrm{p} 824}\) interface must return the CustomElementRegistry \({ }^{\mathrm{p} 706}\) object for that Window \({ }^{\text {p824 }}\) object.

IDL [Exposed=Window]
interface CustomElementRegistry \{
[CEReactions] undefined define(DOMString name, CustomElementConstructor constructor, optional
ElementDefinitionOptions options = \{\});
(CustomElementConstructor or undefined) get(DOMString name);
Promise<undefined> whenDefined(DOMString name);
[CEReactions] undefined upgrade(Node root);
\};
callback CustomElementConstructor \(=\) HTMLElement ();
dictionary ElementDefinition0ptions \{
DOMString extends;
\};

Every CustomElementRegistry \({ }^{\mathrm{p} 766}\) has a set of custom element definitions \({ }^{\mathrm{p} 705}\), initially empty. In general, algorithms in this specification look up elements in the registry by any of name \({ }^{\mathrm{p} 705}\), local name \({ }^{\mathrm{p} 705}\), or constructor \({ }^{\mathrm{p} 705}\).

Every CustomElementRegistry \({ }^{\text {p706 }}\) also has an element definition is running flag which is used to prevent reentrant invocations of element definition \({ }^{\text {p706 }}\). It is initially unset.

Every CustomElementRegistry \({ }^{p 706}\) also has a when-defined promise map, mapping valid custom element names \({ }^{\text {p704 }}\) to promises. It is used to implement the whenDefined() \({ }^{\mathrm{p} 788}\) method.

\section*{For web developers (non-normative)}

\section*{window . customElements \({ }^{\text {p706 }}\). define \({ }^{\text {p706 }}\) (name, constructor)}

Defines a new custom element \({ }^{\text {p703 }}\), mapping the given name to the given constructor as an autonomous custom element \({ }^{\text {p703 }}\).
window . customElements \({ }^{\text {p706 }}\) • define \({ }^{\text {p706 }}\) (name, constructor, \{ extends: baseLocalName \})
Defines a new custom element \({ }^{\text {p703 }}\), mapping the given name to the given constructor as a customized built-in element \({ }^{\text {p703 }}\) for the element type \({ }^{\text {p44 }}\) identified by the supplied baseLocalName. A "NotSupportedError" DOMException will be thrown upon trying to extend a custom element \({ }^{p 703}\) or an unknown element.

\section*{window. customElements \({ }^{\text {p706 }} \cdot\) get \(^{\text {p708 }}\) (name)}

Retrieves the custom element constructor \({ }^{\mathrm{p} 703}\) defined for the given name \({ }^{\mathrm{p} 705}\). Returns undefined if there is no custom element definition \({ }^{\text {p705 }}\) with the given name \({ }^{\text {p705 }}\).
window. customElements \({ }^{\text {p706 }} \cdot\) whenDefined \(^{\text {p708 }}\) (name)
Returns a promise that will be fulfilled when a custom element \({ }^{\text {p703 }}\) becomes defined with the given name. (If such a custom element \({ }^{\text {p703 }}\) is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a "SyntaxError" DOMEXception if not given a valid custom element name \({ }^{\text {p704 }}\).
window. customElements \({ }^{\text {p706 }}\). upgrade \({ }^{\text {p799 }}\) (root)
Tries to upgrade \({ }^{\mathrm{p} 711}\) all shadow-including inclusive descendant elements of root, even if they are not connected.

Element definition is a process of adding a custom element definition \({ }^{\text {p705 }}\) to the CustomElementRegistry \({ }^{\text {p706 }}\). This is accomplished by the define() \({ }^{\text {p706 }}\) method. When invoked, the define(name, constructor, options) method must run these steps:
1. If IsConstructor(constructor) is false, then throw a TypeError.
2. If name is not a valid custom element name \({ }^{\text {p704 }}\), then throw a "SyntaxError" DOMException.
3. If this CustomElementRegistry \({ }^{\text {p706 }}\) contains an entry with name \({ }^{\text {p705 }}\) name, then throw a "NotSupportedError" DOMException.
4. If this CustomElementRegistry \({ }^{\text {p706 }}\) contains an entry with constructor \({ }^{\text {p705 }}\) constructor, then throw a "NotSupportedError" DOMException.
5. Let localName be name.
6. Let extends be the value of the extends member of options, or null if no such member exists.
7. If extends is not null, then:
1. If extends is a valid custom element name \({ }^{\text {p704 }}\), then throw a "NotSupportedError" DOMException.
2. If the element interface for extends and the HTML namespace is HTMLUnknownElement \({ }^{\text {p124 }}\) (e.g., if extends does not indicate an element definition in this specification), then throw a "NotSupportedError" DOMException.
3. Set localName to extends.
8. If this CustomElementRegistry \({ }^{\mathrm{p} 706}\) 's element definition is running \({ }^{\mathrm{p} 706}\) flag is set, then throw a "NotSupportedError" DOMException.
9. Set this CustomElementRegistry \({ }^{\mathrm{p} 706}\) 's element definition is running \({ }^{\mathrm{p} 706}\) flag.
10. Let formAssociated be false.
11. Let disableInternals be false.
12. Let disableShadow be false.
13. Let observedAttributes be an empty sequence<DOMString>.
14. Run the following substeps while catching any exceptions:
1. Let prototype be Get(constructor, "prototype"). Rethrow any exceptions.
2. If Type(prototype) is not Object, then throw a TypeError exception.
3. Let lifecycleCallbacks be a map with the keys "connectedCallback", "disconnectedCallback", "adoptedCallback", and "attributeChangedCallback", each of which belongs to an entry whose value is null.
4. For each of the keys callbackName in lifecycleCallbacks, in the order listed in the previous step:
1. Let callbackValue be Get(prototype, callbackName). Rethrow any exceptions.
2. If callbackValue is not undefined, then set the value of the entry in lifecycleCallbacks with key callbackName to the result of converting callbackValue to the Web IDL Function callback type. Rethrow any exceptions from the conversion.
5. If the value of the entry in lifecycleCallbacks with key "attributeChangedCallback" is not null, then:
1. Let observedAttributesIterable be Get(constructor, "observedAttributes"). Rethrow any exceptions.
2. If observedAttributesIterable is not undefined, then set observedAttributes to the result of converting observedAttributesIterable to a sequence<DOMString>. Rethrow any exceptions from the conversion.
6. Let disabledFeatures be an empty sequence<DOMString>.
7. Let disabledFeaturesIterable be Get(constructor, "disabledFeatures"). Rethrow any exceptions.
8. If disabledFeaturesIterable is not undefined, then set disabledFeatures to the result of converting disabledFeaturesIterable to a sequence<DOMString>. Rethrow any exceptions from the conversion.
9. Set disableInternals to true if disabledFeatures contains "internals".
10. Set disableShadow to true if disabledFeatures contains "shadow".
11. Let formAssociatedValue be Get (constructor, "formAssociated"). Rethrow any exceptions.
12. Set formAssociated to the result of converting formAssociatedValue to a boolean. Rethrow any exceptions from the
conversion.
13. If formAssociated is true, for each of "formAssociatedCallback", "formResetCallback", "formDisabledCallback", and "formStateRestoreCallback" callbackName:
1. Let callbackValue be Get(prototype, callbackName). Rethrow any exceptions.
2. If callbackValue is not undefined, then set the value of the entry in lifecycleCallbacks with key callbackName to the result of converting callbackValue to the Web IDL Function callback type. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:
1. Unset this CustomElementRegistry \({ }^{\mathrm{p} 706}\) 's element definition is running \({ }^{\mathrm{p} 706}\) flag.

Finally, if the first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.
15. Let definition be a new custom element definition \({ }^{\text {p705 }}\) with name \({ }^{\text {p705 }}\) name, local name \({ }^{\text {p705 }}\) localName, constructor \({ }^{\text {p705 }}\) constructor, observed attributes \({ }^{\text {p705 }}\) observedAttributes, lifecycle callbacks \({ }^{\text {p705 }}\) lifecycleCallbacks, form-associated \({ }^{\text {p705 }}\) formAssociated, disable internals \({ }^{\mathrm{p} 705}\) disableInternals, and disable shadow \({ }^{\mathrm{p705}}\) disableShadow.
16. Add definition to this CustomElementRegistry \({ }^{\text {p706 }}\).
17. Let document be this CustomElementRegistry \({ }^{\mathrm{p7066}} \mathrm{~s}\) relevant global object \({ }^{\mathrm{p924}}\) 's s associated Document \({ }^{\mathrm{p} 826}\).
18. Let upgrade candidates be all elements that are shadow-including descendants of document, whose namespace is the HTML namespace and whose local name is localName, in shadow-including tree order. Additionally, if extends is non-null, only include elements whose is value is equal to name.
19. For each element element in upgrade candidates, enqueue a custom element upgrade reaction \({ }^{\text {p713 }}\) given element and definition.
20. If this CustomElementRegistry \({ }^{p 706}\) 's when-defined promise map \({ }^{p 706}\) contains an entry with key name:
1. Let promise be the value of that entry.
2. Resolve promise with undefined.
3. Delete the entry with key name from this CustomElementRegistry \({ }^{p 706}\) 's when-defined promise map \({ }^{p 706}\).

When invoked, the get (name) method must run these steps:
1. If this CustomElementRegistry \({ }^{\mathrm{p} 706}\) contains an entry with name \({ }^{\mathrm{p} 705}\) name, then return that entry's constructor \({ }^{\mathrm{p} 705}\).
2. Otherwise, return undefined.

When invoked, the whenDefined (name) method must run these steps:
1. If name is not a valid custom element name \({ }^{\text {p704 }}\), then return a new promise rejected with a "SyntaxError" DOMException.
2. If this CustomElementRegistry \({ }^{\text {p706 }}\) contains an entry with name \({ }^{\text {p705 }}\) name, then return a new promise resolved with undefined.
3. Let map be this CustomElementRegistry \({ }^{\mathrm{p} 706}\) 's when-defined promise map \({ }^{\text {p706 }}\).
4. If map does not contain an entry with key name, create an entry in map with key name and whose value is a new promise.
5. Let promise be the value of the entry in map with key name.
6. Return promise.

\section*{Example}

The whenDefined ( \()^{\mathrm{p} 708}\) method can be used to avoid performing an action until all appropriate custom elements \({ }^{\mathrm{p703}}\) are defined. In this example, we combine it with the : defined \({ }^{p 724}\) pseudo-class to hide a dynamically-loaded article's contents until we're sure that all of the autonomous custom elements \({ }^{\mathrm{p} 703}\) it uses are defined.
```
articleContainer.hidden = true;
```
```
fetch(articleURL)
    then(response => response.text())
    then(text => {
        articleContainer.innerHTML = text;
        return Promise.all(
            [...articleContainer.querySelectorAll(":not(:defined)")]
                .map(el => customElements.whenDefined(el.localName))
        );
    })
    then(() => {
        articleContainer.hidden = false;
    });
```

When invoked, the upgrade (root) method must run these steps:
1. Let candidates be a list of all of root's shadow-including inclusive descendant elements, in shadow-including tree order.
2. For each candidate of candidates, try to upgrade \({ }^{\mathrm{p} 711}\) candidate.

\section*{Example}

The upgrade() \({ }^{\text {p709 }}\) method allows upgrading of elements at will. Normally elements are automatically upgraded when they become connected, but this method can be used if you need to upgrade before you're ready to connect the element.
```
const el = document.createElement("spider-man");
class SpiderMan extends HTMLElement {}
customElements.define("spider-man", SpiderMan);
console.assert(!(el instanceof SpiderMan)); // not yet upgraded
customElements.upgrade(el);
console.assert(el instanceof SpiderMan); // upgraded!
```

\subsection*{4.13.5 Upgrades \(\S^{\text {p70 }}\)}

To upgrade an element, given as input a custom element definition \({ }^{\text {p705 }}\) definition and an element element, run the following steps:
1. If element's custom element state is not "undefined" or "uncustomized", then return.

\section*{Example}

One scenario where this can occur due to reentrant invocation of this algorithm, as in the following example:
```
<!DOCTYPE html>
<x-foo id="a"></x-foo>
<x-foo id="b"></x-foo>
<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
    constructor() {
        super();
        const b = document.querySelector("#b");
        b.remove();
```
```
        // While this constructor is running for "a", "b" is still
        // undefined, and so inserting it into the document will enqueue a
        // second upgrade reaction for "b" in addition to the one enqueued
        // by defining x-foo.
        document.body.appendChild(b);
    }
})
</script>
```

This step will thus bail out the algorithm early when upgrade an element \({ }^{\text {p709 }}\) is invoked with "b" a second time.
2. Set element's custom element definition to definition.
3. Set element's custom element state to "failed".

Note
It will be set to "custom" after the upgrade succeeds" \({ }^{p 711}\). For now, we set it to "failed" so that any reentrant invocations will hit the above early-exit step \({ }^{\text {p709 }}\).
4. For each attribute in element's attribute list, in order, enqueue a custom element callback reaction \({ }^{\mathrm{p} 713}\) with element, callback name "attributeChangedCallback", and an argument list containing attribute's local name, null, attribute's value, and attribute's namespace.
5. If element is connected, then enqueue a custom element callback reaction \({ }^{\text {p713 }}\) with element, callback name "connectedCallback", and an empty argument list.
6. Add element to the end of definition's construction stack \({ }^{\text {p705 }}\).
7. Let \(C\) be definition's constructor \({ }^{\text {p705 }}\).
8. Run the following substeps while catching any exceptions:
1. If definition's disable shadow \({ }^{\text {p705 }}\) is true and element's shadow root is non-null, then throw a "NotSupportedError" DOMException.

\section*{Note}

This is needed as attachShadow() does not use look up a custom element definition \({ }^{\text {p705 }}\) while attachInternals() \({ }^{\text {p716 }}\) does.
2. Let constructResult be the result of constructing \(C\), with no arguments.

\section*{Note}

If C non-conformantly \({ }^{\text {p702 }}\) uses an API decorated with the [CEReactions] \({ }^{\text {p713 }}\) extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before C finishes and control returns to this algorithm. Otherwise, they will execute after C and the rest of the upgrade process finishes.
3. If SameValue(constructResult, element) is false, then throw a TypeError.

\section*{Note}

This can occur if C constructs another instance of the same custom element before calling super(), or if C uses JavaScript's return-override feature to return an arbitrary HTMLElement \({ }^{\text {p124 }}\) object from the constructor.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:
1. Remove the last entry from the end of definition's construction stack \({ }^{\mathrm{p} 705}\).

\section*{Note}

Assuming C calls super () (as it will if it is conformant \({ }^{\text {p702 }}\) ), and that the call succeeds, this will be the already constructed marker \({ }^{\text {p705 }}\) that replaced the element we pushed at the beginning of this algorithm. (The HTML
```
element constructor }\mp@subsup{}{}{p125}\mathrm{ carries out this replacement.)
```

If C does not call super() (i.e. it is not conformant \({ }^{\text {p702 }}\) ), or if any step in the HTML element constructor \({ }^{\text {p125 }}\) throws, then this entry will still be element.

Finally, if the above steps threw an exception, then:
1. Set element's custom element definition to null.
2. Empty element's custom element reaction queue \({ }^{\mathrm{p} 712}\).
3. Rethrow the exception (thus terminating this algorithm).
```
Note
    If the above steps threw an exception, then element's custom element state will remain "failed".
```
9. If element is a form-associated custom element \({ }^{\mathrm{p704}}\), then:
1. Reset the form owner \({ }^{\mathrm{p567}}\) of element. If element is associated with a form \({ }^{\mathrm{p486}}\) element, then enqueue a custom element callback reaction \({ }^{\text {p713 }}\) with element, callback name "formAssociatedCallback", and « the associated form \({ }^{\text {p486 }}\) ».
2. If element is disabled \({ }^{\mathrm{p} 570}\), then enqueue a custom element callback reaction \({ }^{\mathrm{p713}}\) with element, callback name "formDisabledCallback" and «true ».
10. Set element's custom element state to "custom".

To try to upgrade an element, given as input an element element, run the following steps:
1. Let definition be the result of looking up a custom element definition \({ }^{\text {p705 }}\) given element's node document, element's namespace, element's local name, and element's \(\underline{i s}\) value.
2. If definition is not null, then enqueue a custom element upgrade reaction \({ }^{\mathrm{p} 713}\) given element and definition.

\subsection*{4.13.6 Custom element reactions \(\S_{1}^{p 71}\)}

A custom element \({ }^{\mathrm{p} 703}\) possesses the ability to respond to certain occurrences by running author code:
- When upgraded \({ }^{p 709}\), its constructor \({ }^{\mathrm{p703}}\) is run, with no arguments.
- When it becomes connected \({ }^{\text {p45 }}\), its connectedCallback is called, with no arguments.
- When it becomes disconnected \({ }^{\mathrm{p} 45}\), its disconnectedCallback is called, with no arguments.
- When it is adopted into a new document, its adoptedCallback is called, given the old document and new document as arguments.
- When any of its attributes are changed, appended, removed, or replaced, its attributeChangedCallback is called, given the attribute's local name, old value, new value, and namespace as arguments. (An attribute's old or new value is considered to be null when the attribute is added or removed, respectively.)
- When the user agent resets the form owner \({ }^{\mathrm{p} 567}\) of a form-associated custom element \({ }^{\mathrm{p} 704}\) and doing so changes the form owner, its formAssociatedCallback is called, given the new form owner (or null if no owner) as an argument.
- When the form owner of a form-associated custom element \({ }^{\text {p704 }}\) is reset \({ }^{\text {p603 }}\), its formResetCallback is called.
- When the disabled \({ }^{p 570}\) state of a form-associated custom element \({ }^{\mathrm{p704}}\) is changed, its formDisabledCallback is called, given the new state as an argument.
- When user agent updates a form-associated custom element \({ }^{\text {p704's }}\) 's value on behalf of a user, its formStateRestoreCallback is called, given the new value and a string indicating a reason, "restore" or "autocomplete", as arguments.

We call these reactions collectively custom element reactions.
The way in which custom element reactions \({ }^{\mathrm{p} 711}\) are invoked is done with special care, to avoid running author code during the middle
of delicate operations. Effectively, they are delayed until "just before returning to user script". This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like cloning, or range manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that custom element reactions \({ }^{\mathrm{p} 711}\) always are invoked in the same order as their triggering actions, at least within the local context of a single custom element \({ }^{\mathrm{p} 703}\). (Because custom element reaction \({ }^{\text {p711 }}\) code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

Each similar-origin window agent \({ }^{\text {p913 }}\) has a custom element reactions stack, which is initially empty. A similar-origin window agent \({ }^{\text {p913' }}\) 's current element queue is the element queue \({ }^{\mathrm{p} 712}\) at the top of its custom element reactions stack \({ }^{\text {p712 }}\). Each item in the stack is an element queue, which is initially empty as well. Each item in an element queue \({ }^{\text {p712 }}\) is an element. (The elements are not necessarily custom yet, since this queue is used for upgrades \({ }^{\text {p709 }}\) as well.)

Each custom element reactions stack \({ }^{\text {p712 }}\) has an associated backup element queue, which an initially-empty element queue \({ }^{\text {p712 }}\). Elements are pushed onto the backup element queue \({ }^{\text {p712 }}\) during operations that affect the DOM without going through an API decorated with [CEReactions] \({ }^{\text {p713 }}\), or through the parser's create an element for the token \({ }^{\text {p1127 }}\) algorithm. An example of this is a userinitiated editing operation which modifies the descendants or attributes of an editable element. To prevent reentrancy when processing the backup element queue \({ }^{\text {p712 }}\), each custom element reactions stack \({ }^{\mathrm{p712}}\) also has a processing the backup element queue flag, initially unset.

All elements have an associated custom element reaction queue, initially empty. Each item in the custom element reaction queue \({ }^{\text {p712 }}\) is of one of two types:
- An upgrade reaction, which will upgrade \({ }^{\text {p709 }}\) the custom element and contains a custom element definition \({ }^{\text {p705 }}\); or
- A callback reaction, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

\section*{custom element reactions stack}

To enqueue an element on the appropriate element queue, given an element element, run the following steps:
1. Let reactionsStack be element's relevant agent \({ }^{\text {p914 }}\) 's custom element reactions stack \({ }^{\mathrm{p} 712}\).
2. If reactionsStack is empty, then:
1. Add element to reactionsStack's backup element queue \({ }^{\mathrm{p} 712}\).
2. If reactionsStack's processing the backup element queue \({ }^{\text {p712 }}\) flag is set, then return.
3. Set reactionsStack's processing the backup element queue \({ }^{\mathrm{p} 712}\) flag.
4. Queue a microtask \({ }^{\text {p946 }}\) to perform the following steps:
1. Invoke custom element reactions \({ }^{\mathrm{p} 713}\) in reactionsStack's backup element queue \({ }^{\mathrm{p} 712}\).
2. Unset reactionsStack's processing the backup element queue \({ }^{p 712}\) flag.

To enqueue a custom element callback reaction, given a custom element \({ }^{\mathrm{p} 703}\) element, a callback name callbackName, and a list of arguments args, run the following steps:
1. Let definition be element's custom element definition.
2. Let callback be the value of the entry in definition's lifecycle callbacks \({ }^{\mathrm{p} 705}\) with key callbackName.
3. If callback is null, then return
4. If callbackName is "attributeChangedCallback", then:
1. Let attributeName be the first element of args.
2. If definition's observed attributes \({ }^{\mathrm{p} 705}\) does not contain attributeName, then return.
5. Add a new callback reaction \({ }^{\mathrm{p} 712}\) to element's custom element reaction queue \({ }^{\mathrm{p} 712}\), with callback function callback and arguments args.
6. Enqueue an element on the appropriate element queue \({ }^{\mathrm{p} 712}\) given element.

To enqueue a custom element upgrade reaction, given an element element and custom element definition \({ }^{\text {p705 }}\) definition, run the following steps:
1. Add a new upgrade reaction \({ }^{\text {p712 }}\) to element's custom element reaction queue \({ }^{\mathrm{p712}}\), with custom element definition \({ }^{\text {p705 }}\) definition.
2. Enqueue an element on the appropriate element queue \({ }^{\mathrm{p} 712}\) given element.

To invoke custom element reactions in an element queue \({ }^{\mathrm{p} 712}\) queue, run the following steps:
1. For each custom element \({ }^{\text {p703 }}\) element in queue:
1. Let reactions be element's custom element reaction queue \({ }^{\text {p712 }}\).
2. Repeat until reactions is empty:
1. Remove the first element of reactions, and let reaction be that element. Switch on reaction's type:
\(\rightarrow\) upgrade reaction \({ }^{\mathrm{p} 712}\)
Upgrade \({ }^{\text {p709 }}\) element using reaction's custom element definition \({ }^{\text {p705 }}\).
\(\rightarrow\) callback reaction \({ }^{\text {p712 }}\)
Invoke reaction's callback function with reaction's arguments, and with element as the callback this value.

If this throws an exception, catch it, and report the exception \({ }^{\text {p937 }}\).

To ensure custom element reactions \({ }^{\mathrm{p} 711}\) are triggered appropriately, we introduce the [CEReactions] IDL extended attribute. It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke custom element reactions \({ }^{\mathrm{p} 711}\).

The [CEReactions] \({ }^{p 713}\) extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.

Operations, attributes, setters, or deleters annotated with the [CEReactions] \({ }^{\text {p713 }}\) extended attribute must run the following steps in place of the ones specified in their description:
1. Push a new element queue \({ }^{\mathrm{p} 712}\) onto this object's relevant agent \({ }^{\text {p914' }} \mathrm{s}\) custom element reactions stack \({ }^{\mathrm{p} 712}\).
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let value be the returned value. If they throw an exception, let exception be the thrown exception.
3. Let queue be the result of popping from this object's relevant agent \({ }^{\text {p914 }}\) 's custom element reactions stack \({ }^{\mathrm{p} 712}\).
4. Invoke custom element reactions \({ }^{\text {p713 }}\) in queue.
5. If an exception exception was thrown by the original steps, rethrow exception.
6. If a value value was returned from the original steps, return value.

\section*{Note}

The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause custom element reactions \({ }^{\text {p711 }}\) to occur).

However, in practice this imprecision could lead to non-interoperable implementations of custom element reactions \({ }^{p 711}\), as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause enqueuing a custom element callback reaction \({ }^{\mathrm{p713}}\) or enqueuing a custom element upgrade reaction \({ }^{\mathrm{p713}}\), for example by modifying any attributes or child elements, must also be decorated with the [CEReactions] \({ }^{\mathrm{p} 713}\) attribute.

\section*{Note}

As of the time of this writing, the following nonstandard or not-yet-standardized APIs are known to fall into this category:
- HTMLElement \({ }^{\text {p124 }}\) 's outerText IDL attribute
- HTMLInputElement \({ }^{\text {p494's }}\) 's webkitdirectory and incremental IDL attributes
- HTMLLinkElement \({ }^{\text {p158 }}\) 's scope IDL attribute
- ShadowRoot's innerHTML IDL attribute

\subsection*{4.13.7 The ElementInternals \({ }^{\text {p714 }}\) interface \(\S_{4}^{\text {p71 }}\)}

\section*{For web developers (non-normative)}
element . attachInternals () \({ }^{\text {p716 }}\)
Returns an ElementInternals \({ }^{\mathrm{p} 714}\) object targeting the custom element \({ }^{\mathrm{p} 703}\) element. Throws an exception if element is not a custom element \({ }^{\mathrm{p} 703}\), if the "internals" feature was disabled as part of the element definition, or if it is called twice on the same element.
```
[Exposed=Window]
interface ElementInternals {
    // Form-associated custom elements
    undefined setFormValue((File or USVString or FormData)? value,
                optional (File or USVString or FormData)? state);
    readonly attribute HTMLFormElement? form;
    undefined setValidity(optional ValidityStateFlags flags = {},
                            optional DOMString message,
            optional HTMLElement anchor);
    readonly attribute boolean willValidate;
```
```
    readonly attribute ValidityState validity;
    readonly attribute DOMString validationMessage;
    boolean checkValidity();
    boolean reportValidity();
    readonly attribute NodeList labels;
};
dictionary ValidityStateFlags {
    boolean valueMissing = false;
    boolean typeMismatch = false;
    boolean patternMismatch = false;
    boolean tooLong = false;
    boolean tooShort = false;
    boolean rangeUnderflow = false;
    boolean range0verflow = false;
    boolean stepMismatch = false;
    boolean badInput = false;
    boolean customError = false;
};
```

\section*{For web developers (non-normative)}

\section*{internals . setFormValue \({ }^{\text {p716 }}\) (value)}

Sets both the state \({ }^{\mathrm{p} 716}\) and submission value \({ }^{\mathrm{p} 716}\) of internals's target element \({ }^{\mathrm{p715}}\) to value.
If value is null, the element won't participate in form submission.

\section*{internals. setFormValue \({ }^{\text {p716 }}\) (value, state)}

Sets the submission value \({ }^{\mathrm{p} 716}\) of internals's target element \({ }^{\mathrm{p} 715}\) to value, and its state \({ }^{\mathrm{p} 716}\) to state.
If value is null, the element won't participate in form submission.

\section*{internals . form \({ }^{\text {p568 }}\)}

Returns the form owner \({ }^{\text {p566 }}\) of internals's target element \({ }^{\text {p715 }}\).

\section*{internals. setValidity \({ }^{\mathrm{p} 717}\) (flags, message [, anchor ])}

Marks internals's target element \({ }^{\text {p715 }}\) as suffering from the constraints indicated by the flags argument, and sets the element's validation message to message. If anchor is specified, the user agent might use it to indicate problems with the constraints of internals's target element \({ }^{\mathrm{p} 715}\) when the form owner \({ }^{\mathrm{p566}}\) is validated interactively or reportValidity () \({ }^{\mathrm{p} 595}\) is called.

\section*{internals. setValidity \({ }^{\text {p717 }}\) (\{\})}

Marks internals's target element \({ }^{\mathrm{p} 715}\) as satisfying its constraints \({ }^{\mathrm{p} 591}\).

\section*{internals . willValidate \({ }^{\text {p593 }}\)}

Returns true if internals's target element \({ }^{\mathrm{p} 715}\) will be validated when the form is submitted; false otherwise.

\section*{internals . validity \({ }^{\text {p593 }}\)}

Returns the ValidityState \({ }^{\text {p593 }}\) object for interna/s's target element \({ }^{\text {p715 }}\).
internals . validationMessage \({ }^{\text {p717 }}\)
Returns the error message that would be shown to the user if internals's target element \({ }^{\mathrm{p715}}\) was to be checked for validity.
valid \(=\) internals \(\boldsymbol{\operatorname { c h }}\) checkValidity () \()^{\text {p594 }}\)
Returns true if internals's target element \({ }^{p 715}\) has no validity problems; false otherwise. Fires an invalid \({ }^{\text {p1281 }}\) event at the element in the latter case.
valid \(=\) internals. reportValidity () \({ }^{\text {p595 }}\)
Returns true if internals's target element \({ }^{\text {p715 }}\) has no validity problems; otherwise, returns false, fires an invalid \({ }^{p 1281}\) event at the element, and (if the event isn't canceled) reports the problem to the user.

\section*{internals . labels \({ }^{\text {p492 }}\)}

Returns a NodeList of all the label \({ }^{\mathrm{p} 49 \theta}\) elements that internals's target element \({ }^{\mathrm{p} 715}\) is associated with.

Each ElementInternals \({ }^{\mathrm{p} 714}\) has a target element, which is a custom element \({ }^{\mathrm{p703}}\). ElementInternals \({ }^{\mathrm{p} 714}\) provides various operations and attributes to allow control over internal features which the user agent provides to all elements.

Each HTMLELement \({ }^{\text {p124 }}\) has an attached internals boolean, initially false.
The attachInternals() method on an HTMLElement \({ }^{\text {p124 }}\) element, when invoked, must run the following steps:
1. If element's is value is not null, then throw a "NotSupportedError" DOMException.
2. Let definition be the result of looking up a custom element definition \({ }^{\mathrm{p} 705}\) given element's node document, its namespace, its local name, and null as is value.
3. If definition is null, then throw an "NotSupportedError" DOMException.
4. If definition's disable internals \({ }^{\mathrm{p} 705}\) is true, then throw a "NotSupportedError" DOMException.
5. If element's attached internals \({ }^{\text {p716 }}\) is true, then throw an "NotSupportedError" DOMException.
6. Set element's attached internals \({ }^{\text {p716 }}\) to true.
7. Create a new ElementInternals \({ }^{\mathrm{p} 714}\) instance targeting \({ }^{\mathrm{p} 715}\) element, and return it.

Each form-associated custom element \({ }^{\text {p704 }}\) has submission value. It is used to provide one or more entries on form submission, and The initial value of submission value \({ }^{\mathrm{p} 716}\) is null, and submission value \({ }^{\mathrm{p} 716}\) can be null, a string, a File, or a list of entries.

Each form-associated custom element \({ }^{\mathrm{p} 704}\) has state. It is information with which the user agent can restore a user's input for the element. The initial value of state \({ }^{\mathrm{p} 716}\) is null, and state \({ }^{\mathrm{p} 716}\) can be null, a string, a File, or a list of entries.

The setFormValue( ) \({ }^{\text {p716 }}\) method is used by the custom element author to set the element's submission value \({ }^{\mathrm{p} 716}\) and state \({ }^{\mathrm{p} 716}\), thus communicating these to the user agent.

When the user agent believes it is a good idea to restore a form-associated custom element \({ }^{\text {p704's }} \mathrm{s}\) state \({ }^{\mathrm{p716}}\), for example after navigation or restarting the user agent, they may enqueue a custom element callback reaction \({ }^{\text {p713 }}\) with that element, callback name "formStateRestoreCallback", and an argument list containing the state to be restored, and "restore".

If the user agent has a form-filling assist feature, then when the feature is invoked, it may enqueue a custom element callback reaction \({ }^{\text {p713 }}\) with a form-associated custom element \({ }^{\text {p704 }}\), callback name "formStateRestoreCallback", and an argument list containing the state value determined by history of state value and some heuristics, and "autocomplete".

In general, the state \({ }^{\mathrm{p} 716}\) is information specified by a user, and the submission value \({ }^{\mathrm{p} 716}\) is a value after canonicalization or sanitization, suitable for submission to the server. The following examples makes this concrete:

\section*{Example}

Suppose that we have a form-associated custom element \({ }^{p 704}\) which asks a user to specify a date. The user specifies "3/15/2019", but the control wishes to submit "2019-03-15" to the server. "3/15/2019" would be a state \({ }^{\text {p716 }}\) of the element, and "2019-03-15" would be a submission value \({ }^{\text {p716 }}\).

\section*{Example}

Suppose you develop a custom element emulating a the behavior of the existing checkbox \({ }^{p 513}\) input \({ }^{\text {p493 }}\) type. Its submission value \({ }^{\mathrm{p} 716}\) would be the value of its value content attribute, or the string "on". Its state \({ }^{\mathrm{p} 716}\) would be one of "checked", "unchecked", "checked/indeterminate", or "unchecked/indeterminate".

The setFormValue(value, state) method of the ElementInternals \({ }^{\mathrm{p} 714}\) interface must run the following steps:
1. Let element be this ElementInternals \({ }^{p 714}\) 's target element \({ }^{\mathrm{p715}}\).
2. If element is not a form-associated custom element \({ }^{\text {p704 }}\), then throw a "NotSupportedError" DOMException.
3. Set target element \({ }^{\mathrm{p} 715}\) 's submission value \({ }^{\mathrm{p} 716}\) to value if value is not a FormData object, or to a clone of the entry list associated with value otherwise.
4. If the state argument of the function is omitted, set element's state \({ }^{\mathrm{p} 716}\) to its submission value \({ }^{\mathrm{p} 716}\).
5. Otherwise, if state is a FormData object, set element's state \({ }^{\text {p716 }}\) to clone of the entry list associated with state.
6. Otherwise, set element's state \({ }^{\mathrm{p} 716}\) to state.

Each form-associated custom element \({ }^{\mathrm{p} 704}\) has validity flags named valueMissing, typeMismatch, patternMismatch, tooLong, tooShort, rangeUnderflow, rangeOverflow, stepMismatch, and customError. They are false initially.

Each form-associated custom element \({ }^{\mathrm{p} 704}\) has a validation message string. It is the empty string initially.
Each form-associated custom element \({ }^{\text {p704 }}\) has a validation anchor element. It is null initially.
The setValidity(flags, message, anchor) method of the ElementInternals \({ }^{\mathrm{p} 714}\) interface must run the following steps:
1. Let element be this ElementInternals \({ }^{\mathrm{p} 714}\) 's target element \({ }^{\mathrm{p} 715}\).
2. If element is not a form-associated custom element \({ }^{\text {p704 }}\), then throw a "NotSupportedError" DOMException.
3. If flags contains one or more true values and message is not given or is the empty string, then throw a TypeError.
4. For each entry flag \(\rightarrow\) value of flags, set element's validity flag with the name flag to value.
5. Set element's validation message \({ }^{\mathrm{p} 717}\) to the empty string if message is not given or all of element's validity flags are false, or to message otherwise.
6. If element's customError validity flag is true, then set element's custom validity error message \({ }^{\text {p590 }}\) to element's validation message \({ }^{\mathrm{p} 717}\). Otherwise, set element's custom validity error message \({ }^{\mathrm{p} 590}\) to the empty string.
7. Set element's validation anchor \({ }^{\text {p717 }}\) to null if anchor is not given. Otherwise, if anchor is not a shadow-including descendant of element, then throw a "NotFoundError" DOMException. Otherwise, set element's validation anchor \({ }^{\mathrm{p} 717}\) to anchor.

The validationMessage attribute of ElementInternals \({ }^{\mathrm{p} 714}\) interface, on getting, must return the validation message \({ }^{\mathrm{p} 717}\) of this ElementInternals \({ }^{\mathrm{p} 714}\) 's target element \({ }^{\mathrm{p} 715}\).

When entry construction algorithm for a form-associated custom element \({ }^{\mathrm{p} 704}\) is invoked, given an element element and a list entry list, run the following steps:
1. If element's submission value \({ }^{\mathrm{p} 716}\) is a list of entries, then append each item of element's submission value \({ }^{\text {p716 }}\) to entry list, and return.

\section*{Note}

In this case, user agent does not refer to the name \({ }^{\text {p568 }}\) content attribute value. An implementation of form-associated custom element \({ }^{p 704}\) is responsible to decide names of entries. They can be the name \({ }^{p 568}\) content attribute value, they can be strings based on the name \({ }^{\mathrm{p} 568}\) content attribute value, or they can be unrelated to the name \({ }^{p 568}\) content attribute.
2. If the element does not have a name \({ }^{p 568}\) attribute specified, or its name \({ }^{p 568}\) attribute's value is the empty string, then return.
3. If the element's submission value \({ }^{\text {p716 }}\) is not null, append an entry \({ }^{\text {p601 }}\) to entry list with the name \({ }^{\mathrm{p} 568}\) attribute value and the submission value \({ }^{\mathrm{p} 716}\).

\subsection*{4.14 Common idioms without dedicated elements \(\S_{7}^{p 71}\)}

\subsection*{4.14.1 Bread crumb navigation \(\S^{p 71}\)}

This specification does not provide a machine-readable way of describing bread-crumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The nav \({ }^{\text {p184 }}\) element can be used to mark the section containing these paragraphs as being navigation blocks.

\section*{Example}

In the following example, the current page can be reached via two paths.
```
<nav>
    <p>
        <a href="/">Main</a> *
        <a href="/products/">Products</a> *
        <a href="/products/dishwashers/">Dishwashers</a> *
        <a>Second hand</a>
```
```
</p>
<p>
    <a href="/">Main</a> *
    <a href="/second-hand/">Second hand</a> *
    <a>Dishwashers</a>
    </p>
</nav>
```

\subsection*{4.14.2 Tag clouds \(\S^{p 71}\)}

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as tag clouds). In general, authors are encouraged to either mark up such lists using \(u l^{p 222}\) elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.

\section*{Example}

Here, three tags are included in a short tag cloud:
```
<style>
    .tag-cloud > li > span { display: none; }
    tag-cloud > li { display: inline; }
    tag-cloud-1 { font-size: 0.7em; }
    tag-cloud-2 { font-size: 0.9em; }
    tag-cloud-3 { font-size: 1.1em; }
    tag-cloud-4 { font-size: 1.3em; }
    tag-cloud-5 { font-size: 1.5em; }
@media speech {
    tag-cloud > li > span { display:inline }
}
</style>
<ul class="tag-cloud">
    <li class="tag-cloud-4"><a title="28 instances" href="/t/apple">apple</a> <span>(popular)</span>
    <li class="tag-cloud-2"><a title="6 instances" href="/t/kiwi">kiwi</a> <span>(rare)</span>
    <li class="tag-cloud-5"><a title="41 instances" href="/t/pear">pear</a> <span>(very
popular)</span>
</ul>
```

The actual frequency of each tag is given using the title \({ }^{\text {p139 }}\) attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like "(popular)" or "(rare)" to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The \(u l^{p 222}\) element is used (rather than \(o l^{p 22 \theta}\) ) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The \(t^{2 g^{p 388}} r e^{p 284}\)-keyword is not used on these \(\underline{a}^{p 238}\) elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

\subsection*{4.14.3 Conversations \(\S^{p 71}\)}

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using \(p^{p 211}\) elements and punctuation. Authors who need to mark the speaker for styling purposes are encouraged to use \(s p a n^{p 279}\) or \(\underline{b}^{p 273}\). Paragraphs with their text wrapped in the \(\underline{i}^{p 272}\) element can be
used for marking up stage directions.

\section*{Example}

This example demonstrates this using an extract from Abbot and Costello's famous sketch, Who's on first:
```
<p> Costello: Look, you gotta first baseman?
<p> Abbott: Certainly.
<p> Costello: Who's playing first?
<p> Abbott: That's right.
<p> Costello becomes exasperated.
<p> Costello: When you pay off the first baseman every month, who gets the money?
<p> Abbott: Every dollar of it.
```

\section*{Example}

The following extract shows how an IM conversation log could be marked up, using the data \({ }^{2259}\) element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the time \({ }^{\text {p260 }}\) element does not support, so the data \({ }^{\text {p259 }}\) element is used instead (namely, Unix time_t timestamps). Had the author wished to mark up the data using one of the date and time formats supported by the time \({ }^{\text {p260 }}\) element, that element could have been used instead of data \({ }^{p 259}\). This could be advantageous as it would allow data analysis tools to detect the timestamps unambiguously, without coordination with the page author.
```
<p> <data value="1319898155">14:22</data> <b>egof</b> I'm not that nerdy, I've only seen 30% of
the star trek episodes
<p> <data value="1319898192">14:23</data> <b>kaj</b> if you know what percentage of the star trek
episodes you have seen, you are inarguably nerdy
<p> <data value="1319898200">14:23</data> <b>egof</b> it's unarguably
<p> <data value="1319898228">14:23</data> <i>* kaj blinks</i>
<p> <data value="1319898260">14:24</data> <b>kaj</b> you are not helping your case
```

\section*{Example}

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to mark up. This example shows one possible convention using \(d l^{p 226}\) elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. [DOT] \({ }^{\text {p1287 }}\)
```
<p> Next, you meet a fisher. You can say one of several greetings:
<dl>
    <dt> "Hello there!"
    <dd>
    <p> She responds with "Hello, how may I help you?"; you can respond with:
    <dl>
        <dt> "I would like to buy a fish."
        <dd> <p> She sells you a fish and the conversation finishes.
        <dt> "Can I borrow your boat?"
        <dd>
            <p> She is surprised and asks "What are you offering in return?".
            <dl>
                <dt> "Five gold." (if you have enough)
                <dt> "Ten gold." (if you have enough)
                <dt> "Fifteen gold." (if you have enough)
                <dd> <p> She lends you her boat. The conversation ends.
                <dt> "A fish." (if you have one)
                <dt> "A newspaper." (if you have one)
                <dt> "A pebble." (if you have one)
                <dd> <p> "No thanks", she replies. Your conversation options
                at this point are the same as they were after asking to borrow
                her boat, minus any options you've suggested before.
            </dl>
        </dd>
```
```
    </dl>
    </dd>
    <dt> "Vote for me in the next election!"
    <dd> <p> She turns away. The conversation finishes.
    <dt> "Madam, are you aware that your fish are running away?"
    <dd>
        <p> She looks at you skeptically and says "Fish cannot run, miss".
        <dl>
        <dt> "You got me!"
        <dd> <p> The fisher sighs and the conversation ends.
        <dt> "Only kidding."
        <dd> <p> "Good one!" she retorts. Your conversation options at this
        point are the same as those following "Hello there!" above.
        <dt> "Oh, then what are they doing?"
        <dd> <p> She looks at her fish, giving you an opportunity to steal
        her boat, which you do. The conversation ends.
        </dl>
    </dd>
</dl>
```

\section*{Example}

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:
```
<section>
    <h1>Dialogue</h1>
    <p><small>Some characters repeat their lines in order each time you interact
    with them, others randomly pick from amongst their lines. Those who respond in
    order have numbered entries in the lists below.</small>
    <h2>The Shopkeeper</h2>
    <ul>
        <li>How may I help you?
        <li>Fresh apples!
        <li>A loaf of bread for madam?
    </ul>
    <h2>The pilot</h2>
    <p>Before the accident:
    <ul>
        <li>I'm about to fly out, sorry!
        <li>Sorry, I'm just waiting for flight clearance and then I'll be off!
        </ul>
        <p>After the accident:
        <ol>
        <li>I'm about to fly out, sorry!
        <li>Ok, I'm not leaving right now, my plane is being cleaned.
        <li>0k, it's not being cleaned, it needs a minor repair first.
        <li>0k, ok, stop bothering me! Truth is, I had a crash.
        </ol>
        <h2>Clan Leader</h2>
        <p>During the first clan meeting:
        <ul>
        <li>Hey, have you seen my daughter? I bet she's up to something nefarious again...
        <li>Nice weather we're having today, eh?
        <li>The name is Bailey, Jeff Bailey. How can I help you today?
        <li>A glass of water? Fresh from the well!
        </ul>
        <p>After the earthquake:
        <ol>
        <li>Everyone is safe in the shelter, we just have to put out the fire!
```
```
    <li>I'll go and tell the fire brigade, you keep hosing it down!
    </ol>
</section>
```

\subsection*{4.14.4 Footnotes \(\S_{1}^{p 72}\)}

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the title \({ }^{\text {p139 }}\) attribute could be used.

\section*{Example}

In this example, two parts of a dialogue are annotated with footnote-like content using the title \({ }^{\text {p139 }}\) attribute.
```
<p> <b>Customer</b>: Hello! I wish to register a complaint. Hello. Miss?
<p> <b>Shopkeeper</b>: <span title="Colloquial pronunciation of 'What do you'"
>Watcha</span> mean, miss?
<p> <b>Customer</b>: Uh, I'm sorry, I have a cold. I wish to make a complaint.
<p> <b>Shopkeeper</b>: Sorry, <span title="This is, of course, a lie.">we're
closing for lunch</span>.
```

\section*{Note}

Unfortunately, relying on the title \({ }^{p 139}\) attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

\section*{Note}

If the title \({ }^{p 139}\) attribute is used, CSS can be used to draw the reader's attention to the elements with the attribute.

\section*{Example}

For example, the following CSS places a dashed line below elements that have a title \({ }^{\text {p139 }}\) attribute.
```
CSS [title] { border-bottom: thin dashed; }
```

For longer annotations, the \(a^{p 238}\) element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

\section*{Example}

In this example, a footnote in the dialogue links to a paragraph below the dialogue. The paragraph then reciprocally links back to the dialogue, allowing the user to return to the location of the footnote.
```
<p> Announcer: Number 16: The <i>hand</i>.
<p> Interviewer: Good evening. I have with me in the studio tonight
Mr Norman St John Polevaulter, who for the past few years has been
contradicting people. Mr Polevaulter, why <em>do</em> you
contradict people?
<p> Norman: I don't. <sup><a href="#fn1" id="r1">[1]</a></sup>
<p> Interviewer: You told me you did!
...
<section>
    <p id="fnl"><a href="#rl">[1]</a> This is, naturally, a lie,
```
```
but paradoxically if it were true he could not say so without
contradicting the interviewer and thus making it false.</p>
</section>
```

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the aside \({ }^{\text {p187 }}\) element should be used.

\section*{Example}

In this example, a sidebar is given after a dialogue, giving it some context.
```
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: I'm sorry?
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: No no no, this's'a tobacconist's.
<aside>
    <p>In 1970, the British Empire lay in ruins, and foreign
    nationalists frequented the streets - many of them Hungarians
    (not the streets - the foreign nationals). Sadly, Alexander
    Yalt has been publishing incompetently-written phrase books.
</aside>
```

For figures or tables, footnotes can be included in the relevant figcaption \({ }^{\text {p235 }}\) or caption \({ }^{\text {p458 }}\) element, or in surrounding prose.

\section*{Example}

In this example, a table has cells with footnotes that are given in prose. A figure \({ }^{p 232}\) element is used to give a single legend to the combination of the table and its footnotes.
```
<figure>
    <figcaption>Table 1. Alternative activities for knights.</figcaption>
    <table>
    <tr>
        <th> Activity
        <th> Location
        <th> Cost
    <tr>
        <td> Dance
        <td> Wherever possible
        <td> £0<sup><a href="#fn1">1</a></sup>
    <tr>
        <td> Routines, chorus scenes<sup><a href="#fn2">2</a></sup>
        <td> Undisclosed
        <td> Undisclosed
    <tr>
        <td> Dining<sup><a href="#fn3">3</a></sup>
        <td> Camelot
        <td> Cost of ham, jam, and spam<sup><a href="#fn4">4</a></sup>
    </table>
    <p id="fn1">1. Assumed.</p>
    <p id="fn2">2. Footwork impeccable.</p>
    <p id="fn3">3. Quality described as "well".</p>
    <p id="fn4">4. A lot.</p>
</figure>
```

\subsection*{4.15 Disabled elements \(\S^{p 72}\)}

An element is said to be actually disabled if it is one of the following:
- a button \({ }^{p 535}\) element that is disabled \({ }^{\mathrm{p} 570}\)
- an input \({ }^{\text {p493 }}\) element that is disabled \({ }^{p 570}\)
- a select \({ }^{\text {p537 }}\) element that is disabled \({ }^{\mathrm{p} 570}\)
- a textarea \({ }^{\mathrm{p} 548}\) element that is disabled \({ }^{\mathrm{p} 570}\)
- an optgroup \({ }^{p 544}\) element that has a disabled \({ }^{p 545}\) attribute
- an option \({ }^{p 545}\) element that is disabled \({ }^{p 546}\)
- a fieldset \({ }^{\text {p562 }}\) element that is a disabled fieldset \({ }^{\text {p563 }}\)
- a form-associated custom element \({ }^{\text {p704 }}\) that is disabled \({ }^{\text {p570 }}\)

\section*{Note}

This definition is used to determine what elements are focusable \({ }^{\text {p772 }}\) and which elements match the :enabled \({ }^{p 726}\) and :disabled \({ }^{\text {p726 }}\) pseudo classes.

\subsection*{4.16 Matching HTML elements using selectors and CSS \(\S^{\text {p72 }}\)}

\subsection*{4.16.1 Case-sensitivity of the CSS 'attr()' function \(\S^{\text {p72 }}\)}

CSS Values and Units leaves the case-sensitivity of attribute names for the purpose of the 'attr()' function to be defined by the host language. [CSSVALUES] \({ }^{\text {p1287 }}\)

When comparing the attribute name part of a CSS 'attr()' function to the names of namespace-less attributes on HTML elements \({ }^{\text {p44 }}\) in HTML documents, the name part of the CSS 'attr()' function must first be converted to ASCII lowercase. The same function when compared to other attributes must be compared according to its original case. In both cases, to match the values must be identical to each other (and therefore the comparison is case sensitive).

\section*{Note}

This is the same as comparing the name part of a CSS attribute selector, specified in the next section.

\subsection*{4.16.2 Case-sensitivity of selectors \(\S^{p 72}\)}

Selectors leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [SELECTORS] \({ }^{\text {p1291 }}\)

When comparing a CSS element type selector to the names of HTML elements \({ }^{\text {p44 }}\) in HTML documents, the CSS element type selector must first be converted to ASCII lowercase. The same selector when compared to other elements must be compared according to its original case. In both cases, to match the values must be identical to each other (and therefore the comparison is case sensitive).

When comparing the name part of a CSS attribute selector to the names of attributes on HTML elements \({ }^{\text {p44 }}\) in HTML documents, the name part of the CSS attribute selector must first be converted to ASCII lowercase. The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

Attribute selectors on an HTML element \({ }^{\text {p44 }}\) in an HTML document must treat the values of attributes with the following names as ASCII case-insensitive:
- accept
- accept-charset
- align
- alink
- axis
- bgcolor
- charset
- checked
- clear
- codetype
- color
- compact
- declare
- defer
- dir
- direction
- disabled
- enctype
- face
- frame
- hreflang
- http-equiv
- lang
- language
- link
- media
- method
- multiple
- nohref
- noresize
- noshade
- nowrap
- readonly
- rel
- rev
- rules
- scope
- scrolling
- selected
- shape
- target
- text
- type
- valign
- valuetype
- vlink

\section*{Example}

For example, the selector [bgcolor="\#ffffff"] will match any HTML element with a bgcolor attribute with values including \#ffffff, \#FFFFFF and \#ffffFF. This happens even if bgcolor has no effect for a given element (e.g., div \({ }^{p 237}\) ).

The selector [type=a s] will match any HTML element with a type attribute whose value is a, but not whose value is A, due to the s flag.

All other attribute values and everything else must be treated as entirely identical to each other for the purposes of selector matching. This includes:
- IDs and classes in no-quirks mode and limited-quirks mode
- the names of elements not in the HTML namespace
- the names of HTML elements \({ }^{\text {p44 }}\) in XML documents
- the names of attributes of elements not in the HTML namespace
- the names of attributes of HTML elements \({ }^{\text {p44 }}\) in XML documents
- the names of attributes that themselves have namespaces

\section*{Note}

Selectors defines that ID and class selectors (such as \#foo and .bar), when matched against elements in documents that are in quirks mode, will be matched in an ASCII case-insensitive manner. However, this does not apply for attribute selectors with "id" or "class" as the name part. The selector [class="foobar"] will treat its value as case-sensitive even in quirks mode.

\subsection*{4.16.3 Pseudo-classes \({ }_{4}^{\text {p72 }}\)}

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML elements. [SELECTORS] \({ }^{\text {p1291 }}\) [CSSUI] \({ }^{\text {p1287 }}\)

\section*{: defined}

The : defined \({ }^{\text {p724 }}\) pseudo-class must match any element that is defined.

All \(a^{p 238}\) elements that have an href \(f^{p 284}\) attribute, all area \({ }^{p 443}\) elements that have an href \(f^{p 284}\) attribute, and all link \({ }^{p 157}\) elements that have an href \(f^{\mathrm{p} 158}\) attribute, must match one of :link \({ }^{\mathrm{p} 725}\) and \(:\) visited \(^{\mathrm{p} 725}\).

Other specifications might apply more specific rules regarding how these elements are to match these pseudo-classes, to mitigate some privacy concerns that apply with straightforward implementations of this requirement.
:active
The :active \({ }^{\text {p725 }}\) pseudo-class is defined to match an element "while an element is being activated by the user".
To determine whether a particular element is being activated \({ }^{p 725}\) for the purposes of defining the :active \({ }^{\text {p725 }}\) pseudo-class only, an HTML user agent must use the first relevant entry in the following list.

If the element has a descendant that is currently matching the :active \({ }^{\mathrm{p} 725}\) pseudo-class
The element is being activated \({ }^{p 725}\).
If the element is the labeled control \({ }^{\mathrm{p} 491}\) of a label \(l^{\mathrm{p} 499}\) element that is currently matching :active \({ }^{\mathrm{p} 725}\)
The element is being activated \({ }^{p 725}\).
If the element is a button \({ }^{\text {p535 }}\) element
If the element is an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Submit Button \({ }^{\text {p518 }}\), Image Button \({ }^{\text {p518 }}\), Reset Button \({ }^{\text {p520 }}\), or Button \({ }^{\text {p521 }}\) state

\section*{Example}

For example, if the user is using a keyboard to push a button \({ }^{\text {p535 }}\) element by pressing the space bar, the element would match this pseudo-class in between the time that the element received the keydown event and the time the element received the keyup event.

If the element is an \(a^{\text {p238 }}\) element that has an href \({ }^{\text {p284 }}\) attribute
If the element is an area \({ }^{\mathrm{p} 443}\) element that has an href \({ }^{\mathrm{p} 284}\) attribute
If the element is a link \({ }^{\text {p157 }}\) element that has an href \({ }^{\text {p158 }}\) attribute
If the element is focusable \({ }^{\text {p772 }}\)
The element is being activated \({ }^{p 725}\) if it is in a formal activation state \({ }^{\text {p725 }}\).
If the element is being actively pointed at \({ }^{\text {p725 }}\)
The element is being activated \({ }^{p 725}\).
An element is said to be in a formal activation state between the time the user begins to indicate an intent to trigger the element's activation behavior and either the time the user stops indicating an intent to trigger the element's activation behavior, or the time the element's activation behavior has finished running, which ever comes first.

An element is said to be being actively pointed at while the user indicates the element using a pointing device while that pointing device is in the "down" state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

\section*{:hover}

The :hover \({ }^{p 725}\) pseudo-class is defined to match an element "while the user designates an element with a pointing device". For the purposes of defining the :hover \({ }^{\text {p725 }}\) pseudo-class only, an HTML user agent must consider an element as being one that the user designates if it is:
- An element that the user indicates using a pointing device.
- An element that has a descendant that the user indicates using a pointing device.
- An element that is the labeled control \({ }^{\text {p491 }}\) of a label \({ }^{\text {p490 }}\) element that is currently matching : hover \({ }^{\mathrm{p725}}\).

Example
Consider in particular a fragment such as:
```
<p> <label for=c> <input id=a> </label> <span id=b> <input id=c> </span> </p>
```

If the user designates the element with ID "a" with their pointing device, then the \(p^{p 211}\) element (and all its ancestors not shown in the snippet above), the label \({ }^{p 490}\) element, the element with ID "a", and the element with ID "c" will match the : hover \({ }^{\text {p725 }}\) pseudo-class. The element with ID "a" matches it from condition 1 , the label \({ }^{p 490}\) and \(p^{p 211}\) elements match it because of condition 2 (one of their descendants is designated), and the element with ID "c" matches it through condition 3 (its label \({ }^{\text {p490 }}\) element matches : hover \({ }^{\text {p725 }}\) ). However, the element with ID "b" does not match : hover \({ }^{\text {p725 }}\) : its descendant is not designated, even though it matches: hover \({ }^{\text {p725 }}\).

\section*{: focus}

For the purposes of the CSS : focus \({ }^{p 726}\) pseudo-class, an element has the focus when:
- its top-level browsing context \({ }^{\mathrm{p814}}\) has the system focus;
- it is not itself a browsing context container \({ }^{\mathrm{p} 814}\); and
- at least one of the following is true:
- it is one of the elements listed in the focus chain \({ }^{p 771}\) of the currently focused area of the top-level browsing context \({ }^{\text {p771 }}\), or
- its shadow root shadowRoot is not null and shadowRoot is the root of at least one element that has the focus \({ }^{p 726}\).

\section*{:target}

For the purposes of the CSS : target \({ }^{p 726}\) pseudo-class, the Document \({ }^{\text {p114 }}\) 's target elements are a list containing the Document \({ }^{\text {p114 }} \mathbf{s}\) target element \({ }^{\text {p881 }}\), if it is not null, or containing no elements, if it is. [SELECTORS] \({ }^{\text {p1291 }}\)
: enabled
The : enabled \({ }^{p 726}\) pseudo-class must match any button \({ }^{\text {p535 }}\), input \({ }^{\text {p493 }}\), select \({ }^{\text {p537 }}\), textarea \({ }^{\text {p548 }}\), optgroup \({ }^{p 544}\), option \({ }^{\text {p545 }}\), fieldset \({ }^{p 562}\) element, or form-associated custom element \({ }^{p 704}\) that is not actually disabled \({ }^{\text {p723 }}\).
: disabled
The : disabled \({ }^{\text {p726 }}\) pseudo-class must match any element that is actually disabled \({ }^{\text {p723 }}\).
: checked
The :checked \({ }^{\text {p726 }}\) pseudo-class must match any element falling into one of the following categories:
- input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute is in the Checkbox \({ }^{\text {p513 }}\) state and whose checkedness \({ }^{\text {p566 }}\) state is true
- input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute is in the Radio Button \({ }^{\text {p514 }}\) state and whose checkedness \({ }^{\text {p566 }}\) state is true
- option \({ }^{\text {p545 }}\) elements whose selectedness \({ }^{\text {p547 }}\) is true

\section*{:indeterminate}

The :indeterminate \({ }^{p 726}\) pseudo-class must match any element falling into one of the following categories:
- input \({ }^{p 493}\) elements whose type \({ }^{p 495}\) attribute is in the Checkbox \({ }^{p 513}\) state and whose indeterminate \({ }^{\text {p499 }}\) IDL attribute is set to true
- input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute is in the Radio Button \({ }^{\text {p514 }}\) state and whose radio button group \({ }^{\text {p514 }}\) contains no input \({ }^{p 493}\) elements whose checkedness \({ }^{p 566}\) state is true.
- progress \({ }^{\text {p555 }}\) elements with no value \({ }^{\text {p556 }}\) content attribute

\section*{: default}

The :default \({ }^{\text {p726 }}\) pseudo-class must match any element falling into one of the following categories:
- Submit buttons \({ }^{\text {p486 }}\) that are default buttons \({ }^{\text {p596 }}\) of their form owner \({ }^{\text {p566 }}\).
- input \({ }^{\text {p493 }}\) elements to which the checked \({ }^{\text {p497 }}\) attribute applies and that have a checked \({ }^{\text {p497 }}\) attribute
- option \({ }^{\text {p545 }}\) elements that have a selected \({ }^{\text {p547 }}\) attribute

The : placeholder-shown \({ }^{\text {p727 }}\) pseudo-class must match any element falling into one of the following categories:
- input \({ }^{\text {p493 }}\) elements that have a placeholder \(r^{p 53 \theta}\) attribute whose value is currently being presented to the user.
- textarea \({ }^{p 548}\) elements that have a placeholder \({ }^{p 551}\) attribute whose value is currently being presented to the user.
:valid
The : valid \({ }^{\text {p727 }}\) pseudo-class must match any element falling into one of the following categories:
- elements that are candidates for constraint validation \({ }^{\text {p590 }}\) and that satisfy their constraints \({ }^{\text {p591 }}\)
- form \({ }^{\text {p486 }}\) elements that are not the form owner \({ }^{\mathrm{p566}}\) of any elements that themselves are candidates for constraint validation \({ }^{\mathrm{p} 590}\) but do not satisfy their constraints \({ }^{\mathrm{p591}}\)
- fieldset \({ }^{\mathrm{p} 562}\) elements that have no descendant elements that themselves are candidates for constraint validation \({ }^{\mathrm{p590}}\) but do not satisfy their constraints \({ }^{\text {p591 }}\)
:invalid
The :invalid \({ }^{\text {p727 }}\) pseudo-class must match any element falling into one of the following categories:
- elements that are candidates for constraint validation \({ }^{\text {p590 }}\) but that do not satisfy their constraints \({ }^{\mathrm{p} 591}\)
- form \({ }^{p 866}\) elements that are the form owner \({ }^{p 566}\) of one or more elements that themselves are candidates for constraint validation \({ }^{\mathrm{p} 590}\) but do not satisfy their constraints \({ }^{\mathrm{p} 591}\)
- fieldset \({ }^{\mathrm{p} 562}\) elements that have of one or more descendant elements that themselves are candidates for constraint validation \({ }^{\mathrm{p} 590}\) but do not satisfy their constraints \({ }^{\mathrm{p} 591}\)
:in-range
The :in-range \({ }^{\text {p727 }}\) pseudo-class must match all elements that are candidates for constraint validation \({ }^{\text {p590 }}\), have range limitations \({ }^{\mathrm{p} 527}\), and that are neither suffering from an underflow \({ }^{\mathrm{p} 590}\) nor suffering from an overflow \({ }^{\mathrm{p} 591}\).
: out-of-range
The : out-of-range \({ }^{\mathrm{p} 727}\) pseudo-class must match all elements that are candidates for constraint validation \({ }^{\mathrm{p} 590}\), have range limitations \({ }^{\mathrm{p} 527}\), and that are either suffering from an underflow \({ }^{\text {p590 }}\) or suffering from an overflow \({ }^{\mathrm{p} 591}\).
: required
The : required \({ }^{\text {p727 }}\) pseudo-class must match any element falling into one of the following categories:
- input \({ }^{\text {p493 }}\) elements that are required \({ }^{p 523}\)
- select \({ }^{\text {p537 }}\) elements that have a required \({ }^{\text {p539 }}\) attribute
- textarea \({ }^{p 548}\) elements that have a required \({ }^{p 551}\) attribute

\section*{:optional}

The : optional \({ }^{\text {p727 }}\) pseudo-class must match any element falling into one of the following categories:
- input \({ }^{\text {p493 }}\) elements to which the required \({ }^{p 523}\) attribute applies that are not required \({ }^{p 523}\)
- select \({ }^{\text {p537 }}\) elements that do not have a required \({ }^{p 539}\) attribute
- textarea \({ }^{\mathrm{p548}}\) elements that do not have a required \({ }^{\mathrm{p551}}\) attribute
: read-only
: read-write
The : read-write \({ }^{\text {p727 }}\) pseudo-class must match any element falling into one of the following categories, which for the purposes of Selectors are thus considered user-alterable: [SELECTORS] \({ }^{\text {p1291 }}\)
- input \({ }^{p 493}\) elements to which the readonly \({ }^{p 522}\) attribute applies, and that are mutable \({ }^{p 566}\) (i.e. that do not have the readonly \({ }^{\mathrm{p} 522}\) attribute specified and that are not disabled \({ }^{\mathrm{p} 570}\) )
- textarea \({ }^{\text {p548 }}\) elements that do not have a readonly \({ }^{\text {p549 }}\) attribute, and that are not disabled \({ }^{\text {p570 }}\)
- elements that are editing hosts \({ }^{\text {p789 }}\) or editable and are neither input \({ }^{\text {p493 }}\) elements nor textarea \({ }^{\text {p548 }}\) elements

The : read-only \({ }^{\text {p727 }}\) pseudo-class must match all other HTML elements \({ }^{\text {p44 }}\).
: dir(ltr)
The : dir(ltr) \()^{\text {p728 }}\) pseudo-class must match all elements whose directionality \({ }^{p 142}\) is ' \(\operatorname{ltr}^{p 142}\).
:dir(rtl)
The :dir(rtl) \()^{p 728}\) pseudo-class must match all elements whose directionality \({ }^{p 142}\) is ' \(\left.\mathrm{rt}\right|^{\mathrm{p} 142 \mathrm{I}}\).

\section*{Note}

This specification does not define when an element matches the : lang() dynamic pseudo-class, as it is defined in sufficient detail in a language-agnostic fashion in Selectors. [SELECTORS] \({ }^{\text {p1291 }}\)

\section*{5 Microdata \(\S^{\text {p72 }}\)}

\subsection*{5.1 Introduction \(\S^{p 72}\)}

\subsection*{5.1.1 Overview \(\S^{\text {p72 }}\)}

This section is non-normative.

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

\subsection*{5.1.2 The basic syntax \(\S^{p 72}\)}

This section is non-normative.
At a high level, microdata consists of a group of name-value pairs. The groups are called items \({ }^{\text {p734 }}\), and each name-value pair is a property. Items and properties are represented by regular elements.

To create an item, the itemscope \({ }^{\mathrm{p} 734}\) attribute is used.
To add a property to an item, the itemprop \({ }^{\mathrm{p736}}\) attribute is used on one of the item's \(\mathrm{s}^{\mathrm{p} 734}\) descendants.

\section*{Example}

Here there are two items, each of which has the property "name":
```
<div itemscope>
    <p>My name is <span itemprop="name">Elizabeth</span>.</p>
</div>
<div itemscope>
    <p>My name is <span itemprop="name">Daniel</span>.</p>
</div>
```

Markup without the microdata-related attributes does not have any effect on the microdata model.

\section*{Example}

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:
```

<div itemscope>
    <p>My <em>name</em> is <span itemprop="name">E<strong>liz</strong>abeth</span>.</p>
</div>
<section>
    <div itemscope>
        <aside>
        <p>My name is <span itemprop="name"><a href="/?user=daniel">Daniel</a></span>.</p>
        </aside>
    </div>
</section>
```

Properties generally have values that are strings.

Here the item has three properties:
```

<div itemscope>
    <p>My name is <span itemprop="name">Neil</span>.</p>
    <p>My band is called <span itemprop="band">Four Parts Water</span>.</p>
    <p>I am <span itemprop="nationality">British</span>.</p>
</div>
```

When a string value is a URL, it is expressed using the \(a^{p 238}\) element and its href \(f^{p 284}\) attribute, the img \({ }^{p 32 \theta}\) element and its \(\underline{s r c}^{p 321}\) attribute, or other elements that link to or embed external resources.

\section*{Example}

In this example, the item has one property, "image", whose value is a URL:
```

<div itemscope>
    <img itemprop="image" src="google-logo.png" alt="Google">
</div>
```

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the value \({ }^{\text {p260 }}\) attribute of the data \({ }^{\text {p259 }}\) element, with the human-readable version given in the element's contents.

\section*{Example}

Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product's name is used the human-visible text instead of the ID.
```

<h1 itemscope>
    <data itemprop="product-id" value="9678A0U879">The Instigator 2000</data>
</h1>
```

For numeric data, the meter \({ }^{p 557}\) element and its value \({ }^{\mathrm{p558}}\) attribute can be used instead.

\section*{Example}

Here a rating is given using a meter \({ }^{\text {p557 }}\) element.
```

<div itemscope itemtype="http://schema.org/Product">
    <span itemprop="name">Panasonic White 60L Refrigerator</span>
    <img src="panasonic-fridge-60l-white.jpg" alt="">
    <div itemprop="aggregateRating"
                itemscope itemtype="http://schema.org/AggregateRating">
        <meter itemprop="ratingValue" min=0 value=3.5 max=5>Rated 3.5/5</meter>
        (based on <span itemprop="reviewCount">11</span> customer reviews)
    </div>
</div>

```

Similarly, for date- and time-related data, the time \({ }^{p 260}\) element and its datetime \({ }^{p 261}\) attribute can be used instead.

\section*{Example}

In this example, the item has one property, "birthday", whose value is a date:
```

<div itemscope>
    I was born on <time itemprop="birthday" datetime="2009-05-10">May 10th 2009</time>.
</div>
```

Properties can also themselves be groups of name-value pairs, by putting the itemscope \({ }^{\text {p734 }}\) attribute on the element that declares the property.

Items that are not part of others are called top-level microdata items \({ }^{\text {p739 }}\).

\section*{Example}

In this example, the outer item represents a person, and the inner one represents a band:
```

<div itemscope>
    <p>Name: <span itemprop="name">Amanda</span></p>
    <p>Band: <span itemprop="band" itemscope> <span itemprop="name">Jazz Band</span> (<span
itemprop="size">12</span> players)</span></p>
</div>
```

The outer item here has two properties, "name" and "band". The "name" is "Amanda", and the "band" is an item in its own right, with two properties, "name" and "size". The "name" of the band is "Jazz Band", and the "size" is "12".

The outer item in this example is a top-level microdata item.

Properties that are not descendants of the element with the itemscope \({ }^{\text {p734 }}\) attribute can be associated with the item \({ }^{\text {p734 }}\) using the itemref \({ }^{\text {p735 }}\) attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the itemscope \({ }^{\mathrm{p} 734}\) attribute.

\section*{Example}

This example is the same as the previous one, but all the properties are separated from their items \({ }^{\mathrm{p} 734}\) :
```

<div itemscope id="amanda" itemref="a b"></div>
<p id="a">Name: <span itemprop="name">Amanda</span></p>
<div id="b" itemprop="band" itemscope itemref="c"></div>
<div id="c">
    <p>Band: <span itemprop="name">Jazz Band</span></p>
    <p>Size: <span itemprop="size">12</span> players</p>
</div>
```

This gives the same result as the previous example. The first item has two properties, "name", set to "Amanda", and "band", set to another item. That second item has two further properties, "name", set to "Jazz Band", and "size", set to "12".

An \(\underline{i t e m}{ }^{\text {p734 }}\) can have multiple properties with the same name and different values.

\section*{Example}

This example describes an ice cream, with two flavors:
```

<div itemscope>
    <p>Flavors in my favorite ice cream:</p>
    <ul>
    <li itemprop="flavor">Lemon sorbet</li>
    <li itemprop="flavor">Apricot sorbet</li>
    </ul>
</div>
```

This thus results in an item with two properties, both "flavor", having the values "Lemon sorbet" and "Apricot sorbet".

An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

\section*{Example}

Here we see an item with two properties, "favorite-color" and "favorite-fruit", both set to the value "orange":
```

<div itemscope>
    <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It's important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.

\section*{Example}

There is no semantic difference, for instance, between the following two examples:
```

<figure>
    <img src="castle.jpeg">
    <figcaption><span itemscope><span itemprop="name">The Castle</span></span> (1986)</figcaption>
</figure>
<span itemscope><meta itemprop="name" content="The Castle"></span>

<figure>
    <img src="castle.jpeg">
    <figcaption>The Castle (1986)</figcaption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

\subsection*{5.1.3 Typed items \(\S^{\text {p73 }}\)}

This section is non-normative.
The examples in the previous section show how information could be marked up on a page that doesn't expect its microdata to be reused. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each item \({ }^{\text {p734 }}\) a type, such as "https://example.com/person", or "https://example.org/cat", or "https://band.example.net/". Types are identified as URLs.

The type for an item \({ }^{\mathrm{p} 734}\) is given as the value of an itemtype \({ }^{\mathrm{p} 734}\) attribute on the same element as the \(i\) itemscope \({ }^{\mathrm{p} 734}\) attribute.

\section*{Example}

Here, the item's type is "https://example.org/animals\#cat":
```

<section itemscope itemtype="https://example.org/animals#cat">
    <h1 itemprop="name">Hedral</h1>
    <p itemprop="desc">Hedral is a male american domestic
    shorthair, with a fluffy black fur with white paws and belly.</p>
    <img itemprop="img" src="hedral.jpeg" alt="" title="Hedral, age 18 months">
</section>
```

In this example the "https://example.org/animals\#cat" item has three properties, a "name" ("Hedral"), a "desc" ("Hedral is..."), and an "img" ("hedral.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named "class" given for an item with the type "https://census.example/person" might refer to the economic class of an individual, while a property named "class" given for an item with the type "https://example.com/school/teacher" might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types "https://example.org/people/teacher" and "https://example.org/people/engineer" could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the "https://example.org/people/engineer" type might not typically be used with the "classroom" property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute' value. An item cannot be given two types if they do not use the same vocabulary, however.

\subsection*{5.1.4 Global identifiers for items \(\S^{p 73}\)}

This section is non-normative.
Sometimes, an item \({ }^{\text {p734 }}\) gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the itemtype \({ }^{\mathrm{p} 734}\) attribute) can be designed such that items \({ }^{\mathrm{p} 734}\) get associated with their global identifier in an unambiguous way by expressing the global identifiers as URLs given in an itemid \({ }^{\mathrm{p} 735}\) attribute.

The exact meaning of the URLS given in \(\underline{i t e m i d}{ }^{\text {p735 }}\) attributes depends on the vocabulary used.

\section*{Example}

Here, an item is talking about a particular book:
```

<dl itemscope
        itemtype="https://vocab.example.net/book"
        itemid="urn:isbn:0-330-34032-8">
    <dt>Title
    <dd itemprop="title">The Reality Dysfunction
    <dt>Author
    <dd itemprop="author">Peter F. Hamilton
    <dt>Publication date
    <dd><time itemprop="pubdate" datetime="1996-01-26">26 January 1996</time>
</dl>
```

The "https://vocab.example. net/book" vocabulary in this example would define that the itemid \({ }^{\text {p735 }}\) attribute takes a urn: URL pointing to the ISBN of the book.

\subsection*{5.1.5 Selecting names when defining vocabularies \(\S_{3}^{\text {p73 }}\)}

This section is non-normative.
Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using URLs, or, for properties, as plain words (with no dots or colons). For URLs, conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

\section*{Example}

For instance, if Jon and Adam both write content at example. com, at https://example.com/~jon/... and https://example.com/~adam/... respectively, then they could select identifiers of the form "https://example.com/~jon/name" and "https://example.com/~adam/name" respectively.

Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using URLs can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names (URLs) or ensure that their items are typed.

\section*{Example}

Here, an item is an "https://example.org/animals\#cat", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.
```

<section itemscope itemtype="https://example.org/animals#cat">
    <h1 itemprop="name https://example.com/fn">Hedral</h1>
    <p itemprop="desc">Hedral is a male american domestic
```
```
    shorthair, with a fluffy <span
    itemprop="https://example.com/color">black</span> fur with <span
    itemprop="https://example.com/color">white</span> paws and belly.</p>
    <img itemprop="img" src="hedral.jpeg" alt="" title="Hedral, age 18 months">
</section>
```

This example has one item with the type "https://example.org/animals\#cat" and the following properties:
\begin{tabular}{l|l} 
Property & Value \\
\hline name & Hedral \\
\hline https://example.com/fn & Hedral \\
\hline desc & Hedral is a male american domestic shorthair, with a fluffy black fur with white paws and belly. \\
\hline https://example.com/color & black \\
\hline https://example.com/color & white \\
\hline img & \(\ldots . /\) hedral.jpeg \\
\hline
\end{tabular}

\subsection*{5.2 Encoding microdata \(\S^{p 73}\)}

\subsection*{5.2.1 The microdata model \(\S_{4}^{\text {p73 }}\)}

The microdata model consists of groups of name-value pairs known as items \({ }^{\mathrm{p734}}\).
Each group is known as an item \({ }^{\mathrm{p} 734}\). Each item \({ }^{\mathrm{p} 734}\) can have item types \({ }^{\mathrm{p} 734}\), a global identifier \({ }^{\mathrm{p} 735}\) (if the vocabulary specified by the item types \({ }^{\text {p734 }}\) support global identifiers for items \({ }^{\text {p735 }}\) ), and a list of name-value pairs. Each name in the name-value pair is known as a property \({ }^{\mathrm{p} 739}\), and each property \({ }^{\mathrm{p} 739}\) has one or more values \({ }^{\mathrm{p} 738}\). Each value \({ }^{\mathrm{p} 738}\) is either a string or itself a group of name-value pairs (an item \({ }^{\text {p734 }}\) ). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

\subsection*{5.2.2 Items \(\S^{p 73}\)}

Every HTML element \({ }^{\text {p44 }}\) may have an itemscope attribute specified. The itemscope \({ }^{\text {p734 }}\) attribute is a boolean attribute \({ }^{\text {p67 }}\).
An element with the itemscope \({ }^{p 734}\) attribute specified creates a new item, a group of name-value pairs.

Elements with an itemscope \({ }^{\text {p734 }}\) attribute may have an itemtype attribute specified, to give the item types \({ }^{\text {p734 }}\) of the item \({ }^{\text {p734 }}\).
The itemtype \({ }^{\mathrm{p734}}\) attribute, if specified, must have a value that is an unordered set of unique space-separated tokens \({ }^{\mathrm{p87}}\), none of which are identical to another token and each of which is a valid URL string that is an absolute URL, and all of which are defined to use the same vocabulary. The attribute's value must have at least one token.

The item types of an item \({ }^{p 734}\) are the tokens obtained by splitting the element's itemtype attribute's value on ASCII whitespace. If the itemtype \({ }^{\mathrm{p} 734}\) attribute is missing or parsing it in this way finds no tokens, the item \({ }^{\mathrm{p} 734}\) is said to have no item types \({ }^{\mathrm{p} 734}\).

The item types \({ }^{\mathrm{p} 734}\) must all be types defined in applicable specifications \({ }^{\mathrm{p} 65}\) and must all be defined to use the same vocabulary.
Except if otherwise specified by that specification, the URLs given as the item types \({ }^{\mathrm{p} 734}\) should not be automatically dereferenced.

\section*{Note}

A specification could define that its item type \({ }^{\text {p734 }}\) can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given URL.

Item types \({ }^{\text {p734 }}\) are opaque identifiers, and user agents must not dereference unknown item types \({ }^{\text {p734 }}\), or otherwise deconstruct them, in order to determine how to process items \({ }^{\text {p734 }}\) that use them.

The itemtype \({ }^{\mathrm{p} 734}\) attribute must not be specified on elements that do not have an itemscope \({ }^{\mathrm{p} 734}\) attribute specified.

An item \({ }^{\mathrm{p} 734}\) is said to be a typed item when either it has an item type \({ }^{\mathrm{p} 734}\), or it is the value \({ }^{\mathrm{p} 738}\) of a property \({ }^{\mathrm{p} 739}\) of a typed item \({ }^{\mathrm{p} 735}\). The relevant types for a typed item \({ }^{\text {p735 }}\) is the item \({ }^{\text {p734's }}\) s item types \({ }^{\mathrm{p} 734}\), if it has any, or else is the relevant types \({ }^{\mathrm{p} 735}\) of the item \({ }^{\mathrm{p} 734}\) for which it is a property \({ }^{\mathrm{p} 739} \mathrm{~s}\) value \({ }^{\mathrm{p} 738}\).

Elements with an \(\underline{\text { itemscope }}{ }^{p 734}\) attribute and an \(\underline{\text { itemtype }}{ }^{\text {p734 }}\) attribute that references a vocabulary that is defined to support global identifiers for items may also have an itemid attribute specified, to give a global identifier for the item \({ }^{\mathrm{p} 34}\), so that it can be related to other items \({ }^{\text {p734 }}\) on pages elsewhere on the web.

The itemid \({ }^{p 735}\) attribute, if specified, must have a value that is a valid URL potentially surrounded by spaces \({ }^{\text {p88 }}\).
The global identifier of an item \({ }^{p 734}\) is the value of its element's itemid \(^{p 735}\) attribute, if it has one, parsed \({ }^{p 89}\) relative to the node document of the element on which the attribute is specified. If the itemid \({ }^{p 735}\) attribute is missing or if resolving it fails, it is said to have no global identifier \({ }^{p / 355}\).

The \(\underline{\text { itemid }^{p 735}}\) attribute must not be specified on elements that do not have both an \(\underline{\text { itemscope }}{ }^{\mathrm{p} 734}\) attribute and an \(\underline{\text { itemtype }}{ }^{\mathrm{p} 734}\) attribute specified, and must not be specified on elements with an itemscope \({ }^{\mathrm{p} 734}\) attribute whose \(\underline{i t e m t y p e}^{{ }^{\mathrm{p} 734}}\) attribute specifies a vocabulary that does not support global identifiers for items \({ }^{\text {p735 }}\), as defined by that vocabulary's specification.

The exact meaning of a global identifier \({ }^{\text {p735 }}\) is determined by the vocabulary's specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

Elements with an itemscope \({ }^{\text {p } 734}\) attribute may have an itemref attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the item \({ }^{\text {p734 }}\).

The itemref \({ }^{\text {p } 735}\) attribute, if specified, must have a value that is an unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) none of which are identical to another token and consisting of IDs of elements in the same tree.

The itemref \({ }^{\mathrm{p} 735}\) attribute must not be specified on elements that do not have an itemscope \({ }^{\mathrm{p} 734}\) attribute specified.

\section*{Note}

The itemref \({ }^{\text {p7355 }}\) attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a table so that each column defines a separate itemp \({ }^{\text {p734 }}\), while keeping the properties in the cells.

\section*{Example}

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:

\section*{product-code}

An integer that names the product in the manufacturer's catalog.
name
A brief description of the product.
scale
One of "HO", " 1 ", or "Z" (potentially with leading or trailing whitespace), indicating the scale of the product.
digital
If present, one of "Digital", "Delta", or "Systems" (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

\section*{track-type}

For track-specific products, one of "K", "M", "C" (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined item types \({ }^{\text {p734 }}\) :

\section*{https://md.example.com/loco}

Rolling stock with an engine

\section*{https://md.example.com/passengers}

Passenger rolling stock

\section*{https://md.example.com/track}

Track pieces

\section*{https://md.example.com/lighting}

Equipment with lighting
Each item \({ }^{\mathrm{p} 734}\) that uses this vocabulary can be given one or more of these types, depending on what the product is.
Thus, a locomotive might be marked up as:
```

<dl itemscope itemtype="https://md.example.com/loco
    https://md.example.com/lighting">
    <dt>Name:
    <dd itemprop="name">Tank Locomotive (DB 80)
    <dt>Product code:
    <dd itemprop="product-code">33041
    <dt>Scale:
    <dd itemprop="scale">HO
    <dt>Digital:
    <dd itemprop="digital">Delta
</dl>
```

A turnout lantern retrofit kit might be marked up as:
```

<dl itemscope itemtype="https://md.example.com/track
    https://md.example.com/lighting">
    <dt>Name:
    <dd itemprop="name">Turnout Lantern Kit
    <dt>Product code:
    <dd itemprop="product-code">74470
    <dt>Purpose:
    <dd>For retrofitting 2 <span itemprop="track-type">C</span> Track
    turnouts. <meta itemprop="scale" content="HO">
</dl>
```

A passenger car with no lighting might be marked up as:
```

<dl itemscope itemtype="https://md.example.com/passengers">
    <dt>Name:
    <dd itemprop="name">Express Train Passenger Car (DB Am 203)
    <dt>Product code:
    <dd itemprop="product-code">8710
    <dt>Scale:
    <dd itemprop="scale">Z
</dl>
```

Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

\subsection*{5.2.3 Names: the itemprop attribute \(\S^{\mathrm{p} 73}\)}

Every HTML element \({ }^{\text {p44 }}\) may have an itemprop \({ }^{\text {p736 }}\) attribute specified, if doing so adds one or more properties \({ }^{\text {p739 }}\) to one or more items \({ }^{\mathrm{p} 734}\) (as defined below).

The itemprop \({ }^{\text {p736 }}\) attribute, if specified, must have a value that is an unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) none of which
are identical to another token, representing the names of the name-value pairs that it adds. The attribute's value must have at least one token.

Each token must be either:
- If the item is a typed item \({ }^{\mathrm{p735}}\) : a defined property name allowed in this situation according to the specification that defines the relevant types \({ }^{\mathrm{p735}}\) for the item, or
- A valid URL string that is an absolute URL defined as an item property name allowed in this situation by a vocabulary specification, or
- A valid URL string that is an absolute URL, used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a typed item \({ }^{\text {p735 }}\) : a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification)

Specifications that introduce defined property names \({ }^{\text {p737 }}\) must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:), and no ASCII whitespace.

\section*{Note}

The rules above disallow U+003A COLON characters (:) in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. ASCII whitespace are disallowed because otherwise the values would be parsed as multiple tokens.

When an element with an itemprop \({ }^{\mathrm{p} 736}\) attribute adds a property \({ }^{\mathrm{p} 739}\) to multiple items \({ }^{\mathrm{p} 734}\), the requirement above regarding the tokens applies for each item \({ }^{\text {p734 }}\) individually.

The property names of an element are the tokens that the element's itemprop \({ }^{\mathrm{p} 736}\) attribute is found to contain when its value is split on ASCII whitespace, with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an item \({ }^{\text {p734 }}\), the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines the properties of an item \({ }^{\text {p739 }}\).

\section*{Example}

In the following example, the "a" property has the values "1" and "2", in that order, but whether the "a" property comes before the "b" property or not is not important:
```

<div itemscope>
    <p itemprop="a">1</p>
    <p itemprop="a">2</p>
    <p itemprop="b">test</p>
</div>
```

Thus, the following is equivalent:
```

<div itemscope>
    <p itemprop="b">test</p>
    <p itemprop="a">1</p>
    <p itemprop="a">2</p>
</div>
```

As is the following:
```

<div itemscope>
    <p itemprop="a">1</p>
    <p itemprop="b">test</p>
    <p itemprop="a">2</p>
</div>
```

And the following:
```

<div id="x">
    <p itemprop="a">1</p>
</div>
<div itemscope itemref="x">
    <p itemprop="b">test</p>
    <p itemprop="a">2</p>
</div>
```

\subsection*{5.2.4 Values \({ }_{8}{ }_{8}^{\text {p73 }}\)}

The property value of a name-value pair added by an element with an itemprop \({ }^{\text {p736 }}\) attribute is as given for the first matching case in the following list:
\(\leftrightarrow\) If the element also has an itemscope \({ }^{\text {p734 }}\) attribute
The value is the item \({ }^{\mathrm{p} 734}\) created by the element.
\(\hookrightarrow\) If the element is a meta \({ }^{\text {p164 }}\) element
The value is the value of the element's content \({ }^{p 165}\) attribute, if any, or the empty string if there is no such attribute.
\(\rightarrow\) If the element is an audio \({ }^{\text {p384 }}\), embed \({ }^{\text {p369 }}\), iframe \({ }^{\text {p361 }}\), img \({ }^{\text {p320 }}\), source \({ }^{\text {p317 }}\), track \({ }^{\text {p385 }}\), or video \({ }^{\text {p380 }}\) element The value is the resulting URL string \({ }^{\text {p89 }}\) that results from parsing \({ }^{\text {p89 }}\) the value of the element's src attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing \({ }^{\text {p89 }}\) it results in an error.
\(\leftrightarrow\) If the element is an \(a^{\text {p238 }}\), area \({ }^{\text {p443 }}\), or link \({ }^{\text {p157 }}\) element
The value is the resulting URL string \({ }^{\text {p89 }}\) that results from parsing \({ }^{\text {p89 }}\) the value of the element's href attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing \({ }^{\text {p89 }}\) it results in an error.
\(\rightarrow\) If the element is an object \({ }^{\text {p373 }}\) element
The value is the resulting URL string \({ }^{\text {p89 }}\) that results from parsing \({ }^{\text {p89 }}\) the value of the element's data attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing \({ }^{\mathrm{p89}}\) it results in an error.
\(\rightarrow\) If the element is a data \({ }^{\text {p259 }}\) element
The value is the value of the element's value \({ }^{\mathrm{p} 266}\) attribute, if it has one, or the empty string otherwise.
\(\rightarrow\) If the element is a meter \({ }^{p 557}\) element
The value is the value of the element's value \({ }^{p 558}\) attribute, if it has one, or the empty string otherwise.
\(\hookrightarrow\) If the element is a time \({ }^{\text {p260 }}\) element
The value is the element's datetime value \({ }^{\mathrm{p} 261}\).
\(\leftrightarrow\) Otherwise
The value is the element's descendant text content.
The URL property elements are the \(a^{\text {p238 }}\), area \({ }^{\text {p443 }}\), audio \({ }^{\text {p384 }}\), embed \(^{\text {p369 }}\), iframe \({ }^{\text {p361 }}\), img \({ }^{\text {p329 }}\), link \({ }^{\text {p157 }}\), object \(t^{\text {p373 }}\), source \({ }^{\text {p317 }}\), track \({ }^{p 385}\), and video \({ }^{\text {p380 }}\) elements.

If a property's value \({ }^{\text {p738 }}\), as defined by the property's definition, is an absolute URL, the property must be specified using a URL property element \({ }^{\mathrm{p} 738}\).

\section*{Note}

These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.

For example, a book about the first moon landing could be called "mission:moon". A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an a \({ }^{p 238}\) element, even though it looks like a URL. On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a URL, then the property would expect the title to be given in an a \({ }^{\text {p238 }}\) element (or one of the other URL property elements \({ }^{\text {p738 }}\) ), because of the requirement above.

\subsection*{5.2.5 Associating names with items \(\S^{p 73}\)}

To find the properties of an item defined by the element root, the user agent must run the following steps. These steps are also used to flag microdata errors \({ }^{\mathrm{p} 739}\).
1. Let results, memory, and pending be empty lists of elements.
2. Add the element root to memory.
3. Add the child elements of root, if any, to pending.
4. If root has an itemref \({ }^{\mathrm{p} 735}\) attribute, split the value of that itemref attribute on ASCII whitespace. For each resulting token ID, if there is an element in the tree of root with the ID ID, then add the first such element to pending.
5. While pending is not empty:
1. Remove an element from pending and let current be that element.
2. If current is already in memory, there is a microdata error \({ }^{\mathrm{p739}}\); continue.
3. Add current to memory.
4. If current does not have an itemscope \({ }^{\mathrm{p} 734}\) attribute, then: add all the child elements of current to pending.
5. If current has an itemprop \({ }^{\text {p736 }}\) attribute specified and has one or more property names \({ }^{\mathrm{p} 737}\), then add current to results.
6. Sort results in tree order.
7. Return results.

A document must not contain any items \({ }^{\mathrm{p} 734}\) for which the algorithm to find the properties of an item \({ }^{\mathrm{p} 739}\) finds any microdata errors.
An item \({ }^{\mathrm{p} 734}\) is a top-level microdata item if its element does not have an itemprop \({ }^{\mathrm{p} 736}\) attribute.
All itemref \(f^{p 735}\) attributes in a Document \({ }^{\text {p114 }}\) must be such that there are no cycles in the graph formed from representing each item \({ }^{\text {p734 }}\) in the Document \({ }^{\text {p114 }}\) as a node in the graph and each property \({ }^{\mathrm{p} 739}\) of an item whose value \({ }^{\mathrm{p} 738}\) is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an itemprop \({ }^{p 736}\) attribute that would not be found to be a property of any of the items \({ }^{\mathrm{p} 734}\) in that document were their properties \({ }^{\mathrm{p} 739}\) all to be determined.

\section*{Example}

In this example, a single license statement is applied to two works, using itemref \({ }^{\mathrm{p} 735}\) from the items representing the works:
```

<!DOCTYPE HTML>

<html lang="en">
    <head>
    <title>Photo gallery</title>
        </head>
        <body>
        <h1>My photos</h1>
        <figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
        <img itemprop="work" src="images/house.jpeg" alt="A white house, boarded up, sits in a forest.">
        <figcaption itemprop="title">The house I found.</figcaption>
```
```
    </figure>
    <figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
    <img itemprop="work" src="images/mailbox.jpeg" alt="Outside the house is a mailbox. It has a
leaflet inside.">
    <figcaption itemprop="title">The mailbox.</figcaption>
    </figure>
    <footer>
        <p id="licenses">All images licensed under the <a itemprop="license"
        href="http://www.opensource.org/licenses/mit-license.php">MIT
        license</a>.</p>
    </footer>
    </body>
</html>
```

The above results in two items with the type "http://n.whatwg.org/work", one with:
```

work
images/house.jpeg
title
The house I found.
license
http://www.opensource.org/licenses/mit-license.php
...and one with:

```

\section*{work}
```

    images/mailbox.jpeg
    title
The mailbox.

```

\section*{license}
```

http://www.opensource.org/licenses/mit-license.php

```

\subsection*{5.2.6 Microdata and other namespaces \(\S^{p 74}\)}

Currently, the itemscope \({ }^{\mathrm{p734}}\), itemprop \({ }^{\mathrm{p} 736}\), and other microdata attributes are only defined for HTML elements \({ }^{\text {p44 }}\). This means that attributes with the literal names "itemscope", "itemprop", etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.

\section*{Example}

Thus, in the following example there is only one item, not two.
```

<p itemscope></p> <!-- this is an item (with no properties and no type) -->
<svg itemscope></svg> <!-- this is not, it's just an SVG svg element with an invalid unknown
attribute -->
```

\subsection*{5.3 Sample microdata vocabularies \(\S^{p 74}\)}

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

\subsection*{5.3.1 vCard \(\S^{p 74}\)}

An item with the item type \({ }^{\mathrm{p} 734}\) http://microformats.org/profile/hcard represents a person's or organization's contact information.
This vocabulary does not support global identifiers for items \({ }^{\mathrm{p} 735}\).
The following are the type's defined property names \({ }^{\mathrm{p} 737}\). They are based on the vocabulary defined in vCard Format Specification ( \(v\) Card) and its extensions, where more information on how to interpret the values can be found. [RFC6350] \({ }^{\text {p1291 }}\)
kind
Describes what kind of contact the item represents.
The value \({ }^{\mathrm{p} 738}\) must be text that is identical to one of the kind strings \({ }^{\mathrm{p} 748}\).
A single property with the name kind \({ }^{p 741}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/ hcard \({ }^{p 741}\).
fn
Gives the formatted text corresponding to the name of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
Exactly one property with the name \(f n^{p 741}\) must be present within each item \(^{p 734}\) with the type http://microformats.org/profile/ hcard \({ }^{\text {p741 }}\).
n
Gives the structured name of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be an item \({ }^{\mathrm{p734}}\) with zero or more of each of the family-name \({ }^{\mathrm{p741}}\), given-name \({ }^{\mathrm{p} 741}\), additional-name \({ }^{\mathrm{p} 741}\),
honorific-prefix \({ }^{\text {p741 }}\), and honorific-suffix \({ }^{\text {p742 }}\) properties.
Exactly one property with the name \(\underline{n}^{p 741}\) must be present within each \(\underline{i^{p 734}}\) with the type http://microformats.org/profile/ hcard \({ }^{p 741}\).
family-name (inside \(n^{p 741}\) )
Gives the family name of the person, or the full name of the organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name family-name \({ }^{\mathrm{p} 741}\) may be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of the \(\underline{n}^{\mathrm{p} 741}\) property of an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\).
given-name (inside \(n^{\text {p741 }}\) )
Gives the given-name of the person.
The value \({ }^{\text {p738 }}\) must be text.
Any number of properties with the name given-name \({ }^{\mathrm{p} 741}\) may be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of the \(\underline{\mathrm{n}^{\mathrm{p} 741}}\) property of an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\).
additional-name (inside \(n^{\text {p741 }}\) )
Gives the any additional names of the person.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name additional-name \({ }^{p 741}\) may be present within the item \({ }^{\text {p734 }}\) that forms the value \({ }^{\mathrm{p} 738}\) of the \(\underline{n}^{\mathrm{p} 741}\) property of an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\).
honorific-prefix (inside \(n^{\mathrm{p} 741}\) )
Gives the honorific prefix of the person.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name honorific-prefix \({ }^{\text {p741 }}\) may be present within the item \({ }^{\text {p734 }}\) that forms the value \({ }^{p 738}\) of the
\(\underline{n^{\mathrm{p} 741}}\) property of an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\).
honorific-suffix (inside \(\underline{n}^{\mathrm{p} 74 \mathrm{l}}\) )
Gives the honorific suffix of the person.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name honorific-suffix \({ }^{p 742}\) may be present within the item \({ }^{\text {p734 }}\) that forms the value \({ }^{p 738}\) of the \(\underline{n}^{\mathrm{p} 741}\) property of an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\).
nickname
Gives the nickname of the person or organization.

\section*{Note}

The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the \(\mathrm{fn}^{\mathrm{p741}}\) or \(\mathrm{n}^{\text {p741 }}\) properties.

The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name nickname \({ }^{p 742}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
photo
Gives a photograph of the person or organization.
The value \({ }^{\text {p738 }}\) must be an absolute URL.
Any number of properties with the name photo \({ }^{p 742}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
bday
Gives the birth date of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be a valid date string \({ }^{\mathrm{p} 74}\).
A single property with the name bday \({ }^{p 742}\) may be present within each item \({ }^{\text {p734 }}\) with the type \(h t t p: / / m i c r o f o r m a t s . o r g / p r o f i l e / ~\) hcard \({ }^{p 741}\).
anniversary
Gives the birth date of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be a valid date string \({ }^{\mathrm{p} 74}\).
A single property with the name anniversary \({ }^{\mathrm{p} 742}\) may be present within each \(\mathrm{item}^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcard \({ }^{p 741}\).
sex
Gives the biological sex of the person.
The value \({ }^{\mathrm{p} 738}\) must be one of \(F\), meaning "female", \(M\), meaning "male", \(N\), meaning "none or not applicable", 0 , meaning "other", or U , meaning "unknown".

A single property with the name sex \({ }^{\text {p742 }}\) may be present within each \(i t e m^{p 734}\) with the type http://microformats.org/profile/ hcard \({ }^{\text {p741 }}\).
gender-identity
Gives the gender identity of the person.
The value \({ }^{\mathrm{p} 738}\) must be text.
A single property with the name gender-identity \({ }^{\text {p742 }}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).

Gives the delivery address of the person or organization.
The value \({ }^{p 738}\) must be an item \({ }^{p 734}\) with zero or more type \({ }^{p 743}\), post-office-box \({ }^{p 743}\), extended-address \({ }^{p 743}\), and street-address \({ }^{p 743}\) properties, and optionally a locality \({ }^{p 743}\) property, optionally a region \({ }^{p 743}\) property, optionally a postal-code \({ }^{p 744}\) property, and optionally a country-name \({ }^{p 744}\) property.

If no type \({ }^{p 743}\) properties are present within an item \({ }^{p 734}\) that forms the value \({ }^{p 738}\) of an adr \(r^{p 743}\) property of an item \({ }^{p 734}\) with the type http://microformats.org/profile/hcard \({ }^{p 741}\), then the address type string \({ }^{p 748} \underline{\text { work }}^{\text {p748 }}\) is implied.

Any number of properties with the name \(\underline{a d r^{p 743}}\) may be present within each \(\underline{\operatorname{tem}^{p 734}}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
type (inside adr \({ }^{p 743}\) )
Gives the type of delivery address.

The value \({ }^{\mathrm{p} 738}\) must be text that is identical to one of the address type strings \({ }^{\mathrm{p} 748}\).
Any number of properties with the name \(t y p e^{{ }^{\mathrm{p} 743}}\) may be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of an adr \(\mathrm{r}^{\mathrm{p773}}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\), but within each such adr \({ }^{p 773}\) property item \({ }^{\text {p734 }}\) there must only be one type \({ }^{\text {p743 }}\) property per distinct value.
post-office-box (inside adr \({ }^{p 743}\) )
Gives the post office box component of the delivery address of the person or organization.
The value \({ }^{\text {p738 }}\) must be text.

Any number of properties with the name post-office-box \({ }^{\text {p743 }}\) may be present within the item \({ }^{\text {p734 }}\) that forms the value \({ }^{\text {p738 }}\) of an adr \(r^{p 743}\) property of an item \({ }^{p 734}\) with the type http://microformats.org/profile/hcard \({ }^{p 741}\).

\section*{Note}
vCard urges authors not to use this field.
extended-address (inside adr \({ }^{p 743}\) )
Gives an additional component of the delivery address of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.

Any number of properties with the name extended-address \({ }^{p 743}\) may be present within the item \({ }^{p 734}\) that forms the value \({ }^{p 738}\) of an adr \(r^{p 743}\) property of an item \({ }^{p 734}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).

Note
vCard urges authors not to use this field.
street-address (inside adr \({ }^{p 743}\) )
Gives the street address component of the delivery address of the person or organization.
The value \({ }^{p 738}\) must be text.

Any number of properties with the name street-address \({ }^{p 743}\) may be present within the item \({ }^{p 734}\) that forms the value \({ }^{p 738}\) of an adr \(r^{p 743}\) property of an item \({ }^{p 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\).
locality (inside adr \({ }^{p 743}\) )
Gives the locality component (e.g. city) of the delivery address of the person or organization.

The value \({ }^{p 738}\) must be text.
A single property with the name locality \({ }^{p 743}\) may be present within the item \({ }^{p 734}\) that forms the value \({ }^{p 738}\) of an adr \({ }^{p 743}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
region (inside adr \({ }^{p 743}\) )
Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The value \({ }^{\mathrm{p} 738}\) must be text.
A single property with the name region \({ }^{p 743}\) may be present within the \(\underline{i^{p}{ }^{p 734}}\) that forms the value \({ }^{\mathrm{p738}}\) of an \(\underline{a^{p d r}}{ }^{p 743}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
postal-code (inside adr \({ }^{p 743}\) )
Gives the postal code component of the delivery address of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
A single property with the name postal-code \({ }^{\mathrm{p} 744}\) may be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of an adr \(r^{\mathrm{p743}}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
country-name (inside adr \({ }^{\text {p743 }}\) )
Gives the country name component of the delivery address of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
A single property with the name country-name \({ }^{p 744}\) may be present within the item \({ }^{p 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of an adr \({ }^{\mathrm{p} 743}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
tel
Gives the telephone number of the person or organization.
The value \({ }^{\text {p738 }}\) must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E. 163 and X.121, or an \(\underline{t t e m}{ }^{\text {p734 }}\) with zero or more type \({ }^{\text {p744 }}\) properties and exactly one value \({ }^{\text {p744 }}\) property. [E163] \(]^{\text {p1287 }}[X 121]^{\text {p1292 }}\)

If no type \({ }^{\mathrm{p} 744}\) properties are present within an item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p738}}\) of a \(\mathrm{tel}^{\mathrm{p} 744}\) property of an item \({ }^{\mathrm{p734}}\) with the type http://microformats.org/profile/hcard \({ }^{p 741}\), or if the value \({ }^{\mathrm{p738}}\) of such a \(t e l^{\mathrm{p744}}\) property is text, then the telephone type string \({ }^{\text {p748 }}\) voice \({ }^{\text {p748 }}\) is implied.

Any number of properties with the name \(\underline{t^{p} l^{p 744}}\) may be present within each item \(^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
type (inside tel \({ }^{\mathrm{p} 744}\) )
Gives the type of telephone number.
The value \({ }^{\mathrm{p} 738}\) must be text that is identical to one of the telephone type strings \({ }^{\mathrm{p} 748}\).
Any number of properties with the name type \({ }^{p 744}\) may be present within the item \({ }^{p 734}\) that forms the value \({ }^{\mathrm{p738}}\) of a \(\mathrm{te}^{\mathrm{p} 744}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\), but within each such tel \({ }^{\text {p744 }}\) property item \({ }^{\text {p734 }}\) there must only be one type \({ }^{\text {p744 }}\) property per distinct value.
value (inside tel \({ }^{p 744}\) )
Gives the actual telephone number of the person or organization.
The value \({ }^{\text {p738 }}\) must be text that can be interpreted as a telephone number as defined in the CCITT specifications E. 163 and X.121. \([\mathrm{E} 163]^{\text {p1287 }}[\mathrm{X} 121]^{\text {p1292 }}\)

Exactly one property with the name value \({ }^{\mathrm{p} 744}\) must be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of a tel \({ }^{\mathrm{p} 744}\) property of an item \({ }^{p 734}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
email
Gives the email address of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name email \({ }^{p 744}\) may be present within each \(\underline{\text { item }^{p 734}}\) with the type \(\underline{h t t p: / / m i c r o f o r m a t s . o r g / ~}\) profile/hcard \({ }^{\text {p741 }}\).

\section*{impp}

Gives a URL for instant messaging and presence protocol communications with the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.

Any number of properties with the name impp \({ }^{p 744}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
lang
Gives a language understood by the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be a valid BCP 47 language tag. \([\mathrm{BCP} 47]^{\mathrm{p} 1285}\).
Any number of properties with the name lang \({ }^{p 745}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
tz
Gives the time zone of the person or organization.
The value \({ }^{\text {p738 }}\) must be text and must match the following syntax:
1. Either a U+002B PLUS SIGN character \((+)\) or a U+002D HYPHEN-MINUS character (-).
2. A valid non-negative integer \({ }^{p 69}\) that is exactly two digits long and that represents a number in the range \(00 . .23\).
3. \(A \cup+003 A\) COLON character (:).
4. A valid non-negative integer \({ }^{\text {p69 }}\) that is exactly two digits long and that represents a number in the range \(00 . .59\).

Any number of properties with the name \(\underline{t z^{p 745}}\) may be present within each \(\underline{i t e m}{ }^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).

Gives the geographical position of the person or organization.
The value \({ }^{\text {p738 }}\) must be text and must match the following syntax:
1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. \(\mathrm{A} U+003 \mathrm{~B}\) SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk \(\left({ }^{*}\right)\) should be included, and should have six digits each.

\section*{Note}

The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

Any number of properties with the name geo \({ }^{p 745}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
title
Gives the job title, functional position or function of the person or organization.
The value \({ }^{\text {p738 }}\) must be text.
Any number of properties with the name title \({ }^{\mathrm{p745}}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
role
Gives the role, occupation, or business category of the person or organization.

The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name role \({ }^{\mathrm{p} 745}\) may be present within each \(\underline{i t e m}{ }^{\mathrm{p} 734}\) with the type \(\underline{h t t p}: / / \mathrm{microformats} . \operatorname{org} /\) profile/hcard \({ }^{\mathrm{p741}}\).
logo
Gives the logo of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
Any number of properties with the name logo \({ }^{\mathrm{p} 746}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
agent
Gives the contact information of another person who will act on behalf of the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be either an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p} 741}\), or an absolute URL, or text.
Any number of properties with the name agent \({ }^{p 746}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
org
Gives the name and units of the organization.
The value \({ }^{\mathrm{p} 738}\) must be either text or an item \({ }^{\mathrm{p} 734}\) with one organization-name \({ }^{\mathrm{p} 746}\) property and zero or more organization-unit \({ }^{\mathrm{p746}}\) properties.

Any number of properties with the name org \({ }^{p 746}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
organization-name (inside org \({ }^{\text {p746 }}\) )
Gives the name of the organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
Exactly one property with the name organization-name \({ }^{\mathrm{p} 746}\) must be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of an org \(^{\mathrm{p} 746}\) property of an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p} 741}\).
organization-unit (inside org \({ }^{\text {p746 }}\) )
Gives the name of the organization unit.
The value \({ }^{\text {p738 }}\) must be text.
Any number of properties with the name organization-unit \({ }^{\mathrm{p746}}\) may be present within the item \({ }^{\mathrm{p734}}\) that forms the value \({ }^{\mathrm{p} 738}\) of the org \(^{\mathrm{p746}}\) property of an item \({ }^{\mathrm{p734}}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
member
Gives a URL that represents a member of the group.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
Any number of properties with the name member \({ }^{\mathrm{p746}}\) may be present within each item \({ }^{\mathrm{p734}}\) with the type http://microformats.org/ profile/hcard \({ }^{\mathrm{p741}}\) if the \(\underline{i t e m}^{\mathrm{p} 734}\) also has a property with the name kind \(^{\mathrm{p741}}\) whose value is "group \({ }^{\mathrm{p748}}\) ".
related
Gives a relationship to another entity.
The value \({ }^{\mathrm{p} 738}\) must be an item \({ }^{\mathrm{p} 734}\) with one \(u \mathrm{rl}^{\mathrm{p} 746}\) property and one ret \({ }^{\mathrm{p747}}\) properties.
Any number of properties with the name related \({ }^{\mathrm{p} 746}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
url (inside related \({ }^{\text {p746 }}\) )
Gives the URL for the related entity.

The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
Exactly one property with the name url \({ }^{\mathrm{p} 746}\) must be present within the \(\underline{\operatorname{item}^{\mathrm{p} 734}}\) that forms the value \({ }^{\mathrm{p} 738}\) of a related \({ }^{\mathrm{p} 746}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
rel (inside related \({ }^{\text {p746 }}\) )
Gives the relationship between the entity and the related entity.
The value \({ }^{\mathrm{p} 738}\) must be text that is identical to one of the relationship strings \({ }^{\mathrm{p} 748}\).
Exactly one property with the name rel \({ }^{\mathrm{p} 747}\) must be present within the item \({ }^{\mathrm{p} 734}\) that forms the value \({ }^{\mathrm{p} 738}\) of a related \({ }^{\mathrm{p} 746}\) property of an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
categories
Gives the name of a category or tag that the person or organization could be classified as.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name categories \({ }^{\text {p747 }}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/hcard \({ }^{\text {p741 }}\).
note
Gives supplemental information or a comment about the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name note \({ }^{\mathrm{p} 747}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
rev
Gives the revision date and time of the contact information.
The value \({ }^{\mathrm{p} 738}\) must be text that is a valid global date and time string \({ }^{\mathrm{p} 79}\).

\section*{Note}

The value distinguishes the current revision of the information for other renditions of the information.

Any number of properties with the name rev \({ }^{\mathrm{p747}}\) may be present within each item \({ }^{\mathrm{p734}}\) with the type \(\mathrm{http}: / / \mathrm{microformats} . \mathrm{org} /\) profile/hcard \({ }^{\text {p741 }}\).
sound
Gives a sound file relating to the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
Any number of properties with the name sound \({ }^{p 747}\) may be present within each item \(^{\mathrm{p734}}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).
uid
Gives a globally unique identifier corresponding to the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be text.
A single property with the name uid \({ }^{p 747}\) may be present within each \(\underline{i t e m^{p 734}}\) with the type http://microformats.org/profile/ hcard \({ }^{p 741}\).
url
Gives a URL relating to the person or organization.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
Any number of properties with the name url \({ }^{p 747}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\).

The kind strings are:
individual
Indicates a single entity (e.g. a person).
group
Indicates multiple entities (e.g. a mailing list).
org
Indicates a single entity that is not a person (e.g. a company).
location
Indicates a geographical place (e.g. an office building).
The address type strings are:
home
Indicates a delivery address for a residence.
work
Indicates a delivery address for a place of work.
The telephone type strings are:
home
Indicates a residential number.
work
Indicates a telephone number for a place of work.
text
Indicates that the telephone number supports text messages (SMS).
voice
Indicates a voice telephone number.
fax
Indicates a facsimile telephone number.
cell
Indicates a cellular telephone number.
video
Indicates a video conferencing telephone number.
pager
Indicates a paging device telephone number.
textphone
Indicates a telecommunication device for people with hearing or speech difficulties.
The relationship strings are:
emergency
An emergency contact.
agent
Another entity that acts on behalf of this entity.
```
contact
acquaintance
friend
met
worker
colleague
resident
neighbor
child
parent
sibling
spouse
kin
muse
crush
date
sweetheart
me
Has the meaning defined in XFN. [XFN] [1292
```

\subsection*{5.3.1.1 Conversion to vCard \(\S^{p 74}\)}

Given a list of nodes nodes in a Document \({ }^{\text {p114 }}\), a user agent must run the following algorithm to extract any vCard data represented by those nodes (only the first vCard is returned):
1. If none of the nodes in nodes are items \({ }^{\mathrm{p} 734}\) with the item type \({ }^{\mathrm{p734}}\) http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\), then there is no vCard. Abort the algorithm, returning nothing.
2. Let node be the first node in nodes that is an item \({ }^{p 734}\) with the item type \({ }^{p 734}\) http://microformats.org/profile/hcard \({ }^{p 741}\).
3. Let output be an empty string.
4. Add a vCard line \({ }^{p 751}\) with the type "BEGIN" and the value "VCARD" to output.
5. Add a vCard line \({ }^{\text {p751 }}\) with the type "PROFILE" and the value "VCARD" to output.
6. Add a vCard line \({ }^{p 751}\) with the type "VERSION" and the value "4.0" to output
7. Add a vCard line \({ }^{\mathrm{p} 751}\) with the type "SOURCE" and the result of escaping the vCard text string \({ }^{\mathrm{p} 752}\) that is the document's URL as the value to output.
8. If the title element \({ }^{\mathrm{pl17}}\) is not null, add a vCard line \({ }^{\mathrm{p} 751}\) with the type "NAME" and with the result of escaping the vCard text string \({ }^{\text {p752 }}\) obtained from the the title element \({ }^{p 117}\) 's descendant text content as the value to output.
9. Let sex be the empty string.
10. Let gender-identity be the empty string.
11. For each element element that is a property of the item \({ }^{\text {p739 }}\) node: for each name name in element's property names \({ }^{\text {p737 }}\), run the following substeps:
1. Let parameters be an empty set of name-value pairs.
2. Run the appropriate set of substeps from the following list. The steps will set a variable value, which is used in the next step.

If the property's value \({ }^{\mathrm{p} 738}\) is an item \({ }^{\mathrm{p} 734}\) subitem and name is \(\underline{n}^{\mathrm{p} 741}\)
1. Let value be the empty string.
2. Append to value the result of collecting the first vCard subproperty \({ }^{p 752}\) named family-name \({ }^{p 741}\) in subitem.
3. Append a U+003B SEMICOLON character (;) to value.
4. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named given-name \({ }^{\mathrm{p} 741}\) in subitem.
5. Append a U+003B SEMICOLON character (;) to value.
6. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named additional-name \({ }^{\mathrm{p} 741}\) in subitem.
7. Append a U+003B SEMICOLON character (;) to value.
8. Append to value the result of collecting the first vCard subproperty \({ }^{p 752}\) named honorific-prefix \({ }^{p 741}\) in subitem.
9. Append a U+003B SEMICOLON character (;) to value.
10. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named honorific-suffix \({ }^{\mathrm{p} 742}\) in subitem.

If the property's value \({ }^{\text {p738 }}\) is an item \({ }^{\text {p734 }}\) subitem and name is adr \({ }^{p 743}\)
1. Let value be the empty string.
2. Append to value the result of collecting vCard subproperties \({ }^{p 752}\) named post-office-box \({ }^{p 743}\) in subitem.
3. Append a U+003B SEMICOLON character (;) to value.
4. Append to value the result of collecting vCard subproperties \({ }^{\text {p752 }}\) named extended-address \({ }^{\text {p743 }}\) in subitem.
5. Append a U+003B SEMICOLON character (;) to value.
6. Append to value the result of collecting vCard subproperties \({ }^{p 752}\) named street-address \({ }^{\mathrm{p} 743}\) in subitem.
7. Append a U+003B SEMICOLON character (;) to value.
8. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named locality \({ }^{\mathrm{p} 743}\) in subitem.
9. Append a U+003B SEMICOLON character (;) to value.
10. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named region \({ }^{\mathrm{p} 743}\) in subitem.
11. Append a U+003B SEMICOLON character (;) to value.
12. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named postal-code \({ }^{\mathrm{p744}}\) in subitem.
13. Append a U+003B SEMICOLON character (;) to value.
14. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p752}}\) named country-name \({ }^{\mathrm{p} 744}\) in subitem.
15. If there is a property named \(t y p e^{\mathrm{p} 743}\) in subitem, and the first such property has a value \({ }^{\mathrm{p} 738}\) that is not an item \({ }^{\text {p734 }}\) and whose value consists only of ASCII alphanumerics, then add a parameter named "TYPE" whose value is the value \({ }^{\text {p738 }}\) of that property to parameters.

If the property's value \({ }^{\text {p738 }}\) is an item \({ }^{\text {p734 }}\) subitem and name is org \({ }^{\text {p746 }}\)
1. Let value be the empty string.
2. Append to value the result of collecting the first vCard subproperty \({ }^{\mathrm{p} 752}\) named organization-name \({ }^{\mathrm{p} 746}\) in subitem.
3. For each property named organization-unit \({ }^{\mathrm{p} 746}\) in subitem, run the following steps:
1. If the value \({ }^{\mathrm{p} 738}\) of the property is an item \({ }^{\mathrm{p} 734}\), then skip this property.
2. Append a U+003B SEMICOLON character (;) to value.
3. Append the result of escaping the vCard text string \({ }^{\mathrm{p} 752}\) given by the value \({ }^{\mathrm{p} 738}\) of the property to value.

If the property's value \({ }^{\mathrm{p} 738}\) is an item \({ }^{\mathrm{p} 734}\) subitem with the item type \({ }^{\mathrm{p734}}\) http://microformats.org/ profile/hcard \({ }^{\text {p741 }}\) and name is related \({ }^{\text {p746 }}\)
1. Let value be the empty string.
2. If there is a property named \(u r l^{p 746}\) in subitem, and its element is a URL property element \({ }^{p 738}\), then append the result of escaping the vCard text string \({ }^{\mathrm{p752}}\) given by the value \({ }^{\mathrm{p738}}\) of the first such property to value, and add a parameter with the name "VALUE" and the value "URI" to parameters.
3. If there is a property named \(\mathrm{rel}^{\mathrm{p} 747}\) in subitem, and the first such property has a value \({ }^{\mathrm{p738}}\) that is not an item \({ }^{\text {p734 }}\) and whose value consists only of ASCII alphanumerics, then add a parameter named "RELATION" whose value is the value \({ }^{\text {p738 }}\) of that property to parameters.

\section*{If the property's value \({ }^{\text {p738 }}\) is an item \({ }^{\text {p734 }}\) and name is none of the above}
1. Let value be the result of collecting the first vCard subproperty \({ }^{p 752}\) named value in subitem.
2. If there is a property named type in subitem, and the first such property has a value \({ }^{\text {p738 }}\) that is not an item \({ }^{\text {p734 }}\) and whose value consists only of ASCII alphanumeric, then add a parameter named "TYPE" whose value is the value \({ }^{\text {p738 }}\) of that property to parameters.

If the property's value \({ }^{\text {p738 }}\) is not an item \({ }^{\text {p734 }}\) and its name is sex \({ }^{p 742}\)
If this is the first such property to be found, set sex to the property's value \({ }^{p 738}\).
If the property's value \({ }^{\text {p738 }}\) is not an item \({ }^{\text {p734 }}\) and its name is gender-identity \({ }^{\text {p742 }}\)
If this is the first such property to be found, set gender-identity to the property's value \({ }^{\text {p738 }}\).

\section*{Otherwise (the property's value \({ }^{\text {p738 }}\) is not an item \({ }^{\text {p734 }}\) )}
1. Let value be the property's value \({ }^{\text {p738 }}\).
2. If element is one of the URL property elements \({ }^{\text {p738 }}\), add a parameter with the name "VALUE" and the value "URI" to parameters.
3. Otherwise, if name is bday \({ }^{\mathrm{p} 742}\) or anniversary \({ }^{\mathrm{p} 742}\) and the value is a valid date string \({ }^{\mathrm{p} 74}\), add a parameter with the name "VALUE" and the value "DATE" to parameters.
4. Otherwise, if name is \(\mathrm{rev}^{\mathrm{p} 747}\) and the value is a valid global date and time string \({ }^{\mathrm{p} 79}\), add a parameter with the name "VALUE" and the value "DATE-TIME" to parameters.
5. Prefix every U+005C REVERSE SOLIDUS character ( \((\) ) in value with another U+005C REVERSE SOLIDUS character ( \ ).
6. Prefix every U+002C COMMA character (,) in value with a U+005C REVERSE SOLIDUS character ( \((\) ).
7. Unless name is geo \({ }^{\text {p745 }}\), prefix every \(U+003 B\) SEMICOLON character (;) in value with a \(U+005 C\) REVERSE SOLIDUS character ()).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in value with a U+005C REVERSE SOLIDUS character ( \((\mathrm{l})\) followed by a U+006E LATIN SMALL LETTER \(N\) character ( n ).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character ( \((1)\) followed by a U+006E LATIN SMALL LETTER \(N\) character ( n ).
3. Add a vCard line \({ }^{\mathrm{p} 751}\) with the type name, the parameters parameters, and the value value to output.
12. If either sex or gender-identity has a value that is not the empty string, add a vCard line \({ }^{\mathrm{p} 751}\) with the type "GENDER" and the value consisting of the concatenation of sex, a U+003B SEMICOLON character (;), and gender-identity to output.
13. Add a vCard line \({ }^{\mathrm{p} 751}\) with the type "END" and the value "VCARD" to output.

When the above algorithm says that the user agent is to add a vCard line consisting of a type type, optionally some parameters, and a value value to a string output, it must run the following steps:
1. Let line be an empty string.
2. Append type, converted to ASCII uppercase, to line.
3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:
1. Append a U+003B SEMICOLON character (;) to line.
2. Append the parameter's name to line.
3. Append a U+003D EQUALS SIGN character (=) to line.
4. Append the parameter's value to line.
4. Append a U+003A COLON character (:) to line.
5. Append value to line.
6. Let maximum length be 75 .
7. While line's code point length is greater than maximum length:
1. Append the first maximum length code points of line to output.
2. Remove the first maximum length code points from line.
3. Append a U+000D CARRIAGE RETURN character (CR) to output.
4. Append a U+000A LINE FEED character (LF) to output.
5. Append a U+0020 SPACE character to output.
6. Let maximum length be 74 .
8. Append (what remains of) line to output.
9. Append a U+000D CARRIAGE RETURN character (CR) to output.
10. Append a U+000A LINE FEED character (LF) to output.

When the steps above require the user agent to obtain the result of collecting vCard subproperties named subname in subitem, the user agent must run the following steps:
1. Let value be the empty string.
2. For each property named subname in the item subitem, run the following substeps:
1. If the value \({ }^{\mathrm{p} 738}\) of the property is itself an item \({ }^{\mathrm{p} 734}\), then skip this property.
2. If this is not the first property named subname in subitem (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to value.
3. Append the result of escaping the vCard text string \({ }^{\mathrm{p} 752}\) given by the value \({ }^{\mathrm{p} 738}\) of the property to value.
3. Return value.

When the steps above require the user agent to obtain the result of collecting the first vCard subproperty named subname in subitem, the user agent must run the following steps:
1. If there are no properties named subname in subitem, then return the empty string.
2. If the value \({ }^{\mathrm{p} 738}\) of the first property named subname in subitem is an item \({ }^{\mathrm{p} 734}\), then return the empty string.
3. Return the result of escaping the vCard text string \({ }^{\mathrm{p} 752}\) given by the value \({ }^{\mathrm{p} 738}\) of the first property named subname in subitem.

When the above algorithms say the user agent is to escape the vCard text string value, the user agent must use the following steps:
1. Prefix every U+005C REVERSE SOLIDUS character ( () in value with another U+005C REVERSE SOLIDUS character ( \((\) ).
2. Prefix every U+002C COMMA character (,) in value with a U+005C REVERSE SOLIDUS character ( () .
3. Prefix every U+003B SEMICOLON character (;) in value with a U+005C REVERSE SOLIDUS character ( \((\) ).
4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in value with a U+005C REVERSE SOLIDUS character ( \(\backslash\) ) followed by a U+006E LATIN SMALL LETTER \(N\) character ( n ).
5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character ( \ ) followed by a U+006E LATIN SMALL LETTER N character ( n ).
6. Return the mutated value.

\section*{Note}

This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the http://microformats.org/profile/hcard \({ }^{\text {p741 }}\) item type \({ }^{\text {p734 }}\) and defined property names \({ }^{\text {p737 }}\).

\subsection*{5.3.1.2 Examples \(\mathbb{\S}^{\text {p75 }}\)}

This section is non-normative.

\section*{Example}

Here is a long example vCard for a fictional character called "Jack Bauer":
```
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
    <h1 itemprop="fn">
        <span itemprop="n" itemscope>
        <span itemprop="given-name">Jack</span>
        <span itemprop="family-name">Bauer</span>
        </span>
    </h1>
    <img itemprop="photo" alt="" src="jack-bauer.jpg">
    <p itemprop="org" itemscope>
        <span itemprop="organization-name">Counter-Terrorist Unit</span>
        (<span itemprop="organization-unit">Los Angeles Division</span>)
        </p>
        <p>
        <span itemprop="adr" itemscope>
        <span itemprop="street-address">10201 W. Pico Blvd.</span><br>
        <span itemprop="locality">Los Angeles</span>,
        <span itemprop="region">CA</span>
        <span itemprop="postal-code">90064</span><br>
        <span itemprop="country-name">United States</span><br>
        </span>
        <span itemprop="geo">34.052339;-118.410623</span>
        </p>
        <h2>Assorted Contact Methods</h2>
        <ul>
        <li itemprop="tel" itemscope>
        <span itemprop="value">+1 (310) 597 3781</span> <span itemprop="type">work</span>
        <meta itemprop="type" content="voice">
        </li>
        <li><a itemprop="url" href="https://en.wikipedia.org/wiki/Jack_Bauer">I'm on Wikipedia</a>
        so you can leave a message on my user talk page.</li>
        <li><a itemprop="url" href="http://www.jackbauerfacts.com/">Jack Bauer Facts</a></li>
        <li itemprop="email"><a
    href="mailto:j.bauer@la.ctu.gov.invalid">j.bauer@la.ctu.gov.invalid</a></li>
<li itemprop="tel" itemscope>
<span itemprop="value">+1 (310) 555 3781</span> <span>
<meta itemprop="type" content="cell">mobile phone</span>
</li>
</ul>
<ins datetime="2008-07-20 21:00:00+01:00">

```
```

    <meta itemprop="rev" content="2008-07-20 21:00:00+01:00">
    <p itemprop="tel" itemscope><strong>Update!</strong>
    My new <span itemprop="type">home</span> phone number is
    <span itemprop="value">01632 960 123</span>.</p>
    </ins>
    </section>

```

The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

\section*{Example}

This example shows a site's contact details (using the address \({ }^{\text {p197 }}\) element) containing an address with two street components:
```

<address itemscope itemtype="http://microformats.org/profile/hcard">
    <strong itemprop="fn"><span itemprop="n" itemscope><span itemprop="given-name">Alfred</span>
    <span itemprop="family-name">Person</span></span></strong> <br>
    <span itemprop="adr" itemscope>
        <span itemprop="street-address">1600 Amphitheatre Parkway</span> <br>
        <span itemprop="street-address">Building 43, Second Floor</span> <br>
        <span itemprop="locality">Mountain View</span>,
        <span itemprop="region">CA</span> <span itemprop="postal-code">94043</span>
    </span>
</address>
```

\section*{Example}

The vCard vocabulary can be used to just mark up people's names:
```

<span itemscope itemtype="http://microformats.org/profile/hcard"
><span itemprop=fn><span itemprop="n" itemscope><span itemprop="given-name"
>George</span> <span itemprop="family-name">Washington</span></span
></span></span>

```

This creates a single item with a two name-value pairs, one with the name "fn" and the value "George Washington", and the other with the name " n " and a second item as its value, the second item having the two name-value pairs "given-name" and "familyname" with the values "George" and "Washington" respectively. This is defined to map to the following vCard:
```

BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOURCE:document's address
FN:George Washington
N:Washington;George;;;
END:VCARD

```

\subsection*{5.3.2 vEvent \(\S^{p 75}\)}

An item with the item type \({ }^{p 734}\) http://microformats.org/profile/hcalendar\#vevent represents an event.
This vocabulary does not support global identifiers for items \({ }^{\mathrm{p} 735}\).
The following are the type's defined property names \({ }^{\mathrm{p737}}\). They are based on the vocabulary defined in Internet Calendaring and Scheduling Core Object Specification (iCalendar), where more information on how to interpret the values can be found. [RFC5545] \({ }^{\text {p1290 }}\)

Note
Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar

\section*{instance.}

\section*{attach}

Gives the address of an associated document for the event.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
Any number of properties with the name attach \({ }^{\mathrm{p} 755}\) may be present within each \(\underline{i t e m}^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
categories
Gives the name of a category or tag that the event could be classified as.
The value \({ }^{\text {p738 }}\) must be text.
Any number of properties with the name categories \({ }^{p 755}\) may be present within each item \({ }^{\text {p734 }}\) with the type
http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
class
Gives the access classification of the information regarding the event.
The value \({ }^{\mathrm{p} 738}\) must be text with one of the following values:
- public
- private
- confidential

\section*{\(\triangle\) Warning!}

This is merely advisory and cannot be considered a confidentiality measure.

A single property with the name class \({ }^{p 755}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\text {p754. }}\).
comment
Gives a comment regarding the event.
The value \({ }^{\text {p738 }}\) must be text.
Any number of properties with the name comment \({ }^{\mathrm{p} 755}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type
http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
description
Gives a detailed description of the event.
The value \({ }^{\text {p738 }}\) must be text.
A single property with the name description \({ }^{p 755}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
geo
Gives the geographical position of the event.
The value \({ }^{\mathrm{p} 738}\) must be text and must match the following syntax:
1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

\section*{Note}

The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

A single property with the name geo \({ }^{p 755}\) may be present within each item \(^{p 734}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\text {p754 }}\).
location
Gives the location of the event.
The value \({ }^{\text {p738 }}\) must be text.

A single property with the name location \({ }^{p 756}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
resources
Gives a resource that will be needed for the event.
The value \({ }^{\text {p738 }}\) must be text.
Any number of properties with the name resources \({ }^{\mathrm{p} 756}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\).

\section*{status}

Gives the confirmation status of the event.
The value \({ }^{\mathrm{p} 738}\) must be text with one of the following values:
- tentative
- confirmed
- cancelled

A single property with the name status \({ }^{p 756}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
summary
Gives a short summary of the event.
The value \({ }^{\mathrm{p} 738}\) must be text.
User agents should replace U+000A LINE FEED (LF) characters in the value \({ }^{\text {p738 }}\) by U+0020 SPACE characters when using the value.
A single property with the name summary \({ }^{\mathrm{p} 756}\) may be present within each \(\underline{i t e m}^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
dtend
Gives the date and time by which the event ends.
If the property with the name \(\frac{d t e n d}{}{ }^{p 756}\) is present within an item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\mathrm{p} 754}\) that has a property with the name dtstart \({ }^{\mathrm{p} 757}\) whose value is a valid date string \({ }^{\mathrm{p74}}\), then the value \({ }^{\mathrm{p} 738}\) of the property with the name dtend \({ }^{\mathrm{p} 756}\) must be text that is a valid date string \({ }^{\mathrm{p74}}\) also. Otherwise, the value \({ }^{\mathrm{p738}}\) of the property must be text that is a valid global date and time string \({ }^{\mathrm{p79}}\).

In either case, the value \({ }^{\mathrm{p} 738}\) be later in time than the value of the \(\mathrm{dtstart}^{\mathrm{p} 757}\) property of the same item \({ }^{\mathrm{p} 734}\).

\section*{Note}

The time given by the dtend \({ }^{\mathrm{p} 756}\) property is not inclusive. For day-long events, therefore, the dtend \({ }^{\mathrm{p} 756}\) property's value \({ }^{\text {p738 }}\) will
be the day after the end of the event.

A single property with the name dtend \({ }^{\text {p756 }}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\text {p754 }}\), so long as that http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\) does not have a property with the name duration \({ }^{\mathrm{p} 757}\).
dtstart
Gives the date and time at which the event starts.
The value \({ }^{\mathrm{p} 738}\) must be text that is either a valid date string \({ }^{\mathrm{p} 74}\) or a valid global date and time string \({ }^{\mathrm{p} 79}\).
Exactly one property with the name dtstart \({ }^{\mathrm{p} 757}\) must be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
duration
Gives the duration of the event.
The value \({ }^{\mathrm{p} 738}\) must be text that is a valid vevent duration string \({ }^{\mathrm{p} 758}\).
The duration represented is the sum of all the durations represented by integers in the value.
A single property with the name duration \({ }^{p 757}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\), so long as that http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\) does not have a property with the name dtend \({ }^{\mathrm{p} 756}\).
transp
Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.
The value \({ }^{\text {p738 }}\) must be text with one of the following values:
- opaque
- transparent

A single property with the name transp \({ }^{p 757}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
contact
Gives the contact information for the event.
The value \({ }^{\mathrm{p} 738}\) must be text.
Any number of properties with the name contact \({ }^{\mathrm{p} 757}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
url
Gives a URL for the event.
The value \({ }^{\mathrm{p} 738}\) must be an absolute URL.
A single property with the name url \({ }^{p 757}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\mathrm{p} 754}\).
uid
Gives a globally unique identifier corresponding to the event.
The value \({ }^{\text {p738 }}\) must be text.
A single property with the name uid \({ }^{p 757}\) may be present within each \(\underline{i t e m}^{p 734}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\text {p754. }}\).
exdate
Gives a date and time at which the event does not occur despite the recurrence rules.

The value \({ }^{\mathrm{p} 738}\) must be text that is either a valid date string \({ }^{\mathrm{p} 74}\) or a valid global date and time string \({ }^{\mathrm{p} 79}\).
Any number of properties with the name exdate \({ }^{\mathrm{p} 757}\) may be present within each \(\underline{i t e m^{\mathrm{p} 734}}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{p 754}\).
rdate
Gives a date and time at which the event recurs.
The value \({ }^{\mathrm{p} 738}\) must be text that is one of the following:
- A valid date string \({ }^{\mathrm{p} 74}\).
- A valid global date and time string \({ }^{\mathrm{p} 79}\).
- A valid global date and time string \({ }^{\text {p79 }}\) followed by a U+002F SOLIDUS character (/) followed by a second valid global date and time string \({ }^{\text {p79 }}\) representing a later time.
- A valid global date and time string \({ }^{\text {p79 }}\) followed by a U+002F SOLIDUS character (/) followed by a valid vevent duration string \({ }^{\mathrm{p758}}\).

Any number of properties with the name rdate \({ }^{p 758}\) may be present within each item \(^{p 734}\) with the type http://microformats.org \(/\) profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
rrule
Gives a rule for finding dates and times at which the event occurs.
The value \({ }^{\mathrm{p} 738}\) must be text that matches the RECUR value type defined in iCalendar. [RFC5545] \({ }^{\text {p1290 }}\)
A single property with the name rrule \({ }^{p 758}\) may be present within each item \({ }^{p 734}\) with the type http://microformats.org/profile/ hcalendar\#vevent \({ }^{\mathrm{p} 754}\).
created
Gives the date and time at which the event information was first created in a calendaring system.
The value \({ }^{\mathrm{p} 738}\) must be text that is a valid global date and time string \({ }^{\mathrm{p} 79}\).
A single property with the name created \({ }^{p 758}\) may be present within each \(\underline{\text { item }^{\mathrm{p} 734}}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).

\section*{last-modified}

Gives the date and time at which the event information was last modified in a calendaring system.
The value \({ }^{\mathrm{p} 738}\) must be text that is a valid global date and time string \({ }^{\mathrm{p} 79}\).
A single property with the name last-modified \({ }^{\mathrm{p} 758}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754 }}\).
sequence
Gives a revision number for the event information.
The value \({ }^{\text {p738 }}\) must be text that is a valid non-negative integer \({ }^{\text {p69 }}\).
A single property with the name sequence \({ }^{p 758}\) may be present within each item \({ }^{\text {p734 }}\) with the type http://microformats.org/ profile/hcalendar\#vevent \({ }^{\text {p754. }}\).

A string is a valid vevent duration string if it matches the following pattern:
1. A U+0050 LATIN CAPITAL LETTER \(P\) character (P).
2. One of the following:
- A valid non-negative integer \({ }^{p 69}\) followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
- At least one, and possible both in this order, of the following:
1. A valid non-negative integer \({ }^{\text {p69 }}\) followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second of the following in that order, or the second and third of the following in that order, or all three of the following in this order:
1. A valid non-negative integer \({ }^{\text {p69 }}\) followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.
2. A valid non-negative integer \({ }^{\text {p69 }}\) followed by a U+004D LATIN CAPITAL LETTER M character (M). The integer represents a duration of that number of minutes.
3. A valid non-negative integer \({ }^{\text {p69 }}\) followed by a U+0053 LATIN CAPITAL LETTER \(S\) character ( S ). The integer represents a duration of that number of seconds.

\subsection*{5.3.2.1 Conversion to iCalendar \(\AA_{9}^{\mathrm{p}^{\mathrm{p} 5}}\)}

Given a list of nodes nodes in a Document \({ }^{p 114}\), a user agent must run the following algorithm to extract any vEvent data represented by those nodes:
1. If none of the nodes in nodes are items \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcalendar\#vevent \({ }^{\mathrm{p} 754}\), then there is no vEvent data. Abort the algorithm, returning nothing.
2. Let output be an empty string.
3. Add an iCalendar line \({ }^{\text {p760 }}\) with the type "BEGIN" and the value "VCALENDAR" to output.
4. Add an iCalendar line \({ }^{\text {p760 }}\) with the type "PRODID" and the value equal to a user-agent-specific string representing the user agent to output.
5. Add an iCalendar line \({ }^{\text {p760 }}\) with the type "VERSION" and the value " 2.0 " to output.
6. For each node node in nodes that is an item \({ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcalendar\#vevent \({ }^{\text {p754 }}\), run the following steps:
1. Add an iCalendar line \({ }^{\mathrm{p} 760}\) with the type "BEGIN" and the value "VEVENT" to output.
2. Add an iCalendar line \({ }^{\text {p760 }}\) with the type "DTSTAMP" and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation "VALUE=DATE-TIME", to output. [RFC5545] \({ }^{\text {p1290 }}\)
3. For each element element that is a property of the item \({ }^{\text {p739 }}\) node: for each name name in element's property names \({ }^{\text {p737 }}\), run the appropriate set of substeps from the following list:

If the property's value \({ }^{\text {p738 }}\) is an item \({ }^{\text {p734 }}\)
Skip the property.
If the property is dtend \({ }^{\text {p756 }}\)
If the property is dtstart \({ }^{\text {p757 }}\)
If the property is exdate \({ }^{\mathrm{p} 757}\)
If the property is rdate \({ }^{\text {p758 }}\)
If the property is created \({ }^{\text {p758 }}\)
If the property is last-modified \({ }^{\text {p758 }}\)
Let value be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (:) characters from the property's value \({ }^{\text {p738 }}\).

If the property's value \({ }^{\mathrm{p} 738}\) is a valid date string \({ }^{\mathrm{p74}}\) then add an iCalendar line \({ }^{\mathrm{p} 760}\) with the type name and the value value to output, with the annotation "VALUE=DATE".

Otherwise, if the property's value \({ }^{\mathrm{p} 738}\) is a valid global date and time string \({ }^{\mathrm{p} 79}\) then add an iCalendar line \({ }^{\mathrm{p} 760}\) with the type name and the value value to output, with the annotation "VALUE=DATE-TIME".

Otherwise skip the property.

\section*{Otherwise}

Add an iCalendar line \({ }^{\text {p760 }}\) with the type name and the property's value \({ }^{\text {p738 }}\) to output.
4. Add an iCalendar line \({ }^{\text {p760 }}\) with the type "END" and the value "VEVENT" to output.
7. Add an iCalendar line \({ }^{\text {p760 }}\) with the type "END" and the value "VCALENDAR" to output.

When the above algorithm says that the user agent is to add an iCalendar line consisting of a type type, a value value, and optionally an annotation, to a string output, it must run the following steps:
1. Let line be an empty string.
2. Append type, converted to ASCII uppercase, to line.
3. If there is an annotation:
1. Append a U+003B SEMICOLON character (;) to line.
2. Append the annotation to line.
4. Append a U+003A COLON character (:) to line.
5. Prefix every U+005C REVERSE SOLIDUS character ( \((\) ) in value with another U+005C REVERSE SOLIDUS character ( \((\) ).
6. Prefix every U+002C COMMA character (,) in value with a U+005C REVERSE SOLIDUS character ( \()\) ).
7. Prefix every U+003B SEMICOLON character (;) in value with a U+005C REVERSE SOLIDUS character ( \((\) ).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in value with a U+005C REVERSE SOLIDUS character ( \((1)\) followed by a U+006E LATIN SMALL LETTER \(N\) character ( n ).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in value with a U+005C REVERSE SOLIDUS character ( V ) followed by a U+006E LATIN SMALL LETTER N character ( n ).
10. Append value to line.
11. Let maximum length be 75 .
12. While line's code point length is greater than maximum length:
1. Append the first maximum length code points of line to output.
2. Remove the first maximum length code points from line.
3. Append a U+000D CARRIAGE RETURN character (CR) to output.
4. Append a U+000A LINE FEED character (LF) to output.
5. Append a U+0020 SPACE character to output.
6. Let maximum length be 74 .
13. Append (what remains of) line to output.
14. Append a U+000D CARRIAGE RETURN character (CR) to output.
15. Append a U+000A LINE FEED character (LF) to output.

\section*{Note}

This algorithm can generate invalid iCalendar output, if the input does not conform to the rules described for the http://microformats.org/profile/hcalendar\#vevent \({ }^{p 754}\) item type \({ }^{p 734}\) and defined property names \({ }^{p 737}\).

\subsection*{5.3.2.2 Examples \(\S^{p 76}\)}

This section is non-normative.

\section*{Example}

Here is an example of a page that uses the vEvent vocabulary to mark up an event:
<body itemscope itemtype="http://microformats.org/profile/hcalendar\#vevent">
```

<h1 itemprop="summary">Bluesday Tuesday: Money Road</h1>
...
<time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th @ 7pm</time>
(until <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>)
<a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
        rel="bookmark" itemprop="url">Link to this page</a>
...
<p>Location: <span itemprop="location">The RoadHouse</span></p>
...
<p><input type=button value="Add to Calendar"
            onclick="location = getCalendar(this)"></p>

<meta itemprop="description" content="via livebrum.co.uk">
</body>

```

The getCalendar() function is left as an exercise for the reader.
The same page could offer some markup, such as the following, for copy-and-pasting into blogs:
```

<div itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
    <p>I'm going to
    <strong itemprop="summary">Bluesday Tuesday: Money Road</strong>,
    <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th at 7pm</time>
    to <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>,
    at <span itemprop="location">The RoadHouse</span>!</p>
    <p><a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
        itemprop="url">See this event on livebrum.co.uk</a>.</p>
    <meta itemprop="description" content="via livebrum.co.uk">
</div>
```

\subsection*{5.3.3 Licensing works \(\S^{p 76}\)}

An item with the item type \({ }^{\text {p734 }}\) http://n.whatwg. org/work represents a work (e.g. an article, an image, a video, a song, etc). This type is primarily intended to allow authors to include licensing information for works.

The following are the type's defined property names \({ }^{\text {p737 }}\).
work
Identifies the work being described.
The value \({ }^{\text {p738 }}\) must be an absolute URL.
Exactly one property with the name work \({ }^{\mathrm{p} 761}\) must be present within each \(\underline{i^{p} \mathrm{~m}^{\mathrm{p} 734}}\) with the type http://n.whatwg.org/work \({ }^{\mathrm{p761}}\).
title
Gives the name of the work.
A single property with the name title \({ }^{\mathrm{p761}}\) may be present within each \(\operatorname{item}^{\mathrm{p734}}\) with the type http://n. whatwg.org/work \({ }^{\mathrm{p761}}\).
author
Gives the name or contact information of one of the authors or creators of the work.
The value \({ }^{\mathrm{p} 738}\) must be either an \(\underline{\text { item }}{ }^{\mathrm{p} 734}\) with the type http://microformats.org/profile/hcard \({ }^{\mathrm{p741}}\), or text.
Any number of properties with the name author \({ }^{\mathrm{p761}}\) may be present within each item \({ }^{\mathrm{p} 734}\) with the type http://n. whatwg.org/ work \({ }^{\text {p761 }}\).

Identifies one of the licenses under which the work is available.
The value \({ }^{\text {p738 }}\) must be an absolute URL.
Any number of properties with the name license \({ }^{p 762}\) may be present within each item \({ }^{p 734}\) with the type http://n. whatwg.org/ work \({ }^{\text {p761 }}\).

\subsection*{5.3.3.1 Examples \({ }^{\AA^{p 76}}\)}

This section is non-normative.

\section*{Example}

This example shows an embedded image entitled My Pond, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.
```

<figure itemscope itemtype="http://n.whatwg.org/work">
    <img itemprop="work" src="mypond.jpeg">
    <figcaption>
    <p><cite itemprop="title">My Pond</cite></p>
    <p><small>Licensed under the <a itemprop="license"
    href="https://creativecommons.org/licenses/by-sa/4.0/">Creative
    Commons Attribution-Share Alike 4.0 International License</a>
    and the <a itemprop="license"
    href="http://www.opensource.org/licenses/mit-license.php">MIT
    license</a>.</small>
    </figcaption>
</figure>
```

\subsection*{5.4 Converting HTML to other formats \(\S^{p 76}\)}

\subsection*{5.4.1 JSON \(\S_{2}^{\text {p76 }}\)}

Given a list of nodes nodes in a Document \({ }^{\text {p114 }}\), a user agent must run the following algorithm to extract the microdata from those nodes into a JSON form:
1. Let result be an empty object.
2. Let items be an empty array.
3. For each node in nodes, check if the element is a top-level microdata item \({ }^{\mathrm{p739}}\), and if it is then get the object \({ }^{\mathrm{p762}}\) for that element and add it to items.
4. Add an entry to result called "items" whose value is the array items.
5. Return the result of serializing result to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "e" used, when appropriate, in the representation of any numbers. [JSON] \({ }^{\text {p1288 }}\)

\section*{Note}

This algorithm returns an object with a single property that is an array, instead of just returning an array, so that it is possible to extend the algorithm in the future if necessary.

When the user agent is to get the object for an item item, optionally with a list of elements memory, it must run the following substeps:
1. Let result be an empty object.
2. If no memory was passed to the algorithm, let memory be an empty list.
3. Add item to memory.
4. If the item has any item types \({ }^{\text {p734 }}\), add an entry to result called "type" whose value is an array listing the item types \({ }^{\text {p734 }}\) of item, in the order they were specified on the itemtype \({ }^{\text {p734 }}\) attribute.
5. If the item has a global identifier \({ }^{\text {p735 }}\), add an entry to result called "id" whose value is the global identifier \({ }^{\text {p735 }}\) of item.
6. Let properties be an empty object.
7. For each element element that has one or more property names \({ }^{\text {p737 }}\) and is one of the properties of the item \({ }^{\text {p739 }}\) item, in the order those elements are given by the algorithm that returns the properties of an item \({ }^{\mathrm{p739}}\), run the following substeps:
1. Let value be the property value \({ }^{\mathrm{p} 738}\) of element.
2. If value is an item \({ }^{\mathrm{p} 734}\), then: If value is in memory, then let value be the string "ERROR". Otherwise, get the object \({ }^{\text {p762 }}\) for value, passing a copy of memory, and then replace value with the object returned from those steps.
3. For each name name in element's property names \({ }^{\mathrm{p} 737}\), run the following substeps:
1. If there is no entry named name in properties, then add an entry named name to properties whose value is an empty array.
2. Append value to the entry named name in properties.
8. Add an entry to result called "properties" whose value is the object properties.
9. Return result.

\section*{Example}

For example, take this markup:
```

<!DOCTYPE HTML>

<html lang="en">
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
    <header>
    <h1 itemprop="headline">Progress report</h1>
    <p><time itemprop="datePublished" datetime="2013-08-29">today</time></p>
    <link itemprop="url" href="?comments=0">
    </header>
    <p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble
    putting his head in, but we got it down.</p>
    <section>
    <h1>Comments</h1>
    <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="cl">
        <link itemprop="url" href="#cl">
        <footer>
            <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
            <span itemprop="name">Greg</span>
            </span></p>
            <p><time itemprop="commentTime" datetime="2013-08-29">15 minutes ago</time></p>
            </footer>
            <p>Ha!</p>
    </article>
    <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c2">
        <link itemprop="url" href="#c2">
        <footer>
            <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
            <span itemprop="name">Charlotte</span>
            </span></p>
            <p><time itemprop="commentTime" datetime="2013-08-29">5 minutes ago</time></p>
        </footer>
        <p>When you say "we got it down"...</p>
```
```
    </article>
    </section>
</article>
```

It would be turned into the following JSON by the algorithm above (supposing that the page's URL was https://blog.example.com/progress-report):
```
{
    "items": [
        {
            "type": [ "http://schema.org/BlogPosting" ],
            "properties": {
                "headline": [ "Progress report" ],
                "datePublished": [ "2013-08-29" ],
                "url": [ "https://blog.example.com/progress-report?comments=0" ],
            "comment": [

                            "name": [ "Charlotte" ]
                            }
                                }
                                ],
                                "commentTime": [ "2013-08-29" ]
                    }
                }
            ]
            }
        }
    ]
}
```

\section*{6 User interaction \(\S^{\text {p76 }}\) \\ 5}

\subsection*{6.1 The hidden attribute \(\S^{\text {p76 }}\)}

All HTML elements \({ }^{\text {p44 }}\) may have the hidden \({ }^{\text {p765 }}\) content attribute set. The hidden \({ }^{p 765}\) attribute is a boolean attribute \({ }^{\text {p677 }}\). When specified on an element, it indicates that the element is not yet, or is no longer, directly relevant to the page's current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. User agents should not render elements that have the hidden \({ }^{\text {p765 }}\) attribute specified. This requirement may be implemented indirectly through the style layer. For example, an HTML+CSS user agent could implement these requirements using the rules suggested in the Rendering section \({ }^{\text {p1193 }}\).

\section*{Note}

Because this attribute is typically implemented using CSS, it's also possible to override it using CSS. For instance, a rule that applies 'display: block' to all elements will cancel the effects of the hidden \({ }^{\mathrm{p} 765}\) attribute. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected.

\section*{Example}

In the following skeletal example, the attribute is used to hide the web game's main screen until the user logs in:
```
<h1>The Example Game</h1>
<section id="login">
    <h2>Login</h2>
    <form>
    <!-- calls login() once the user's credentials have been checked -->
    </form>
    <script>
        function login() {
            // switch screens
            document.getElementById('login').hidden = true;
            document.getElementById('game').hidden = false;
    }
    </script>
</section>
<section id="game" hidden>
    ...
</section>
```

The hidden \({ }^{\text {p765 }}\) attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use hidden \({ }^{\text {p765 }}\) to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation - if something is marked hidden \({ }^{\mathrm{p765}}\), it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves hidden \({ }^{p 765}\) must not hyperlink \({ }^{p 283}\) to elements that are hidden \({ }^{\mathrm{p765}}\). The for attributes of label \({ }^{\mathrm{p} 490}\) and output \({ }^{\text {p553 }}\) elements that are not themselves hidden \({ }^{\text {p765 }}\) must similarly not refer to elements that are hidden \({ }^{\text {p765 }}\). In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are hidden \({ }^{\text {p765 }}\) in other contexts.

\section*{Example}

For example, it would be incorrect to use the href \(f^{p 284}\) attribute to link to a section marked with the hidden \({ }^{\mathrm{p765}}\) attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA aria-describedby attribute to refer to descriptions that are themselves hidden \({ }^{\text {p765 }}\). While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the
specific context of being referenced from the elements that they describe.
Similarly, a canvas \({ }^{\text {p634 }}\) element with the hidden \({ }^{\text {p765 }}\) attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden form \({ }^{\mathrm{p486}}\) element using its form \({ }^{\mathrm{p566}}\) attribute.

Elements in a section hidden by the hidden \({ }^{p 765}\) attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.

The hidden IDL attribute must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.

\subsection*{6.2 Inert subtrees \(\S^{\text {p76 }}\)}

\section*{Note}

This section does not define or create any content attribute named "inert". This section merely defines an abstract concept of inertness \({ }^{p 766}\).

A node (in particular elements and text nodes) can be marked as inert. When a node is inert \({ }^{\mathrm{p} 766}\), then the user agent must act as if the node was absent for the purposes of targeting user interaction events, may ignore the node for the purposes of find-in-page \({ }^{\text {p793 }}\), and may prevent the user from selecting text in that node. User agents should allow the user to override the restrictions on search and text selection, however.

\section*{Example}

For example, consider a page that consists of just a single inert \({ }^{\text {p766 }}\) paragraph positioned in the middle of a body \({ }^{\text {p178 }}\). If a user moves their pointing device from the body \({ }^{\text {p178 }}\) over to the inert \({ }^{\text {p766 }}\) paragraph and clicks on the paragraph, no mouseover event would be fired, and the mousemove and click events would be fired on the body \({ }^{\text {p178 }}\) element rather than the paragraph.

\section*{Note}
\[
\text { When a node is inert, it generally cannot be focused. Inert nodes that are commands }{ }^{p 607} \text { will also get disabled. }
\]

While a browsing context container \({ }^{\text {p814 }}\) is marked as inert \({ }^{\text {p766 }}\), its nested browsing context \({ }^{\text {p814 }}\) 's active document \({ }^{\text {p811 }}\), and all nodes in that Document \({ }^{\text {p114 }}\), must be marked as inert \({ }^{\text {p766 }}\).

An element is expressly inert if it is inert \({ }^{\mathrm{p} 766}\) and its node document is not inert \({ }^{\mathrm{p} 766}\).
A Document \({ }^{\text {p114 }}\) document is blocked by a modal dialog subject if subject is the topmost dialog \({ }^{\text {p610 }}\) element in document's top layer. While document is so blocked, every node that is connected to document, with the exception of the subject element and its shadowincluding descendants, must be marked inert \({ }^{\text {p766 }}\). (The elements excepted by this paragraph can additionally be marked inert \({ }^{\text {p766 }}\) through other means; being part of a modal dialog does not "protect" a node from being marked inert \({ }^{\mathrm{p766}}\).)

\section*{Note}

The dialog \({ }^{\text {p610 }}\) element's showModal() \()^{\text {p612 }}\) method causes this mechanism to trigger, by adding the dialog \({ }^{\text {p610 }}\) element to its node document's top layer.

\subsection*{6.3 Tracking user activation \(\S^{p 76}\)}

To prevent abuse of certain APIs that could be annoying to users (e.g., opening popups or vibrating phones), user agents allow these APIs only when the user is actively interacting with the web page or has interacted with the page at least once. This "active interaction" state is maintained through the mechanisms defined in this section.

\subsection*{6.3.1 Data model \(\S^{p 76}\)}

For the purpose of tracking user activation, each Window \({ }^{\mathrm{p} 824} W\) has a last activation timestamp. This is a number indicating the last time \(W\) got an activation notification \({ }^{\text {p767 }}\). It corresponds to a DOMHighResTimeStamp value except for two cases: positive infinity indicates that \(W\) has never been activated, while negative infinity indicates that a user activation-gated API \({ }^{\text {p768 }}\) has consumed \({ }^{\text {p768 }}\) the last user activation of \(W\). The initial value is positive infinity.

A user agent also defines a transient activation duration, which is a constant number indicating how long a user activation is available for certain user activation-gated APIs \({ }^{\text {p768 }}\) (e.g., for opening popups).

\section*{Note}

The transient activation duration \({ }^{\text {p767 }}\) is expected be at most a few seconds, so that the user can possibly perceive the link between an interaction with the page and the page calling the activation-gated API.

These two values imply two boolean user activation states for \(W\) :

\section*{Sticky activation}

When the current high resolution time is greater than or equal to the last activation timestamp \({ }^{\text {p767 }}\) in \(W, W\) is said to have sticky activation \({ }^{\mathrm{p} 767}\).

This is W's historical activation state, indicating whether the user has ever interacted in W. It starts false, then changes to true (and never changes back to false) when \(W\) gets the very first activation notification \({ }^{\text {p767 }}\).

\section*{Transient activation}

When the current high resolution time is greater than or equal to the last activation timestamp \({ }^{\text {p767 }}\) in \(W\), and less than the last activation timestamp \({ }^{\mathrm{p767}}\) in \(W\) plus the transient activation duration \({ }^{\mathrm{p} 767}\), then \(W\) is said to have transient activation \({ }^{\mathrm{p767}}\).

This is W's current activation state, indicating whether the user has interacted in \(W\) recently. This starts with a false value, and remains true for a limited time after every activation notification \({ }^{\mathrm{p} 767} W\) gets.

The transient activation \({ }^{\mathrm{p} 767}\) state is considered expired if it becomes false because the transient activation duration \({ }^{\mathrm{p} 767}\) time has elapsed since the last user activation. Note that it can become false even before the expiry time through an activation consumption \({ }^{\text {p768 }}\).

\subsection*{6.3.2 Processing model \(\S^{p 76}\)}

When a user interaction in a browsing context \({ }^{\text {8811 }} B\) causes firing of an activation triggering input event \({ }^{p 767}\) in \(B^{\prime} \mathrm{s}\) active document \({ }^{\mathrm{p} 811}\) \(D\), the user agent must perform the following activation notification steps before dispatching the event:
1. Let browsingContexts be a list consisting of:
- B,
- all ancestor browsing contexts \({ }^{\text {p814 }}\) of \(B\), and
- all the descendant browsing contexts \({ }^{\mathrm{p} 814}\) of \(D\) that have active documents \({ }^{\mathrm{p} 811}\) from the same origin \({ }^{\mathrm{p} 838}\) as that of \(D\).
2. Let windows be the list of Window \({ }^{\mathrm{p824}}\) objects constructed by taking the active window \({ }^{\mathrm{p} 811}\) of each item in browsingContexts.
3. For each window in windows, set window's last activation timestamp \({ }^{\text {p767 }}\) to the current high resolution time.

An activation triggering input event is any event whose isTrusted attribute is true and whose type is one of:
- change \({ }^{\text {p1281 }}\)
- click
- contextmenu \({ }^{\text {p1281 }}\)
- dblclick
- mouseup
- pointerup
- reset \({ }^{\text {p1282 }}\)
- submit \({ }^{\text {p1282 }}\)
- touchend

The event set is inconsistent across major browsers. See issue \#3849.

Activation consuming APIs \({ }^{\text {p768 }}\) defined in this and other specifications can consume user activation by performing the following steps, given a Window \({ }^{\text {p824 }} \mathrm{W}\) :
1. If \(W^{\prime} \mathrm{s} \underline{\text { browsing context }{ }^{\mathrm{p826}}}\) is null, then return.
2. Let top be W's browsing context \({ }^{\text {p826 }}\) ' s top-level browsing context \({ }^{\mathrm{p} 814}\).
3. Let browsingContexts be the list of the descendant browsing contexts \({ }^{\mathrm{p} 814}\) of top's active document \({ }^{\mathrm{p} 811}\).
4. Append top to browsingContexts.
5. Let windows be the list of Window \({ }^{\mathrm{p} 824}\) objects constructed by taking the active window \({ }^{\mathrm{p} 811}\) of each item in browsingContexts.
6. For each window in windows, if window's last activation timestamp \({ }^{p 767}\) is not positive infinity, then set window's last activation timestamp \({ }^{\text {p767 }}\) to negative infinity.

The spec is not clear about how to traverse a tree of documents. See issue \#5020.

\section*{Note}

Note the asymmetry in the sets of browsing contexts \({ }^{p 811}\) in the page that are affected by an activation notification \({ }^{p 767}\) vs an activation consumption \({ }^{p 768}\) : an activation consumption changes (to false) the transient activation \({ }^{p 767}\) states for all browsing contexts in the page, but an activation notification changes (to true) the states for a subset of those browsing contexts. The exhaustive nature of consumption here is deliberate: it prevents malicious sites from making multiple calls to an activation consuming API \({ }^{p 768}\) from a single user activation (possibly by exploiting a deep hierarchy of iframe \({ }^{\text {p361 }}\) s).

\subsection*{6.3.3 APIs gated by user activation \(\S^{p 76}\)}

APIs that are dependent on user activation are classified into three different levels. The levels are as follows, sorted by their "strength of dependence" on user activation (from weakest to strongest):

\section*{Sticky activation-gated APIs}

These APIs require the sticky activation \({ }^{\mathrm{p} 767}\) state to be true, so they are blocked until the very first user activation.

\section*{Transient activation-gated APIs}

These APIs require the transient activation \({ }^{\mathrm{p767}}\) state to be true, but they don't consume \({ }^{\mathrm{p} 768}\) it, so multiple calls are allowed per user activation until the transient state expires \({ }^{p 767}\).

\section*{Transient activation-consuming APIs}

These APIs require the transient activation \({ }^{\text {p767 }}\) state to be true, and they consume user activation \({ }^{\text {p768 }}\) in each call to prevent multiple calls per user activation.

\subsection*{6.4 Activation behavior of elements \(\S_{8}^{\mathrm{p} 76}\)}

Certain elements in HTML have an activation behavior, which means that the user can activate them. This is always caused by a click event.

The user agent should allow the user to manually trigger elements that have an activation behavior, for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined activation behavior in a manner other than clicking it, the default action of the interaction event must be to fire a click event \({ }^{\text {p965 }}\) at the element.

\section*{For web developers (non-normative)}
element. click \(^{\text {p769 }}\) ()
Acts as if the element was clicked.

Each element has an associated click in progress flag, which is initially unset.
The click() method must run the following steps:
1. If this element is a form control that is disabled \({ }^{\text {p570 }}\), then return.
2. If this element's click in progress flag \({ }^{\mathrm{p} 769}\) is set, then return.
3. Set this element's click in progress flag \({ }^{\mathrm{p} 769}\).
4. Fire a synthetic mouse event \({ }^{\text {p965 }}\) named click at this element, with the not trusted flag set.
5. Unset this element's click in progress flag \({ }^{\mathrm{p} 769}\).

\subsection*{6.5 Focus \(\S^{\text {p76 }}\)}

\subsection*{6.5.1 Introduction \(\S^{\mathrm{p} 76}\)}

This section is non-normative.
An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes, browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be focused \({ }^{p 771}\).

\section*{Example}

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as well as the dialog. The dialog itself would have as its children the text control and the button.

If the widget with focus \({ }^{\text {p771 }}\) in this example was the text control in the dialog box, then key input would be channeled from the graphical system to (1) the web browser, then to (2) the tab, then to (3) the dialog, and finally to (4) the text control.

Keyboard events are always targeted at this focused \({ }^{\text {p771 }}\) element.

\subsection*{6.5.2 Data model \(\S^{p 77}\)}

The term focusable area is used to refer to regions of the interface that can become the target of keyboard input. Focusable areas can be elements, parts of elements, or other regions managed by the user agent.

Each focusable area \({ }^{\text {p770 }}\) has a DOM anchor, which is a Node object that represents the position of the focusable area \({ }^{\text {p770 }}\) in the DOM. (When the focusable area \({ }^{\text {p770 }}\) is itself a Node, it is its own DOM anchor \({ }^{p 770}\).) The DOM anchor \({ }^{p 770}\) is used in some APIs as a substitute for the focusable area \({ }^{\mathrm{p} 770}\) when there is no other DOM object to represent the focusable area \({ }^{\mathrm{p} 770}\).

The following table describes what objects can be focusable areas \({ }^{\mathrm{p} 770}\). The cells in the left column describe objects that can be focusable areas \({ }^{\text {p770 }}\); the cells in the right column describe the DOM anchors \({ }^{\text {p770 }}\) for those elements. (The cells that span both columns are non-normative examples.)
\begin{tabular}{|c|c|}
\hline Focusable area \({ }^{\text {p770 }}\) & DOM anchor \({ }^{\text {p770 }}\) \\
\hline \multicolumn{2}{|l|}{Examples} \\
\hline \begin{tabular}{l}
Elements that meet all the following criteria: \\
- the element's tabindex value \({ }^{\text {p774 }}\) is non-null, or the element is determined by the user agent to be focusable; \\
- the element is either not a shadow host, or has a shadow root whose delegates focus is false; \\
- the element is not actually disabled \({ }^{\text {p723 }}\); \\
- the element is not expressly inert \({ }^{p 766}\); \\
- the element is either being rendered \({ }^{\text {p1192 }}\) or being used as relevant canvas fallback content \({ }^{\text {p635 }}\).
\end{tabular} & The element itself. \\
\hline
\end{tabular}

\section*{Example}

Itrame \({ }^{\text {p361 }}, \leq i n p u t\) type \(=\) text \(>^{\text {p499 }}\), sometimes \(\leq a\) href \(=\) " " \(>^{\text {p238 }}\) (depending on platform conventions).
\begin{tabular}{ll|l}
\hline The shapes of \(a r e a^{\text {p443 }}\) elements in an image map \({ }^{\text {p445 }}\) associated with an \(\underline{i m g}^{\text {p326 }}\) element that is being & The \(\underline{i m g}^{\text {p320 }}\) element.
\end{tabular} rendered \({ }^{\text {p1192 }}\) and is not expressly inert \({ }^{\text {p766 }}\).

\section*{Example}

In the following example, the area \({ }^{\text {p443 }}\) element creates two shapes, one on each image. The DOM anchor \({ }^{\mathrm{p} 770}\) of the first shape is the first \(\underline{i m g}^{\mathrm{p} 32 \theta}\) element, and the DOM anchor \({ }^{\text {p770 }}\) of the second shape is the second img \(^{\text {p320 }}\) element.
```
<map id=wallmap><area alt="Enter Door" coords="10,10,100,200" href="door.html"></map>
<img src="images/innerwall.jpeg" alt="There is a white wall here, with a door." usemap="#wallmap">
<img src="images/outerwall.jpeg" alt="There is a red wall here, with a door." usemap="#wallmap">
```

The user-agent provided subwidgets of elements that are being rendered \({ }^{\text {p1192 }}\) and are not actually disabled \({ }^{\text {p723 }}\) or expressly inert \({ }^{\text {p766 }}\).

The element for which the focusable area \({ }^{\text {p770 }}\) is a subwidget.

Example
The controls in the user interface \({ }^{\text {p436 }}\) for a video \(0^{\text {p388 }}\) element, the up and down buttons in a spin-control version of \(\leq\) input type=number \(>^{\text {p509 }}\), the part of a details \({ }^{\text {p604 }}\) element's rendering that enables the element to be opened or closed using keyboard input.
\begin{tabular}{l|l}
\hline The scrollable regions of elements that are being rendered \({ }^{\text {p1192 }}\) and are not expressly inert \({ }^{\text {p766. }}\). & \begin{tabular}{l} 
The element for which the box that the \\
scrollable region scrolls was created.
\end{tabular} \\
\hline
\end{tabular}

\section*{Example}
me CSS 'overflow' property's 'scroll' value typically creates a scrollable region.

\section*{Example}

A user agent could make all list item bullets sequentially focusable \({ }^{\text {p772 }}\), so that a user can more easily navigate lists.

\section*{Example}

SImilarly, a user agent could make all elements with \(\underline{\text { title }}{ }^{p 139}\) attributes sequentially focusable \({ }^{\mathrm{p} 772}\), so that their advisory information can be accessed.

\section*{Note}

A browsing context container \({ }^{p 814}\) (e.g. an iframe \({ }^{p 361}\) ) is a focusable area \({ }^{p 770}\), but key events routed to a browsing context container \({ }^{p 814}\) get immediately routed to its nested browsing context \({ }^{p 814}\) 's active document \({ }^{p 811}\). Similarly, in sequential focus navigation a browsing context container \({ }^{p 814}\) essentially acts merely as a placeholder for its nested browsing context \(t^{p 814}\) 's active document \({ }^{\text {p811 }}\).

One focusable area \({ }^{\mathrm{p770}}\) in each Document \({ }^{p 114}\) is designated the focused area of the document. Which control is so designated changes over time, based on algorithms in this specification.

The currently focused area of a top-level browsing context topLeveIBC at any particular time is the focusable area \({ }^{\text {p770 }}\) returned by this algorithm:
1. Let candidate be topLeveIBC's active document \({ }^{\text {p811 }}\).
2. While candidate's focused area \({ }^{\mathrm{p} 771}\) is a browsing context container \({ }^{\mathrm{p} 814}\) with a non-null nested browsing context \({ }^{\mathrm{p} 814}\) : set candidate to the active document \({ }^{\mathrm{p} 811}\) of that browsing context container \({ }^{\mathrm{p} 814}\) 's nested browsing context \({ }^{\mathrm{p} 814}\).
3. If candidate's focused area \({ }^{\mathrm{p} 771}\) is non-null, set candidate to candidate's focused area \({ }^{\mathrm{p} 771}\).
4. Return candidate.

An element that is the DOM anchor \({ }^{\mathrm{p} 770}\) of a focusable area \({ }^{\mathrm{p} 770}\) is said to gain focus when that focusable area \({ }^{\mathrm{p} 770}\) becomes the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\). When an element is the DOM anchor \({ }^{\mathrm{p770}}\) of a focusable area \({ }^{\mathrm{p} 770}\) of the currently focused area of a top-level browsing context \({ }^{\mathrm{p} 771}\), it is focused.

The focus chain of a focusable area \({ }^{\text {p770 }}\) subject is the ordered list constructed as follows:
1. Let current object be subject.
2. Let output be an empty list.
3. Loop: Append current object to output.
4. If current object is an area \({ }^{\text {p443 }}\) element's shape, append that area \({ }^{\text {p443 }}\) element to output.

Otherwise, if current object is a focusable area \({ }^{\text {p770 }}\) whose DOM anchor \({ }^{\text {p770 }}\) is an element that is not current object itself, append that DOM anchor \({ }^{\text {p770 }}\) element to output.
5. If current object is a Document \({ }^{\mathrm{p} 114}\) whose browsing context \({ }^{\mathrm{p} 811}\) is a child browsing context \({ }^{\mathrm{p814}}\), then set current object to current object's browsing context \({ }^{\text {p811 }}\) 's container \({ }^{p 814}\) and return to the step labeled loop.
6. Return output.

The chain starts with subject and (if subject is or can be the currently focused area of a top-level browsing context \({ }^{p 771}\) ) continues up the focus hierarchy up to the Document \({ }^{\text {p114 }}\) of the top-level browsing context \({ }^{p 814}\).

All elements that are focusable areas \({ }^{\mathrm{p} 770}\) are said to be focusable.
There are two special types of focusability for focusable areas \({ }^{\mathrm{p} 770}\) :
- A focusable area \({ }^{\text {p770 }}\) is said to be sequentially focusable if it is included in its Document \({ }^{\text {p114' }}\) 's sequential focus navigation order \({ }^{\text {p779 }}\) and the user agent determines that it is sequentially focusable.
- A focusable area \({ }^{\mathrm{p} 770}\) is said to be click focusable if the user agent determines that it is click focusable. User agents should consider focusable areas with non-null tabindex values \({ }^{\text {p774 }}\) to be click focusable.
```
Note
Elements which are not focusable \({ }^{\text {p772 }}\) are not focusable areas \({ }^{\text {p770 }}\), and thus not sequentially focusable \({ }^{\text {p772 }}\) and not click focusable \({ }^{\text {p772 }}\).
```

\section*{Note}

Being focusable \({ }^{\text {p772 }}\) is a statement about whether an element can be focused programmatically, e.g. via the focus() \({ }^{\text {p782 }}\) method or autofocus \({ }^{\text {p782 }}\) attribute. In contrast, sequentially focusable \({ }^{p 772}\) and click focusable \({ }^{\text {p772 }}\) govern how the user agent responds to user interaction: respectively, to sequential focus navigation \({ }^{p 779}\) and as activation behavior \({ }^{p 0}\).

The user agent might determine that an element is not sequentially focusable \({ }^{\text {p772 }}\) even if it is focusable \({ }^{\text {p772 }}\) and is included in its Document \({ }^{\text {p114' }}\) s sequential focus navigation order \({ }^{\text {p779 }}\), according to user preferences. For example, macOS users can set the user agent to skip non-form control elements, or can skip links when doing sequential focus navigation \({ }^{\text {p779 }}\) with just the Tab key (as opposed to using both the Option and Tab keys).

Similarly, the user agent might determine that an element is not click focusable \({ }^{\text {p772 }}\) even if it is focusable \({ }^{\text {p772 }}\). For example, in some user agents, clicking on a non-editable form control does not focus it, i.e. the user agent has determined that such controls are not click focusable.

Thus, an element can be focusable \({ }^{\text {p772, }}\), but neither sequentially focusable \({ }^{\text {p772 }}\) nor click focusable \({ }^{p 772}\). For example, in some user agents, a non-editable form-control with a negative-integer tabindex value \({ }^{\text {p774 }}\) would not be focusable via user interaction, only via programmatic APIs.

When a user activates \({ }^{\mathrm{p} 768}\) a click focusable \({ }^{\mathrm{p} 772}\) focusable area \({ }^{\mathrm{p} 770}\), the user agent must run the focusing steps \({ }^{\mathrm{p} 776}\) on the focusable area \({ }^{\mathrm{p} 770}\) with focus trigger set to "click".

\section*{Note}

Note that focusing is not an activation behavior, i.e. calling the click() \({ }^{\text {p769 }}\) method on an element or dispatching a synthetic click event on it won't cause the element to get focused.

A node is a focus navigation scope owner if it is a document \({ }^{\text {p114 }}\), a shadow host or a slot \({ }^{\text {p633 }}\).
Each focus navigation scope owner \({ }^{\text {p772 }}\) has a focus navigation scope, which is a list of elements. Its contents are determined as follows:

Every element element has an associated focus navigation owner, which is either null or a focus navigation scope owner \({ }^{\text {p772 }}\). It is determined by the following algorithm:
1. If element's parent is null, then return null.
2. If element's parent is a shadow host, then return element's assigned slot.
3. If element's parent is a shadow root, then return the parent's host.
4. If element's parent is the document element, then return the parent's node document.
5. Return element's parent's associated focus navigation owner \({ }^{\mathrm{p} 772}\).

Then, the contents of a given focus navigation scope owner \({ }^{\mathrm{p} 772}\) owner's focus navigation scope \({ }^{\mathrm{p} 772}\) are all elements whose associated focus navigation owner \({ }^{\mathrm{p} 772}\) is owner.

\section*{Note}

The order of elements within a focus navigation scope \({ }^{\text {p772 }}\) does not impact any of the algorithms in this specification. Ordering only becomes important for the tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\) and flattened tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\) concepts defined below.

A tabindex-ordered focus navigation scope is a list of focusable areas \({ }^{\text {p770 }}\) and focus navigation scope owners \({ }^{\text {p772 }}\). Every focus navigation scope owner \({ }^{\text {p772 }}\) owner has tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\), whose contents are determined as follows:
- It contains all elements in owner's focus navigation scope \({ }^{\text {p772 }}\) that are themselves focus navigation scope owners \({ }^{\text {p772 }}\), except the elements whose tabindex value \({ }^{\text {p774 }}\) is a negative integer.
- It contains all of the focusable areas \({ }^{\mathrm{p} 770}\) whose DOM anchor \({ }^{\text {p770 }}\) is an element in owner's focus navigation scope \({ }^{\text {p772 }}\), except the focusable areas \({ }^{\mathrm{p} 770}\) whose tabindex value \({ }^{\mathrm{p} 774}\) is a negative integer.

The order within a tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\) is determined by each element's tabindex value \({ }^{\mathrm{p} 774}\), as described in the section below.

\section*{Note}

The rules there do not give a precise ordering, as they are composed mostly of "should" statements and relative orderings.

A flattened tabindex-ordered focus navigation scope is a list of focusable areas \({ }^{\text {p770 }}\). Every focus navigation scope owner \({ }^{\text {p772 }}\) owner owns a distinct flattened tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\), whose contents are determined by the following algorithm:
1. Let result be a clone of owner's tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\).
2. For each item of result:
1. If item is not a focus navigation scope owner \({ }^{\text {p772 }}\), then continue.
2. If item is not a focusable area \({ }^{\text {p770 }}\), then replace item with all of the items in item's flattened tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\).
3. Otherwise, insert the contents of item's flattened tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\) after item.

\subsection*{6.5.3 The tabindex \({ }^{\mathrm{p} 773}\) attribute \(\S_{3}^{\mathrm{p} 77}\)}

The tabindex content attribute allows authors to make an element and regions that have the element as its DOM anchor \({ }^{\text {p770 }}\) be focusable areas \({ }^{\text {p770 }}\), allow or prevent them from being sequentially focusable \({ }^{\text {p772 }}\), and determine their relative ordering for sequential focus navigation \({ }^{\text {p779 }}\).

The name "tab index" comes from the common use of the Tab key to navigate through the focusable elements. The term "tabbing" refers to moving forward through sequentially focusable \({ }^{\mathrm{p} 772}\) focusable areas \({ }^{\mathrm{p} 770}\).

The tabindex \({ }^{\mathrm{p773}}\) attribute, if specified, must have a value that is a valid integer \({ }^{\mathrm{p} 68}\). Positive numbers specify the relative position of the element's focusable areas \({ }^{\mathrm{p770}}\) in the sequential focus navigation order \({ }^{\mathrm{p} 779}\), and negative numbers indicate that the control is not sequentially focusable \({ }^{\mathrm{p} 772}\).

Developers should use caution when using values other than 0 or -1 for their tabindex \({ }^{\text {p773 }}\) attributes as this is complicated to do correctly.

\section*{Note}

The following provides a non-normative summary of the behaviors of the possible tabindex \({ }^{\mathrm{p} 773}\) attribute values. The below processing model gives the more precise rules.
omitted (or non-integer values)
The user agent will decide whether the element is focusable \({ }^{\text {p772 }}\), and if it is, whether it is sequentially focusable \({ }^{\text {p772 }}\) or click
focusable \({ }^{\text {p772 }}\) (or both).
-1 (or other negative integer values)
Causes the element to be focusable \({ }^{\text {p772 }}\), and indicates that the author would prefer the element to be click focusable \({ }^{\text {p772 }}\) but not sequentially focusable \({ }^{p 772}\). The user agent might ignore this preference for click and sequential focusability, e.g., for specific element types according to platform conventions, or for keyboard-only users.

0
Causes the element to be focusable \({ }^{\text {p772 }}\), and indicates that the author would prefer the element to be both click focusable \({ }^{\text {p772 }}\) and sequentially focusable \({ }^{p 772}\). The user agent might ignore this preference for click and sequential focusabiity.

\section*{positive integer values}

Behaves the same as 0 , but in addition creates a relative ordering within a tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\), so that elements with higher tabindex \({ }^{\text {p773 }}\) attribute value come later.

Note that the tabindex \({ }^{\text {p773 }}\) attribute cannot be used to make an element non-focusable. The only way a page author can do that is by disabling \({ }^{p 723}\) the element, or making it inert \({ }^{p 766}\).

The tabindex value of an element is the value of its tabindex \({ }^{\text {p773 }}\) attribute, parsed using the rules for parsing integers \({ }^{\text {p68 }}\). If parsing fails or the attribute is not specified, then the tabindex value \({ }^{\text {p774 }}\) is null.

The tabindex value \({ }^{\mathrm{p} 774}\) of a focusable area \({ }^{\mathrm{p} 770}\) is the tabindex value \({ }^{\mathrm{p} 774}\) of its DOM anchor \({ }^{\mathrm{p} 770}\).
The tabindex value \({ }^{\mathrm{p} 774}\) of an element must be interpreted as follows:

\section*{If the value is null}

The user agent should follow platform conventions to determine if the element should be considered as a focusable area \({ }^{\text {p770 }}\) and if so, whether the element and any focusable areas \({ }^{\mathrm{p} 770}\) that have the element as their DOM anchor \({ }^{\mathrm{p770}}\) are sequentially focusable \({ }^{\mathrm{p} 772}\), and if so, what their relative position in their tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\) is to be. If the element is a focus navigation scope owner \({ }^{\text {p772 }}\), it must be included in its tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\) even if it is not a focusable area \({ }^{\mathrm{p} 770}\).

The relative ordering within a tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\) for elements and focusable areas \({ }^{\mathrm{p} 770}\) that belong to the same focus navigation scope \({ }^{p 772}\) and whose tabindex value \({ }^{\text {p774 }}\) is null should be in shadow-including tree order.

Modulo platform conventions, it is suggested that the following elements should be considered as focusable areas \({ }^{\text {p770 }}\) and be sequentially focusable \({ }^{\mathrm{p} 772}\) :
- \(a^{p 238}\) elements that have an href \({ }^{p 284}\) attribute
- link \(^{\text {p157 }}\) elements that have an href \({ }^{\text {p158 }}\) attribute
- button \({ }^{\text {p535 }}\) elements
- input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute are not in the Hidden \({ }^{\text {p499 }}\) state
- select \({ }^{\text {p537 }}\) elements
- textarea \({ }^{p 548}\) elements
- summary \({ }^{p 607}\) elements that are the first summary \({ }^{p 607}\) element child of a details \({ }^{p 664}\) element
- Elements with a draggable \({ }^{\text {p889 }}\) attribute set, if that would enable the user agent to allow the user to begin a drag operations for those elements without the use of a pointing device
- Editing hosts \({ }^{\text {p789 }}\)
- Browsing context containers \({ }^{\text {p814 }}\)

\section*{If the value is a negative integer}

The user agent must consider the element as a focusable area \({ }^{\text {p770 }}\), but should omit the element from any tabindex-ordered focus navigation scope \({ }^{\text {p773 }}\).

\section*{Note}

One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user's only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative tabindex \({ }^{\text {p773 }}\), so that user's user agent would be well justified in allowing the user to tab to the control regardless.

\section*{If the value is a zero}

The user agent must allow the element to be considered as a focusable area \({ }^{\text {p770 }}\) and should allow the element and any focusable areas \({ }^{\mathrm{p} 770}\) that have the element as their DOM anchor \({ }^{\mathrm{p} 770}\) to be sequentially focusable \({ }^{\mathrm{p} 772}\).

The relative ordering within a tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\) for elements and focusable areas \({ }^{\mathrm{p} 770}\) that belong to the same focus navigation scope \({ }^{\mathrm{p} 772}\) and whose tabindex value \({ }^{\mathrm{p} 774}\) is zero should be in shadow-including tree order.

\section*{If the value is greater than zero}

The user agent must allow the element to be considered as a focusable area \({ }^{\text {p770 }}\) and should allow the element and any focusable areas \({ }^{\mathrm{p} 770}\) that have the element as their DOM anchor \({ }^{\mathrm{p} 770}\) to be sequentially focusable \({ }^{\mathrm{p} 772}\), and should place the element referenced as candidate below - and the aforementioned focusable areas \({ }^{\mathrm{p770}}\) in the tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\) where the element is a part of so that, relative to other elements and focusable areas \({ }^{\mathrm{p} 770}\) that belong to the same focus navigation scope \({ }^{\text {p772 }}\), they are:
- before any focusable area \({ }^{\mathrm{p} 770}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is an element whose tabindex \({ }^{\mathrm{p} 773}\) attribute has been omitted or whose value, when parsed, returns an error,
- before any focusable area \({ }^{\mathrm{p} 770}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is an element whose tabindex \({ }^{\mathrm{p} 773}\) attribute has a value equal to or less than zero,
- after any focusable area \({ }^{\mathrm{p770}}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is an element whose tabindex \({ }^{\mathrm{p773}}\) attribute has a value greater than zero but less than the value of the tabindex \({ }^{\mathrm{p773}}\) attribute on candidate,
- after any focusable area \({ }^{\mathrm{p} 770}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is an element whose tabindex \({ }^{\mathrm{p} 773}\) attribute has a value equal to the value of the tabindex \({ }^{\text {p773 }}\) attribute on candidate but that is located earlier than candidate in shadow-including tree order,
- before any focusable area \({ }^{\mathrm{p770}}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is an element whose tabindex \({ }^{\mathrm{p773}}\) attribute has a value equal to the value of the tabindex \({ }^{\mathrm{p} 773}\) attribute on candidate but that is located later than candidate in shadow-including tree order, and
- before any focusable area \({ }^{\mathrm{p} 770}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is an element whose tabindex \({ }^{\mathrm{p} 773}\) attribute has a value greater than the value of the tabindex \({ }^{\text {p773 }}\) attribute on candidate.

The tabIndex IDL attribute must reflect \({ }^{\mathrm{p94}}\) the value of the \(\mathrm{tabindex}{ }^{\mathrm{p773}}\) content attribute. The default value is 0 if the element is an \(a^{p 238}\), area \({ }^{\text {p443 }}\), button \({ }^{p 535}\), frame \({ }^{\text {p1240 }}\), iframe \({ }^{\text {p361 }}\), input \({ }^{\text {p493 }}\), object \({ }^{\text {p373 }}\), select \({ }^{p 537}\), textarea \({ }^{\text {p548 }}\), or SVG a element, or is a summary \({ }^{\text {p607 }}\) element that is a summary for its parent details \({ }^{\mathrm{p607}}\). The default value is -1 otherwise.

\section*{Note}

The varying default value based on element type is a historical artifact.

\subsection*{6.5.4 Processing model \(\S^{p 77}\)}

To get the focusable area for a focus target that is either an element that is not a focusable area \({ }^{\mathrm{p} 770}\), or is a browsing context \({ }^{\text {p811 }}\), given an optional string focus trigger, run the first matching set of steps from the following list:
\(\rightarrow\) If focus target is an area \({ }^{\text {p443 }}\) element with one or more shapes that are focusable areas \({ }^{\text {p770 }}\)
Return the shape corresponding to the first \(\underline{i m g}{ }^{\mathrm{p} 32 \theta}\) element in tree order that uses the image map to which the area \({ }^{\text {p443 }}\) element belongs.
\(\rightarrow\) If focus target is an element with one or more scrollable regions that are focusable areas \({ }^{\text {p770 }}\)
Return the element's first scrollable region, according to a pre-order, depth-first traversal of the flat tree. [CSSSCOPING] \({ }^{\text {p1287 }}\)
\(\rightarrow\) If focus target is the document element of its Document \({ }^{\text {p114 }}\)
Return the Document \({ }^{\text {p114 ' }} \mathrm{s}\) viewport.

Return the browsing context \({ }^{\mathrm{p} 811}\) 's active document \({ }^{\mathrm{p} 811}\).
\(\rightarrow\) If focus target is a browsing context container \({ }^{\text {p814 }}\) with a non-null nested browsing context \({ }^{\text {p814 }}\)
Return the browsing context container \({ }^{\mathrm{p814}}\) 's nested browsing context \({ }^{\mathrm{p814}}\) 's active document \({ }^{\mathrm{p} 811}\).

\section*{\(\leftrightarrow\) If focus target is a shadow host whose shadow root's delegates focus is true}
1. If focus target is a shadow-including inclusive ancestor of the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\) 's DOM anchor \({ }^{\text {p770 }}\), then return null.
2. Otherwise:
1. If focus trigger is "click", then let possible focus delegates be the list of all click focusable \({ }^{\text {p772 }}\) focusable areas \({ }^{\mathrm{p} 770}\) whose DOM anchor \({ }^{\mathrm{p} 770}\) is a descendant of focus target in the flat tree.
2. Otherwise, let possible focus delegates be the list of all focusable areas \({ }^{\text {p770 }}\) whose DOM anchor \({ }^{\text {p770 }}\) is a descendant of focus target in the flat tree.
3. Return the first focusable area \({ }^{p 770}\) in tree order of their DOM anchors \({ }^{\text {p770 }}\) in possible focus delegates, or null if possible focus delegates is empty.

\section*{Note}

For sequential focusability \({ }^{p 772}\), the handling of shadow hosts and delegates focus is done when constructing the sequential focus navigation order \({ }^{p 779}\). That is, the focusing steps \({ }^{p 776}\) will never be called on such shadow hosts as part of sequential focus navigation.

\section*{\(\hookrightarrow\) Otherwise}

Return null.
The focusing steps for an object new focus target that is either a focusable area \({ }^{\text {p770 }}\), or an element that is not a focusable area \({ }^{\text {p770 }}\), or a browsing context \({ }^{\text {p811 }}\), are as follows. They can optionally be run with a fallback target and a string focus trigger.
1. If new focus target is not a focusable area \({ }^{\text {p770 }}\), then set new focus target to the result of getting the focusable area \({ }^{\text {p775 }}\) for new focus target, given focus trigger if it was passed.
2. If new focus target is null, then:
1. If no fallback target was specified, then return.
2. Otherwise, set new focus target to the fallback target.
3. If new focus target is a browsing context container \({ }^{p 814}\) with non-null nested browsing context \({ }^{\text {p814 }}\), then set new focus target to the nested browsing context \({ }^{\text {p814 }}\) 's active document \({ }^{\text {p811 }}\), and redo this step.
4. If new focus target is a focusable area \({ }^{\text {p770 }}\) and its DOM anchor \({ }^{p 770}\) is inert \({ }^{p 766}\), then return.
5. If new focus target is the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\), then return.
6. Let old chain be the focus chain \({ }^{\text {p771 }}\) of the currently focused area of the top-level browsing context \({ }^{\text {p771 }}\) in which new focus target finds itself.
7. Let new chain be the focus chain \({ }^{\text {p771 }}\) of new focus target.
8. Run the focus update steps \({ }^{\text {p777 }}\) with old chain, new chain, and new focus target respectively.

User agents must immediately \({ }^{\text {p42 }}\) run the focusing steps \({ }^{\text {p776 }}\) for a focusable area \({ }^{\text {p770 }}\) or browsing context \({ }^{\text {p811 }}\) candidate \(^{\text {whenever the }}\) user attempts to move the focus to candidate.

The unfocusing steps for an object old focus target that is either a focusable area \({ }^{\text {p770 }}\) or an element that is not a focusable area \({ }^{\text {p770 }}\) are as follows:
1. If old focus target is inert \({ }^{\mathrm{p} 766}\), then return.
2. If old focus target is an area \({ }^{\mathrm{p} 443}\) element and one of its shapes is the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\), or, if old focus target is an element with one or more scrollable regions, and one of them is the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\), then let old focus target be that currently focused area of a top-level browsing
context \({ }^{\text {p771 }}\).
3. Let old chain be the focus chain \({ }^{p 771}\) of the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\).
4. If old focus target is not one of the entries in old chain, then return.
5. If old focus target is a focusable area \({ }^{\mathrm{p} 770}\), then let new focus target be its Document \({ }^{\text {p114 }}\) 's viewport. Otherwise, let new focus target be null.
6. If new focus target is not null, then run the focusing steps \({ }^{p 776}\) for new focus target.

When the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\) is somehow unfocused without another element being explicitly focused in its stead, the user agent must immediately \({ }^{p 42}\) run the unfocusing steps \({ }^{p 776}\) for that object.

\section*{Note}

The unfocusing steps \({ }^{p 776}\) do not always result in the focus changing, even when applied to the currently focused area of a top-level browsing context \({ }^{p 771}\). For example, if the currently focused area of a top-level browsing context \({ }^{p 771}\) is a viewport, then it will usually keep its focus regardless until another focusable area \({ }^{p 770}\) is explicitly focused with the focusing steps \({ }^{p 776}\).

Focus fixup rule: When the designated focused area of the document \({ }^{p 771}\) is removed from that Document \({ }^{\text {p114 }}\) in some way (e.g. it stops being a focusable area \({ }^{\text {p770 }}\), it is removed from the DOM, it becomes expressly inert \({ }^{\mathrm{p766}}\), etc.), designate the Document \({ }^{\text {p114 }}\).s viewport to be the new focused area of the document \({ }^{p 771}\).

\section*{Example}

For example, this might happen because an element is removed from its Document \({ }^{\text {p114 }}\), or has a hidden \({ }^{\text {p765 }}\) attribute added. It might also happen to an input \({ }^{\text {p493 }}\) element when the element gets disabled \({ }^{\text {p570 }}\).

\section*{Example}

In a Document \({ }^{\text {p114 }}\) whose focused area \({ }^{\text {p771 }}\) is a button \({ }^{\text {p535 }}\) element, removing, disabling, or hiding that button would cause the page's new focused area \({ }^{\text {p771 }}\) to be the viewport of the Document \({ }^{p 114}\). This would, in turn, be reflected through the activeElement \({ }^{\text {p781 }}\) API as the body element \({ }^{\text {p118 }}\).

The focus update steps, given an old chain, a new chain, and a new focus target respectively, are as follows:
1. If the last entry in old chain and the last entry in new chain are the same, pop the last entry from old chain and the last entry from new chain and redo this step.
2. For each entry entry in old chain, in order, run these substeps:
1. If entry is an input \({ }^{\text {p493 }}\) element, and the change \({ }^{\text {p1281 }}\) event applies \({ }^{\text {p496 }}\) to the element, and the element does not have a defined activation behavior, and the user has changed the element's value \({ }^{p 566}\) or its list of selected files \({ }^{\text {p515 }}\) while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then fire an event named change \({ }^{\text {p1281 }}\) at the element, with the bubbles attribute initialized to true.
2. If entry is an element, let blur event target be entry.

If entry is a Document \({ }^{\mathrm{p114}}\) object, let blur event target be that Document \({ }^{\mathrm{p114}}\) object's relevant global object \({ }^{\mathrm{p922}}\).
Otherwise, let blur event target be null.
3. If entry is the last entry in old chain, and entry is an Element, and the last entry in new chain is also an Element, then let related blur target be the last entry in new chain. Otherwise, let related blur target be null.
4. If blur event target is not null, fire a focus event \({ }^{\mathrm{p} 778}\) named blur \({ }^{\text {p1281 }}\) at blur event target, with related blur target as the related target.

\section*{Note}

In some cases, e.g. if entry is an area \({ }^{\text {p443 }}\) element's shape, a scrollable region, or a viewport, no event is fired.
3. Apply any relevant platform-specific conventions for focusing new focus target. (For example, some platforms select the
contents of a text control when that control is focused.)
4. For each entry entry in new chain, in reverse order, run these substeps:
1. If entry is a focusable area \({ }^{\mathrm{p} 770}\) : designate entry as the focused area of the document \({ }^{\mathrm{p} 771}\).
2. If entry is an element, let focus event target be entry.

If entry is a Document \({ }^{\mathrm{p} 114}\) object, let focus event target be that Document \({ }^{\mathrm{p} 114}\) object's relevant global object \({ }^{\mathrm{p924}}\).
Otherwise, let focus event target be null.
3. If entry is the last entry in new chain, and entry is an Element, and the last entry in old chain is also an Element, then let related focus target be the last entry in old chain. Otherwise, let related focus target be null.
4. If focus event target is not null, fire a focus event \({ }^{p 778}\) named focus \({ }^{p 1281}\) at focus event target, with related focus target as the related target.

\section*{Note}

In some cases, e.g. if entry is an area \({ }^{\mathrm{p443}}\) element's shape, a scrollable region, or a viewport, no event is fired.

To fire a focus event named \(e\) at an element \(t\) with a given related target \(r\), fire an event named \(e\) at \(t\), using FocusEvent, with the relatedTarget attribute initialized to \(r\), the view attribute initialized to \(t\) 's node document's relevant global object \({ }^{p 924}\), and the composed flag set.

When a key event is to be routed in a top-level browsing context \({ }^{\mathrm{p814}}\), the user agent must run the following steps:
1. Let target area be the currently focused area of the top-level browsing context \({ }^{p 771}\).
2. If target area is a focusable area \({ }^{\text {p770 }}\), let target node be target area's DOM anchor \({ }^{\text {p770 }}\). Otherwise, target area is a dialog \({ }^{\text {p610 }}\); let target node be target area.
3. If target node is a Document \({ }^{\text {p114 }}\) that has a body element \({ }^{p 118}\), then let target node be the body element \({ }^{\text {p118 }}\) of that Document \({ }^{\text {p114 }}\).

Otherwise, if target node is a Document \({ }^{\text {p114 }}\) object that has a non-null document element, then let target node be that document element.
4. If target node is not inert \({ }^{p 766}\), then:

\section*{Note}

It is possible for the currently focused area of a top-level browsing context \({ }^{p 771}\) to be inert \({ }^{\text {p766 }}\), for example if a modal dialog is shown \({ }^{p 612}\), and then that dialog \({ }^{p 610}\) element is made inert \({ }^{p 766}\). It is likely to be the result of a logic error in the application, though.
1. Let canHandle be the result of dispatching the key event at target node.
2. If canHandle is true, then let target area handle the key event. This might include firing a click event \({ }^{\text {p965 }}\) at target node.

The has focus steps, given a Document \({ }^{\text {p114 }}\) object target, are as follows:
1. Let candidate be target's top-level browsing context \({ }^{p 814}\) 's active document \({ }^{p 811}\).
2. While true:
1. If candidate is target, then return true.
2. If the focused area \({ }^{\mathrm{p771}}\) of candidate is a browsing context container \({ }^{\mathrm{p814}}\) with a non-null nested browsing context \({ }^{\mathrm{p} 814}\), then set candidate to the active document \({ }^{\mathrm{p811}}\) of that browsing context container \({ }^{\mathrm{p} 814}\) 's nested browsing context \({ }^{\text {p814 }}\).
3. Otherwise, return false.

\subsection*{6.5.5 Sequential focus navigation \(\S^{p 77}\)}

Each Document \({ }^{\text {p114 }}\) has a sequential focus navigation order, which orders some or all of the focusable areas \({ }^{\mathrm{p} 770}\) in the Document \({ }^{p 114}\) relative to each other. Its contents and ordering are given by the flattened tabindex-ordered focus navigation scope \({ }^{\mathrm{p} 773}\) of the Document \({ }^{\text {p114 }}\).

\section*{Note}

Per the rules defining the flattened tabindex-ordered focus navigation scope \({ }^{p 773}\), the ordering is not necessarily related to the tree order of the Document \({ }^{\text {p114 }}\).

If a focusable area \({ }^{\mathrm{p} 770}\) is omitted from the sequential focus navigation order \({ }^{\mathrm{p} 779}\) of its Document \({ }^{\mathrm{p} 114}\), then it is unreachable via sequential focus navigation \({ }^{\text {p779 }}\).

There can also be a sequential focus navigation starting point. It is initially unset. The user agent may set it when the user indicates that it should be moved.

\section*{Example}

For example, the user agent could set it to the position of the user's click if the user clicks on the document contents.

\section*{Note}

User agents are required to set the sequential focus navigation starting point \({ }^{p 779}\) to the target element \({ }^{p 881}\) when navigating to a fragment \({ }^{p 880}\).

When the user requests that focus move from the currently focused area of a top-level browsing context \({ }^{\text {p771 }}\) to the next or previous focusable area \({ }^{\text {p770 }}\) (e.g. as the default action of pressing the tab key), or when the user requests that focus sequentially move to a toplevel browsing context \({ }^{\mathrm{p} 814}\) in the first place (e.g. from the browser's location bar), the user agent must use the following algorithm:
1. Let starting point be the currently focused area of a top-level browsing context \({ }^{\mathrm{p} 771}\), if the user requested to move focus sequentially from there, or else the top-level browsing context \({ }^{\text {p814 }}\) itself, if the user instead requested to move focus from outside the top-level browsing context \({ }^{\text {p814 }}\).
2. If there is a sequential focus navigation starting point \({ }^{\text {p779 }}\) defined and it is inside starting point, then let starting point be the sequential focus navigation starting point \({ }^{\text {p779 }}\) instead.
3. Let direction be forward if the user requested the next control, and backward if the user requested the previous control.

Note
Typically, pressing tab requests the next control, and pressing shift+tab requests the previous control.
4. Loop: Let selection mechanism be sequential if the starting point is a browsing context \({ }^{\text {p811 }}\) or if starting point is in its Document \({ }^{\text {p114 }}\) 's sequential focus navigation order \({ }^{\text {p779 }}\).

Otherwise, starting point is not in its Document \({ }^{\text {p114' }}\) 's sequential focus navigation order \({ }^{\text {p779 }}\); let selection mechanism be DOM.
5. Let candidate be the result of running the sequential navigation search algorithm \({ }^{\text {p780 }}\) with starting point, direction, and selection mechanism as the arguments.
6. If candidate is not null, then run the focusing steps \({ }^{\mathrm{p} 776}\) for candidate and return.
7. Otherwise, unset the sequential focus navigation starting point \({ }^{\mathrm{p} 779}\).
8. If starting point is the top-level browsing context \({ }^{\mathrm{p} 814}\), or a focusable area \({ }^{\mathrm{p770}}\) in the top-level browsing context \({ }^{p 814}\), the user agent should transfer focus to its own controls appropriately (if any), honouring direction, and then return.

\section*{Example}

For example, if direction is backward, then the last sequentially focusable \({ }^{\text {p772 }}\) control before the browser's rendering area would be the control to focus.

If the user agent has no sequentially focusable \({ }^{\mathrm{p} 772}\) controls - a kiosk-mode browser, for instance - then the user agent may instead restart these steps with the starting point being the top-level browsing context \({ }^{\text {p814 }}\) itself.
9. Otherwise, starting point is a focusable area \({ }^{\mathrm{p} 770}\) in a child browsing context \({ }^{\mathrm{p814}}\). Set starting point to that child browsing context \({ }^{8814}\) 's container \({ }^{\text {p814 }}\) and return to the step labeled loop.

The sequential navigation search algorithm consists of the following steps. This algorithm takes three arguments: starting point, direction, and selection mechanism.
1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

The appropriate cell is the one that is from the column whose header describes direction and from the first row whose header describes starting point and selection mechanism.
\begin{tabular}{|c|c|c|}
\hline & direction is forward & direction is backward \\
\hline starting point is a browsing context \({ }^{\text {p811 }}\) & Let candidate be the first suitable sequentially focusable area \({ }^{\text {p780 }}\) in starting point's active document \({ }^{\text {p811 }}\), if any; or else null & Let candidate be the last suitable sequentially focusable area \({ }^{\text {p780 }}\) in starting point's active document \({ }^{\text {p811 }}\), if any; or else null \\
\hline selection mechanism is DOM & Let candidate be the first suitable sequentially focusable area \({ }^{\mathrm{p} 780}\) in the home document \({ }^{\mathrm{p} 780}\) following starting point, if any; or else null & Let candidate be the last suitable sequentially focusable area \({ }^{\text {p780 }}\) in the home document \({ }^{\text {p780 }}\) preceding starting point, if any; or else null \\
\hline selection mechanism is sequential & Let candidate be the first suitable sequentially focusable area \({ }^{\mathrm{p} 780}\) in the home sequential focus navigation order \({ }^{\mathrm{p} 780}\) following starting point, if any; or else null & Let candidate be the last suitable sequentially focusable area \({ }^{\text {p780 }}\) in the home sequential focus navigation order \({ }^{\mathrm{p} 780}\) preceding starting point, if any; or else null \\
\hline
\end{tabular}

A suitable sequentially focusable area is a focusable area \({ }^{\text {p770 }}\) whose DOM anchor \({ }^{\mathrm{p770}}\) is not inert \({ }^{\mathrm{p766}}\) and is sequentially focusable \({ }^{\text {p772 }}\).

The home document is the Document \({ }^{\text {p114 }}\) to which starting point belongs.
The home sequential focus navigation order is the sequential focus navigation order \({ }^{\mathrm{p} 779}\) to which starting point belongs.

\section*{Note}

The home sequential focus navigation order \({ }^{p 780}\) is the home document \({ }^{\text {p780 }}\) 's sequential focus navigation order \({ }^{\text {p779 }}\), but is only used when the starting point is in that sequential focus navigation order \({ }^{\text {p779 }}\) (when it's not, selection mechanism will be DOM).
2. If candidate is a browsing context container \({ }^{p 814}\) with a non-null nested browsing context \({ }^{p 814}\), then let new candidate be the result of running the sequential navigation search algorithm \({ }^{\text {p780 }}\) with candidate's nested browsing context \({ }^{\mathrm{p} 814}\) as the first argument, direction as the second, and sequential as the third.

If new candidate is null, then let starting point be candidate, and return to the top of this algorithm. Otherwise, let candidate be new candidate.
3. Return candidate.

\subsection*{6.5.6 Focus management APIs \(\S^{p 78}\)}
```
IDL dictionary FocusOptions {
    boolean preventScroll = false;
};
```

\section*{For web developers (non-normative)}

\section*{documentOrShadowRoot . activeElement \({ }^{\text {p781 }}\)}

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.
For the purposes of this API, when a child browsing context \({ }^{\text {p814 }}\) is focused, its container \({ }^{\text {p814 }}\) is focused \({ }^{\text {p771 }}\) in the parent browsing context \({ }^{\mathrm{p} 814}\). For example, if the user moves the focus to a text control in an iframe \({ }^{\mathrm{p} 361}\), the iframe \({ }^{\mathrm{p} 361}\) is the element returned by the activeElement \({ }^{\mathrm{p} 781}\) API in the iframe \({ }^{\mathrm{p} 361}\) 's node document.

Similarly, when the focused element is in a different node tree than documentOrShadowRoot, the element returned will be the host that's located in the same node tree as documentOrShadowRoot if documentOrShadowRoot is a shadow-including inclusive ancestor of the focused element, and null if not.

\section*{document . hasFocus \({ }^{\mathrm{p} 781}\) ()}

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

\section*{window. focus \({ }^{\text {p781 }}\) ()}

Moves the focus to the window's browsing context \({ }^{\text {p826 }}\), if any.
element . focus \({ }^{\mathrm{p782}}\) ([ \{ preventScroll \({ }^{\mathrm{p782}}\) : true \} ])
Moves the focus to the element.
If the element is a browsing context container \({ }^{\text {p814 }}\), moves the focus to its nested browsing context \({ }^{\mathrm{p} 814}\) instead.
By default, this method also scrolls the element into view. Providing the preventScroll \({ }^{\text {p782 }}\) option and setting it to true prevents this behavior.
element. blur \({ }^{\text {p782 }}\) ()
Moves the focus to the viewport. Use of this method is discouraged; if you want to focus the viewport, call the focus() \({ }^{\text {p782 }}\) method on the Document \({ }^{p 114}\) 's document element.
Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use a CSS rule to override the 'outline' property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn't made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

\section*{Example}

For example, to hide the outline from links and instead use a yellow background to indicate focus, you could use:
```
:link:focus, :visited:focus { outline: none; background: yellow; color: black; }
```

The activeElement attribute's getter must run these steps:
1. Let candidate be the DOM anchor \({ }^{\mathrm{p} 770}\) of the focused area \({ }^{\mathrm{p} 771}\) of this DocumentOrShadowRoot \({ }^{\mathrm{p} 115}\) 's node document.
2. Set candidate to the result of retargeting candidate against this Document0rShadowRoot \({ }^{p 115}\).
3. If candidate's root is not this DocumentOrShadowRoot \({ }^{\text {p115 }}\), then return null.
4. If candidate is not a Document \({ }^{p 114}\) object, then return candidate.
5. If candidate has a body element \({ }^{\text {p118 }}\), then return that body element \({ }^{\mathrm{p} 118}\).
6. If candidate's document element is non-null, then return that document element.
7. Return null.

The hasFocus() method on the Document \({ }^{p 114}\) object, when invoked, must return the result of running the has focus steps \({ }^{\text {p778 }}\) with the Document \({ }^{\text {p114 }}\) object as the argument.

The focus() method, when invoked, must run these steps:
1. Let current be this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\text {p826 }}\).
2. If current is null, then return.
3. Run the focusing steps \({ }^{\text {p776 }}\) with current.
4. If current is a top-level browsing context \({ }^{\mathrm{p} 814}\), user agents are encouraged to trigger some sort of notification to indicate to the user that the page is attempting to gain focus.

The blur() method, when invoked, provides a hint to the user agent that the script believes the user probably is not currently interested in the contents of this Window \({ }^{p 824}\) object's browsing context \({ }^{\text {p826 }}\), if non-null, but that the contents might become interesting again in the future.

User agents are encouraged to ignore calls to this \(\underline{b l u r()^{p 781}}\) method entirely.

\section*{Note}

Historically, the focus() \({ }^{\mathrm{p} 781}\) and blur() \({ }^{\text {p781 }}\) methods actually affected the system-level focus of the system widget (e.g., tab or window) that contained the browsing context \({ }^{p 811}\), but hostile sites widely abuse this behavior to the user's detriment.

The focus(options) method on elements, when invoked, must run the following steps:
1. If the element is marked as locked for focus \({ }^{p 782}\), then return.
2. Mark the element as locked for focus.
3. Run the focusing steps \({ }^{\text {p776 }}\) for the element.
4. If the value of the preventScroll dictionary member of options is false, then scroll the element into view with scroll behavior "auto", block flow direction position set to an implementation-defined value, and inline base direction position set to an implementation-defined value.
5. Unmark the element as locked for focus \({ }^{p 782}\).

The blur() method, when invoked, should run the unfocusing steps \({ }^{\mathrm{p} 776}\) for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.

\section*{Example}

For example, if the blur() \()^{\mathrm{p} 782}\) method is unwisely being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.

\subsection*{6.5.7 The autofocus \({ }^{\mathrm{p} 782}\) attribute \(\S_{2}^{\mathrm{p} 78}\)}

The autofocus content attribute allows the author to indicate that an element is to be focused as soon as the page is loaded or as soon as the dialog \({ }^{\text {p610 }}\) within which it finds itself is shown, allowing the user to just start typing without having to manually focus the main element.

The autofocus \({ }^{\mathrm{p} 782}\) attribute is a boolean attribute \({ }^{\mathrm{p} 67}\).
An element's nearest ancestor autofocus scoping root element is the element itself if the element is a dialog \({ }^{\text {p610 }}\) element, or else is the element's nearest ancestor dialog \({ }^{\text {p610 }}\) element, if any, or else is the element's last inclusive ancestor element.

There must not be two elements with the same nearest ancestor autofocus scoping root element \({ }^{\text {p782 }}\) that both have the autofocus \({ }^{\text {p782 }}\) attribute specified.

Each Document \({ }^{p 114}\) has an autofocus candidates list, initially empty.
Each Document \({ }^{\text {p114 }}\) has an autofocus processed flag boolean, initially false.
When an element with the autofocus \({ }^{\mathrm{p} 782}\) attribute specified is inserted into a document \({ }^{\mathrm{p} 44}\), run the following steps:
1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.
2. Let target be the element's node document.
3. If target's browsing context \({ }^{\text {p811 }}\) is null, then return.
4. If target's active sandboxing flag set \({ }^{\mathrm{p} 844}\) has the sandboxed automatic features browsing context flag \({ }^{\mathrm{p} 842}\), then return.
5. Let topDocument be the active document \({ }^{p 811}\) of target's browsing context \({ }^{p 811}\) 's top-level browsing context \({ }^{p 814}\).
6. If target's origin \({ }^{\text {p837 }}\) is not the same \({ }^{\text {p838 }}\) as the origin \({ }^{\text {p837 }}\) of topDocument, then return.
7. If topDocument's autofocus processed flag \({ }^{\mathrm{p} 782}\) is false, then remove the element from topDocument's autofocus candidates \({ }^{\mathrm{p} 782}\), and append the element to topDocument's autofocus candidates \({ }^{\mathrm{p} 782}\).

\section*{Note}

We do not check if an element is a focusable area \({ }^{\text {p770 }}\) before storing it in the autofocus candidates \({ }^{\text {p782 }}\) list, because even if it is not a focusable area when it is inserted, it could become one by the time flush autofocus candidates \({ }^{p 782}\) sees it.

To flush autofocus candidates for a document topDocument, run these steps:
1. If topDocument's autofocus processed flag \({ }^{\mathrm{p} 782}\) is true, then return.
2. Let candidates be topDocument's autofocus candidates \({ }^{\mathrm{p} 782}\).
3. If candidates is empty, then return.
4. If topDocument's focused area \({ }^{\text {p771 }}\) is not topDocument itself, or topDocument's \(\underline{\text { URL's }}\) fragment is not empty, then:
1. Empty candidates.
2. Set topDocument's autofocus processed flag \({ }^{\text {p782 }}\) to true.
3. Return.
5. While candidates is not empty:
1. Let element be candidates[0].
2. Let doc be element's node document.
3. If doc is not fully active \({ }^{\mathrm{p815}}\), then remove element from candidates, and continue.
4. If doc's browsing context \({ }^{\text {p811 }}\) 's top-level browsing context \({ }^{\mathrm{p} 814}\) is not same as topDocument's browsing context \({ }^{\mathrm{p} 811}\), then remove element from candidates, and continue.
5. If doc's script-blocking style sheet counter \({ }^{\mathrm{p178}}\) is greater than 0 , then return.

\section*{Note}

In this case, element is the currently-best candidate, but doc is not ready for autofocusing. We'll try again next time flush autofocus candidates \({ }^{p 782}\) is called.
6. Remove element from candidates.
7. Let inclusiveAncestorDocuments be a list consisting of doc, plus the active documents \({ }^{p 811}\) of each of doc's browsing context \({ }^{\mathrm{p} 811}\) 's ancestor browsing contexts \({ }^{\mathrm{p} 814}\).
8. If URL's fragment of any Document \({ }^{\text {p114 }}\) in inclusiveAncestorDocuments is not empty, then continue.
9. Let target be element.
10. If target is not a focusable area \({ }^{\mathrm{p} 770}\), then set target to the result of getting the focusable area \({ }^{\mathrm{p} 775}\) for target.

\section*{Note}

Autofocus candidates \({ }^{p 782}\) can contain elements which are not focusable areas \({ }^{p 770}\). In addition to the special cases handled in the get the focusable area \({ }^{\text {p775 }}\) algorithm, this can happen because a non-focusable area \({ }^{\text {p770 }}\) element with an autofocus \({ }^{\text {p782 }}\) attribute was inserted into a document \({ }^{p 44}\) and it never became focusable, or because the element was focusable but its status changed while it was stored in autofocus candidates \({ }^{\text {p782 }}\).
11. If target is not null, then:
1. Empty candidates.
2. Set topDocument's autofocus processed flag \({ }^{\text {p782 }}\) to true.
3. Run the focusing steps \({ }^{\mathrm{p} 776}\) for target.

\section*{Note}

This handles the automatic focusing during document load. The show() \()^{\text {p611 }}\) and showModal() \()^{\text {p612 }}\) methods of dialog p610 elements also processes the autofocus \({ }^{\text {p782 }}\) attribute.

Note
Focusing the element does not imply that the user agent has to focus the browser window if it has lost focus.

The autofocus IDL attribute must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.

In the following snippet, the text control would be focused when the document was loaded.
```
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search">
```

\section*{Example}

The autofocus \({ }^{\mathrm{p} 782}\) attribute applies to all elements, not just to form controls. This allows examples such as the following:
```
<div contenteditable autofocus>Edit <strong>me!</strong><div>
```

\subsection*{6.6 Assigning keyboard shortcuts \(\S^{p 78}\)}

\subsection*{6.6.1 Introduction \(\S^{p 78}\)}

This section is non-normative.
Each element that can be activated or focused can be assigned a single key combination to activate it, using the accesskey \({ }^{\mathrm{p} 785}\) attribute.

The exact shortcut is determined by the user agent, based on information about the user's keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the accesskey \({ }^{\text {p785 }}\) attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the accesskey \({ }^{\text {p785 }}\) attribute.

Each alternative consists of a single character, such as a letter or digit.
User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The accessKeyLabe \({ }^{\text {p786 }}\) IDL attribute returns a string representing the actual key combination assigned by the user agent.

\section*{Example}

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided " 1 " as another possibly key.
```
<input type=button value=Collect onclick="collect()"
    accesskey="C 1" id=c>
```

\section*{Example}

To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button's label:
```
function addShortcutKeyLabel(button) {
    if (button.accessKeyLabel != '')
        button.value += ' (' + button.accessKeyLabel + ')';
}
addShortcutKeyLabel(document.getElementById('c'));
```

Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display "Ctrl+Shift+C", whereas a Mac browser might display "^^C", while an Emacs browser might just display "C-C". Similarly, if the key combination is the Alt key and the Escape key, Windows might use "Alt+Esc", Mac might use "te", and an Emacs browser might use "M-ESC" or "ESC ESC".

In general, therefore, it is unwise to attempt to parse the value returned from the accessKeyLabel \({ }^{\mathrm{p} 786}\) IDL attribute.

\subsection*{6.6.2 The accesskey attribute \(\S_{5}^{p 78}\)}

All HTML elements \({ }^{\text {p44 }}\) may have the accesskey \({ }^{\mathrm{p} 785}\) content attribute set. The accesskey \({ }^{\mathrm{p} 785}\) attribute's value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an ordered set of unique space-separated tokens \({ }^{p 87}\) none of which are identical to another token and each of which must be exactly one code point in length.

\section*{Example}

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:
```
<nav>
    <p>
    <a title="Consortium Activities" accesskey="A" href="/Consortium/activities">Activities</a> |
    <a title="Technical Reports and Recommendations" accesskey="T" href="/TR/">Technical Reports</a>
|
    <a title="Alphabetical Site Index" accesskey="S" href="/Consortium/siteindex">Site Index</a> |
    <a title="About This Site" accesskey="B" href="/Consortium/">About Consortium</a> |
    <a title="Contact Consortium" accesskey="C" href="/Consortium/contact">Contact</a>
    </p>
</nav>
```

\section*{Example}

In the following example, the search field is given two possible access keys, "s" and "0" (in that order). A user agent on a device with a full keyboard might pick \(C t r l+A l t+S\) as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key 0 :
```
<form action="/search">
    <label>Search: <input type="search" name="q" accesskey="s 0"></label>
    <input type="submit">
</form>
```

\section*{Example}

In the following example, a button has possible access keys described. A script then tries to update the button's label to advertise the key combination the user agent selected.
```
<input type=submit accesskey="N @ 1" value="Compose">
<script>
    function labelButton(button) {
        if (button.accessKeyLabel)
        button.value += ' (' + button.accessKeyLabel + ')';
    }
    var inputs = document.getElementsByTagName('input');
    for (var i = 0; i < inputs.length; i += 1) {
        if (inputs[i].type == "submit")
        labelButton(inputs[i]);
    }
</script>
```

On one user agent, the button's label might become "Compose ( \(\mathscr{H}\) )". On another, it might become "Compose (Alt \(+\uparrow+1\) )". If the user agent doesn't assign a key, it will be just "Compose". The exact string depends on what the assigned access key \({ }^{\text {p786 }}\) is, and on
how the user agent represents that key combination.

\subsection*{6.6.3 Processing model \(\S^{\mathrm{p} 78}\)}

An element's assigned access key is a key combination derived from the element's accesskey \({ }^{\text {p785 }}\) content attribute. Initially, an element must not have an assigned access key \({ }^{\text {p786 }}\).

Whenever an element's accesskey \({ }^{\text {p785 }}\) attribute is set, changed, or removed, the user agent must update the element's assigned access key \({ }^{\text {p786 }}\) by running the following steps:
1. If the element has no accesskey \({ }^{\text {p785 }}\) attribute, then skip to the fallback step below.
2. Otherwise, split the attribute's value on ASCII whitespace, and let keys be the resulting tokens.
3. For each value in keys in turn, in the order the tokens appeared in the attribute's value, run the following substeps:
1. If the value is not a string exactly one code point in length, then skip the remainder of these steps for this value.
2. If the value does not correspond to a key on the system's keyboard, then skip the remainder of these steps for this value.
3. If the user agent can find a mix of zero or more modifier keys that, combined with the key that corresponds to the value given in the attribute, can be used as the access key, then the user agent may assign that combination of keys as the element's assigned access key \({ }^{\mathrm{p786}}\) and return.
4. Fallback: Optionally, the user agent may assign a key combination of its choosing as the element's assigned access key \(^{\text {p786 }}\) and then return.
5. If this step is reached, the element has no assigned access key \({ }^{\mathrm{p} 786}\).

Once a user agent has selected and assigned an access key for an element, the user agent should not change the element's assigned access key \({ }^{\mathrm{p} 786}\) unless the accesskey \({ }^{\mathrm{p} 785}\) content attribute is changed or the element is moved to another Document \({ }^{\text {p114 }}\).

When the user presses the key combination corresponding to the assigned access key \({ }^{\text {p786 }}\) for an element, if the element defines a command \({ }^{\text {p607 }}\), the command's Hidden State \({ }^{\text {p608 }}\) facet is false (visible), the command's Disabled State \({ }^{\text {p608 }}\) facet is also false (enabled), the element is in a document that has a non-null browsing context \({ }^{p 811}\), and neither the element nor any of its ancestors has a hidden \({ }^{\mathrm{p} 765}\) attribute specified, then the user agent must trigger the Action \({ }^{\mathrm{p} 608}\) of the command.

\section*{Note}

User agents might expose \({ }^{\text {p608 }}\) elements that have an accesskey \({ }^{\text {p785 }}\) attribute in other ways as well, e.g. in a menu displayed in response to a specific key combination.

The accessKey IDL attribute must reflect \({ }^{\text {p94 }}\) the accesskey \({ }^{\mathrm{p785}}\) content attribute.
The accessKey Label IDL attribute must return a string that represents the element's assigned access key \({ }^{\text {p786 }}\), if any. If the element does not have one, then the IDL attribute must return the empty string.

\subsection*{6.7 Editing \(\S^{\text {p78 }}\)}

\subsection*{6.7.1 Making document regions editable: The contenteditable \({ }^{\text {p787 }}\) content attribute \(\underset{6}{\S^{p 78}}\)}

IDL
```
interface mixin ElementContentEditable {
    [CEReactions] attribute DOMString contentEditable;
    [CEReactions] attribute DOMString enterKeyHint;
    readonly attribute boolean isContentEditable;
    [CEReactions] attribute DOMString inputMode;
```

The contenteditable content attribute is an enumerated attribute \({ }^{\text {p68 }}\) whose keywords are the empty string, true, and false. The empty string and the true keyword map to the true state. The false keyword maps to the false state. In addition, there is a third state, the inherit state, which is the missing value default \({ }^{p 68}\) and the invalid value default \({ }^{p 68}\).

The true state indicates that the element is editable. The inherit state indicates that the element is editable if its parent is. The false state indicates that the element is not editable.

\section*{Example}

For example, consider a page that has a form \({ }^{\text {p486 }}\) and a textarea \({ }^{\text {p548 }}\) to publish a new article, where the user is expected to write the article using HTML:
```
<form method=POST>
    <fieldset>
        <legend>New article</legend>
        <textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
    </fieldset>
    <p><button>Publish</button></p>
</form>
```

When scripting is enabled, the textarea \({ }^{\mathrm{p548}}\) element could be replaced with a rich text control instead, using the contenteditable \({ }^{\mathrm{p} 787}\) attribute:
```
<form method=POST>
    <fieldset>
        <legend>New article</legend>
        <textarea id=textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
        <div id=div style="white-space: pre-wrap" hidden><p>Hello world.</p></div>
        <script>
        let textarea = document.getElementById("textarea");
        let div = document.getElementById("div");
        textarea.hidden = true;
        div.hidden = false;
        div.contentEditable = "true";
        div.oninput = (e) => {
            textarea.value = div.innerHTML;
        };
    </script>
    </fieldset>
    <p><button>Publish</button></p>
</form>
```

Features to enable, e.g., inserting links, can be implemented using the document. execCommand () API, or using Selection APIs and other DOM APIs. [EXECCOMMAND] \({ }^{\text {p1287 }}\) [SELECTION] \({ }^{\text {p1291 }}[D O M]^{\text {p1287 }}\)

\section*{Example}

The contenteditable \({ }^{\text {p787 }}\) attribute can also be used to great effect:
```
<!doctype html>
<html lang=en>
<title>Live CSS editing!</title>
<style style=white-space:pre contenteditable>
html { margin:.2em; font-size:2em; color:lime; background:purple }
head, title, style { display:block }
body { display:none }
</style>
```
```
element. contentEditable }\mp@subsup{}{}{\mathrm{ p7888}}[= value ] [
```

Returns "true", "false", or "inherit", based on the state of the contenteditable \({ }^{\text {p787 }}\) attribute.
Can be set, to change that state.
Throws a "SyntaxError" DOMException if the new value isn't one of those strings.
element . isContentEditable \({ }^{\text {p788 }}\)
Returns true if the element is editable; otherwise, returns false.

The contentEditable IDL attribute, on getting, must return the string "true" if the content attribute is set to the true state, "false" if the content attribute is set to the false state, and "inherit" otherwise. On setting, if the new value is an ASCII case-insensitive match for the string "inherit" then the content attribute must be removed, if the new value is an ASCII case-insensitive match for the string "true" then the content attribute must be set to the string "true", if the new value is an ASCII case-insensitive match for the string "false" then the content attribute must be set to the string "false", and otherwise the attribute setter must throw a "SyntaxError" DOMException.

The isContentEditable IDL attribute, on getting, must return true if the element is either an editing host \({ }^{\mathrm{p} 789}\) or editable, and false otherwise.

\subsection*{6.7.2 Making entire documents editable: the designMode \({ }^{\mathrm{p} 788}\) getter and setter \(\underset{8}{\S_{8}^{\mathrm{p78}}}\)}

\section*{For web developers (non-normative)}

\section*{document . designMode \({ }^{\text {p788 }}\) [ = value ]}

Returns "on" if the document is editable, and "off" if it isn't.
Can be set, to change the document's current state. This focuses the document and resets the selection in that document.

Document \({ }^{\text {p114 }}\) objects have an associated design mode enabled, which is a boolean. It is initially false.
The designMode getter steps are to return "on" if this's design mode enabled \({ }^{\text {p788 }}\) is true; otherwise "off".
The designMode \({ }^{\mathrm{p} 788}\) setter steps are:
1. Let value be the given value, converted to ASCII lowercase.
2. If value is "on" and this's design mode enabled \({ }^{\text {p788 }}\) is false, then:
1. Set this's design mode enabled \({ }^{\mathrm{p} 788}\) to true.
2. Reset this's active range's start and end boundary points to be at the start of this.
3. Run the focusing steps \({ }^{\mathrm{p} 776}\) for this's document element, if non-null.
3. If value is "off", then set this's design mode enabled \({ }^{p 788}\) to false.

\subsection*{6.7.3 Best practices for in-page editors \(\underset{8}{\AA^{p 78}}\)}

Authors are encouraged to set the 'white-space' property on editing hosts \({ }^{\mathrm{p} 789}\) and on markup that was originally created through these editing mechanisms to the value 'pre-wrap'. Default HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not work correctly in some corner cases if 'white-space' is left at its default value.

\section*{Example}

As an example of problems that occur if the default 'normal' value is used instead, consider the case of the user typing "yellow \({ }_{\text {ни }}\) ball", with two spaces (here represented by " ") between the words. With the editing rules in place for the default value of 'white-space' ('normal'), the resulting markup will either consist of "yellow\&nbsp; ball" or "yellow \&nbsp; ball"; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the 'normal' value for 'white-space' requires adjacent regular spaces to be collapsed together.

In the former case, "yellow \({ }_{\Psi}\) " might wrap to the next line (" \(v\) " being used here to represent a non-breaking space) even though "yellow" alone might fit at the end of the line; in the latter case, " \(\mathrm{v}^{\text {ball", if wrapped to the start of the line, would have visible }}\) indentation from the non-breaking space.

When 'white-space' is set to 'pre-wrap', however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.

\subsection*{6.7.4 Editing APIs \(\S^{\text {p78 }}\)}

An editing host is either an HTML element \({ }^{\mathrm{p} 44}\) with its contenteditable \({ }^{\text {p787 }}\) attribute in the true state, or a child HTML element \({ }^{\text {p44 }}\) of a Document \({ }^{p 114}\) whose design mode enabled \({ }^{\text {p788 }}\) is true.

The definition of the terms active range, editing host of, and editable, the user interface requirements of elements that are editing hosts \({ }^{\text {p789 }}\) or editable, the execCommand(), queryCommandEnabled(), queryCommandIndeterm( ), queryCommandState( ), queryCommandSupported (), and queryCommandValue() methods, text selections, and the delete the selection algorithm are defined in execCommand. [EXECCOMMAND] \({ }^{\text {p1287 }}\)

\subsection*{6.7.5 Spelling and grammar checking \(\S^{p 78}\)}

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of textarea \({ }^{\mathrm{p548}}\) elements), or in elements in an editing host \({ }^{\mathrm{p} 789}\) (e.g. using contenteditable \({ }^{\mathrm{p787}}\) ).

For each element, user agents must establish a default behavior, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:

\section*{true-by-default}

The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the spellcheck \({ }^{\text {p789 }}\) attribute.

\section*{false-by-default}

The element will never be checked for spelling and grammar unless spellchecking is explicitly enabled through the spellcheck \({ }^{\text {p789 }}\) attribute.

\section*{inherit-by-default}

The element's default behavior is the same as its parent element's. Elements that have no parent element cannot have this as their default behavior.

The spellcheck attribute is an enumerated attribute \({ }^{\mathrm{p} 68}\) whose keywords are the empty string, true and false. The empty string and the true keyword map to the true state. The false keyword maps to the false state. In addition, there is a third state, the default state, which is the missing value default \({ }^{p 68}\) and the invalid value default \({ }^{p 68}\).

\section*{Note}

The true state indicates that the element is to have its spelling and grammar checked. The default state indicates that the element is to act according to a default behavior, possibly based on the parent element's own spellcheck \({ }^{\mathrm{p789}}\) state, as defined below. The false state indicates that the element is not to be checked.

\section*{For web developers (non-normative)}

\section*{element . spellcheck \({ }^{\text {p789 }}\) [ = value ]}

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.
Can be set, to override the default and set the spellcheck \({ }^{\text {p789 }}\) content attribute.

The spellcheck IDL attribute, on getting, must return true if the element's spellcheck \({ }^{\text {p789 }}\) content attribute is in the true state, or if the element's spellcheck \({ }^{\text {p789 }}\) content attribute is in the default state and the element's default behavior \({ }^{\text {p789 }}\) is true-by-default \({ }^{\text {p789 }}\), or if
the element's spellcheck \({ }^{\text {p789 }}\) content attribute is in the default state and the element's default behavior \({ }^{\text {p789 }}\) is inherit-by-default \({ }^{\text {p789 }}\) and the element's parent element's spellcheck \({ }^{\text {p789 }}\) IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.

\section*{Note}

The spellcheck \({ }^{\text {p789 }}\) IDL attribute is not affected by user preferences that override the spellcheck \({ }^{\text {p789 }}\) content attribute, and therefore might not reflect the actual spellchecking state.

On setting, if the new value is true, then the element's spellcheck \({ }^{\text {p789 }}\) content attribute must be set to the literal string "true", otherwise it must be set to the literal string "false".

User agents must only consider the following pieces of text as checkable for the purposes of this feature:
- The value \({ }^{\text {p566 }}\) of \(\underline{\text { input }}{ }^{\text {p493 }}\) elements whose \(\underline{\text { type }^{\text {p495 }}}\) attributes are in the Text \(^{\text {p499 }}\), \(\underline{\text { Search }^{\text {p499 }}}\), \(\underline{\text { URL }^{\text {p501 }}}\), or Email \(\underline{\text { E502 }}\) states and that are mutable \({ }^{p 566}\) (i.e. that do not have the readonly \({ }^{p 522}\) attribute specified and that are not disabled \({ }^{p 570}\) ).
- The value \({ }^{\mathrm{p} 566}\) of \(t e x t a r e a^{\mathrm{p} 548}\) elements that do not have a readonly \({ }^{\mathrm{p} 549}\) attribute and that are not disabled \({ }^{\mathrm{p} 570}\).
- Text in Text nodes that are children of editing hosts \({ }^{\text {p789 }}\) or editable elements.
- Text in attributes of editable elements.

For text that is part of a Text node, the element with which the text is associated is the element that is the immediate parent of the first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute's element. For the values of input \({ }^{\text {p493 }}\) and textarea \({ }^{\text {p548 }}\) elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammarchecking enabled, the UA must use the following algorithm:
1. If the user has disabled the checking for this text, then the checking is disabled.
2. Otherwise, if the user has forced the checking for this text to always be enabled, then the checking is enabled.
3. Otherwise, if the element with which the text is associated has a spellcheck \({ }^{\mathrm{p789}}\) content attribute, then: if that attribute is in the true state, then checking is enabled; otherwise, if that attribute is in the false state, then checking is disabled.
4. Otherwise, if there is an ancestor element with a spellcheck \({ }^{p 789}\) content attribute that is not in the default state, then: if the nearest such ancestor's spellcheck \({ }^{\text {p789 }}\) content attribute is in the true state, then checking is enabled; otherwise, checking is disabled.
5. Otherwise, if the element's default behavior \({ }^{\text {p789 }}\) is true-by-default \({ }^{p 789}\), then checking is enabled.
6. Otherwise, if the element's default behavior \({ }^{\mathrm{p} 789}\) is false-by-default \({ }^{\mathrm{p789}}\), then checking is disabled.
7. Otherwise, if the element's parent element has its checking enabled, then checking is enabled.
8. Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user's preferred language settings. UAs should use input \({ }^{\text {p493 }}\) element attributes such as pattern \({ }^{p 525}\) to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that text.

\section*{Example}

The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.
```
<div contenteditable="true">
    <span spellcheck="false" id="a">Hell</span><em>o!</em>
</div>
```

The element with ID " b " in the following example would have checking enabled (the leading space character in the attribute's value on the input \({ }^{\text {p493 }}\) element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).
```
<p spellcheck="true">
    <label>Name: <input spellcheck=" false" id="b"></label>
</p>
```

\section*{Note}

This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.

\subsection*{6.7.6 Autocapitalization \(\S^{\text {p79 }}\)}

Some methods of entering text, for example virtual keyboards on mobile devices, and also voice input, often assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The autocapitalize \({ }^{\text {p791 }}\) attribute allows authors to control such behavior.

The autocapitalize \({ }^{\text {p791 }}\) attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)

The autocapitalize \({ }^{\mathrm{p} 791}\) attribute can be used on an editing host \({ }^{\mathrm{p} 789}\) to control autocapitalization behavior for the hosted editable region, on an input \({ }^{\mathrm{p493}}\) or textarea \({ }^{\mathrm{p548}}\) element to control the behavior for inputting text into that element, or on a form \({ }^{\text {p486 }}\) element to control the default behavior for all autocapitalize-inheriting elements \({ }^{\text {p486 }}\) associated with the form \({ }^{\text {p486 }}\) element.

The autocapitalize \({ }^{\mathrm{p} 791}\) attribute never causes autocapitalization to be enabled for input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute is in one of the URL \({ }^{\mathrm{P} 501}\), Email \({ }^{5502}\), or Password \({ }^{\mathrm{P503}}\) states. (This behavior is included in the used autocapitalization hint \({ }^{\text {p792 }}\) algorithm below.)

The autocapitalization processing model is based on selecting among five autocapitalization hints, defined as follows:

\section*{default}

The user agent and input method should use make their own determination of whether or not to enable autocapitalization.

\section*{none}

No autocapitalization should be applied (all letters should default to lowercase).

\section*{sentences}

The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

\section*{words}

The first letter of each word should default to a capital letter; all other letters should default to lowercase.

\section*{characters}

All letters should default to uppercase.
The autocapitalize attribute is an enumerated attribute \({ }^{\mathrm{p} 68}\) whose states are the possible autocapitalization hints \({ }^{\mathrm{p} 791}\). The autocapitalization hint \({ }^{\text {p791 }}\) specified by the attribute's state combines with other considerations to form the used autocapitalization hint \({ }^{\mathrm{p} 792}\), which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:
\begin{tabular}{l|l}
\multicolumn{1}{c|}{ Keyword } & \multicolumn{1}{c}{ State } \\
\hline off & none \(^{\mathrm{p} 791}\) \\
\hline none & \\
\hline on & sentences \(^{\mathrm{p791}}\) \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\multicolumn{1}{c|}{ Keyword } & \multicolumn{1}{c}{ State } \\
\hline sentences & \\
\hline words & words \(^{\mathrm{p} 791}\) \\
\hline characters & characters \(^{\mathrm{p} 791}\) \\
\hline
\end{tabular}

The invalid value default \({ }^{\text {p68 }}\) is the sentences \({ }^{\text {p791 }}\) state. The missing value default \({ }^{\text {p68 }}\) is the default \({ }^{\text {p791 }}\) state.

\section*{For web developers (non-normative)}
element . autocapitalize \({ }^{\text {p792 }}\) [ = value ]
Returns the current autocapitalization state for the element, or an empty string if it hasn't been set. Note that for \(\underline{\text { input }}{ }^{\text {p493 }}\) and textarea \({ }^{\mathrm{p} 548}\) elements that inherit their state from a form \({ }^{\text {p486 }}\) element, this will return the autocapitalization state of the form \({ }^{\text {p486 }}\) element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the editing host \({ }^{\mathrm{p} 789}\) ).
Can be set, to set the autocapitalize \({ }^{\text {p791 }}\) content attribute (and thereby change the autocapitalization behavior for the element).

To compute the own autocapitalization hint of an element element, run the following steps:
1. If the autocapitalize \({ }^{\text {p791 }}\) content attribute is present on element, and its value is not the empty string, return the state of the attribute.
2. If element is an autocapitalize-inheriting element \({ }^{\text {p486 }}\) and has a non-null form owner \({ }^{p 566}\), return the own autocapitalization hint \({ }^{\text {p792 }}\) of element's form owner \({ }^{\text {p566 }}\).
3. Return default \({ }^{\mathrm{p791}}\).

The autocapitalize IDL attribute, on getting, must return the string value corresponding to own autocapitalization hint \({ }^{\mathrm{p792}}\) of the element, with the exception that the default \({ }^{\text {p791 }}\) state maps to the empty string. On setting, it must set the autocapitalize \({ }^{\text {p791 }}\) content attribute to the given new value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the used autocapitalization hint for the element. This will be an autocapitalization hint \({ }^{\mathrm{p791}}\) that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the used autocapitalization hint \({ }^{\mathrm{p792}}\) in certain circumstances.
The used autocapitalization hint \({ }^{\mathrm{p792}}\) for an element element is computed using the following algorithm:
1. If element is an input \({ }^{\text {p493 }}\) element whose \(t y p e^{\text {p495 }}\) attribute is in one of the URL \(\underline{L}^{\mathrm{p} 501}\), Email \({ }^{\mathrm{p} 502}\), or Password \({ }^{\mathrm{p} 503}\) states, then return default \({ }^{\mathrm{p} 791}\).
2. If element is an input \({ }^{\text {p493 }}\) element or a textarea \({ }^{\text {p548 }}\) element, then return element's own autocapitalization hint \({ }^{\text {p792 }}\).
3. If element is an editing host \({ }^{\mathrm{p789}}\) or an editable element, then return the own autocapitalization hint \({ }^{\mathrm{p792}}\) of the editing host of element.
4. Assert: this step is never reached, since text input only occurs in elements that meet one of the above criteria.

\subsection*{6.7.7 Input modalities: the inputmode \({ }^{\text {p792 }}\) attribute \(\underset{2}{\S_{2}^{\text {p79 }}}\)}

User agents can support the inputmode \({ }^{\text {p792 }}\) attribute on form controls (such as the value of textarea \({ }^{\text {p548 }}\) elements), or in elements in an editing host \({ }^{\text {p789 }}\) (e.g., using contenteditable \({ }^{\mathrm{p} 787}\) ).

The inputmode content attribute is an enumerated attribute \({ }^{\text {p68 }}\) that specifies what kind of input mechanism would be most helpful for users entering content.

\section*{Keyword}

\section*{Description}
\begin{tabular}{l|l}
\hline none & The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control. \\
\hline text & The user agent should display a virtual keyboard capable of text input in the user's locale.
\end{tabular}
\begin{tabular}{l|l}
\hline tel & \begin{tabular}{l} 
The user agent should display a virtual keyboard capable of telephone number input. This should including keys for the digits 0 to 9, the "\#" \\
character, and the "*" character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled " 2 " is historically \\
also labeled with the letters A, B, and C).
\end{tabular} \\
\hline url & \begin{tabular}{l} 
The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of URLs, such as that for \\
the "/" and "." characters and for quick input of strings commonly found in domain names such as "www." or ".com".
\end{tabular} \\
\hline email & \begin{tabular}{l} 
The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of email addresses, such as \\
that for the "@" character and the "." character.
\end{tabular} \\
\hline numeric & The user agent should display a virtual keyboard capable of numeric input. This keyword is useful for PIN entry. \\
\hline decimal & \begin{tabular}{l} 
The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be \\
shown.
\end{tabular} \\
\hline search & The user agent should display a virtual keyboard optimized for search. \\
\hline
\end{tabular}

The inputMode IDL attribute must reflect \({ }^{\text {p94 }}\) the inputmode \({ }^{\text {p792 }}\) content attribute, limited to only known values \({ }^{\text {p95 }}\).
When inputmode \({ }^{\mathrm{p} 792}\) is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the input type \({ }^{\text {p495 }}\) or pattern \({ }^{\text {p525 }}\) attributes should be used to determine which type of virtual keyboard should be presented to the user.

\subsection*{6.7.8 Input modalities: the enterkeyhint \({ }^{\text {p793 }}\) attribute \(\S_{3}^{\text {p79 }}\)}

User agents can support the enterkeyhint \({ }^{\text {p793 }}\) attribute on form controls (such as the value of textarea \({ }^{p 548}\) elements), or in elements in an editing host \({ }^{\text {p789 }}\) (e.g., using contenteditable \({ }^{\mathrm{p} 787}\) ).

The enterkeyhint content attribute is an enumerated attribute \({ }^{\text {p68 }}\) that specifies what action label (or icon) to present for the enter key on virtual keyboards. This allows authors to customize the presentation of the enter key in order to make it more helpful for users.

\section*{Description}
\begin{tabular}{ll}
\hline enter & The user agent should present a cue for the operation 'enter', typically inserting a new line. \\
\hline done & \begin{tabular}{l} 
The user agent should present a cue for the operation 'done', typically meaning there is nothing more to input and the input method editor (IME) will \\
be closed.
\end{tabular} \\
\hline go & The user agent should present a cue for the operation 'go', typically meaning to take the user to the target of the text they typed. \\
\hline next & The user agent should present a cue for the operation 'next', typically taking the user to the next field that will accept text. \\
\hline previous & The user agent should present a cue for the operation 'previous', typically taking the user to the previous field that will accept text. \\
\hline search & The user agent should present a cue for the operation 'search', typically taking the user to the results of searching for the text they have typed. \\
\hline
\end{tabular}

The enterKeyHint IDL attribute must reflect \({ }^{\text {p94 }}\) the enterkeyhint \({ }^{\text {p793 }}\) content attribute, limited to only known values \({ }^{\text {p95 }}\).
When enterkeyhint \({ }^{\text {p793 }}\) is unspecified (or is in a state not supported by the user agent), the user agent should determine the default action label (or icon) to present. Contextual information such as the inputmode \({ }^{p 792}\), type \({ }^{\text {p495 }}\), or pattern \({ }^{\mathrm{p} 525}\) attributes should be used to determine which action label (or icon) to present on the virtual keyboard.

\subsection*{6.8 Find-in-page \(\S_{3}^{\text {p79 }}\)}

\subsection*{6.8.1 Introduction \(\S^{\text {p79 }}\)}

This section defines find-in-page - a common user-agent mechanism which allows users to search through the contents of the page for particular information.

Access to find-in-page \({ }^{\text {p793 }}\) feature is provided via a find-in-page interface. This is a user-agent provided user interface, which allows the user to specify input and the parameters of the search. This interface can appear as a result of a shortcut or a menu selection.

A combination of text input and settings in the find-in-page interface \({ }^{\text {p793 }}\) represents the user query. This typically includes the text that the user wants to search for, as well as optional settings (e.g., the ability to restrict the search to whole words only).

The user-agent processes page contents for a given query \({ }^{\mathrm{p} 793}\), and identifies zero or more matches, which are content ranges that satisfy the user query \({ }^{\mathrm{p} 793}\).

One of the matches \({ }^{\text {p793 }}\) is identified to the user as the active match. It is highlighted and scrolled into view. The user can navigate through the matches \({ }^{\mathrm{p793}}\) by advancing the active match \({ }^{\mathrm{p} 794}\) using the find-in-page interface \({ }^{\mathrm{p793}}\).

Issue \#3539 tracks standardizing how find-in-page \({ }^{\text {p793 }}\) underlies the currently-unspecified window. find () API.

\subsection*{6.8.2 Interaction with selection \(\S^{p 79}\)}

The find-in-page process is invoked in the context of a document, and may have an effect on the selection of that document. Specifically, the range that defines the active match \({ }^{\text {p794 }}\) can dictate the current selection. These selection updates, however, can happen at different times during the find-in-page process (e.g. upon the find-in-page interface \({ }^{\text {p793 }}\) dismissal or upon a change in the active match \({ }^{\text {p794 }}\) range).

\subsection*{6.9 Drag and drop \(\S^{p 79}\)}

This section defines an event-based drag-and-drop mechanism.
This specification does not define exactly what a drag-and-drop operation actually is.
On a visual medium with a pointing device, a drag operation could be the default action of a mousedown event that is followed by a series of mousemove events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

\subsection*{6.9.1 Introduction \(\$_{4}^{\text {p79 }}\)}

This section is non-normative.
To make an element draggable, give the element a draggable \({ }^{\text {p889 }}\) attribute, and set an event listener for dragstart \({ }^{\text {p889 }}\) that stores the data being dragged.

The event handler typically needs to check that it's not a text selection that is being dragged, and then needs to store data into the DataTransfer \({ }^{\text {p797 }}\) object and set the allowed effects (copy, move, link, or some combination).

For example:
```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)">
    <li draggable="true" data-value="fruit-apple">Apples</li>
    <li draggable="true" data-value="fruit-orange">0ranges</li>
    <li draggable="true" data-value="fruit-pear">Pears</li>
</ol>
<script>
    var internalDNDType = 'text/x-example'; // set this to something specific to your site
    function dragStartHandler(event) {
        if (event.target instanceof HTMLLIElement) {
            // use the element's data-value="" attribute as the value to be moving:
            event.dataTransfer.setData(internalDNDType, event.target.dataset.value);
```
```
            event.dataTransfer.effectAllowed = 'move'; // only allow moves
            } else {
            event.preventDefault(); // don't allow selection to be dragged
        }
    }
</script>
```

To accept a drop, the drop target has to listen to the following events:
1. The dragenter \({ }^{\text {p809 }}\) event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The dragover \({ }^{p 809}\) event handler specifies what feedback will be shown to the user, by setting the dropEffect \({ }^{p 798}\) attribute of the DataTransfer \({ }^{p 797}\) associated with the event. This event also needs to be canceled.
3. The drop \({ }^{p 809}\) event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the dropEffect \({ }^{p 798}\) attribute's value can be used by the source. Otherwise, the drop operation is rejected.

For example:
```
<p>Drop your favorite fruits below:</p>
<ol ondragenter="dragEnterHandler(event)" ondragover="drag0verHandler(event)"
    ondrop="dropHandler(event)">
</ol>
<script>
    var internalDNDType = 'text/x-example'; // set this to something specific to your site
    function dragEnterHandler(event) {
        var items = event.dataTransfer.items;
        for (var i = 0; i < items.length; ++i) {
            var item = items[i];
            if (item.kind == 'string' && item.type == internalDNDType) {
                event.preventDefault();
                return;
            }
        }
    }
    function drag0verHandler(event) {
        event.dataTransfer.dropEffect = 'move';
        event.preventDefault();
    }
    function dropHandler(event) {
        var li = document.createElement('li');
        var data = event.dataTransfer.getData(internalDNDType);
        if (data == 'fruit-apple') {
            li.textContent = 'Apples';
        } else if (data == 'fruit-orange') {
            li.textContent = 'Oranges';
        } else if (data == 'fruit-pear') {
            li.textContent = 'Pears';
        } else {
            li.textContent = 'Unknown Fruit';
        }
        event.target.appendChild(li);
    }
</script>
```

To remove the original element (the one that was dragged) from the display, the dragend \({ }^{p 809}\) event can be used.

For our example here, that means updating the original markup to handle that event:
```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)">
    ...as before...
</ol>
<script>
    function dragStartHandler(event) {
        // ...as before...
    }
    function dragEndHandler(event) {
        if (event.dataTransfer.dropEffect == 'move') {
                // remove the dragged element
                event.target.parentNode.removeChild(event.target);
        }
    }
</script>
```

\subsection*{6.9.2 The drag data store \({ }_{6}^{\S_{6}^{p 79}}\)}

The data that underlies a drag-and-drop operation, known as the drag data store, consists of the following information:
- A drag data store item list, which is a list of items representing the dragged data, each consisting of the following information:

\section*{The drag data item kind}

The kind of data:

\section*{Text}

Text.

File
Binary data with a file name.

\section*{The drag data item type string}

A Unicode string giving the type or format of the data, generally given by a MIME type. Some values that are not MIME types are special-cased for legacy reasons. The API does not enforce the use of MIME types; other values can be used as well. In all cases, however, the values are all converted to ASCII lowercase by the API.

There is a limit of one text item per item type string \({ }^{\text {p796 }}\).

\section*{The actual data}

A Unicode or binary string, in some cases with a file name (itself a Unicode string), as per the drag data item kind \({ }^{\text {p796 }}\).
The drag data store item list \({ }^{\text {p796 }}\) is ordered in the order that the items were added to the list; most recently added last.
- The following information, used to generate the UI feedback during the drag:
- User-agent-defined default feedback information, known as the drag data store default feedback.
- Optionally, a bitmap image and the coordinate of a point within that image, known as the drag data store bitmap and drag data store hot spot coordinate.
- A drag data store mode, which is one of the following:

\section*{Read/write mode}

For the dragstart \({ }^{\text {p899 }}\) event. New data can be added to the drag data store \({ }^{\mathrm{p} 796}\).

\section*{Read-only mode}

For the drop \({ }^{\text {p889 }}\) event. The list of items representing dragged data can be read, including the data. No new data can be added.

\section*{Protected mode}

For all other events. The formats and kinds in the drag data store \({ }^{\text {p796 }}\) list of items representing dragged data can be
enumerated, but the data itself is unavailable and no new data can be added.
- A drag data store allowed effects state, which is a string.

When a drag data store \({ }^{\mathrm{p} 796}\) is created, it must be initialized such that its drag data store item list \({ }^{\mathrm{p796}}\) is empty, it has no drag data store default feedback \({ }^{\text {p796 }}\), it has no drag data store bitmap \({ }^{\text {p796 }}\) and drag data store hot spot coordinate \({ }^{\text {p796 }}\), its drag data store mode \(^{\mathrm{p796}}\) is protected mode \({ }^{\mathrm{p796}}\), and its drag data store allowed effects state \({ }^{\mathrm{p797}}\) is the string "uninitialized \({ }^{\mathrm{p} 798 \mathrm{n}}\).

\subsection*{6.9.3 The DataTransfer \({ }^{\text {p797 }}\) interface \(\S^{p 79}\)}

DataTransfer \({ }^{\text {p797 }}\) objects are used to expose the drag data store \({ }^{\text {p796 }}\) that underlies a drag-and-drop operation.

\section*{IDL}
```
[Exposed=Window]
interface DataTransfer {
    constructor();
    attribute DOMString dropEffect;
    attribute DOMString effectAllowed;
    [SameObject] readonly attribute DataTransferItemList items;
    undefined setDragImage(Element image, long x, long y);
    /* old interface */
    readonly attribute FrozenArray<DOMString> types;
    DOMString getData(DOMString format);
    undefined setData(DOMString format, DOMString data);
    undefined clearData(optional DOMString format);
    [SameObject] readonly attribute FileList files;
};
```

\section*{For web developers (non-normative)}

\section*{dataTransfer \(=\) new DataTransfer \(\left.{ }^{\text {p798 }} \mathbf{(}\right)\)}

Creates a new DataTransfer \({ }^{\text {p797 }}\) object with an empty drag data store \({ }^{\text {p796 }}\).
dataTransfer. dropEffect \(^{\text {p798 }}\) [ = value ]
Returns the kind of operation that is currently selected. If the kind of operation isn't one of those that is allowed by the effectAllowed \({ }^{\text {p798 }}\) attribute, then the operation will fail.

Can be set, to change the selected operation.
The possible values are "none \({ }^{\text {p798", "copy }}{ }^{\text {p798", "link }}{ }^{\text {p798 ", and "move }}\) " 798 ".
dataTransfer. effectAllowed \({ }^{\text {p798 }}\) [ = value]
Returns the kinds of operations that are to be allowed.
Can be set (during the dragstart \({ }^{\text {p809 }}\) event), to change the allowed operations.
 and "uninitialized \({ }^{\text {p798" }}\),
dataTransfer. items \(^{\text {p798 }}\)
Returns a DataTransferItemList \({ }^{\text {p800 }}\) object, with the drag data.
dataTransfer. setDragImage \({ }^{\text {p798 }}\) (element, \(\boldsymbol{x}, \boldsymbol{y}\) )
Uses the given element to update the drag feedback, replacing any previously specified feedback.

\section*{dataTransfer. types \({ }^{\text {p798 }}\)}

Returns a frozen array listing the formats that were set in the dragstart \({ }^{\text {p889 }}\) event. In addition, if any files are being dragged, then one of the types will be the string "Files".

\section*{data \(=\) dataTransfer . getData \({ }^{\text {p799 }}\) (format)}

Returns the specified data. If there is no such data, returns the empty string.

\section*{dataTransfer. setData \({ }^{\text {p799 }}\) (format, data)}

Adds the specified data.
dataTransfer. clearData \({ }^{\text {p799 }}\) ([ format ])
Removes the data of the specified formats. Removes all data if the argument is omitted.
dataTransfer. files \({ }^{\text {p799 }}\)
Returns a FileList of the files being dragged, if any.

DataTransfer \({ }^{\text {p797 }}\) objects that are created as part of drag-and-drop events \({ }^{\mathrm{p809}}\) are only valid while those events are being fired.
A DataTransfer \({ }^{\mathrm{p} 797}\) object is associated with a drag data store \({ }^{\mathrm{p} 796}\) while it is valid.
A DataTransfer \({ }^{\text {p797 }}\) object has an associated types array, which is a FrozenArray<DOMString \(\geq\), initially empty. When the contents of the DataTransfer \({ }^{p 797}\) object's drag data store item list \({ }^{\text {p796 }}\) change, or when the DataTransfer \({ }^{\text {p797 }}\) object becomes no longer associated with a drag data store \({ }^{\mathrm{p} 796}\), run the following steps:
1. Let \(L\) be an empty sequence.
2. If the DataTransfer \({ }^{\text {p797 }}\) object is still associated with a drag data store \({ }^{\mathrm{p} 796}\), then:
1. For each item in the DataTransfer \({ }^{\text {p797 }}\) object's drag data store item list \({ }^{p 796}\) whose kind \({ }^{p 796}\) is text, add an entry to \(L\) consisting of the item's type string \({ }^{\mathrm{p} 796}\).
2. If there are any items in the DataTransfer \({ }^{\mathrm{p} 797}\) object's drag data store item list \({ }^{\mathrm{p} 796}\) whose kind \(^{\mathrm{p} 796}\) is File, then add an entry to \(L\) consisting of the string "Files". (This value can be distinguished from the other values because it is not lowercase.)
3. Set the DataTransfer \({ }^{\mathrm{p797}}\) object's types array \({ }^{\mathrm{p} 798}\) to the result of creating a frozen array from \(L\).

The DataTransfer() constructor, when invoked, must return a newly created DataTransfer \({ }^{\mathrm{p797}}\) object initialized as follows:
1. Set the drag data store \({ }^{\mathrm{p} 796}\) 's item list \({ }^{\mathrm{p796}}\) to be an empty list.
2. Set the drag data store \({ }^{\mathrm{p} 796}\) 's mode \({ }^{\mathrm{p} 796}\) to read/write mode \({ }^{\text {p796 }}\).
3. Set the dropEffect \({ }^{\mathrm{p} 798}\) and effectAllowed \({ }^{\mathrm{p} 798}\) to "none".

The dropEffect attribute controls the drag-and-drop feedback that the user is given during a drag-and-drop operation. When the DataTransfer \({ }^{\text {p797 }}\) object is created, the dropEffect \({ }^{\text {p798 }}\) attribute is set to a string value. On getting, it must return its current value. On setting, if the new value is one of "none", "copy", "link", or "move", then the attribute's current value must be set to the new value. Other values must be ignored.

The effectAllowed attribute is used in the drag-and-drop processing model to initialize the dropEffect \({ }^{p 798}\) attribute during the \(d r a g e n t e r{ }^{p 889}\) and dragover \({ }^{p 809}\) events. When the DataTransfer \({ }^{p 797}\) object is created, the effectAllowed \({ }^{p 798}\) attribute is set to a string value. On getting, it must return its current value. On setting, if drag data store \({ }^{p 796}\) 's mode \({ }^{\text {p796 }}\) is the read/write mode \({ }^{\text {p796 }}\) and the new value is one of "none", "copy", "copyLink", "copyMove", "link", "linkMove", "move", "all", or "uninitialized", then the attribute's current value must be set to the new value. Otherwise it must be left unchanged.

The items attribute must return a DataTransferItemList \({ }^{\text {p80日 }}\) object associated with the DataTransfer \({ }^{\text {p797 }}\) object.
The setDragImage(element, \(x, y\) ) method must run the following steps:
1. If the DataTransfer \({ }^{p 797}\) object is no longer associated with a drag data store \({ }^{\mathrm{p} 796}\), return. Nothing happens.
2. If the drag data store \({ }^{\mathrm{p} 796}\) 's mode \({ }^{\mathrm{p} 796}\) is not the read/write mode \({ }^{\mathrm{p796}}\), return. Nothing happens.
3. If element is an img \(^{\text {p320 }}\) element, then set the drag data store bitmap \({ }^{\text {p796 }}\) to the element's image (at its intrinsic size); otherwise, set the drag data store bitmap \({ }^{\text {p796 }}\) to an image generated from the given element (the exact mechanism for doing so is not currently specified).
4. Set the drag data store hot spot coordinate \({ }^{\text {p796 }}\) to the given \(x, y\) coordinate.

The types attribute must return this DataTransfer \({ }^{p 797}\) object's types array \({ }^{\mathrm{p} 798}\).

The getData(format) method must run the following steps:
1. If the DataTransfer \({ }^{\text {p797 }}\) object is no longer associated with a drag data store \({ }^{\mathrm{p} 796}\), then return the empty string.
2. If the drag data store \({ }^{\text {p796 }}\) 's mode \(e^{\text {p796 }}\) is the protected mode \({ }^{\text {p796 }}\), then return the empty string.
3. Let format be the first argument, converted to ASCII lowercase.
4. Let convert-to-URL be false.
5. If format equals "text", change it to "text/plain".
6. If format equals "url", change it to "text/uri-list" and set convert-to-URL to true.
7. If there is no item in the drag data store item list \({ }^{\mathrm{p} 796}\) whose kind \(^{\mathrm{p796}}\) is text and whose type string \({ }^{\mathrm{p796}}\) is equal to format, return the empty string.
8. Let result be the data of the item in the drag data store item list \({ }^{\mathrm{p} 796}\) whose kind \({ }^{\mathrm{p} 796}\) is Plain Unicode string and whose type string \({ }^{\text {p796 }}\) is equal to format.
9. If convert-to-URL is true, then parse result as appropriate for text/uri-list data, and then set result to the first URL from the list, if any, or the empty string otherwise. [RFC2483] \({ }^{\text {p1290 }}\)
10. Return result.

The setData(format, data) method must run the following steps:
1. If the DataTransfer \({ }^{p 797}\) object is no longer associated with a drag data store \({ }^{\mathrm{p} 796}\), return. Nothing happens.
2. If the drag data store \({ }^{\mathrm{p} 796} \mathrm{~s}\) mode \({ }^{\mathrm{p} 796}\) is not the read/write mode \({ }^{\mathrm{p796}}\), return. Nothing happens.
3. Let format be the first argument, converted to ASCII lowercase.
4. If format equals "text", change it to "text/plain".

If format equals "url", change it to "text/uri-list".
5. Remove the item in the drag data store item list \({ }^{\text {p796 }}\) whose kind \({ }^{p 796}\) is text and whose type string \({ }^{\text {p796 }}\) is equal to format, if there is one.
6. Add an item to the drag data store item list \({ }^{\mathrm{p} 796}\) whose kind \(^{\mathrm{p} 796}\) is text, whose type string \({ }^{\mathrm{p} 796}\) is equal to format, and whose data is the string given by the method's second argument.

The clearData() method must run the following steps:
1. If the DataTransfer \({ }^{p 797}\) object is no longer associated with a drag data store \({ }^{\mathrm{p} 796}\), return. Nothing happens.
2. If the drag data store \({ }^{\text {p796 }}\) 's mode \(^{\text {p796 }}\) is not the read/write mode \({ }^{\text {p796 }}\), return. Nothing happens.
3. If the method was called with no arguments, remove each item in the drag data store item list \({ }^{\text {p796 }}\) whose kind \({ }^{\text {p796 }}\) is Plain Unicode string, and return.
4. Let format be the first argument, converted to ASCII lowercase.
5. If format equals "text", change it to "text/plain".

If format equals "url", change it to "text/uri-list".
6. Remove the item in the drag data store item list \({ }^{\text {p796 }}\) whose kind \(^{p 796}\) is text and whose type string \({ }^{\text {p796 }}\) is equal to format, if there is one.

\section*{Note}

The clearData( ( \({ }^{\text {p799 }}\) method does not affect whether any files were included in the drag, so the types \({ }^{\text {p798 }}\) attribute's list might still not be empty after calling clearData() \({ }^{\text {p799 }}\) (it would still contain the "Files" string if any files were included in the drag).

The files attribute must return a live \({ }^{\mathrm{p45}}\) FileList sequence consisting of File objects representing the files found by the following steps. Furthermore, for a given FileList object and a given underlying file, the same File object must be used each time.
1. Start with an empty list \(L\).

2．If the DataTransfer \({ }^{p 797}\) object is no longer associated with a drag data store \({ }^{\mathrm{p} 796}\) ，the fileList is empty．Return the empty list \(L\) ．

3．If the drag data store \({ }^{\mathrm{p} 796} \mathrm{~s}\) mode \({ }^{\mathrm{p} 796}\) is the protected mode \({ }^{\mathrm{p} 796}\) ，Return the empty list \(L\) ．
4．For each item in the drag data store item list \({ }^{p 796}\) whose kind \({ }^{p 796}\) is File，add the item＇s data（the file，in particular its name and contents，as well as its type \({ }^{\text {p796 }}\) ）to the list \(L\) ．

5．The files found by these steps are those in the list \(L\) ．

Note
This version of the API does not expose the types of the files during the drag．

\section*{6．9．3．1 The DataTransferItemList \({ }^{\text {p880 }}\) interface \(\S^{\S^{p 80}}\)}

Each DataTransfer \({ }^{\text {p797 }}\) object is associated with a DataTransferItemList \({ }^{\text {p800 }}\) object．
IDL［Exposed＝Window］
```
interface DataTransferItemList {
    readonly attribute unsigned long length;
    getter DataTransferItem (unsigned long index);
    DataTransferItem? add(DOMString data, DOMString type);
    DataTransferItem? add(File data);
    undefined remove(unsigned long index);
    undefined clear();
};
```

\section*{For web developers（non－normative）}

\section*{items．length \({ }^{\text {p800 }}\)}

Returns the number of items in the drag data store \({ }^{\text {p796 }}\) ．

\section*{items［index］}

Returns the DataTransferItem \({ }^{\text {p801 }}\) object representing the indexth entry in the drag data store \({ }^{\text {p796 }}\) ．
items ．remove \({ }^{\text {p801 }}\)（index）
Removes the indexth entry in the drag data store \({ }^{\mathrm{p} 796}\) ．
items．clear \({ }^{\text {p801 }}\)（）
Removes all the entries in the drag data store \({ }^{\mathrm{p} 796}\) ．
items．add \({ }^{\text {p801 }}\)（data）
items ．add \({ }^{\mathrm{p} 801}\)（data，type）
Adds a new entry for the given data to the drag data store \({ }^{\text {p796 }}\) ．If the data is plain text then a type string has to be provided also．

While the DataTransferItemList \({ }^{\text {p80日 }}\) object＇s DataTransfer \({ }^{p 797}\) object is associated with a drag data store \({ }^{\mathrm{p} 796}\) ，the DataTransferItemList \({ }^{\text {p800 }}\) object＇s mode is the same as the drag data store mode \({ }^{\text {p796 }}\) ．When the DataTransferItemList \({ }^{\text {p800 }}\) object＇s DataTransfer \({ }^{\text {p797 }}\) object is not associated with a drag data store \({ }^{\text {p796 }}\) ，the DataTransferItemList \({ }^{\text {p800 }}\) object＇s mode is the disabled mode．The drag data store \({ }^{\text {p796 }}\) referenced in this section（which is used only when the DataTransferItemList \({ }^{\text {p880 }}\) object is not in the disabled mode）is the drag data store \({ }^{\text {p796 }}\) with which the DataTransferItemList \({ }^{\text {p80日 }}\) object＇s DataTransfer \(r^{\text {p797 }}\) object is associated．

The length attribute must return zero if the object is in the disabled mode；otherwise it must return the number of items in the drag data store item list \({ }^{\mathrm{p} 796}\) ．

When a DataTransferItemList \({ }^{p 800}\) object is not in the disabled mode，its supported property indices are the numbers in the range 0 ．． \(n-1\) ，where \(n\) is the number of items in the drag data store item list \({ }^{p 796}\) ．

To determine the value of an indexed property \(i\) of a DataTransferItemList \({ }^{\text {p80日 }}\) object，the user agent must return a DataTransferItem \({ }^{\text {p801 }}\) object representing the \(i\) th item in the drag data store \({ }^{\mathrm{p} 796}\) ．The same object must be returned each time a particular item is obtained from this DataTransferItemList \({ }^{\text {p800 }}\) object．The DataTransferItem \({ }^{\text {p801 }}\) object must be associated with the same DataTransfer \({ }^{\text {p797 }}\) object as the DataTransferItemList \({ }^{\text {p880 }}\) object when it is first created．

The add() method must run the following steps:
1. If the DataTransferItemList \({ }^{\text {p880 }}\) object is not in the read/write mode \({ }^{\text {p796 }}\), return null.
2. Jump to the appropriate set of steps from the following list:

\section*{\(\rightarrow\) If the first argument to the method is a string}

If there is already an item in the drag data store item list \({ }^{\mathrm{p} 796}\) whose kind \(^{\mathrm{p} 796}\) is text and whose type string \({ }^{\mathrm{p796}}\) is equal to the value of the method's second argument, converted to ASCII lowercase, then throw a "NotSupportedError" DOMException.

Otherwise, add an item to the drag data store item list \({ }^{\text {p796 }}\) whose kind \(^{\text {p796 }}\) is text, whose type string \({ }^{\text {p796 }}\) is equal to the value of the method's second argument, converted to ASCII lowercase, and whose data is the string given by the method's first argument.
\(\hookrightarrow\) If the first argument to the method is a File
Add an item to the drag data store item list \({ }^{\mathrm{p} 96}\) whose kind \({ }^{\mathrm{p796}}\) is File, whose type string \({ }^{\mathrm{p} 796}\) is the type of the File, converted to ASCII lowercase, and whose data is the same as the File's data.
3. Determine the value of the indexed property \({ }^{8800}\) corresponding to the newly added item, and return that value (a newly created DataTransferItem \({ }^{\text {p801 }}\) object).

The remove() method, when invoked with the argument \(i\), must run these steps:
1. If the DataTransferItemList \({ }^{\text {p800 }}\) object is not in the read/write mode \({ }^{\text {p796 }}\), throw an "InvalidStateError" DOMException.
2. Remove the ith item from the drag data store \({ }^{\mathrm{p} 796}\).

The clear() method, if the DataTransferItemList \({ }^{p 89 \theta}\) object is in the read/write mode \({ }^{p 796}\), must remove all the items from the drag data store \({ }^{\mathrm{p} 796}\). Otherwise, it must do nothing.
6.9.3.2 The DataTransferItem \({ }^{\text {p801 }}\) interface \(\S^{\text {p80 }}\)

Each DataTransferItem \({ }^{\text {p801 }}\) object is associated with a DataTransfer \({ }^{\text {p797 }}\) object.
IDL
```
[Exposed=Window]
interface DataTransferItem {
    readonly attribute DOMString kind;
    readonly attribute DOMString type;
    undefined getAsString(FunctionStringCallback? _callback);
    File? getAsFile();
};
callback FunctionStringCallback = undefined (DOMString data);
```

\section*{For web developers (non-normative)}

\section*{item . kind \({ }^{\text {p802 }}\)}

Returns the drag data item kind \({ }^{\text {p796 }}\), one of: "string", "file".
item . type \({ }^{\text {p882 }}\)
Returns the drag data item type string \({ }^{\text {p796 }}\).
item . getAsString \({ }^{\text {p802 }}\) (callback)
Invokes the callback with the string data as the argument, if the drag data item kind \({ }^{\text {p796 }}\) is text.

\section*{file \(=\) item . getAsFile \({ }^{\text {p802 }}()\)}

Returns a File object, if the drag data item kind \({ }^{\text {p796 }}\) is File.

While the DataTransferItem \({ }^{\text {p801 }}\) object's DataTransfer \({ }^{p 797}\) object is associated with a drag data store \({ }^{\text {p796 }}\) and that drag data store \({ }^{\text {p796's }}\) drag data store item list \({ }^{\text {p796 }}\) still contains the item that the DataTransferItem \({ }^{\text {p801 }}\) object represents, the DataTransferItem \({ }^{\text {p801 }}\) object's mode is the same as the drag data store mode \({ }^{\text {p796 }}\). When the DataTransferItem \({ }^{\text {p801 }}\) object's DataTransfer \({ }^{\text {p797 }}\) object is not associated
with a drag data store \({ }^{\mathrm{p} 796}\), or if the item that the DataTransferItem \({ }^{\text {p801 }}\) object represents has been removed from the relevant drag data store item list \({ }^{\mathrm{p} 796}\), the DataTransferItem \({ }^{\text {p881 }}\) object's mode is the disabled mode. The drag data store \({ }^{\text {p796 }}\) referenced in this section (which is used only when the DataTransferItem \({ }^{\text {p801 }}\) object is not in the disabled mode) is the drag data store \({ }^{\text {p796 }}\) with which the DataTransferItem \({ }^{\text {p801 }}\) object's DataTransfer \({ }^{\text {p797 }}\) object is associated.

The kind attribute must return the empty string if the DataTransferItem \({ }^{\text {p801 }}\) object is in the disabled mode; otherwise it must return the string given in the cell from the second column of the following table from the row whose cell in the first column contains the drag data item kind \({ }^{\text {p796 }}\) of the item represented by the DataTransferItem \({ }^{\text {p881 }}\) object:
\begin{tabular}{l|l} 
Kind & String \\
\hline Text & "string" \\
\hline File & "file" \\
\hline
\end{tabular}

The type attribute must return the empty string if the DataTransferItem \({ }^{\mathrm{p} 801}\) object is in the disabled mode; otherwise it must return the drag data item type string \({ }^{\text {p796 }}\) of the item represented by the DataTransferItem \({ }^{\text {p801 }}\) object.

The getAsString(callback) method must run the following steps:
1. If the callback is null, return.
2. If the DataTransferItem \({ }^{\text {p801 }}\) object is not in the read/write mode \({ }^{\text {p796 }}\) or the read-only mode \({ }^{\text {p796 }}\), return. The callback is never invoked.
3. If the drag data item kind \({ }^{\text {p796 }}\) is not text, then return. The callback is never invoked.
4. Otherwise, queue a task \({ }^{\text {p945 }}\) to invoke callback, passing the actual data of the item represented by the DataTransferItem \({ }^{\text {p801 }}\) object as the argument.

The getAsFile() method must run the following steps:
1. If the DataTransferItem \({ }^{\text {p801 }}\) object is not in the read/write mode \({ }^{\text {p796 }}\) or the read-only mode \({ }^{\text {p796 }}\), then return null.
2. If the drag data item kind \({ }^{\text {p796 }}\) is not File, then return null.
3. Return a new File object representing the actual data of the item represented by the DataTransferItem \({ }^{\text {p801 }}\) object.

\subsection*{6.9.4 The DragEvent \({ }^{\text {p802 }}\) interface \(\S_{2}^{\text {p80 }}\)}

The drag-and-drop processing model involves several events. They all use the DragEvent \({ }^{\mathrm{p882}}\) interface.
IDL [Exposed=Window]
interface DragEvent : MouseEvent \{
constructor(DOMString type, optional DragEventInit eventInitDict = \{\});
readonly attribute DataTransfer? dataTransfer;
\};
dictionary DragEventInit : MouseEventInit \{
DataTransfer? dataTransfer = null;
\};

For web developers (non-normative)
event . dataTransfer \({ }^{\text {p803 }}\)
Returns the DataTransfer \({ }^{\text {p797 }}\) object for the event.

\section*{Note}

Although, for consistency with other event interfaces, the DragEvent \({ }^{\mathrm{p} 802}\) interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful DataTransfer \({ }^{\text {p797 }}\) object from script, as DataTransfer \({ }^{\text {p797 }}\) objects have a processing and security model that is coordinated by the browser during drag-and-drops.

The dataTransfer attribute of the DragEvent \({ }^{\text {p882 }}\) interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to fire a DND event named e at an element, using a particular drag data store \({ }^{\text {p796 }}\), and optionally with a specific related target, the user agent must run the following steps:
1. Let dataDragStoreWasChanged be false.
2. If no specific related target was provided, set related target to null.
3. Let window be the relevant global object \({ }^{\text {p924 }}\) of the Document \({ }^{\text {p114 }}\) object of the specified target element.
4. If \(e\) is dragstart \({ }^{\mathrm{p} 899}\), then set the drag data store mode \({ }^{\mathrm{p} 796}\) to the read/write mode \({ }^{\mathrm{p} 796}\) and set dataDragStoreWasChanged to true.

If \(e\) is \(\frac{\text { drop }^{p 899}}{}\), set the drag data store mode \({ }^{\text {p796 }}\) to the read-only mode \({ }^{\mathrm{p} 796}\).
5. Let dataTransfer be a newly created DataTransfer \({ }^{p 797}\) object associated with the given drag data store \({ }^{\text {p796 }}\).
6. Set the effectAllowed \({ }^{\text {p798 }}\) attribute to the drag data store \({ }^{\mathrm{p} 796}\) 's drag data store allowed effects state \({ }^{\mathrm{p} 797}\).
7. Set the dropEffect \({ }^{p 798}\) attribute to "none \(e^{p 798 "}\) if \(e\) is dragstart \({ }^{p 899}\), drag \(^{\text {p889 }}\), or \(\underline{d r a g l e a v e}^{\text {p899 }}\); to the value corresponding to the current drag operation \({ }^{\text {p806 }}\) if \(e\) is drop \({ }^{\text {p889 }}\) or dragend \({ }^{\text {p809 }}\); and to a value based on the effectAllowed \({ }^{\text {p798 }}\) attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if e is dragenter \({ }^{\text {p809 }}\) or dragover \(r^{\text {p889 }}\) ):
\begin{tabular}{|c|c|}
\hline effectAllowed \({ }^{\text {p798 }}\) & dropEffect \({ }^{\text {p798 }}\) \\
\hline "none \({ }^{\text {p798." }}\) & "none \({ }^{\text {p798." }}\) \\
\hline "copy \({ }^{\text {p798." }}\) & "copy \({ }^{\text {p798. }}\) \\
\hline "copyLink \({ }^{\text {p798 }}{ }^{\text {" }}\) & "copy \({ }^{\text {p798" }}\), or, if appropriate \({ }^{\text {p803 }}\), "link \({ }^{\text {p798 }}\) " \\
\hline "copyMove \({ }^{\text {p798." }}\) & "copy \({ }^{\text {p798 } ", ~ o r, ~ i f ~ a p p r o p r i a t e ~}{ }^{\text {p803 }}\), "move \({ }^{\text {p798 }}\) " \\
\hline "all \({ }^{\text {p798" }}\) & "copy \({ }^{\text {p798" }}\), or, if appropriate \({ }^{\text {p803 }}\), either "link \({ }^{\text {p798" " or }}\) "move \({ }^{\text {p798 }}\) " \\
\hline "link \({ }^{\text {p798." }}\) & "link \({ }^{\text {p798." }}\) \\
\hline "linkMove \({ }^{\text {p798." }}\) & "link \({ }^{\text {p798" }}\), or, if appropriate \({ }^{\text {p803 }}\), "move \({ }^{\text {p798 " }}\) \\
\hline "move \({ }^{\text {p798." }}\) & "move \({ }^{\text {p798." }}\) \\
\hline "uninitialized \({ }^{\text {p798 " }}\) when what is being dragged is a selection from a text control & "move \({ }^{\mathrm{p} 798 \text { " }}\), or, if appropriate \({ }^{\mathrm{p} 803}\), either "copy \({ }^{\mathrm{p} 798 \text { " }}\) or "link \({ }^{\text {p798." }}\) \\
\hline "uninitialized \({ }^{\text {p798 }}\) " when what is being dragged is a selection & "copy \({ }^{\text {p798" }}\), or, if appropriate \({ }^{\text {p803 }}\), either "link \({ }^{\text {p798" }}\) or "move \({ }^{\text {p798." }}\) \\
\hline "uninitialized \({ }^{\text {p798" }}\) " when what is being dragged is an \(\underline{a}^{\text {p238 }}\) element with an href \(f^{\text {p284 }}\) attribute & "link \({ }^{\text {p798" }}\), or, if appropriate \({ }^{\text {p803 }}\), either "copy \({ }^{\text {p798" }}\) or "move \({ }^{\text {p798." }}\) \\
\hline Any other case & "copy \({ }^{\text {p798 " }}\), or, if appropriate \({ }^{\text {p803 }}\), either "link \({ }^{\text {p798" " or }}\) "move \({ }^{\text {p798." }}\) \\
\hline
\end{tabular}

Where the table above provides possibly appropriate alternatives, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.

\section*{Example}

For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "link \({ }^{\text {p798" }}\) is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "copy \({ }^{\text {p798 " }}\) or "move \({ }^{\text {p798 " }}\).
8. Let event be the result of creating an event using DragEvent \({ }^{\mathrm{p} 882}\).
9. Initialize event's type attribute to \(e\), its bubbles attribute to true, its view attribute to window, its relatedTarget attribute to related target, and its dataTransfer \({ }^{\mathrm{p883}}\) attribute to dataTransfer.
10. If \(e\) is not dragleave \({ }^{\text {p889 }}\) or \(d\) ragend \({ }^{p 809}\), then initialize event's cancelable attribute to true.
11. Initialize event's mouse and key attributes initialized according to the state of the input devices as they would be for user interaction events.

If there is no relevant pointing device, then initialize event's screenX, screenY, clientX, clientY, and button attributes to 0.
12. Dispatch event at the specified target element.
13. Set the drag data store allowed effects state \({ }^{\text {p797 }}\) to the current value of dataTransfer's effectAllowed \({ }^{\text {p798 }}\) attribute. (It can only have changed value if \(e\) is dragstart \({ }^{\text {p8999 }}\).)
14. If dataDragStoreWasChanged is true, then set the drag data store mode \({ }^{\text {p796 }}\) back to the protected mode \({ }^{\text {p796 }}\).
15. Break the association between dataTransfer and the drag data store \({ }^{\mathrm{p} 796}\).

\subsection*{6.9.5 Processing model \(\S^{\text {p80 }}\)}

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent's purview.
1. Determine what is being dragged, as follows:

If the drag operation was invoked on a selection, then it is the selection that is being dragged.
Otherwise, if the drag operation was invoked on a Document \({ }^{\text {p114 }}\), it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute draggable \({ }^{\text {p899 }}\) set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

Otherwise, the drag operation was invoked outside the user agent's purview. What is being dragged is defined by the document or application where the drag was started.

Note
img \({ }^{\text {p328 }}\) elements and \(a^{\text {p238 }}\) elements with an href \(f^{\text {p284 }}\) attribute have their draggable \({ }^{\text {p899 }}\) attribute set to true by default.
2. Create a drag data store \({ }^{\mathrm{p} 797}\). All the DND events fired subsequently by the steps in this section must use this drag data store \({ }^{\text {p796 }}\).
3. Establish which DOM node is the source node, as follows:

If it is a selection that is being dragged, then the source node \({ }^{\text {p804 }}\) is the Text node that the user started the drag on (typically the Text node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of "the selection", then the source node \({ }^{\text {p804 }}\) is the first Text node containing a part of the selection.

Otherwise, if it is an element that is being dragged, then the source node \({ }^{\text {p804 }}\) is the element that is being dragged.
Otherwise, the source node \({ }^{\text {p804 }}\) is part of another document or application. When this specification requires that an event be dispatched at the source node \({ }^{\mathrm{p} 804}\) in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

\section*{Note}
\[
\text { Multiple events are fired on the source node }{ }^{p 804} \text { during the course of the drag-and-drop operation. }
\]
4. Determine the list of dragged nodes, as follows:

If it is a selection that is being dragged, then the list of dragged nodes \({ }^{\text {p804 }}\) contains, in tree order, every node that is partially or completely included in the selection (including all their ancestors).

Otherwise, the list of dragged nodes \({ }^{\text {p804 }}\) contains only the source node \({ }^{\text {p804 }}\), if any.
5. If it is a selection that is being dragged, then add an item to the drag data store item list \({ }^{\mathrm{p} 796}\), with its properties set as follows:

\section*{The drag data item type string \({ }^{\text {p796 }}\)}
"text/plain"
The drag data item kind \({ }^{\text {p796 }}\)
Text

\section*{The actual data}

The text of the selection

Otherwise, if any files are being dragged, then add one item per file to the drag data store item list \({ }^{\text {p796 }}\), with their properties set as follows:

The drag data item type string \({ }^{\mathrm{p} 796}\)
The MIME type of the file, if known, or "application/octet-stream" otherwise.

\section*{The drag data item kind \({ }^{\text {p796 }}\) \\ File}

\section*{The actual data}

The file's contents and name.

\section*{Note}

Dragging files can currently only happen from outside a browsing context \({ }^{p 811}\), for example from a file system manager application.

If the drag initiated outside of the application, the user agent must add items to the \(\underline{\text { drag data store item list }{ }^{\text {p796 }} \text { as }}\) appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use MIME types to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the drag data item type strings \({ }^{\text {p796 }}\) must be converted to ASCII lowercase.

User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.
6. If the list of dragged nodes \({ }^{\text {p804 }}\) is not empty, then extract the microdata from those nodes into a JSON form \({ }^{\text {p762 }}\), and add one item to the drag data store item list \({ }^{\text {p796 }}\), with its properties set as follows:

\section*{The drag data item type string \({ }^{\text {p796 }}\)}
application/microdata+json \({ }^{\text {p1255 }}\)

\section*{The drag data item kind \({ }^{\text {p796 }}\)}

Text

\section*{The actual data}

The resulting JSON string.
7. Run the following substeps:
1. Let urls be an empty list of absolute URLs.
2. For each node in the list of dragged nodes \({ }^{\text {p804 }}\) :

If the node is an \(a^{\text {p238 }}\) element with an href \(f^{\text {p284 }}\) attribute
Add to urls the result of parsing \({ }^{p 89}\) the element's href \({ }^{p 284}\) content attribute relative to the element's node document.

If the node is an \(\underline{i m g}{ }^{\mathrm{p} 32 \theta}\) element with a src \({ }^{\mathrm{p} 321}\) attribute
Add to urls the result of parsing \({ }^{p 89}\) the element's \(\underline{s r c}^{p 321}\) content attribute relative to the element's node document.
3. If urls is still empty, then return.
4. Let url string be the result of concatenating the strings in urls, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).
5. Add one item to the drag data store item list \({ }^{\text {p796 }}\), with its properties set as follows:

The drag data item type string \({ }^{\text {p796 }}\)
text/uri-list \({ }^{\text {p1284 }}\)
The drag data item kind \({ }^{\text {p796 }}\)
Text
The actual data
url string
8. Update the drag data store default feedback \({ }^{\mathrm{p796}}\) as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element's rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback
should be used).
9. Fire a DND event \({ }^{\mathrm{p} 803}\) named \(d\) ragstart \({ }^{\mathrm{p} 899}\) at the source node \({ }^{\mathrm{p} 804}\).

If the event is canceled, then the drag-and-drop operation should not occur; return.

\section*{Note}

Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.
10. Initiate the drag-and-drop operation \({ }^{\text {p806 }}\) in a manner consistent with platform conventions, and as described below. The drag-and-drop feedback must be generated from the first of the following sources that is available:
1. The drag data store bitmap \({ }^{\text {p796 }}\), if any. In this case, the drag data store hot spot coordinate \({ }^{\text {p796 }}\) should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in CSS pixels from the left side and from the top side of the image respectively. [CSS] \({ }^{\text {p1285 }}\)
2. The drag data store default feedback \({ }^{\mathrm{p} 796}\).

From the moment that the user agent is to initiate the drag-and-drop operation, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the immediate user selection. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the immediate user selection \({ }^{\text {p806 }}\) is not necessarily the current target element, which is the element currently selected for the drop part of the drag-anddrop operation.

The immediate user selection \({ }^{\text {p806 }}\) changes as the user selects different elements (either by pointing at them with a pointing device, or by selecting them in some other way). The current target element \({ }^{\text {p806 }}\) changes when the immediate user selection \({ }^{\text {p806 }}\) changes, based on the results of event listeners in the document, as described below.

Both the current target element \({ }^{\mathrm{p806}}\) and the immediate user selection \({ }^{\mathrm{p806}}\) can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-web) programs altogether. (For example, a user could drag text to a word-processor.) The current target element \({ }^{\text {p806 }}\) is initially null.

In addition, there is also a current drag operation, which can take on the values "none", "copy", "link", and "move". Initially, it has the value "none \({ }^{\text {p806". }}\). It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is initiated \({ }^{\text {p806 }}\) and every 350 ms ( \(\pm 200 \mathrm{~ms}\) ) thereafter for as long as the drag operation is ongoing, queue a task \({ }^{\text {p945 }}\) to perform the following steps in sequence:
1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).
2. Fire a DND event \({ }^{\mathrm{p} 803}\) named \(\mathrm{drag}^{\mathrm{p} 899}\) at the source node \({ }^{\mathrm{p804}}\). If this event is canceled, the user agent must set the current drag operation \({ }^{\text {p806 }}\) to "none \({ }^{\text {p886" }}\) (no drag operation).
3. If the \({ }^{d r a g}{ }^{\text {p889 }}\) event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:
1. If the user is indicating a different immediate user selection \({ }^{\text {p806 }}\) than during the last iteration (or if this is the first iteration), and if this immediate user selection \({ }^{\text {p806 }}\) is not the same as the current target element \({ }^{\text {p806 }}\), then update the current target element \({ }^{\text {p806 }}\) as follows:
\(\leftrightarrow\) If the new immediate user selection \({ }^{\text {p806 }}\) is null Set the current target element \({ }^{\mathrm{p} 806}\) to null also.
\(\hookrightarrow\) If the new immediate user selection \({ }^{\text {p806 }}\) is in a non-DOM document or application Set the current target element \({ }^{\text {p806 }}\) to the immediate user selection \({ }^{\text {p806 }}\).

\section*{\(\rightarrow\) Otherwise}

Fire a DND event \({ }^{\text {p803 }}\) named dragenter \(r^{\text {p889 }}\) at the immediate user selection \({ }^{\text {p806 }}\). If the event is canceled, then set the current target element \({ }^{\mathrm{p} 806}\) to the immediate user selection \({ }^{\text {p806 }}\).

Otherwise, run the appropriate step from the following list:
\(\rightarrow\) If the immediate user selection \({ }^{\text {p806 }}\) is a text control (e.g., textarea \({ }^{\text {p548 }}\), or an input \(t^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Text \({ }^{\text {p499 }}\) state) or an editing host \({ }^{\text {p789 }}\) or editable element, and the drag data store item list \({ }^{\mathrm{p} 796}\) has an item with the drag data item type string \({ }^{\mathrm{p} 796}\) "text/plain" and the drag data item kind \({ }^{\text {p796 }}\) text

Set the current target element \({ }^{\mathrm{p} 806}\) to the immediate user selection \({ }^{\mathrm{p} 806}\) anyway.
\(\rightarrow\) If the immediate user selection \({ }^{\text {p806 }}\) is the body element \({ }^{\text {p118 }}\)
Leave the current target element \({ }^{\text {p806 }}\) unchanged.
\(\hookrightarrow\) Otherwise
Fire a DND event \({ }^{p 803}\) named dragenter \(r^{p 809}\) at the body element \({ }^{p 118}\), if there is one, or at the Document \({ }^{\text {p114 }}\) object, if not. Then, set the current target element \({ }^{\text {p806 }}\) to the body element \({ }^{\text {p118 }}\), regardless of whether that event was canceled or not.
2. If the previous step caused the current target element \({ }^{p 806}\) to change, and if the previous target element was not null or a part of a non-DOM document, then fire a DND event \({ }^{p 803}\) named dragleave \({ }^{\text {p809 }}\) at the previous target element, with the new current target element \({ }^{p 806}\) as the specific related target.
3. If the current target element \({ }^{p 806}\) is a DOM element, then fire a DND event \({ }^{\mathrm{p} 803}\) named dragover \({ }^{p 899}\) at this current target element \({ }^{8806}\).

If the \(\underline{d r a g o v e r}{ }^{\text {p889 }}\) event is not canceled, run the appropriate step from the following list:
\(\rightarrow\) If the current target element \({ }^{\text {p806 }}\) is a text control (e.g., textarea \({ }^{\text {p548 }}\), or an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Text \({ }^{\text {p499 }}\) state) or an editing host \({ }^{\text {p789 }}\) or editable element, and the drag data store item list \({ }^{\text {p796 }}\) has an item with the drag data item type string \({ }^{\text {p796 }}\) "text/plain" and the drag data item kind \({ }^{\text {p796 }}\) text

Set the current drag operation \({ }^{\text {p806 }}\) to either "copy \({ }^{\text {p806" }}\) or "move \({ }^{\text {p806" }}\), as appropriate given the platform conventions.

\section*{\(\rightarrow\) Otherwise}

Reset the current drag operation \({ }^{\text {p806 }}\) to "none \({ }^{\text {p806" }}\).
Otherwise (if the dragover \({ }^{p 889}\) event is canceled), set the current drag operation \({ }^{\text {p806 }}\) based on the values of the effectAllowed \({ }^{\text {p798 }}\) and dropEffect \({ }^{p 798}\) attributes of the DragEvent \({ }^{p 882}\) object's dataTransfer \({ }^{p 883}\) object as they stood after the event dispatch finished, as per the following table:
\begin{tabular}{|c|c|c|}
\hline effectallowed \({ }^{\text {p798 }}\) & dropEffect \({ }^{\text {p798 }}\) & Drag operation \\
\hline "uninitialized \({ }^{\text {p798 }}\) ", "copy \({ }^{\text {p798" }}\) " "copyLink \({ }^{\text {p798 }}\) ", "copyMove \({ }^{\text {p798" }}\), or "all \({ }^{\text {p798" }}\) & "copy \({ }^{\text {p798." }}\) & "copy \({ }^{\text {p886 }}\) " \\
\hline "uninitialized \({ }^{\text {p798 " }}\), "link \({ }^{\text {p798" }}\), "copyLink \({ }^{\text {p798", "linkMove }}{ }^{\text {p798" }}\), or "all \({ }^{\text {p798." }}\) & "link \({ }^{\text {p798." }}\) & "link \({ }^{\text {p8066." }}\) \\
\hline "uninitialized \({ }^{\text {p798 } ", ~ " m o v e ~}{ }^{\text {p798 }}\) ", "copyMove \({ }^{\text {p798 } ", ~ " l i n k M o v e ~}{ }^{\text {p798" }}\), or "all \({ }^{\text {p798 }}\) " & "move \({ }^{\text {p798. }}\) & "move \({ }^{\text {p806 }}\) " \\
\hline Any other case & & "none \({ }^{\text {p886 " }}\) \\
\hline
\end{tabular}
4. Otherwise, if the current target element \({ }^{\text {p806 }}\) is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the current drag operation \({ }^{\text {p806 }}\) accordingly.
5. Update the drag feedback (e.g. the mouse cursor) to match the current drag operation \({ }^{\text {p806 }}\), as follows:
\begin{tabular}{l|l} 
Drag operation & \multicolumn{1}{|c}{ Feedback } \\
\hline "copy \({ }^{\text {p806" }}\) & Data will be copied if dropped here. \\
\hline "link \({ }^{\text {p806" } " ~}\) & Data will be linked if dropped here. \\
\hline "move \({ }^{\text {p886" } " ~}\) & Data will be moved if dropped here. \\
\hline "none \({ }^{\text {p806" } " ~}\) & No operation allowed, dropping here will cancel the drag-and-drop operation. \\
\hline
\end{tabular}
4. Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-anddrop interface), or if the drag \({ }^{\text {p889 }}\) event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop operation:
1. If the current drag operation \({ }^{\text {p806 }}\) is "none \({ }^{\text {p886" ( }}\) (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the Escape key), or if the current target element \({ }^{\text {p806 }}\) is null, then the drag operation failed. Run these substeps:
1. Let dropped be false.
2. If the current target element \({ }^{p 806}\) is a DOM element, fire a DND event \({ }^{p 803}\) named dragleave \({ }^{\text {p809 }}\) at it; otherwise, if it is not null, use platform-specific conventions for drag cancelation.
3. Set the current drag operation \({ }^{\text {p806 }}\) to "none \({ }^{\text {p886" }}\).

Otherwise, the drag operation might be a success; run these substeps:
1. Let dropped be true.
2. If the current target element \({ }^{p 806}\) is a DOM element, fire a DND event \({ }^{\text {p803 }}\) named drop \({ }^{\text {p809 }}\) at it; otherwise, use platform-specific conventions for indicating a drop.
3. If the event is canceled, set the current drag operation \({ }^{\text {p806 }}\) to the value of the dropEffect \({ }^{\text {p798 }}\) attribute of the DragEvent \({ }^{\text {p802 }}\) object's dataTransfer \({ }^{\text {p803 }}\) object as it stood after the event dispatch finished.

Otherwise, the event is not canceled; perform the event's default action, which depends on the exact target as follows:
\(\leftrightarrow\) If the current target element \({ }^{\text {p806 }}\) is a text control (e.g., textarea \({ }^{\text {p548 }}\), or an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Text \({ }^{\text {p499 }}\) state) or an editing host \({ }^{\text {p789 }}\) or editable element, and the drag data store item list \({ }^{\text {p796 }}\) has an item with the drag data item type string \({ }^{\text {p796 }}\) "text/plain" and the drag data item kind \({ }^{\text {p796 }}\) text

Insert the actual data of the first item in the drag data store item list \({ }^{p 796}\) to have a drag data item type string \({ }^{\mathrm{p} 796}\) of "text/plain" and a drag data item kind \({ }^{\text {p796 }}\) that is text into the text control or editing host \({ }^{\mathrm{p} 789}\) or editable element in a manner consistent with platform-specific conventions (e.g. inserting it at the current mouse cursor position, or inserting it at the end of the field).

\section*{\(\hookrightarrow\) Otherwise}

Reset the current drag operation \({ }^{\text {p806 }}\) to "none \({ }^{\text {p806" } " . ~}\)
2. Fire a DND event \({ }^{p 803}\) named dragend \({ }^{\text {p889 }}\) at the source node \({ }^{p 804}\).
3. Run the appropriate steps from the following list as the default action of the dragend \({ }^{\text {p889 }}\) event:
\(\leftrightarrow\) If dropped is true, the current target element \({ }^{\text {p806 }}\) is a text control (see below), the current drag operation \({ }^{\text {p806 }}\) is "move \({ }^{\text {p806" }}\), and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an editing host \({ }^{\text {p789 }}\)

Delete the selection.
\(\rightarrow\) If dropped is true, the current target element \({ }^{\text {p806 }}\) is a text control (see below), the current drag operation \({ }^{\text {p806 }}\) is "move \({ }^{\text {p886" }}\), and the source of the drag-and-drop operation is a selection in a text control

The user agent should delete the dragged selection from the relevant text control.
\(\hookrightarrow\) If dropped is false or if the current drag operation \({ }^{\text {p806 }}\) is "none \({ }^{\text {p886" }}\)
The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.

\section*{\(\rightarrow\) Otherwise}

The event has no default action.
For the purposes of this step, a text control is a textarea \({ }^{\text {p548 }}\) element or an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\)

```
Note
User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the viewport on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.
```

\section*{Note}

This model is independent of which Document \({ }^{\text {p114 }}\) object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

\subsection*{6.9.6 Events summary \(\S^{p 80}\)}

This section is non-normative.
The following events are involved in the drag-and-drop model.
\begin{tabular}{|c|c|c|c|c|c|}
\hline Event name & Target & Cancelable? & Drag data store mode \({ }^{\text {p796 }}\) & dropEffect \({ }^{\text {p798 }}\) & Default Action \\
\hline dragstart & Source node \({ }^{\text {p804 }}\) & \(\checkmark\) Cancelable & Read/write mode \({ }^{\text {p796 }}\) & "none \({ }^{\text {p798." }}\) & Initiate the drag-and-drop operation \\
\hline drag & Source node \({ }^{\text {p804 }}\) & \(\checkmark\) Cancelable & Protected mode \({ }^{\text {p796 }}\) & "none \({ }^{\text {p798." }}\) & Continue the drag-and-drop operation \\
\hline dragenter & Immediate user selection \({ }^{\text {p806 }}\) or the body element \({ }^{\text {p118 }}\) & \(\checkmark\) Cancelable & Protected mode \({ }^{\text {p796 }}\) & Based on effectAllowed value \({ }^{\text {p803 }}\) & Reject immediate user selection \({ }^{\text {p806 }}\) as potential target element \({ }^{\text {p806 }}\) \\
\hline dragleave & Previous target element \({ }^{\text {p806 }}\) & - & Protected mode \({ }^{\text {p796 }}\) & "none \({ }^{\text {p798." }}\) & None \\
\hline dragover & Current target element \({ }^{\text {p806 }}\) & \(\checkmark\) Cancelable & Protected mode \({ }^{\text {p796 }}\) & Based on effectAllowed value \({ }^{\text {p803 }}\) & Reset the current drag operation \({ }^{\text {p806 }}\) to "none" \\
\hline drop & Current target element \({ }^{\text {p806 }}\) & \(\checkmark\) Cancelable & Read-only mode \({ }^{\text {p796 }}\) & Current drag operation \({ }^{\text {p806 }}\) & Varies \\
\hline dragend & Source node \({ }^{\text {p804 }}\) & - & Protected mode \({ }^{\text {p796 }}\) & Current drag operation \({ }^{\text {p806 }}\) & Varies \\
\hline
\end{tabular}

Not shown in the above table: all these events bubble, are composed, and the effectAllowed \({ }^{\text {p798 }}\) attribute always has the value it had after the dragstart \({ }^{\text {p889 }}\) event, defaulting to "uninitialized \({ }^{\text {p798" }}\) in the dragstart \({ }^{\text {p809 }}\) event.

\subsection*{6.9.7 The draggable attribute \(\S_{9}^{\text {p80 }}\)}

All HTML elements \({ }^{p 44}\) may have the draggable \({ }^{p 899}\) content attribute set. The draggable \({ }^{p 889}\) attribute is an enumerated attribute \({ }^{p 68}\). It has three states. The first state is true and it has the keyword true. The second state is false and it has the keyword false. The third state is auto; it has no keywords but it is the missing value default \({ }^{p 68}\) and the invalid value default \(t^{p 68}\).

The true state means the element is draggable; the false state means that it is not. The auto state uses the default behavior of the user agent.

An element with a draggable \({ }^{\text {p889 }}\) attribute should also have a title \({ }^{p 139}\) attribute that names the element for the purpose of non-visual interactions.

\section*{For web developers (non-normative)}

\section*{element . draggable \({ }^{\text {p809 }}\) [ = value ]}

Returns true if the element is draggable; otherwise, returns false.
Can be set, to override the default and set the draggable \({ }^{\text {p809 }}\) content attribute.

The draggable IDL attribute, whose value depends on the content attribute's in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose draggable \({ }^{\text {p809 }}\) IDL attribute is true become draggable as well.

If an element's \(\underline{d r a g g a b l e}{ }^{\text {p899 }}\) content attribute has the state true, the draggable \({ }^{\text {p889 }}\) IDL attribute must return true.
Otherwise, if the element's \(\underline{d r a g g a b l e} e^{\text {p809 }}\) content attribute has the state false, the \(\underline{d r a g g a b l e}{ }^{\text {p889 }}\) IDL attribute must return false.
Otherwise, the element's \(\underline{\text { draggable }}{ }^{\text {p809 }}\) content attribute has the state auto. If the element is an \(\underline{i m g}{ }^{\mathrm{p} 329}\) element, an object \({ }^{\mathrm{p} 773}\) element that represents \({ }^{p 123}\) an image, or an \(a^{p 238}\) element with an href \(f^{p 284}\) content attribute, the draggable \({ }^{\text {p889 }}\) IDL attribute must return true; otherwise, the draggable \({ }^{\text {p889 }}\) IDL attribute must return false.

If the draggable \({ }^{\text {p889 }}\) IDL attribute is set to the value false, the draggable \({ }^{\text {p889 }}\) content attribute must be set to the literal value "false". If the draggable \({ }^{p 889}\) IDL attribute is set to the value true, the draggable \({ }^{\text {p889 }}\) content attribute must be set to the literal value "true".

\subsection*{6.9.8 Security risks in the drag-and-drop model \(\S^{\text {p8i }}\)}

User agents must not make the data added to the DataTransfer \({ }^{p 797}\) object during the dragstart \({ }^{\text {p889 }}\) event available to scripts until the drop \({ }^{\text {p889 }}\) event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation - if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the drop \({ }^{\text {p889 }}\) event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user's consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safelist of known-safe features. Similarly, relative URLs should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.

\section*{Example}

Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page's contenteditable \({ }^{\text {p787 }}\) region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would thus enable a cross-site scripting attack.

\section*{7 Loading web pages \(\S^{p 81}\)}

This section describes features that apply most directly to web browsers. Having said that, except where specified otherwise, the requirements defined in this section do apply to all user agents, whether they are web browsers or not.

\subsection*{7.1 Browsing contexts \(\S^{p 81}\)}

A browsing context is an environment in which Document \({ }^{p 114}\) objects are presented to the user.

\section*{Note}

A tab or window in a web browser typically contains a browsing context \(t^{p 811}\), as does an iframe \({ }^{\mathrm{p} 361}\) or frame \({ }^{p 1240}\) s in a frameset \({ }^{p 1239}\).

A browsing context \({ }^{\text {p811 }}\) has a corresponding WindowProxy \({ }^{\text {p834 }}\) object.
A browsing context \({ }^{\text {p811 }}\) has an opener browsing context, which is null or a browsing context \({ }^{\text {p811 }}\). It is initially null.
A browsing context \({ }^{\text {p811 }}\) has a disowned boolean. It is initially false.
A browsing context \({ }^{\text {p811 }}\) has an is closing boolean. It is initially false.

\section*{Example}

The following example illustrates the various possibilities of a browsing context \({ }^{\mathrm{p} 811}\). It can be disowned \({ }^{\mathrm{p} 811}\), is closing \({ }^{\mathrm{p} 811}\), neither, or both.
```
// Neither disowned nor is closing:
const popup1 = window.open();
// Disowned, but not is closing:
const popup2 = window.open();
popup2.opener = null;
// Not disowned, but is closing:
const popup3 = window.open();
popup3.close();
// Disowned, is closing:
const popup4 = window.open();
popup4.opener = null;
popup4.close();
```

A browsing context \({ }^{\mathrm{p} 811}\) has a session history \({ }^{\mathrm{p} 849}\), which lists the Document \({ }^{\mathrm{pr14}}\) objects that the browsing context \({ }^{\mathrm{p811}}\) has presented, is presenting, or will present. A Document's browsing context is the browsing context \({ }^{\mathrm{p811}}\) whose session history \({ }^{\mathrm{p849}}\) contains the Document \({ }^{p 114}\), if any such browsing context exists and has not been discarded \({ }^{\mathrm{p831}}\), and null otherwise.

\section*{Note}

A Document \({ }^{\text {p114 }}\) does not necessarily have a non-null browsing context \({ }^{p 811}\). In particular, data mining tools are likely to never instantiate browsing contexts. A Document \({ }^{\text {p114 }}\) created using an API such as createDocument () never has a non-null browsing context \({ }^{p 811}\). And the Document \({ }^{p 114}\) originally created for an iframe \({ }^{p 361}\) element, which has since been removed from the \(\underline{\text { document }{ }^{p 44}}\), has no associated browsing context, since that browsing context was discarded \({ }^{p 831}\).

A browsing context \({ }^{\mathrm{p} 811}\) 's active window is its WindowProxy \({ }^{p 834}\) object's [[Window]] \({ }^{\mathrm{p834}}\) internal slot value. A browsing context \({ }^{\text {p811 }}\) 's active document is its active window \({ }^{\text {p811 }}\) 's associated Document \({ }^{\mathrm{p} 826}\).

In general, there is a 1-to-1 mapping from the Window \({ }^{\text {p824 }}\) object to the Document \({ }^{\text {p114 }}\) object, as long as the Document \({ }^{\text {p114 }}\) object has a non-null browsing context \({ }^{p 811}\). There is one exception. A Window \({ }^{p 824}\) can be reused for the presentation of a second Document \({ }^{p 114}\) in the same browsing context \({ }^{p 811}\), such that the mapping is then 1-to-2. This occurs when a browsing context \({ }^{p 811}\) is navigated \({ }^{p 866}\) from the initial about:blank \({ }^{\text {p51 }}\) Document \(^{p 114}\) to another, with historyHandling \({ }^{\text {p866 }}\) set to "replace \({ }^{\text {p866" }}\).

\subsection*{7.1.1 Creating browsing contexts \(\stackrel{8}{2}_{\text {p81 }}^{\text {2 }}\)}

To set the active document of a browsing context \({ }^{\text {p811 }}\) browsingContext to a Document \({ }^{\text {p114 }}\) object document, run these steps:
1. Let window be document's relevant global object \({ }^{\mathrm{p} 924}\).

Per this standard document can be created before window, which does not make much sense. See issue \#2688.
2. Set browsingContext's active window \({ }^{\text {p811 }}\) to window.
3. Set window's associated Document \({ }^{\mathrm{p} 826}\) to document.
4. Set window's relevant settings object \({ }^{\text {p924 }}\) 's execution ready flag \({ }^{\text {p917 }}\).

A browsing context \({ }^{\text {p811 }}\) has an associated creator origin (null or returns an origin \({ }^{\text {p837 }}\) ), creator URL (null or returns a URL), and creator base URL (null or returns a URL). These are all initially null.

To determine the origin, given browsing context \({ }^{\mathrm{p} 811}\) browsingContext, URL url, sandboxing flag set \({ }^{\mathrm{p} 842}\) sandboxFlags, and two origins \({ }^{\text {p837 }}\) invocationOrigin and activeDocumentNavigationOrigin:
1. If sandboxFlags has its sandboxed origin browsing context flag \({ }^{\text {p842 }}\) set, then return a new opaque origin \({ }^{\text {p837 }}\).
2. If \(u r l\) is null, then return a new opaque origin \({ }^{p 837}\).
3. If activeDocumentNavigationOrigin is not null, and url's scheme is "javascript", then return activeDocumentNavigationOrigin.
4. If invocationOrigin is non-null and url is about:blank \({ }^{p 51}\), then return invocationOrigin.

\section*{Note}

The result here is that two documents end up with the same underlying origin \({ }^{p 837}\), meaning that document. domain \({ }^{\text {p840 }}\) affects both.
5. If \(u r l\) is about: \(\operatorname{srcdoc}^{\mathrm{p88}}\), then return the origin \({ }^{\mathrm{p837}}\) of browsingContext's container document \({ }^{\mathrm{p814}}\).
6. Return url's origin.

To create a new browsing context, given null or a Document \({ }^{\text {p114 }}\) object creator, null or an element embedder, and a browsing context group \({ }^{\text {p818 }}\) group, run these steps:
1. Let browsingContext be a new browsing context \({ }^{\text {p811 }}\).
2. If creator is non-null, then set browsingContext's creator origin \({ }^{\text {p812 }}\) to return creator's origin \({ }^{\text {p837 }}\), browsingContext's creator \(\underline{U R L^{\mathrm{p} 812}}\) to return creator's URL, and browsingContext's creator base URL \({ }^{\text {p812 }}\) to return creator's base URL \({ }^{\text {p88 }}\).
3. Let sandboxFlags be the result of determining the creation sandboxing flags \({ }^{\mathrm{p844}}\) given browsingContext and embedder.
4. Let origin be the result of determining the origin \({ }^{\mathrm{p} 812}\) given browsingContext, about:blank \({ }^{\mathrm{p51}}\), sandboxFlags, browsingContext's creator origin \({ }^{\text {p812 }}\), and null.
5. Let permissionsPolicy be the result of creating a permissions policy given browsingContext and origin. [PERMISSIONSPOLICY] \({ }^{\text {p1289 }}\)

> This needs to use embedder.
6. Let agent be the result of obtaining a similar-origin window agent \({ }^{\text {p914 }}\) given origin, group, and false.
7. Let realm execution context be the result of creating a new JavaScript realm \({ }^{\text {p918 }}\) given agent and the following customizations:
- For the global object, create a new Window \({ }^{\text {p824 }}\) object.
- For the global this binding, use browsingContext's WindowProxy \({ }^{\text {p834 }}\) object.
8. Let topLeveICreationURL be about:blank \({ }^{p 51}\) if embedder is null; otherwise embedder's relevant settings object \({ }^{\text {p924' }} \mathrm{s}\) top-level creation URL \({ }^{\text {p916 }}\).
9. Let topLevelOrigin be origin if embedder is null; otherwise embedder's relevant settings object \({ }^{\text {p924' }} \mathrm{s}\) top-level origin \({ }^{\text {p916 }}\).
10. Let settingsObject be the result of setting up a window environment settings object \({ }^{\text {p833 }}\) with realm execution context, null, topLeveICreationURL, and topLeveIOrigin.
11. Let coop be "unsafe-none \({ }^{\text {p845" }}\).
12. If creator is non-null and creator's origin \({ }^{\mathrm{p837}}\) is same origin \({ }^{\mathrm{p838}}\) with creator's relevant settings object \({ }^{\text {p924 ' }} \mathrm{s}\) top-level origin \({ }^{\text {p916 }}\), then set coop to creator's browsing context \({ }^{\text {p811 }}\) 's top-level browsing context \({ }^{\text {p814 ' }}\) ' active document \({ }^{\text {p811 ' 's cross-origin opener }}\) policy \({ }^{\text {p115 }}\).
13. Let document be a new Document \({ }^{\text {p114 }}\), marked as an HTML document in quirks mode, whose content type is "text/html", origin \(^{\text {p837 }}\) is origin, active sandboxing flag set \({ }^{\mathrm{p844}}\) is sandboxFlags, permissions policy \({ }^{\text {p115 }}\) is permissionsPolicy, cross-origin opener policy \({ }^{\text {p115 }}\) is coop, and which is ready for post-load tasks \({ }^{\text {p1165 }}\).
14. Ensure that document has a single child \(h t m 2^{p 152}\) node, which itself has two empty child nodes: a head \({ }^{p 153}\) element, and a body \({ }^{\text {p178 }}\) element.
15. Set the active document \({ }^{\text {p812 }}\) of browsingContext to document.
16. If browsingContext's creator URL \({ }^{\mathrm{p} 812}\) is non-null, then set document's referrer \({ }^{p 114}\) to the serialization of it.
17. If creator is non-null, then set document's referrer policy \({ }^{\text {p115 }}\) to creator's referrer policy \({ }^{\text {p115 }}\).
18. If creator is non-null, then set document's embedder policy \({ }^{p 115}\) to creator's embedder policy \({ }^{p 115}\).
19. Add document to browsingContext's session history \({ }^{\mathrm{p} 849}\).
20. Completely finish loading \({ }^{\text {p885 }}\) document.
21. Return browsingContext.

\section*{To create a new top-level browsing context:}
1. Let group be the result of creating a new browsing context group \({ }^{\text {p818 }}\).
2. Return group's browsing context set \({ }^{\mathrm{p} 818}[0]\).

\section*{Note}

This creates a top-level browsing context \({ }^{p 814}\).

To create a new auxiliary browsing context, given a browsing context \({ }^{\mathrm{p} 811}\) opener:
1. Let group be opener's top-level browsing context \({ }^{\text {p814 }}\) 's group \({ }^{\text {p814 }}\)
2. Assert: group is non-null, as navigating \({ }^{\mathrm{p866}}\) invokes this directly.
3. Let browsingContext be the result of creating a new browsing context \({ }^{\mathrm{p} 812}\) with opener's active document \({ }^{\mathrm{p811}}\), null, and group.
4. Append \({ }^{\mathrm{p} 818}\) browsingContext to group.
5. Set browsingContext's opener browsing context \({ }^{\text {p811 }}\) to opener.
6. Legacy-clone a browsing session storage shed with opener's browsing session \({ }^{\text {p849 }}\) and browsingContext's browsing session \({ }^{\text {p849 }}\). [STORAGE] \({ }^{\text {p1291 }}\)
7. Return browsingContext.

To create a new nested browsing context, given an element element:
1. Let group be element's node document's browsing context \({ }^{\text {p811' }}\) ' top-level browsing context \({ }^{\text {p814 }}\) 's group \({ }^{p 814}\).
2. Let browsingContext be the result of creating a new browsing context \({ }^{\text {p812 }}\) with element's node document, element, and group.
3. Set element's nested browsing context \({ }^{\text {p814 }}\) to browsingContext.
4. If element has a name attribute, then set browsingContext's name \({ }^{\text {p819 }}\) to the value of this attribute.

\subsection*{7.1.2 Related browsing contexts \(\S_{4}^{\text {p81 }}\)}

Certain elements (for example, iframe \({ }^{\text {p361 }}\) elements) can instantiate further browsing contexts \({ }^{\text {p811 }}\). These elements are called browsing context containers.

Each browsing context container \({ }^{\text {p814 }}\) has a nested browsing context, which is either a browsing context \({ }^{\text {p811 }}\) or null. It is initially null.
The container of a browsing context \({ }^{\mathrm{p} 811} b c\) is the browsing context container \({ }^{\mathrm{p} 814}\) whose nested browsing context \({ }^{\mathrm{p814}}\) is \(b c\), or null if there is no such element.

Each browsing context \({ }^{\text {p811 }} b c\) has a container document, which is the result of running these steps:
1. If \(b c^{\prime} \mathrm{s}\) container \({ }^{\mathrm{p814}}\) is null, then return null.
2. Return \(b c\) 's container \({ }^{\text {p814 }}\) 's node document.

\section*{Note}

This is equal to bc's container \({ }^{p 814}\) 's shadow-including root as bc's container \({ }^{p 814}\) has to be connected.

A browsing context \({ }^{8811}\) child is said to be a child browsing context of another browsing context \({ }^{p 811}\) parent, if child's container document \({ }^{\mathrm{p} 814}\) is non-null and child's container document \({ }^{\mathrm{p} 814}\) 's browsing context \({ }^{\mathrm{p} 811}\) is parent.

A browsing context \({ }^{\text {p811 }}\) child is a document-tree child browsing context of parent if child is a child browsing context \({ }^{\text {p814 }}\) and child's container \({ }^{\mathrm{p814}}\) is in a document tree.

A browsing context \({ }^{\text {p811 }}\) child may have a parent browsing context. This is the unique browsing context \({ }^{\mathrm{p811}}\) that has child as a child browsing context \({ }^{\mathrm{p814}}\), if any such browsing context exists. Otherwise, the browsing context \({ }^{\mathrm{p} 811}\) has no parent browsing context \({ }^{p 814}\).

A browsing context \({ }^{p 811} A\) is said to be an ancestor of a browsing context \(B\) if there exists a browsing context \(A^{\prime}\) that is a child browsing context \({ }^{\mathrm{p814}}\) of \(A\) and that is itself an ancestor \({ }^{\mathrm{p814}}\) of \(B\), or if the browsing context \(A\) is the parent browsing context \({ }^{\mathrm{p} 814}\) of \(B\).

A browsing context \({ }^{\text {p811 }}\) that has no parent browsing context \({ }^{\text {p814 }}\) is the top-level browsing context for itself and all of the browsing contexts for which it is an ancestor browsing context \({ }^{8814}\).

A top-level browsing context \({ }^{\text {p814 }}\) has an associated group (null or a browsing context group \({ }^{\text {p818 }}\) ). It is initially null.
It is possible to create new browsing contexts that are related to a top-level browsing context \({ }^{\text {p814 }}\) while their container \({ }^{\text {p814 }}\) is null. Such browsing contexts are called auxiliary browsing contexts. Auxiliary browsing contexts are always top-level browsing contexts \({ }^{\text {p814 }}\).

The transitive closure of parent browsing contexts \({ }^{p 814}\) for a browsing context \({ }^{p 811}\) that is a child browsing context \({ }^{p 814}\) gives the list of ancestor browsing contexts \({ }^{\text {p814 }}\).

The list of the descendant browsing contexts of a Document \({ }^{p 114} d\) is the (ordered) list returned by the following algorithm:
1. Let list be an empty list.
2. For each browsing context container \({ }^{\text {p814 }}\) container, whose nested browsing context \({ }^{p 814}\) is non-null and whose shadowincluding root is \(d\), in shadow-including tree order:
1. Let nested \(B C\) be container's nested browsing context \({ }^{\mathrm{p} 814}\).
2. Append nestedBC to list.
3. Extend list with the list of the descendant browsing contexts \({ }^{p 814}\) of nestedBC's active document \({ }^{\mathrm{p} 811}\).
3. Return list.

A Document \(t^{p 114} d\) is said to be fully active when \(d^{\prime} s\) browsing context \({ }^{\mathrm{p} 811}\) is non-null, \(d^{\prime} \mathrm{s}\) browsing context \({ }^{\mathrm{p} 811}\) 's active document \({ }^{\mathrm{p811}}\) is \(d\), and either \(d^{\prime} \mathrm{s}\) browsing context \({ }^{\mathrm{p} 811}\) is a top-level browsing context \({ }^{\mathrm{p} 814}\), or \(d^{\prime} \mathrm{s}\) container document \({ }^{\mathrm{p} 814}\) is fully active \({ }^{\mathrm{p} 815}\).

Because they are associated with an element, child browsing contexts \({ }^{\text {p814 }}\) are always tied to a specific Document \({ }^{\text {p114 }}\) in their parent browsing context \({ }^{\mathrm{p814}}\). User agents must not allow the user to interact with child browsing contexts \({ }^{\mathrm{p} 814}\) of elements that are in Document \({ }^{\text {p114 }}\) s that are not themselves fully active \({ }^{\text {p815 }}\).

\section*{Example}

The following example illustrates the differences between active \({ }^{\text {p811 }}\) and fully active \({ }^{\text {p815 }}\) Document \({ }^{\text {p114 }}\) objects. Here a.html is loaded into a browser window, b-1.html starts out loaded into an iframe \({ }^{\mathrm{p} 361}\) as shown, and b-2.html and c.html are omitted (they can simply be an empty document).
```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context A</title>
<iframe src="b-1.html"></iframe>
<button onclick="frames[0].location.href = 'b-2.html'">Click me</button>
<!-- b-1.html -->
<!DOCTYPE html>
<html lang="en">
<title>Browsing context B</title>
<iframe src="c.html"></iframe>
```

At this point, the documents given by a.html, b-1.html, and c.html are all the active documents \({ }^{\text {p811 }}\) of their respective browsing contexts \({ }^{\text {p811 }}\). They are also all fully active \({ }^{\text {p815 }}\).

After clicking on the button \({ }^{\text {p535 }}\), and thus loading a new Document \({ }^{\text {p114 }}\) from b-2.html into browsing context B, we have the following results:
- The a.html Document \({ }^{\text {p114 }}\) remains both the active document \({ }^{p 811}\) of browsing context A , and fully active \({ }^{\mathrm{p} 815}\).
- The b-1.html Document \({ }^{\text {p114 }}\) is now not the active document \({ }^{\text {p811 }}\) of browsing context B . As such it is also not fully active \({ }^{\mathrm{p} 815}\).
- The new b-2.html Document \({ }^{p 114}\) is now the active document \({ }^{p 811}\) of browsing context B , and is also fully active \({ }^{\text {p815 }}\).
- The c.html Document \({ }^{\text {p114 }}\) is still the active document \({ }^{\mathrm{p811}}\) of browsing context C. However, since C's container document \({ }^{\text {p814 }}\) is the b-1.html Document \({ }^{p 114}\), which is itself not fully active \({ }^{\text {p815 }}\), this means the \(\mathrm{c} . \mathrm{html}\) Document \({ }^{\text {p114 }}\) is now not fully active \({ }^{\mathrm{p} 815}\) (even though it is active \({ }^{\mathrm{p} 811}\) ).

For more explorations of the complexities involved here, especially as it impacts the session history \({ }^{\text {p849 }}\), see A Model of Navigation History. [NAVMODEL] \({ }^{\text {p1289 }}\)

A child browsing context \({ }^{\text {p814 }}\) can be put into a delaying load events mode. This is used when it is navigated \({ }^{p 866}\), to delay the load event \({ }^{\text {p1165 }}\) of its container \({ }^{\text {p814 }}\) before the new Document \({ }^{\text {p114 }}\) is created.

The document family of a browsing context \({ }^{\mathrm{p} 811}\) consists of the union of all the Document \({ }^{\mathrm{p} 114}\) objects in that browsing context \({ }^{\mathrm{p} 811}\) 's session history \({ }^{\text {p849 }}\) and the document families \({ }^{\text {p815 }}\) of all those Document \({ }^{\text {p114 }}\) objects. The document family \({ }^{\text {p815 }}\) of a Document \({ }^{\text {p114 }}\) object consists of the union of all the document families \({ }^{\text {p815 }}\) of the browsing contexts \({ }^{\text {p811 }}\) in the list of the descendant browsing contexts \({ }^{p 814}\) of the Document \({ }^{\text {p114 }}\) object.

The content document of a browsing context container \({ }^{p 814}\) container is the result of the following algorithm:
1. If container's nested browsing context \({ }^{\text {p814 }}\) is null, then return null.
2. Let context be container's nested browsing context \({ }^{\mathrm{p} 814}\).
3. Let document be context's active document \({ }^{\mathrm{p} 811}\).
4. If document's origin \({ }^{\text {p837 }}\) and container's node document's origin \({ }^{\text {p837 }}\) are not same origin-domain \({ }^{\text {p838 }}\), then return null.
5. Return document.

\subsection*{7.1.2.1 Navigating related browsing contexts in the DOM}

For web developers (non-normative)

\section*{window. top \({ }^{\text {p816 }}\)}

Returns the WindowProxy \({ }^{\text {p834 }}\) for the top-level browsing context \({ }^{\text {p814 }}\).
window. opener \({ }^{\text {p816 }}\) [ = value ]
Returns the WindowProxy \({ }^{\text {p834 }}\) for the opener browsing context \({ }^{\text {p811 }}\).
Returns null if there isn't one or if it has been set to null.
Can be set to null.

\section*{window . parent \({ }^{\text {p817 }}\)}

Returns the WindowProxy \({ }^{\mathrm{p834}}\) for the parent browsing context \({ }^{\mathrm{p814}}\).
window. frameElement \({ }^{\text {p817 }}\)
Returns the Element for the browsing context container \({ }^{\text {p814 }}\).
Returns null if there isn't one, and in cross-origin situations.

The top attribute's getter must run these steps:
1. If this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{p 826}\) is null, then return null.
2. Return this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\mathrm{p} 826}\) 's top-level browsing context \({ }^{\mathrm{p} 814}\) 's WindowProxy \({ }^{\mathrm{p} 834}\) object.

The opener attribute's getter must run these steps:
1. Let current be this Window \({ }^{p 824}\) object's browsing context \({ }^{\text {p826 }}\).
2. If current is null, then return null.
3. If current's disowned \({ }^{\text {p811 }}\) is true, then return null.
4. If current's opener browsing context \({ }^{\mathrm{p} 811}\) is null, then return null.
5. Return current's opener browsing context \({ }^{\text {p811 }}\) 's WindowProxy \({ }^{\text {p834 }}\) object.

The opener \({ }^{p 816}\) attribute's setter must run these steps:
1. If the given value is null and this Window \({ }^{p 824}\) object's browsing context \({ }^{\mathrm{p} 826}\) is non-null, then set this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\text {p826 }}\) 's disowned \({ }^{\text {p811 }}\) to true.
2. If the given value is non-null, then return ? OrdinaryDefineOwnProperty(this Window \({ }^{\text {p824 }}\) object, "opener", \{ [[Value]]: the given value, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true \}).

\section*{Note}

If a browsing context \({ }^{p 811}\) 's disowned \({ }^{p 811}\) is true, its window. opener \({ }^{p 816}\) attribute is null. That prevents scripts in the browsing context \({ }^{p 811}\) from changing any properties of its opener browsing context \(t^{p 811}\) 's Window \({ }^{p 824}\) object (i.e., the Window \({ }^{p 824}\) object from which the browsing context \({ }^{p 811}\) was created).

Otherwise, if a browsing context \({ }^{p 811}\) 's disowned \({ }^{p 811}\) is false, then scripts in that browsing context \({ }^{p 811}\) can use window. opener \({ }^{p 816}\) to change properties of its opener browsing context \({ }^{p 811}\) 's Window \({ }^{p 824}\) object. For example, a script running in the browsing context \({ }^{p 811}\) can change the value of window. opener. location, causing the opener browsing context \({ }^{\text {p811 }}\) to navigate to a completely different

The parent attribute's getter must run these steps:
1. Let current be this Window \({ }^{p 824}\) object's browsing context \({ }^{p 826}\).
2. If current is null, then return null.
3. If current is a child browsing context \({ }^{p 814}\) of another browsing context \({ }^{\text {p811 }}\) parent, then return parent's WindowProxy \({ }^{p 834}\) object.
4. Assert: current is a top-level browsing context \({ }^{\mathrm{p} 814}\).
5. Return current's WindowProxy \({ }^{\text {p834 }}\) object.

The frameElement attribute's getter must run these steps:
1. Let current be this Window \({ }^{\mathrm{p} 824}\) object's browsing context \({ }^{\mathrm{p} 826}\).
2. If current is null, then return null.
3. Let container be current's container \({ }^{\mathrm{p814}}\).
4. If container is null, then return null.
5. If container's node document's origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the current settings object \({ }^{\text {p924 }}\) 's origin \({ }^{\text {p917 }}\), then return null.
6. Return container.

\section*{Example}

An example of when these IDL attributes can return null is as follows:
```
<!DOCTYPE html>
<iframe></iframe>
<script>
"use strict";
const element = document.querySelector("iframe");
const iframeWindow = element.contentWindow;
element.remove();
console.assert(iframeWindow.top === null);
console.assert(iframeWindow.parent === null);
console.assert(iframeWindow.frameElement === null);
</script>
```

Here the browsing context \({ }^{p 811}\) corresponding to iframeWindow was discarded \({ }^{\text {p831 }}\) when element was removed from the document.

\subsection*{7.1.3 Security \({ }_{7}^{{ }^{\mathrm{pB1}}}\)}

A browsing context \({ }^{p 811} A\) is familiar with a second browsing context \({ }^{p 811} B\) if one of the following conditions is true:
- Either the origin \({ }^{\mathrm{p} 837}\) of the active document \({ }^{\mathrm{p} 811}\) of \(A\) is the same \({ }^{\mathrm{p} 838}\) as the origin \({ }^{\mathrm{p} 837}\) of the active document \({ }^{\mathrm{p} 811}\) of \(B\), or
- The browsing context \(A\) is a child browsing context \({ }^{\mathrm{p} 814}\) and its top-level browsing context \({ }^{\mathrm{p} 814}\) is \(B\), or
- The browsing context \(B\) is an auxiliary browsing context \({ }^{p 814}\) and \(A\) is familiar with \({ }^{\mathrm{p} 817} B^{\prime} \mathrm{s}\) opener browsing context \({ }^{\mathrm{p} 811}\), or
- The browsing context \(B\) is not a top-level browsing context \({ }^{\mathrm{p} 814}\), but there exists an ancestor browsing context \({ }^{\mathrm{p} 814}\) of \(B\) whose active document \({ }^{\mathrm{p} 811}\) has the same \({ }^{\mathrm{p838}}\) origin \({ }^{\mathrm{p837}}\) as the active document \({ }^{\mathrm{p811}}\) of \(A\) (possibly in fact being \(A\) itself).

A browsing context \({ }^{\mathrm{p} 811} A\) is allowed to navigate a second browsing context \({ }^{\mathrm{p811}} B\) if the following algorithm returns true:
1. If \(A\) is not the same browsing context \({ }^{\mathrm{p811}}\) as \(B\), and \(A\) is not one of the ancestor browsing contexts \({ }^{\mathrm{p} 814}\) of \(B\), and \(B\) is not a toplevel browsing context \({ }^{p 814}\), and \(A\) 's active document \({ }^{p 811}\) 's active sandboxing flag set \({ }^{\mathrm{p844}}\) has its sandboxed navigation browsing context flag \({ }^{\mathrm{p} 842}\) set, then return false.
2. Otherwise, if \(B\) is a top-level browsing context \({ }^{\mathrm{p} 814}\), and is one of the ancestor browsing contexts \({ }^{\mathrm{p814}}\) of \(A\), then:
1. If \(A\) 's active window \({ }^{\text {p811 }}\) has transient activation \({ }^{\mathrm{p} 767}\) and \(A\) 's active document \({ }^{\mathrm{p} 811}\) 's active sandboxing flag set \({ }^{\mathrm{p} 844}\) has its sandboxed top-level navigation with user activation browsing context flag \({ }^{\text {p842 }}\) set, then return false.
2. Otherwise, if \(A\) 's active window \({ }^{p 811}\) does not have transient activation \({ }^{\mathrm{p767}}\) and \(A^{\prime}\) 's active document \({ }^{p 811}\) 's active sandboxing flag set \({ }^{\mathrm{p} 844}\) has its sandboxed top-level navigation without user activation browsing context flag \({ }^{\mathrm{p} 842}\) set, then return false.
3. Otherwise, if \(B\) is a top-level browsing context \({ }^{\mathrm{p814}}\), and is neither \(A\) nor one of the ancestor browsing contexts \({ }^{\mathrm{p} 814}\) of \(A\), and \(A^{\prime} \mathrm{s}\) Document \({ }^{\text {p114' }}\) s active sandboxing flag set \({ }^{\mathrm{p} 844}\) has its sandboxed navigation browsing context flag \({ }^{\mathrm{p} 842}\) set, and \(A\) is not the one permitted sandboxed navigator \({ }^{\mathrm{p} 842}\) of \(B\), then return false.
4. Return true.

An element has a browsing context scope origin if its Document \({ }^{\text {p114 }} \mathrm{s}\) browsing context \({ }^{\mathrm{p811}}\) is a top-level browsing context \({ }^{\mathrm{p} 814}\) or if all of its Document \({ }^{\text {p114 }}\) 's ancestor browsing contexts \({ }^{\text {p814 }}\) all have active documents \({ }^{\text {p811 }}\) whose origin \({ }^{\text {p837 }}\) are the same origin \({ }^{\text {p838 }}\) as the element's node document's origin \({ }^{\text {p837. If }}\). If element has a browsing context scope origin \({ }^{\text {p818 }}\), then its value is the origin \({ }^{\text {p837 }}\) of the element's node document.

\subsection*{7.1.4 Groupings of browsing contexts \(\S_{8}^{p 81}\)}

A user agent holds a browsing context group set (a set of browsing context groups \({ }^{\text {p818 }}\) ).
A browsing context group holds a browsing context set (a set of top-level browsing contexts \({ }^{p 814}\) ).

\section*{Note}

A top-level browsing context \({ }^{p 814}\) is added to the group \({ }^{p 818}\) when the group is created \({ }^{p 818}\). All subsequent top-level browsing contexts \({ }^{p 814}\) added to the group \({ }^{p 818}\) will be auxiliary browsing contexts \({ }^{p 814}\).

A browsing context group \({ }^{\text {p818 }}\) has an associated agent cluster map (a weak map of agent cluster keys \({ }^{\text {p914 }}\) to agent clusters). User agents are responsible for collecting agent clusters when it is deemed that nothing can access them anymore.

A browsing context group \({ }^{\text {p818 }}\) has a cross-origin isolated boolean. It is initially false.
A browsing context group \({ }^{p 818}\) has an associated historical agent cluster key map, which is a map of origins \({ }^{p 837}\) to agent cluster keys \(^{\text {p914 }}\). This map is used to ensure the consistency of the origin isolation \({ }^{\text {p841 }}\) feature by recording what agent cluster keys were previously used for a given origin.

\section*{Note}

The historical agent cluster key map \({ }^{\text {p818 }}\) only ever gains entries over the lifetime of the browsing context group.

To create a new browsing context group, run these steps:
1. Let group be a new browsing context group \({ }^{\text {p818 }}\).
2. Append group to the user agent's browsing context group set \({ }^{\text {p818 }}\).
3. Let browsingContext be the result of creating a new browsing context \({ }^{\text {p812 }}\) with null, null, and group.
4. Append \({ }^{\text {p818 }}\) browsingContext to group.
5. Return group.

To append a top-level browsing context \({ }^{\text {p814 }}\) browsingContext to a browsing context group \({ }^{\text {p818 }}\) group, run these steps: 818
1. Append browsingContext to group's browsing context set \({ }^{\text {p818 }}\).
2. Set browsingContext's group \({ }^{\text {p814 }}\) to group.

To remove a top-level browsing context \({ }^{\text {p814 }}\) browsingContext, run these steps:
1. Assert: browsingContext's group \({ }^{\mathrm{p} 814}\) is non-null, because a browsing context \({ }^{\mathrm{p811}}\) only gets discarded \({ }^{\mathrm{p} 831}\) once.
2. Let group be browsingContext's group \({ }^{\text {p814 }}\).
3. Set browsingContext's group \({ }^{p 814}\) to null.
4. Remove browsingContext from group's browsing context set \({ }^{\mathrm{p} 818}\).
5. If group's browsing context set \({ }^{\mathrm{p} 818}\) is empty, then remove group from the user agent's browsing context group set \({ }^{\mathrm{p} 818}\).
```
Note
Append \({ }^{p 818}\) and remove \({ }^{p 819}\) are primitive operations that help define the lifetime of a browsing context group \({ }^{p 818}\). They are called from creating a new browsing context group \({ }^{p 818}\), creating a new auxiliary browsing context \({ }^{p 813}\), and discarding a browsing context \({ }^{p 831}\).
```

\section*{Note}

The HTML Standard used to define "unit of related browsing contexts" and "unit of related similar-origin browsing contexts". These have been removed as they were not adequate.

\subsection*{7.1.5 Browsing context names \(\S^{p 81}\)}

Browsing contexts can have a browsing context name. Unless stated otherwise, it is the empty string.
A valid browsing context name is any string with at least one character that does not start with a U+005F LOW LINE character. (Names starting with an underscore are reserved for special keywords.)

A valid browsing context name or keyword is any string that is either a valid browsing context name \({ }^{\text {p819 }}\) or that is an ASCII caseinsensitive match for one of: _blank, _self, _parent, or _top.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, "current" means the browsing context \({ }^{p 811}\) that the link or script is in, "parent" means the parent browsing context \({ }^{\text {p814 }}\) of the one the link or script is in, "top" means the top-level browsing context \({ }^{\mathrm{p814}}\) of the one the link or script is in, "new" means a new top-level browsing context \({ }^{p 814}\) or auxiliary browsing context \({ }^{p 814}\) is to be created, subject to various user preferences and user agent policies, "none" means that nothing will happen, and "maybe new" means the same as "new" if the "allow-popups \({ }^{\text {p843" }}\) keyword is also specified on the sandbox \({ }^{\text {p365 }}\) attribute (or if the user overrode the sandboxing), and the same as "none" otherwise.
\begin{tabular}{|c|c|c|c|}
\hline \multirow[t]{2}{*}{Keyword} & \multirow[t]{2}{*}{Ordinary effect} & \multicolumn{2}{|r|}{Effect in an iframe \({ }^{\text {p361 }}\) with...} \\
\hline & & sandbox="'" & sandbox="allow-topnavigation" \\
\hline none specified, for links and form submissions & current & current & current \\
\hline empty string & current & current & current \\
\hline blank & new & maybe new & maybe new \\
\hline self & current & current & current \\
\hline parent if there isn't a parent & current & current & current \\
\hline parent if parent is also top & parent/top & none & parent/top \\
\hline parent if there is one and it's not top & parent & none & none \\
\hline top if top is current & current & current & current \\
\hline top if top is not current & top & none & top \\
\hline name that doesn't exist & new & maybe new & maybe new \\
\hline name that exists and is a descendant & specified descendant & specified descendant & specified descendant \\
\hline name that exists and is current & current & current & current \\
\hline name that exists and is an ancestor that is top & specified ancestor & none & specified ancestor/top \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline \multirow[t]{2}{*}{Keyword} & \multirow[t]{2}{*}{Ordinary effect} & \multicolumn{2}{|r|}{Effect in an iframe \({ }^{\text {p361 }}\) with...} \\
\hline & & sandbox="" & sandbox="allow-top- navigation" \\
\hline name that exists and is an ancestor that is not top & specified ancestor & none & none \\
\hline other name that exists with common top & specified & none & none \\
\hline name that exists with different top, if familiar \({ }^{\mathrm{p817}}\) and one permitted sandboxed navigator \({ }^{\text {p842 }}\) & specified & specified & specified \\
\hline name that exists with different top, if familiar \({ }^{\text {p817 }}\) but not one permitted sandboxed navigator \({ }^{\text {p842 }}\) & specified & none & none \\
\hline name that exists with different top, not familiar \({ }^{\text {p817 }}\) & new & maybe new & maybe new \\
\hline
\end{tabular}

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the navigation \({ }^{\text {p866 }}\) algorithm, not the rules for choosing a browsing context \({ }^{\text {p820 }}\) given below.

The rules for choosing a browsing context, given a browsing context name \({ }^{\text {p819 }}\) name, a browsing context \({ }^{\mathrm{p} 811}\) current, and a boolean noopener are as follows:
1. Let chosen be null.
2. Let windowType be "existing or none".
3. Let sandboxingFlagSet be current's active document \({ }^{\mathrm{p} 811}\) 's active sandboxing flag set \({ }^{\mathrm{p} 844}\).
4. If name is the empty string or an ASCII case-insensitive match for "_self", then set chosen to current.
5. Otherwise, if name is an ASCII case-insensitive match for "_parent", set chosen to current's parent browsing context \({ }^{\text {p814 }}\), if any, and current otherwise.
6. Otherwise, if name is an ASCII case-insensitive match for "_top", set chosen to current's top-level browsing context \({ }^{\text {p814 }}\), if any, and current otherwise.
7. Otherwise, if name is not an ASCII case-insensitive match for "_blank", there exists a browsing context whose name \({ }^{\text {p819 }}\) is the same as name, current is familiar with \({ }^{\text {p817 }}\) that browsing context, and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, set chosen to that browsing context. If there are multiple matching browsing contexts, the user agent should set chosen to one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related.

This will be made more precise in issue \#313.
8. Otherwise, a new browsing context is being requested, and what happens depends on the user agent's configuration and abilities - it is determined by the rules given for the first applicable option from the following list:
\(\rightarrow\) If current's active window \({ }^{\text {p811 }}\) does not have transient activation \({ }^{\text {p767 }}\) and the user agent has been configured to not show popups (i.e., the user agent has a "popup blocker" enabled)

The user agent may inform the user that a popup has been blocked.
\(\rightarrow\) If sandboxingFlagSet has the sandboxed auxiliary navigation browsing context flag \({ }^{\text {p842 }}\) set
The user agent may report to a developer console that a popup has been blocked.
\(\leftrightarrow\) If the user agent has been configured such that in this instance it will create a new browsing context
1. Set windowType to "new and unrestricted".
2. If current's top-level browsing context \({ }^{p 814}\) 's active document \({ }^{p 811}\) 's cross-origin opener policy \({ }^{p 115}\) is "sameorigin \({ }^{\mathrm{p845}}\) " or "same-origin-plus-COEP \({ }^{\text {p845" }}\), then:
1. Let currentDocument be current's active document \({ }^{\mathrm{p} 811}\).
2. If currentDocument's origin \({ }^{p 837}\) is not same origin \({ }^{p 838}\) with currentDocument's relevant settings object \({ }^{\text {p924 }}\) 's top-level origin \({ }^{\text {p916 }}\), then set noopener to true, name to "_blank", and windowType to "new with no opener".

\section*{Note}

In the presence of a cross-origin opener policy \({ }^{\text {p844 }}\), nested documents that are cross-origin
3. If noopener is true, then set chosen to the result of creating a new top-level browsing context \({ }^{\text {p813 }}\).
4. Otherwise:
1. Set chosen to the result of creating a new auxiliary browsing context \({ }^{\mathrm{p} 813}\) with current.
2. If sandboxingFlagSet's sandboxed navigation browsing context flag \({ }^{\text {p842 }}\) is set, then current must be set as chosen's one permitted sandboxed navigator \({ }^{\text {p842 }}\).
5. If sandboxingFlagSet's sandbox propagates to auxiliary browsing contexts flag \({ }^{\mathrm{p} 843}\) is set, then all the flags that are set in sandboxingFlagSet must be set in chosen's popup sandboxing flag set \({ }^{\text {p844 }}\).
6. If name is not an ASCII case-insensitive match for "_blank", then set chosen's name \({ }^{\text {p819 }}\) to name.

\section*{Note}

If the newly created browsing context \({ }^{p 811}\) is immediately navigated \({ }^{p 866}\), then the navigation will be done with historyHandling \({ }^{\text {p866 }}\) set to "replace \({ }^{\text {p866" }}\).
\(\leftrightarrow\) If the user agent has been configured such that in this instance it will reuse current
Set chosen to current.
\(\leftrightarrow\) If the user agent has been configured such that in this instance it will not find a browsing context Do nothing.

\section*{Note}

User agents are encouraged to provide a way for users to configure the user agent to always reuse current.
9. Return chosen and windowType.

\subsection*{7.2 Security infrastructure for Window \({ }^{\text {p824 }}\), WindowProxy \({ }^{\text {p834 }}\), and Location \({ }^{\text {p857 }}\) objects \(\S^{\S^{p 82}}\)}

Although typically objects cannot be accessed across origins \({ }^{\text {p837 }}\), the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

\subsection*{7.2.1 Integration with IDL \(\S^{\text {p82 }}\)}

When perform a security check is invoked, with a platformObject, identifier, and type, run these steps:
1. If platformObject is not a Window \({ }^{p 824}\) or Location \({ }^{\text {p857 }}\) object, then return.
2. For each e of ! CrossOriginProperties \({ }^{\text {p822 }}\) (platformObject):
1. If SameValue(e.[[Property]], identifier) is true, then:
1. If type is "method" and e has neither [[NeedsGet]] nor [[NeedsSet]], then return.
2. Otherwise, if type is "getter" and e.[[NeedsGet]] is true, then return.
3. Otherwise, if type is "setter" and e.[[NeedsSet]] is true, then return.
3. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (platformObject) is false, then throw a "SecurityError" DOMException.

\subsection*{7.2.2 Shared internal slot: [[CrossOriginPropertyDescriptorMap]]}

Window \({ }^{p 824}\) and Location \({ }^{\mathrm{p} 857}\) objects both have a [[CrossOriginPropertyDescriptorMap]] internal slot, whose value is initially an

\section*{Note}

The [[CrossOriginPropertyDescriptorMapl] \({ }^{p 821}\) internal slot contains a map with entries whose keys are (currentGlobal, objectGlobal, propertyKey)-tuples and values are property descriptors, as a memoization of what is visible to scripts when currentGlobal inspects a Window \({ }^{\text {p824 }}\) or Location \({ }^{\text {p857 }}\) object from objectGlobal. It is filled lazily by CrossOriginGetOwnPropertyHelper \({ }^{\text {p823 }}\), which consults it on future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

\section*{Example}

For example, with const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href").set the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map when document. domain \({ }^{\text {p84e }}\) is set. This is not observable as document. domain \({ }^{\text {p840 }}\) cannot revisit an earlier value.

\section*{Example}

For example, setting document. domain \({ }^{p 840}\) to "example.com" on www.example.com means user agents can remove all key-value pairs from the map where part of the key is www.example.com, as that can never be part of the origin \({ }^{\text {p837 }}\) again and therefore the corresponding value could never be retrieved from the map.

\subsection*{7.2.3 Shared abstract operations \(\S^{p 82}\)}

\subsection*{7.2.3.1 CrossOriginProperties (O) \(\S_{2}^{\mathrm{p82}}\)}
1. Assert: \(O\) is a Location \({ }^{p 857}\) or Window \({ }^{p 824}\) object.
2. If \(O\) is a Location \({ }^{\text {p857 }}\) object, then return « \{ [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true \}, \{ [[Property]]: "replace" \} ».
3. Return « \{ [[Property]]: "window", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "self", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "location", [[NeedsGet]]: true, [[NeedsSet]]: true \}, \{ [[Property]]: "close" \}, \{ [[Property]]: "closed", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "focus" \}, \{ [[Property]]: "blur" \}, \{ [[Property]]: "frames", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "length", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "top", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "opener", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "parent", [[NeedsGet]]: true, [[NeedsSet]]: false \}, \{ [[Property]]: "postMessage" \} ».

Note
Indexed properties do not need to be safelisted as they are handled directly by the WindowProxy \({ }^{\text {p834 }}\) object.

\subsection*{7.2.3.2 CrossOriginPropertyFallback ( \(\boldsymbol{P}\) ) \(\S^{p 82}\)}
1. If \(P\) is "then", @@toStringTag \({ }^{\mathrm{p54}}\), @@hasInstance \({ }^{\mathrm{p54}}\), or @@isConcatSpreadable \({ }^{\mathrm{p54}}\), then return PropertyDescriptor \(\{[[V a l u e]]:\) undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true \}.
2. Throw a "SecurityError" DOMException.

\subsection*{7.2.3.3 IsPlatformObjectSameOrigin (O) \(\S^{p 82}\)}
1. Return true if the current settings object \({ }^{\text {p924' }} \mathrm{s}\) origin \({ }^{\text {p917 }}\) is same origin-domain \({ }^{\text {p838 }}\) with \(O\) 's relevant settings object \({ }^{\text {p924's } s}\) origin \({ }^{\text {p917 }}\), and false otherwise.

Here the current settings object \({ }^{p 924}\) roughly corresponds to the "caller", because this check occurs before the execution context for the getter/setter/method in question makes its way onto the JavaScript execution context stack. For example, in the code w. document, this step is invoked before the document \({ }^{p 826}\) getter is reached as part of the [[Get]] \({ }^{p 836}\) algorithm for the WindowProxy \({ }^{\text {p834 }}\) w.

\subsection*{7.2.3.4 CrossOriginGetOwnPropertyHelper ( \(O, P\) ) \(\S_{3}^{p 82}\)}

\section*{Note}

If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a "SecurityError" DOMException. In practice this is handled by the caller calling CrossOriginPropertyFallback \({ }^{\text {p822 }}\).
1. Let crossOriginKey be a tuple consisting of the current settings object \({ }^{\mathrm{p924}}, O\) 's relevant settings object \({ }^{\mathrm{p924}}\), and \(P\).
2. For each e of! CrossOriginProperties \({ }^{\mathrm{p} 822}(O)\) :
1. If SameValue(e.[[Property]], \(P\) ) is true, then:
1. If the value of the [[CrossOriginPropertyDescriptorMap] \(]^{p 821}\) internal slot of \(O\) contains an entry whose key is crossOriginKey, then return that entry's value.
2. Let originalDesc be OrdinaryGetOwnProperty \((O, P)\).
3. Let crossOriginDesc be undefined.
4. If e.[[NeedsGet]] and e.[[NeedsSet]] are absent, then:
1. Let value be originalDesc.[[Value]].
2. If! IsCallable(value) is true, then set value to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the IDL operation \(P\) on object \(O\).
3. Set crossOriginDesc to PropertyDescriptor \{ [[Value]]: value, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true \}.
5. Otherwise:
1. Let crossOriginGet be undefined.
2. If e.[[NeedsGet]] is true, then set crossOriginGet to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the getter of the IDL attribute \(P\) on object \(O\).
3. Let crossOriginSet be undefined.
4. If e.[[NeedsSet]] is true, then set crossOriginSet to an anonymous built-in function, created in the current Realm Record, that performs the same steps as the setter of the IDL attribute \(P\) on object \(O\).
5. Set crossOriginDesc to PropertyDescriptor\{ [[Get]]: crossOriginGet, [[Set]]: crossOriginSet, [[Enumerable]]: false, [[Configurable]]: true \}.
6. Create an entry in the value of the [[CrossOriginPropertyDescriptorMap]] \({ }^{p 821}\) internal slot of \(O\) with key crossOriginKey and value crossOriginDesc.
7. Return crossOriginDesc.
3. Return undefined.

\section*{Note}

The reason that the property descriptors produced here are configurable is to preserve the invariants of the essential internal methods required by the JavaScript specification. In particular, since the value of the property can change as a consequence of navigation, it is required that the property be configurable. (However, see tc39/ecma262 issue \#672 and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing web content.)

\section*{Note}

The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See issue \#3183 for details.

\subsection*{7.2.3.5 CrossOriginGet ( \(O, P\), Receiver ) \(\S^{\text {p82 }}\)}
1. Let desc be ? O.[[GetOwnProperty]](P).
2. Assert: desc is not undefined.
3. If! IsDataDescriptor(desc) is true, then return desc.[[Value]].
4. Assert: IsAccessorDescriptor(desc) is true.
5. Let getter be desc.[[Get]].
6. If getter is undefined, then throw a "SecurityError" DOMException.
7. Return ? Call(getter, Receiver).

1. Let desc be ? O.[[GetOwnProperty]](P).
2. Assert: desc is not undefined.
3. If desc.[[Set]] is present and its value is not undefined, then:
1. Perform ? Call(setter, Receiver, «V»).
2. Return true.
4. Throw a "SecurityError" DOMException.

\subsection*{7.2.3.7 CrossOriginOwnPropertyKeys (O) § \({ }^{\text {p82 }}\)}
1. Let keys be a new empty List.
2. For each e of ! CrossOriginProperties \({ }^{p 822}(O)\), append e.[[Property]] to keys.
3. Return the concatenation of keys and «"then", @@toStringTag \({ }^{\mathrm{p54}}\), @@hasInstance \({ }^{\mathrm{p} 54}\), @@isConcatSpreadable \({ }^{\mathrm{p} 54}\) ».

\subsection*{7.3 The Window \({ }^{p 824}\) object \(\S^{\text {p82 }}\)}
```
[Global=Window,
Exposed=Window,
LegacyUnenumerableNamedProperties]
interface Window : EventTarget {
    // the current browsing context
        [LegacyUnforgeable] readonly attribute WindowProxy window;
        [Replaceable] readonly attribute WindowProxy self;
        [LegacyUnforgeable] readonly attribute Document document;
```
```
    attribute DOMString name;
    [PutForwards=href, LegacyUnforgeable] readonly attribute Location location;
    readonly attribute History history;
    readonly attribute CustomElementRegistry customElements;
    [Replaceable] readonly attribute BarProp locationbar;
    [Replaceable] readonly attribute BarProp menubar;

    boolean confirm(optional DOMString message = "");
    DOMString? prompt(optional DOMString message = "", optional DOMString default = "");
    undefined print();
    undefined postMessage(any message, USVString targetOrigin, optional sequence<object> transfer = []);
    undefined postMessage(any message, optional WindowPostMessageOptions options = {});
    // also has obsolete members
};
Window includes GlobalEventHandlers;
Window includes WindowEventHandlers;
dictionary WindowPostMessageOptions : PostMessageOptions {
    USVString targetOrigin = "/";
};
```

\section*{For web developers (non-normative)}
window . window \({ }^{\text {p826 }}\)
window. frames \({ }^{\text {p826 }}\)
window. selff \({ }^{\text {p826 }}\)
These attributes all return window.

\section*{window. document \({ }^{\text {p826 }}\)}

Returns the Document \({ }^{\text {p114 }}\) associated with window.
document. defaultView \({ }^{\text {p826 }}\)
Returns the Window \({ }^{\text {p824 }}\) object of the active document \({ }^{\text {p811 }}\).

The Window \({ }^{\text {p824 }}\) object has an associated Document, which is a Document \({ }^{\text {p114 }}\) object. It is set when the Window \({ }^{p 824}\) object is created, and only ever changed during navigation \({ }^{\text {p866 }}\) from the initial about:blank \({ }^{\text {p51 }}\) Document \(^{\text {p114 }}\).

The Window \({ }^{p 824}\) object's browsing context is the Window \({ }^{\mathrm{p} 824}\) object's associated Document \({ }^{\mathrm{p} 826}\) 's browsing context \({ }^{\mathrm{p} 811}\). It is either null or a browsing context \({ }^{p 811}\).

The window, frames, and self attributes' getters must return this Window \({ }^{\text {p824 }}\) object's relevant Realm \({ }^{\text {p924 }}\).[[GlobalEnv]]'s EnvironmentRecord's [[GlobalThisValue]].

The document IDL attribute, on getting, must return this Window \({ }^{\text {p824 }}\) object's associated Document \({ }^{\text {p826 }}\).

\section*{Note}

The Document \({ }^{p 114}\) object associated with a Window \({ }^{\text {p824 }}\) object can change in exactly one case: when the navigate \({ }^{p 866}\) algorithm creates a new Document object \({ }^{p 873}\) for the first page loaded in a browsing context \({ }^{p 811}\). In that specific case, the Window \({ }^{p 824}\) object of the original about:blank \({ }^{p 51}\) page is reused and gets a new Document \({ }^{\text {p114 }}\) object.

The defaultView attribute's getter, when invoked, must run these steps:
1. If this Document \({ }^{\text {p114 }}\) object's browsing context \({ }^{\text {p811 }}\) is null, then return null.
2. Return this Document \({ }^{p 114}\) object's browsing context \({ }^{\text {p811 }}\) ' \(s\) WindowProxy \({ }^{\text {p834 }}\) object.

For historical reasons, Window \({ }^{\text {p824 }}\) objects must also have a writable, configurable, non-enumerable property named HTMLDocument whose value is the Document \({ }^{\text {p114 }}\) interface object.

\subsection*{7.3.1 APIs for creating and navigating browsing contexts by name \(\S^{188}\)}

\section*{For web developers (non-normative)}
window = window. open \(^{\text {p827 }}\) ([ url [, target [, features ] ] ] )
Opens a window to show url (defaults to about: blank \({ }^{\text {p51 }}\) ), and returns it. The target argument gives the name of the new window. If a window exists with that name already, it is reused. The features argument can be used to influence the rendering of the new window.
window . name \({ }^{\text {p829 }}\) [ = value ]
Returns the name of the window.
Can be set, to change the name.

\section*{window. close \({ }^{\text {p829 }}\) ()}

Closes the window.
window. closed \(^{\text {p829 }}\)
Returns true if the window has been closed, false otherwise.
window. stop \({ }^{\text {p829 }}\) ()
Cancels the document load.

The window open steps, given a string url, a string target, and a string features, are as follows:
1. If the event loop \({ }^{\text {p944' }}\) 's termination nesting level \({ }^{p 885}\) is nonzero, return null.
2. Let source browsing context be the entry global object \({ }^{\text {p921 }}\) 's browsing context \({ }^{\text {p826 }}\).
3. If target is the empty string, then set target to "_blank".
4. Let tokenizedFeatures be the result of tokenizing \({ }^{\text {p828 }}\) features.
5. Let noopener and noreferrer be false.
6. If tokenizedFeatures["noopener"] exists, then:
1. Set noopener to the result of parsing tokenizedFeatures["noopener"] as a boolean feature \({ }^{\text {p829 }}\).
2. Remove tokenizedFeatures["noopener"].
7. If tokenizedFeatures["noreferrer"] exists, then:
1. Set noreferrer to the result of parsing tokenizedFeatures["noreferrer"] as a boolean feature \({ }^{\text {p829 }}\).
2. Remove tokenizedFeatures["noreferrer"].
8. If noreferrer is true, then set noopener to true.
9. Let target browsing context and windowType be the result of applying the rules for choosing a browsing context \({ }^{p 820}\) given target, source browsing context, and noopener.

\section*{Example}

If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose onclick \({ }^{\text {p961 }}\) handler uses the window. open( ) \({ }^{\text {p827 }}\) API to open a page in an iframe \({ }^{\text {p361 }}\) element, the user agent could override the selection of the target browsing context to instead target a new tab.
10. Let new be true if windowType is either "new and unrestricted" or "new with no opener", and false otherwise.
11. If target browsing context is null, then return null.
12. If new is true, then set up browsing context features for target browsing context given tokenizedFeatures. [CSSOMVIEW] \({ }^{\text {p1286 }}\)
13. Let urIRecord be the URL "about: blank \({ }^{\text {p51 " }}\).
14. If \(u r l\) is not the empty string or new is true, then:
1. If \(u r l\) is not the empty string, then parse \({ }^{\mathrm{p} 89}\) url relative to the entry settings object \({ }^{\mathrm{p} 921}\), and set urlRecord to the resulting URL record \({ }^{\text {p89 }}\), if any. If the parse a URL \({ }^{\text {p89 }}\) algorithm failed, then throw a "SyntaxError" DOMException.
2. Let request be a new request whose URL is urlRecord.
3. If noreferrer is true, then set request's referrer to "noreferrer".
4. Let window be target browsing context's active window \({ }^{\mathrm{p} 811}\).
5. If urIRecord is "about: blank \({ }^{\text {p51" }}\) " and new is true, then queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) given window to fire an event named load \({ }^{\text {p1282 }}\) at window, with the legacy target override flag set.
6. Otherwise:
1. Let historyHandling be "replace \({ }^{\text {p866" }}\) if new is true; otherwise "default \({ }^{\text {p866" }}\).
2. Navigate \({ }^{\text {p866 }}\) target browsing context to request, with exceptionsEnabled \({ }^{\text {p866 }}\) set to true, historyHandling \({ }^{\text {p866 }}\) set to historyHandling, and the source browsing context \({ }^{\text {p866 }}\) set to source browsing context.
15. If noopener is true or windowType is "new with no opener", then return null.
16. Otherwise, if new is false, set target browsing context's opener browsing context \({ }^{8811}\) to source browsing context.
```
Note
    If new is true this is done as part of creating a new auxiliary browsing context p813.
```
17. Return target browsing context's WindowProxy \({ }^{\text {p834 }}\) object.

The open (url, target, features) method on Window \({ }^{p 824}\) objects provides a mechanism for navigating \({ }^{\text {p866 }}\) an existing browsing context \({ }^{\mathrm{p811}}\) or opening and navigating an auxiliary browsing context \({ }^{\mathrm{p} 814}\).

When the method is invoked, the user agent must run the window open steps \({ }^{\text {p826 }}\) with url, target, and features.

\section*{To tokenize the features argument:}
1. Let tokenizedFeatures be a new ordered map.
2. Let position point at the first code point of features.
3. While position is not past the end of features:
1. Let name be the empty string.
2. Let value be the empty string.
3. Collect a sequence of code points that are feature separators \({ }^{\text {p828 }}\) from features given position. This skips past leading separators before the name.
4. Collect a sequence of code points that are not feature separators \({ }^{\text {p828 }}\) from features given position. Set name to the collected characters, converted to ASCII lowercase.
5. Set name to the result of normalizing the feature name \({ }^{\mathrm{p} 828}\) name.
6. While position is not past the end of features and the code point at position in features is not U+003D (=):
1. If the code point at position in features is \(U+002 C(\),\() , or if it is not a feature separator { }^{\text {p828 }}\), then break.
2. Advance position by 1 .

\section*{Note}

This skips to the first \(U+003 D(=)\) but does not skip past a U+002C (,) or a non-separator.
7. If the code point at position in features is a feature separator \({ }^{\mathrm{p} 828}\) :
1. While position is not past the end of features and the code point at position in features is a feature separator \({ }^{\text {p828 }}\) :
1. If the code point at position in features is \(\mathrm{U}+002 \mathrm{C}(\),\() , then break.\)
2. Advance position by 1 .

\section*{Note}

This skips to the first non-separator but does not skip past a U+002C (,).
2. Collect a sequence of code points that are not feature separators \({ }^{\text {p828 }}\) code points from features given position. Set value to the collected code points, converted to ASCII lowercase.
8. If name is not the empty string, then set tokenizedFeatures[name] to value.
4. Return tokenizedFeatures.

A code point is a feature separator if it is ASCII whitespace, \(\mathrm{U}+003 \mathrm{D}(=)\), or \(\mathrm{U}+002 \mathrm{C}(\),\() .\)
For legacy reasons, there are some aliases of some feature names. To normalize a feature name name, switch on name:
```
@ "screenx"
    Return "left".
@ "screeny"
    Return "top".
\hookrightarrow "innerwidth"
    Return "width".
@ "innerheight"
    Return "height".
```
\(\rightarrow\) Anything else
    Return name.

To parse a boolean feature given a string value:
1. If value is the empty string, then return true.
2. If value is "yes", then return true.
3. Let parsed be the result of parsing value as an integer \({ }^{\text {p68 }}\).
4. If parsed is an error, then set it to 0 .
5. Return false if parsed is 0 , and true otherwise.

The name attribute's getter must run these steps:
1. If this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\text {p826 }}\) is null, then return the empty string.
2. Return this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\text {p826 }}\) 's name \({ }^{\text {p819 }}\).

The name \({ }^{\text {p829 }}\) attribute's setter must run these steps:
1. If this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\text {p826 }}\) is null, then return.
2. Set this Window \({ }^{p 824}\) object's browsing context \({ }^{p 826}\) 's name \({ }^{p 819}\) to the given value.

\section*{Note}

The name gets reset \({ }^{p 882}\) when the browsing context is navigated \({ }^{p 866}\) to another origin \({ }^{p 837}\).

The close() method must run these steps:
1. Let current be this Window \({ }^{p 824}\) object's browsing context \({ }^{\mathrm{p} 826}\).
2. If current is null or its is closing \({ }^{\text {p811 }}\) is true, then return.
3. If all the following are true
- current is script-closable \({ }^{\text {p829 }}\)
- the incumbent global object \({ }^{\text {p922 }}\) 's browsing context \({ }^{\mathrm{p} 826}\) is familiar with \({ }^{\text {p817 }}\) current
- the incumbent global object \({ }^{\text {p922 }}\) 's browsing context \({ }^{\text {p826 }}\) is allowed to navigate \({ }^{\text {p818 }}\) current
then:
1. Set current's is closing \({ }^{\text {p811 }}\) to true.
2. Queue a task \({ }^{\mathrm{p945}}\) on the DOM manipulation task source \({ }^{\mathrm{p952}}\) to close \({ }^{\mathrm{p} 831}\) current.

A browsing context \({ }^{\mathrm{p} 811}\) is script-closable if it is an auxiliary browsing context \({ }^{\text {p814 }}\) that was created by a script (as opposed to by an action of the user), or if it is a top-level browsing context \({ }^{\text {p814 }}\) whose session history \({ }^{\text {p849 }}\) contains only one Document \({ }^{p 114}\).

The closed attribute's getter must return true if this Window \({ }^{\text {p824 }}\) object's browsing context \({ }^{\mathrm{p} 826}\) is null or its is closing \({ }^{\text {p811 }}\) is true, and false otherwise.

The stop() method must stop document loading \({ }^{\text {p888 }}\) given this Window \({ }^{\text {p824 }}\) object's associated Document \({ }^{\text {p826 }}\).

\subsection*{7.3.2 Accessing other browsing contexts \(\S^{p 82}\)}

\section*{For web developers (non-normative)}

\section*{window. length \({ }^{\text {p830 }}\)}

Returns the number of document-tree child browsing contexts \({ }^{\text {p814 }}\).

\section*{window[index]}

Returns the indicated document-tree child browsing context \({ }^{\text {p814 }}\).

The number of document-tree child browsing contexts of a Window \({ }^{\mathrm{p} 824}\) object \(W\) is the result of running these steps:
1. If \(W^{\prime}\) 's browsing context \({ }^{\text {p826 }}\) is null, then return 0 .
2. Return the number of document-tree child browsing contexts \({ }^{\mathrm{p} 814}\) of \(W^{\prime}\) 's browsing context \({ }^{\mathrm{p} 826}\).

The length IDL attribute's getter must return the number of document-tree child browsing contexts \({ }^{\mathrm{p} 830}\) of this \(\underline{\text { Wind }^{\mathrm{p}}{ }^{\mathrm{p} 824} \text { object. }}\)

\section*{Note}

Indexed access to document-tree child browsing contexts \({ }^{p 814}\) is defined through the [[GetOwnProperty]] \({ }^{p 835}\) internal method of the WindowProxy \({ }^{\text {p834 }}\) object.

\subsection*{7.3.3 Named access on the Window \({ }^{\text {p824 }}\) object \(\S^{p 83}\)}

\section*{For web developers (non-normative)}

\section*{window[name]}

Returns the indicated element or collection of elements.
As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the web platform, for example. Instead of this, use document.getElementById () or document. querySelector().

The document-tree child browsing context name property set of a Window \({ }^{p 824}\) object window is the return value of running these steps:
1. If window's browsing context \({ }^{p 826}\) is null, then return the empty list.
2. Let childBrowsingContexts be all document-tree child browsing contexts \({ }^{\text {p814 }}\) of window's browsing context \({ }^{\text {p826 }}\) whose browsing context name \({ }^{\mathrm{p} 819}\) is not the empty string, in order, and including only the first document-tree child browsing context \({ }^{\text {p814 }}\) with a given name \({ }^{\text {p819 }}\) if multiple document-tree child browsing contexts \({ }^{\mathrm{p} 814}\) have the same one.
3. Remove each browsing context \({ }^{\mathrm{p} 811}\) from childBrowsingContexts whose active document \({ }^{\mathrm{p8111}}\) 's origin \({ }^{\mathrm{p} 837}\) is not same origin \({ }^{\mathrm{p} 838}\) with window's relevant settings object \({ }^{\text {p924' }} \mathrm{s}\) origin \({ }^{\text {p917 }}\) and whose browsing context name \({ }^{\text {p819 }}\) does not match the name of its container \({ }^{\text {p814 }}\) 's name content attribute value.
4. Return the browsing context names \({ }^{\text {p819 }}\) of childBrowsingContexts, in the same order.

\section*{Example}

This means that in the following example, hosted on https://example.org/, assuming https://elsewhere.example/ sets window. name \({ }^{p 829}\) to "spices", evaluating window. spices after everything has loaded will yield undefined:
<iframe src=https://elsewhere.example.com/></iframe>
<iframe name=spices></iframe>

The Window \({ }^{\mathrm{p} 824}\) object supports named properties. The supported property names of a Window \({ }^{\mathrm{p} 824}\) object window at any moment consist of the following, in tree order according to the element that contributed them, ignoring later duplicates:
- window's document-tree child browsing context name property set \({ }^{\mathrm{p} 830}\);
 name content attribute and are in a document tree with window's associated Document \({ }^{\text {p826 }}\) as their root; and
- the value of the \(\underline{i d^{p 137}}\) content attribute for all HTML elements \({ }^{p 44}\) that have a non-empty \(\underline{i d^{p 137}}\) content attribute and are in a document tree with window's associated Document \({ }^{\text {p826 }}\) as their root.

To determine the value of a named property name in a Window \({ }^{\text {p824 }}\) object window, the user agent must return the value obtained using the following steps:
1. Let objects be the list of named objects \({ }^{\text {p831 }}\) of window with the name name.

There will be at least one such object, by definition.
2. If objects contains a browsing context \({ }^{\text {p811 }}\), then return the WindowProxy \({ }^{\text {p834 }}\) object of the nested browsing context \({ }^{\text {p814 }}\) of the first browsing context container \({ }^{\text {p814 }}\) in tree order whose nested browsing context \({ }^{\text {p814 }}\) is in objects.
3. Otherwise, if objects has only one element, return that element.
4. Otherwise return an HTMLCollection rooted at window's associated Document \({ }^{\text {p826 }}\), whose filter matches only named objects \({ }^{\text {p831 }}\) of window with the name name. (By definition, these will all be elements.)

Named objects of Window \({ }^{\text {p824 }}\) object window with the name name, for the purposes of the above algorithm, consist of the following:
- document-tree child browsing contexts \({ }^{\mathrm{p} 814}\) of window's associated Document \({ }^{\mathrm{p} 826}\) whose name \({ }^{\mathrm{p} 819}\) is name;
- embed \({ }^{\mathrm{p} 369}\), form \({ }^{\mathrm{p} 486}\), \(\mathrm{img}^{\mathrm{p} 329}\), or object \({ }^{\mathrm{p} 373}\) elements that have a name content attribute whose value is name and are in a document tree with window's associated Document \({ }^{\text {p826 }}\) as their root; and
- HTML elements \({ }^{\text {p44 }}\) that have an \(\underline{i d^{p 137}}\) content attribute whose value is name and are in a document tree with window's associated Document \({ }^{\text {p826 }}\) as their root.

\subsection*{7.3.4 Discarding browsing contexts \(\S_{1}^{p 83}\)}

To discard a Document \({ }^{\text {p114 }}\) document:
1. Set document's salvageable \({ }^{p 885}\) state to false.
2. Run any unloading document cleanup steps \({ }^{\text {p887 }}\) for document that are defined by this specification and other applicable specifications \({ }^{p 65}\).
3. \(\mathrm{Abort}{ }^{\mathrm{p887}}\) document.
4. Remove any tasks \({ }^{\text {p944 }}\) associated with document in any task source \({ }^{\text {p945 }}\), without running those tasks.
5. Discard \({ }^{\mathrm{p} 831}\) all the child browsing contexts \({ }^{\mathrm{p} 814}\) of document.
6. For each session history entry \({ }^{\text {p849 }}\) entry with a Document \({ }^{\text {p114 }}\) object equal to document, remove entry's Document \({ }^{\text {p114 }}\) object.
7. Set document's browsing context \({ }^{\text {p811 }}\) to null.
8. Remove document from the owner set \({ }^{\mathrm{p} 1045}\) of each WorkerGlobalScope \({ }^{\text {p1944 }}\) object whose set contains document.

To discard a browsing context \({ }^{\text {p811 }}\) browsingContext, run these steps:
1. Discard \({ }^{\mathrm{p} 831}\) all Document \({ }^{\text {p114 }}\) objects for all the entries in browsingContext's session history \({ }^{\mathrm{p849}}\).
2. If browsingContext is a top-level browsing context \({ }^{\text {p814 }}\), then remove \({ }^{\text {p819 }}\) browsingContext.

User agents may discard \({ }^{\text {p831 }}\) top-level browsing contexts \({ }^{\text {p814 }}\) at any time (typically, in response to user requests, e.g., when a user force-closes a window containing one or more top-level browsing contexts \({ }^{\text {p814 }}\) ). Other browsing contexts \({ }^{\text {p811 }}\) must be discarded once their WindowProxy \({ }^{\text {834 }}\) object is eligible for garbage collection, in addition to the other places where this specification requires them to be discarded.

\subsection*{7.3.5 Closing browsing contexts \(\S^{p 83}\)}

To close a browsing context browsingContext, run these steps:
1. Prompt to unload \({ }^{\mathrm{p} 885}\) browsingContext's active document \({ }^{\mathrm{p} 811}\). If the user refused to allow the document to be unloaded \({ }^{\mathrm{p} 886}\), then return.
2. Unload \({ }^{p 886}\) browsingContext's active document \({ }^{p 811}\).
3. Remove browsingContext from the user interface (e.g., close or hide its tab in a tabbed browser).
4. Discard \({ }^{\mathrm{p} 831}\) browsingContext.

User agents should offer users the ability to arbitrarily close \({ }^{\mathrm{p} 831}\) any top-level browsing context \({ }^{\mathrm{p} 814}\).

\subsection*{7.3.6 Browser interface elements \(\S_{2}^{p 83}\)}

To allow web pages to integrate with web browsers, certain web browser interface elements are exposed in a limited way to scripts in web pages.

Each interface element is represented by a BarProp \({ }^{\text {p832 }}\) object:
```
IDL [Exposed=Window]
interface BarProp {
    readonly attribute boolean visible;
};
```

For web developers (non-normative)
window. locationbar \({ }^{\text {p833 }} \cdot\) visible \(^{\text {p832 }}\)
Returns true if the location bar is visible; otherwise, returns false.
window. menubar \({ }^{\text {p833 }} \cdot\) visible \(^{\text {p832 }}\)
Returns true if the menu bar is visible; otherwise, returns false.
window. personalbar \({ }^{\text {p833 }} \cdot\) visible \(^{\text {p832 }}\)
Returns true if the personal bar is visible; otherwise, returns false.
window. scrollbars \({ }^{\text {p833 }} \cdot\) visible \(^{\text {p832 }}\)
Returns true if the scrollbars are visible; otherwise, returns false.
window. statusbar \({ }^{p 833} \cdot\) visible \(^{p 832}\)
Returns true if the status bar is visible; otherwise, returns false.
window. toolbar \({ }^{\text {p833 }} \cdot\) visible \(^{\text {p832 }}\)
Returns true if the toolbar is visible; otherwise, returns false.

The visible attribute's getter must run these steps:
1. If this BarProp \({ }^{p 832}\) object's relevant global object \({ }^{\text {p924 }}\) 's browsing context \({ }^{p 826}\) is null, then return false.
2. If the user agent does not have a user interface element that the object represents, as described below, then return true.
3. Return true or a value determined by the user agent to most accurately represent the visibility state of the user interface element that the object represents, as described below.

The following BarProp \({ }^{\text {p832 }}\) objects must exist for each Window \({ }^{\text {p824 }}\) object:

\section*{The location bar BarProp object}

Represents the user interface element that contains a control that displays the URL of the active document \({ }^{\text {p811 }}\), or some similar interface concept.

\section*{The menu bar BarProp object}

Represents the user interface element that contains a list of commands in menu form, or some similar interface concept.

\section*{The personal bar BarProp object}

Represents the user interface element that contains links to the user's favorite pages, or some similar interface concept.

\section*{The scrollbar BarProp object}

Represents the user interface element that contains a scrolling mechanism, or some similar interface concept.

\section*{The status bar BarProp object}

Represents a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is current indicating. If the user agent has no such user interface element, then the object may act as if the corresponding user
interface element was absent (i.e. its visible \({ }^{p 832}\) attribute may return false).

\section*{The toolbar BarProp object}

Represents the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides session history \({ }^{\mathrm{p849}}\) traversal controls (back and forward buttons, reload buttons, etc). If the user agent has no such user interface element, then the object may act as if the corresponding user interface element was absent (i.e. its visible \({ }^{\text {p832 }}\) attribute may return false).

The locationbar attribute must return the location bar BarProp object \({ }^{\text {p832 }}\).
The menubar attribute must return the menu bar BarProp object \({ }^{p 832}\).
The personalbar attribute must return the personal bar BarProp object \({ }^{\text {p832 }}\).
The scrollbars attribute must return the scrollbar BarProp object \({ }^{p 832}\).
The statusbar attribute must return the status bar BarProp object \({ }^{\mathrm{p} 832}\).
The toolbar attribute must return the toolbar BarProp object \({ }^{\text {p833 }}\).

For historical reasons, the status attribute on the Window \({ }^{p 824}\) object must, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the Window \({ }^{\text {p824 }}\) object is created, the attribute must be set to the empty string. It does not do anything else.

\subsection*{7.3.7 Script settings for Window \({ }^{\text {p824 }}\) objects \(\S_{3}^{\text {p83 }}\)}

To set up a window environment settings object, given a JavaScript execution context execution context, null or an environment \({ }^{\text {p916 }}\) reservedEnvironment, a URL topLeveICreationURL, and an origin \({ }^{\text {p837 }}\) topLevelOrigin, run these steps:
1. Let realm be the value of execution context's Realm component.
2. Let window be realm's global object \({ }^{\mathrm{p918}}\).
3. Let url be a copy of the URL of window's associated Document \({ }^{\mathrm{p} 826}\).
4. Let settings object be a new environment settings object \({ }^{\text {p917 }}\) whose algorithms are defined as follows:

\section*{The realm execution context \({ }^{\text {p917 }}\)}

Return execution context.

\section*{The module map \({ }^{\text {p917 }}\)}

Return the module map \({ }^{\text {p115 }}\) of window's associated Document \({ }^{\text {p826 }}\).

\section*{The responsible document \({ }^{\text {p917 }}\)}

Return window's associated Document \({ }^{\text {p826 }}\).
The API URL character encoding \({ }^{\text {p917 }}\)
Return the current character encoding of window's associated Document \({ }^{\mathrm{p} 826}\).

\section*{The API base URL \({ }^{\text {p917 }}\)}

Return the current base URL \({ }^{\text {p88 }}\) of window's associated Document \({ }^{\mathrm{p} 826}\).

\section*{The origin \({ }^{\text {p917 }}\)}

Return the origin \({ }^{\text {p837 }}\) of window's associated Document \({ }^{\text {p826 }}\).

\section*{The referrer policy \({ }^{\text {p917 }}\)}
1. Let document be window's associated Document \({ }^{\text {p826 }}\).
2. While document is an iframe srcdoc document \({ }^{\mathrm{p} 362}\) and document's referrer policy \({ }^{\mathrm{p} 115}\) is the empty string, set document to document's browsing context \({ }^{\mathrm{p} 811}\) 's container document \({ }^{\mathrm{p814}}\).
3. Return document's referrer policy \({ }^{\text {p115 }}\).

\section*{The embedder policy \({ }^{\text {p917 }}\)}

Return window's associated Document \({ }^{p 826}\) 's embedder policy \({ }^{\text {p115 }}\).
The cross-origin isolated capability \({ }^{\text {p917 }}\)
Return the logical conjunction of realm's agent cluster's cross-origin isolated \({ }^{\text {p914 }}\) and whether window's associated Document \({ }^{p 826}\) is allowed to use \({ }^{p 367}\) the "cross-origin-isolated \({ }^{p 67 "}\) feature.
5. If reservedEnvironment is non-null, then:
1. Set settings object's \(\underline{i d}^{\mathrm{p916}}\) to reservedEnvironment's \(\underline{i d}^{\mathrm{p916}}\), settings object's target browsing context \({ }^{\mathrm{p917}}\) to reservedEnvironment's target browsing context \({ }^{\text {p917 }}\), and settings object's active service worker \({ }^{\text {p917 }}\) to reservedEnvironment's active service worker \({ }^{\text {p917 }}\).
2. Set reservedEnvironment's \(\underline{i d}^{\mathrm{p916}}\) to the empty string.

\section*{Note}

The identity of the reserved environment is considered to be fully transferred to the created environment settings object \({ }^{p 917}\). The reserved environment is not searchable by the environment \({ }^{p 916}\) 's \(\underline{i d}^{p 916}\) from this point on.
6. Otherwise, set settings object's \(\underline{i d}^{p 916}\) to a new unique opaque string, settings object's target browsing context \({ }^{\text {p917 }}\) to null, and settings object's active service worker \({ }^{p 917}\) to null.
7. Set settings object's creation URL \({ }^{\text {p916 }}\) to url, settings object's top-level creation URL \({ }^{\text {p916 }}\) to topLevelCreationURL, and settings object's top-level origin \({ }^{\text {p916 }}\) to topLevelOrigin.
8. Set realm's [[HostDefined]] field to settings object.
9. Return settings object.

\subsection*{7.4 The WindowProxy \({ }^{\text {p834 }}\) exotic object \(\S_{4}^{p 83}\)}

A WindowProxy is an exotic object that wraps a Window \({ }^{p 824}\) ordinary object, indirecting most operations through to the wrapped object. Each browsing context \({ }^{\text {p811 }}\) has an associated WindowProxy \({ }^{\text {p834 }}\) object. When the browsing context \({ }^{\text {p811 }}\) is navigated \({ }^{\text {p866 }}\), the \(\underline{W i n d o w}^{\text {p824 }}\) object wrapped by the browsing context \({ }^{\text {p811 }}\) 's associated WindowProxy \({ }^{\text {p834 }}\) object is changed.

The WindowProxy \({ }^{\text {p834 }}\) exotic object must use the ordinary internal methods except where it is explicitly specified otherwise below.
There is no WindowProxy \({ }^{\text {p834 }}\) interface object.
Every WindowProxy \({ }^{\text {p834 }}\) object has a [[Window]] internal slot representing the wrapped Window \({ }^{\text {p824 }}\) object.

\section*{Note}

Although WindowProxy \({ }^{\mathrm{p} 834}\) is named as a "proxy", it does not do polymorphic dispatch on its target's internal methods as a real proxy would, due to a desire to reuse machinery between WindowProxy \({ }^{\mathrm{p} 834}\) and Location \({ }^{\mathrm{p} 857}\) objects. As long as the Window \({ }^{\mathrm{p824}}\) object remains an ordinary object this is unobservable and can be implemented either way.

\subsection*{7.4.1 [[GetPrototypeOf]] ( ) \(\S_{4}^{p 83}\)}
1. Let \(W\) be the value of the \([[W i n d o w]]^{p 834}\) internal slot of this.
2. If! IsPlatformObjectSameOrigin \({ }^{p 822}(W)\) is true, then return! OrdinaryGetPrototypeOf \((W)\).
3. Return null.

\subsection*{7.4.2 [[SetPrototypeOf]] (V) § \({ }^{p 83}\)}
1. Return! SetImmutablePrototype(this, \(V\) ).

\subsection*{7.4.3 [[IsExtensible]] ( ) \({\underset{5}{\text { § }} \text { p83 }}^{88}\)}
1. Return true.

\subsection*{7.4.4 [[PreventExtensions]] ( ) \(\S^{p 83}\)}
1. Return false.

\subsection*{7.4.5 [[GetOwnProperty]] ( P ) \({ }_{5}^{\text {p83 }}\)}
1. Let \(W\) be the value of the \([[\text { Window }]]^{8834}\) internal slot of this.
2. If \(P\) is an array index property name, then:
1. Let index be! ToUint32(P).
2. Let maxProperties be the number of document-tree child browsing contexts \({ }^{p 830}\) of \(W\).
3. Let value be undefined.
4. If maxProperties is greater than 0 and index is less than maxProperties, then set value to the WindowProxy \({ }^{\text {p834 }}\) object of the indexth document-tree child browsing context \({ }^{\mathrm{p} 814}\) of \(W\) 's browsing context \({ }^{\mathrm{p} 826}\), sorted in the order that their browsing context container \({ }^{p 814}\) elements were most recently inserted into \(W\) 's associated Document \({ }^{p 826}\), the WindowProxy \({ }^{\text {p834 }}\) object of the most recently inserted browsing context container \({ }^{\text {p814 }}\) 's nested browsing context \({ }^{\text {p814 }}\) being last.
5. If value is undefined, then:
1. If! IsPlatformObjectSameOrigin \({ }^{\mathrm{p} 822}(W)\) is true, then return undefined.
2. Throw a "SecurityError" DOMException.
6. Return PropertyDescriptor\{ [[Value]]: value, [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: true \}.
3. If ! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}(W)\) is true, then return! OrdinaryGetOwnProperty \((W, P)\).

\section*{Note}

This is a willful violation \({ }^{p 27}\) of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing web content. See tc39/ecma262 issue \#672 for more information. [JAVASCRIPT] \({ }^{\text {p1288 }}\)
4. Let property be! CrossOriginGetOwnPropertyHelper \({ }^{\text {p823 }}(W, P)\).
5. If property is not undefined, then return property.
6. If property is undefined and \(P\) is in \(W\) 's document-tree child browsing context name property set \({ }^{\text {p830 }}\), then:
1. Let value be the WindowProxy \({ }^{\text {p834 }}\) object of the named object \({ }^{\text {p831 }}\) of \(W\) with the name \(P\).
2. Return PropertyDescriptor \(\{[[V a l u e]]:\) value, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true \}.

\section*{Note}

The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See issue \#3183 for details.
7. Return ? CrossOriginPropertyFallback \({ }^{\text {p822 }}(P)\).
7.4.6 [[DefineOwnProperty]] ( \(\boldsymbol{P}\), Desc ) \(\S^{p 83}\)
1. Let \(W\) be the value of the \([[W i n d o w]]^{p 834}\) internal slot of this.
2. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}(W)\) is true, then:
1. If \(P\) is an array index property name, return false.
2. Return ? OrdinaryDefineOwnProperty ( \(W, ~ P\), Desc).

\section*{Note}

This is a willful violation \({ }^{p 27}\) of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing web content. See tc39/ecma262 issue \#672 for more information. \([J A V A S C R I P T]{ }^{p 1288}\)
3. Throw a "SecurityError" DOMException.

\subsection*{7.4.7 [[Get]] ( P, Receiver) \(\S^{\text {p83 }}\)}
1. Let \(W\) be the value of the \([[\text { Window }]]^{p 834}\) internal slot of this.
2. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}(W)\) is true, then return ? OrdinaryGet(this, \(P\), Receiver).
3. Return ? CrossOriginGet \({ }^{\mathrm{p} 824}\) (this, \(P\), Receiver).

Note
this is passed rather than W as OrdinaryGet and CrossOriginGet \({ }^{p 824}\) will invoke the \([\text { GetOwnProperty] }]^{p 835}\) internal method.

\subsection*{7.4.8 [[Set]] ( P, V, Receiver ) \(\S^{p 83}\)}
1. Let \(W\) be the value of the \([[W \text { Window }]]^{p 834}\) internal slot of this.
2. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}(W)\) is true, then return ? OrdinarySet(this, \(P, V\), Receiver).
3. Return ? CrossOriginSet \({ }^{p 824}\) (this, \(P, V\), Receiver \()\).

\section*{Note}
this is passed rather than W as OrdinarySet and CrossOriginSet \({ }^{p 824}\) will invoke the [[GetOwnProperty]] \(]^{p 835}\) internal method. OrdinarySet will also invoke the [[DefineOwnProperty]] \({ }^{p 836}\) internal method.

\subsection*{7.4.9 [[Delete]] ( P ) \({ }_{6}^{\text {§83 }}\)}
1. Let \(W\) be the value of the \([[W \text { Window }]]^{p 834}\) internal slot of this.
2. If ! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}(W)\) is true, then:
1. If \(P\) is an array index property name, then:
1. Let desc be! this.[[GetOwnProperty]](P).
2. If desc is undefined, then return true.
3. Return false.
2. Return ? OrdinaryDelete \((W, P)\).
3. Throw a "SecurityError" DOMException.

\subsection*{7.4.10 [[OwnPropertyKeys]] ( ) § \({ }^{p 83}\)}
1. Let \(W\) be the value of the \([[W i n d o w]]^{p 834}\) internal slot of this.
2. Let keys be a new empty List.
3. Let maxProperties be the number of document-tree child browsing contexts \({ }^{\mathrm{p} 830}\) of \(W\).
4. Let index be 0 .
5. Repeat while index < maxProperties,
1. Add! ToString(index) as the last element of keys.
2. Increment index by 1 .
6. If! IsPlatformObjectSameOrigin \({ }^{\mathrm{p} 822}(W)\) is true, then return the concatenation of keys and! OrdinaryOwnPropertyKeys \((W)\).
7. Return the concatenation of keys and! CrossOriginOwnPropertyKeys \({ }^{\text {p824 }}(W)\).

\subsection*{7.5 Origin \(\S^{p 83}\)}

Origins are the fundamental currency of the web's security model. Two actors in the web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

\section*{Example}

For example, if Example Bank's web site, hosted at bank. example. com, tries to examine the DOM of Example Charity's web site, hosted at charity. example.org, a "SecurityError" DOMException will be raised.

An origin is one of the following:

\section*{An opaque origin}

An internal value, with no serialization it can be recreated from (it is serialized as "null" per serialization of an origin \({ }^{\text {p838 }}\) ), for which the only meaningful operation is testing for equality.

\section*{A tuple origin}

A tuple \({ }^{\text {p837 }}\) consists of:
- A scheme (a scheme).
- A host (a host).
- A port (a port).
- A domain (null or a domain). Null unless stated otherwise.

\section*{Note}

Origins \({ }^{p 837}\) can be shared, e.g., among multiple Document \({ }^{\text {p114 }}\) objects. Furthermore, origins \({ }^{p 837}\) are generally immutable. Only the domain \({ }^{p 837}\) of a tuple origin \({ }^{p 837}\) can be changed, and only through the document. domain \({ }^{p 848}\) API.

The effective domain of an origin \({ }^{\mathrm{p} 837}\) origin is computed as follows:
1. If origin is an opaque origin \({ }^{\text {p837 }}\), then return null.
2. If origin's domain \({ }^{\text {p837 }}\) is non-null, then return origin's domain \({ }^{\text {p837 }}\).
3. Return origin's host \({ }^{\mathrm{p837}}\).

Various specification objects are defined to have an origin \({ }^{\text {p837 }}\). These origins \({ }^{\mathrm{p} 837}\) are determined as follows:
For Document \({ }^{\text {p114 }}\) objects
The create a new browsing context \({ }^{\text {p812 }}\) and navigation \({ }^{\text {p866 }}\) algorithms assign the origin \({ }^{\text {p837 }}\) at construction time. Otherwise, the
default default behavior as defined in DOM applies. [DOM] \(]^{\text {p1287 }}\)

\section*{For images of \(\underline{\mathrm{img}}^{\mathrm{p} 32 \theta}\) elements}
\(\rightarrow\) If the image data \({ }^{\text {p336 }}\) is CORS-cross-origin \({ }^{\text {p90 }}\)
A unique opaque origin \({ }^{\text {p837 }}\) assigned when the image is created.
\(\leftrightarrow\) If the image data \({ }^{\text {p336 }}\) is CORS-same-origin \({ }^{\text {p90 }}\)
The img \({ }^{\text {p320 }}\) element's node document's origin \({ }^{\text {p837 }}\).
For audio \({ }^{\text {p384 }}\) and video \({ }^{\text {p388 }}\) elements
\(\rightarrow\) If the media data \({ }^{\text {p389 }}\) is CORS-cross-origin \({ }^{\text {p90 }}\)
A unique opaque origin \({ }^{\text {p837 }}\) assigned when the media data \({ }^{\text {p389 }}\) is fetched.
\(\rightarrow\) If the media data \({ }^{\text {p389 }}\) is CORS-same-origin \({ }^{\text {p90 }}\)
The media element \({ }^{\text {p387' }}\) 's node document's origin \({ }^{\text {p837 }}\).
Other specifications can override the above definitions by themselves specifying the origin of a particular Document \({ }^{\text {p114 }}\) object, image, or media element \({ }^{\mathrm{p} 387}\).

The serialization of an origin is the string obtained by applying the following algorithm to the given origin \({ }^{p 837}\) origin:
1. If origin is an opaque origin \({ }^{\text {p837 }}\), then return "null".
2. Otherwise, let result be origin's scheme \({ }^{\mathrm{p837}}\).
3. Append "://" to result.
4. Append origin's host \({ }^{\mathrm{p837}}\), serialized, to result.
5. If origin's port \({ }^{\mathrm{p} 837}\) is non-null, append a U+003A COLON character (:), and origin's port \({ }^{\mathrm{p837}}\), serialized, to result.
6. Return result.

\section*{Example}

The serialization \({ }^{\text {p838 }}\) of ("https", "xn--maraa-rta.example", null, null) is "https://xn--maraa-rta.example".

\section*{Note}

There used to also be a Unicode serialization of an origin. However, it was never widely adopted.

Two origins \({ }^{\text {p837 }}, A\) and \(B\), are said to be same origin if the following algorithm returns true:
1. If \(A\) and \(B\) are the same opaque origin \({ }^{\text {p837 }}\), then return true.
2. If \(A\) and \(B\) are both tuple origins \({ }^{\mathrm{p} 837}\) and their schemes \({ }^{\mathrm{p837}}\), hosts \({ }^{\mathrm{p837}}\), and port \({ }^{\mathrm{p837}}\) are identical, then return true.
3. Return false.

Two origins \({ }^{\mathrm{p837}}, A\) and \(B\), are said to be same origin-domain if the following algorithm returns true:
1. If \(A\) and \(B\) are the same opaque origin \({ }^{\text {p837 }}\), then return true.
2. If \(A\) and \(B\) are both tuple origins \({ }^{\text {p837 }}\), run these substeps:
1. If \(A\) and \(B^{\prime} s \underline{\text { schemes }}^{\mathrm{p837}}\) are identical, and their domains \({ }^{\mathrm{p} 837}\) are identical and non-null, then return true.
2. Otherwise, if \(A\) and \(B\) are same origin \({ }^{\mathrm{p} 838}\) and their domains \({ }^{\mathrm{p} 837}\) are identical and null, then return true.
3. Return false.
Example
\begin{tabular}{l|l|l|l}
\(\boldsymbol{A}\) & \(\boldsymbol{B}\) & same origin \(^{\text {p838 }}\) & same origin-domain \(^{\text {p838 }}\) \\
\hline ("https", "example.org", null, null) & ("https", "example.org", null, null) & & \\
\hline
\end{tabular}
\begin{tabular}{l|l|l|l}
\hline ("https", "example.org", 314, null) & ("https", "example.org", 420, null) & \(\times\) & \(\times\) \\
\hline ("https", "example.org", 314, "example.org") & ("https", "example.org", 420, "example.org") & \(\times\) & \(\left(\begin{array}{l}\text { ("htps", "example.org", null, null) }\end{array}\right.\) \\
\hline ("https", "example.org", null, "example.org") & \(\checkmark\) & \(\times\) \\
\hline ("https", "example.org", null, "example.org") & ("http", "example.org", null, "example.org") & \(\times\) & \(\times\) \\
\hline
\end{tabular}

\subsection*{7.5.1 Sites \({ }^{\S^{p 83}}\)}

A scheme-and-registrable-domain is a tuple of a scheme and a domain.
A site is an opaque origin \({ }^{\text {p837 }}\), a tuple origin \({ }^{p 837}\) whose host \({ }^{\mathrm{p} 837}\) 's registrable domain is null, or a scheme-and-registrable-domain \({ }^{\mathrm{p839}}\).
To obtain a site, given an origin origin, run these steps:
1. If origin is an opaque origin \({ }^{\text {p837 }}\), then return origin.
2. If origin's host \({ }^{p 837}\) ' \(s\) registrable domain is null, then return origin.
3. Return (origin's scheme \({ }^{\text {p837 }}\), origin's host \({ }^{\mathrm{p} 837}\) 's registrable domain).

Two origins \({ }^{\mathrm{p} 837}, A\) and \(B\), are said to be schemelessly same site if the following algorithm returns true:
1. If \(A\) and \(B\) are the same opaque origin \({ }^{\mathrm{p837}}\), then return true.
2. If \(A\) and \(B\) are both tuple origins \({ }^{\text {p837 }}\), then:
1. Let hostA be \(A\) 's host \({ }^{\mathrm{p} 837}\), and let hostB be \(B^{\prime} \mathrm{s}\) host \({ }^{\mathrm{p} 837}\).
2. If hostA equals hostB and hostA's registrable domain is null, then return true.
3. If hostA's registrable domain equals hostB's registrable domain and is non-null, then return true.
3. Return false.

Two origins \({ }^{\text {p837 }}, A\) and \(B\), are said to be same site if both of the following statements are true:
- \(A\) and \(B\) are schemelessly same site \({ }^{\text {p839 }}\)
- \(A\) and \(B\) are either both opaque origins \({ }^{p 837}\), or both tuple origins \({ }^{p 837}\) with the same scheme \({ }^{\text {p837 }}\)

\section*{Note}

Unlike the same origin \({ }^{p 838}\) and same origin-domain \({ }^{p 838}\) concepts, for schemelessly same site \({ }^{p 839}\) and same site \({ }^{p 839}\), the port \({ }^{p 837}\) and domain \({ }^{p 837}\) components are ignored.

\section*{\(\triangle\) Warning!}

For the reasons explained in URL, the same site \({ }^{\text {p839 }}\) and schemelessly same site \({ }^{\text {p839 }}\) concepts should be avoided when possible, in favor of same origin \({ }^{p 838}\) checks.

\section*{Example}

Given that wildlife.museum, museum, and com are public suffixes and that example.com is not:
\begin{tabular}{l|l|l|l}
\(\boldsymbol{A}\) & \(\boldsymbol{B}\) & schemelessly same site \(^{\text {p839 }}\) & same site \({ }^{\text {p839 }}\) \\
\hline ("https", "example.com") & ("https", "sub.example.com") & \(\checkmark\) & \(\checkmark\) \\
\hline ("https", "example.com") & ("https", "sub.other.example.com") & \(\checkmark\) & \(\checkmark\) \\
\hline ("https", "example.com") & ("http", "non-secure.example.com") & \(\checkmark\) & \(\times\) \\
\hline ("https", "r.wildlife.museum") & ("https", "sub.r.wildlife.museum") & \(\checkmark\) & \(\checkmark\) \\
\hline ("https", "r.wildlife.museum") & ("https", "sub.other.r.wildlife.museum") & \(\checkmark\) & \(\checkmark\) \\
\hline ("https", "r.wildlife.museum") & ("https", "other.wildlife.museum") & \(\times\) & \(\times\) \\
\hline ("https", "r.wildlife.museum") & ("https", "wildlife.museum") & \(\times\) & \(\times\) \\
\hline
\end{tabular}
(Here we have omitted the port \({ }^{\mathrm{p} 837}\) and domain \({ }^{\mathrm{p} 837}\) components since they are not considered.)

\subsection*{7.5.2 Relaxing the same-origin restriction \(\S^{p 84}\)}

\section*{For web developers (non-normative)}

\section*{document . domain \({ }^{\text {p84e }}\) [ = domain ]}

Returns the current domain used for security checks.
Can be set to a value that removes subdomains, to change the origin \({ }^{\text {p837' }} \mathrm{s}\) domain \({ }^{\text {p837 }}\) to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. This enables pages on different hosts of a domain to synchronously access each other's DOMs.
In sandboxed iframe \({ }^{\mathrm{p} 361} \mathrm{~s}\), Document \({ }^{\mathrm{p} 14} \mathrm{~s}\) with opaque origins \({ }^{\mathrm{p837}}\), Document \({ }^{\mathrm{p} 114} \mathrm{~s}\) without a browsing context \({ }^{\mathrm{p} 811}\), and when the "document-domain \({ }^{\text {p67" }}\) feature is disabled, the setter will throw a "SecurityError" exception. In cases where cross0riginIsolated \({ }^{p 966}\) or originIsolated \({ }^{p 841}\) return true, the setter will do nothing.

Avoid using the document. domain \({ }^{\text {p840 }}\) setter. It undermines the security protections provided by the same-origin policy. This is especially acute when using shared hosting; for example, if an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the document. domain \({ }^{\text {p848 }}\) setter has been used.

Because of these security pitfalls, this feature is in the process of being removed from the web platform. (This is a long process that takes many years.)

Instead, use postMessage( \()^{\text {p1018 }}\) or MessageChannet \({ }^{\text {p1021 }}\) objects to communicate across origins in a safe manner.

The domain getter steps are:
1. Let effectiveDomain be this's origin \({ }^{\text {p837' }} \mathrm{s}\) effective domain \({ }^{\text {p837 }}\).
2. If effectiveDomain is null, then return the empty string.
3. Return effectiveDomain, serialized.

The domain \({ }^{\text {p840 }}\) setter steps are:
1. If this's browsing context \({ }^{\text {p811 }}\) is null, then throw a "SecurityError" DOMException.
2. If this's active sandboxing flag set \({ }^{\mathrm{p844}}\) has its sandboxed document. domain browsing context flag \({ }^{\mathrm{p843}}\) set, then throw a "SecurityError" DOMException.
3. If this is not allowed to use \({ }^{\mathrm{p} 367}\) the "document-domain \({ }^{\mathrm{p67}}\) " feature, then throw a "SecurityError" DOMException.
4. Let effectiveDomain be this's origin \({ }^{\text {p837 }}\) ' effective domain \({ }^{\mathrm{p837}}\).
5. If effectiveDomain is null, then throw a "SecurityError" DOMException.
6. If the given value is not a registrable domain suffix of and is not equal to \({ }^{\text {p840 }}\) effectiveDomain, then throw a "SecurityError" DOMException.
7. If the surrounding agent's agent cluster's cross-origin isolated \({ }^{\text {p914 }}\) is true, then return.
8. If the surrounding agent's agent cluster's origin-isolated \({ }^{\text {p914 }}\) is true, then return.
9. Set this's origin \({ }^{\text {p837' }} \mathrm{s}\) domain \({ }^{\mathrm{p} 837}\) to the result of parsing the given value.

To determine if a string hostSuffixString is a registrable domain suffix of or is equal to a host originalHost, run these steps:
1. If hostSuffixString is the empty string, then return false.
2. Let host be the result of parsing hostSuffixString.
3. If host is failure, then return false.
4. If host does not equal originalHost, then:
1. If host or originalHost is not a domain, then return false.

\section*{Note}

This excludes hosts that are an IPv4 address or an IPv6 address.
2. If host, prefixed by a U+002E FULL STOP (.), does not exactly match the end of originalHost, then return false.
3. If host equals host's public suffix, then return false. [URL] \({ }^{\text {p1292 }}\)
5. Return true.

\subsection*{7.5.3 Origin isolation \(\S_{1}^{p 84}\)}

\section*{For web developers (non-normative)}
window . originIsolated \({ }^{\text {p841 }}\)
Returns true if this Window \({ }^{\mathrm{p} 824}\) is origin-isolated in the manner described in this section.

A Document \({ }^{\text {p114 }}\) delivered over a secure context \({ }^{\text {p924 }}\) can opt in to origin isolation, by using the ` \({ }^{\text {Origin-Isolation }}{ }^{\text {p1258` }}\) HTTP response header. This header is a structured header whose value must be a boolean. [STRUCTURED-FIELDS] \({ }^{p 1291}\)

Per the processing model in the create and initialize a new Document object \({ }^{\text {p873 }}\), values that are not the structured header boolean true value (i.e., `?1`) will be ignored.

The consequences of using this header are that the resulting Document \({ }^{\text {p114 }}\) 's agent cluster key \({ }^{\text {p914 }}\) is its origin \({ }^{\text {p837 }}\), instead of the corresponding site \({ }^{\text {p839 }}\). In terms of observable effects, this means that attempting to relax the same-origin restriction \({ }^{\text {p840 }}\) using document. domain \({ }^{\text {p840 }}\) will instead do nothing, and it will not be possible to send WebAssembly. Module objects to cross-origin Document \({ }^{\text {p114 }} s\) (even if they are same site \({ }^{\text {p839 }}\) ). Behind the scenes, this isolation can allow user agents to allocate implementationspecific resources corresponding to agent clusters, such as processes or threads, more efficiently.

Note that within a browsing context group \({ }^{\text {p818 }}\), the `origin-Isolation \({ }^{\text {p1258. }}\) header can never cause same-origin Document \({ }^{\text {p114 }}\) objects to end up in different agent clusters, even if one sends the header and the other doesn't. This is prevented by means of the historical agent cluster key map \({ }^{\text {p818 }}\).

\section*{Note}

This means that the originIsolated \({ }^{p 841}\) getter can return false, even if the header is set, if the header was omitted on a previously-loaded same-origin page in the same browsing context group \({ }^{\text {p818 }}\). Similarly, it can return true even when the header is not set.

The originIsolated getter steps are to return the surrounding agent's agent cluster's origin-isolated \({ }^{\text {p914 }}\).

\section*{Note}

Document \({ }^{p 114}\) s for which obtain a site \({ }^{p 839}\) returns an origin \({ }^{p 837}\) can be considered unconditionally origin-isolated; for them the header has no effect.

\section*{Note}

Similarly, Document \({ }^{\text {p114 }}\) s in a cross-origin isolated \({ }^{p 914}\) agent cluster are automatically origin-isolated. The `Origin-Isolation \({ }^{\text {p1258, }}\) header might be useful as an additional hint to implementations about resource allocation, since the `cross-Origin-OpenerPolicy \({ }^{\text {p1257. }}\) and `Cross-Origin-Embedder-Policy \({ }^{\text {p1257. }}\) headers used to achieve cross-origin isolation are more about ensuring that everything in the same address space opts in to being there. But adding it would have no additional observable effects on author code.

\subsection*{7.6 Sandboxing \(\S^{\text {p84 }}\)}

A sandboxing flag set is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:

\section*{The sandboxed navigation browsing context flag}

This flag prevents content from navigating browsing contexts other than the sandboxed browsing context itself \({ }^{8866}\) (or browsing contexts further nested inside it), auxiliary browsing contexts \({ }^{\text {p814 }}\) (which are protected by the sandboxed auxiliary navigation browsing context flag \({ }^{\text {p842 }}\) defined next), and the top-level browsing context \({ }^{\text {p814 }}\) (which is protected by the sandboxed top-level navigation without user activation browsing context flag \({ }^{\mathrm{p842}}\) and sandboxed top-level navigation with user activation browsing context flag \({ }^{\text {p842 }}\) defined below).

If the sandboxed auxiliary navigation browsing context flag \({ }^{\text {p842 }}\) is not set, then in certain cases the restrictions nonetheless allow popups (new top-level browsing contexts \({ }^{8814}\) ) to be opened. These browsing contexts \({ }^{\text {p811 }}\) always have one permitted sandboxed navigator, set when the browsing context is created, which allows the browsing context \({ }^{8811}\) that created them to actually navigate them. (Otherwise, the sandboxed navigation browsing context flag \({ }^{p 842}\) would prevent them from being navigated even if they were opened.)

\section*{The sandboxed auxiliary navigation browsing context flag}

This flag prevents content from creating new auxiliary browsing contexts \({ }^{\text {p820 }}\), e.g. using the target \({ }^{p 284}\) attribute or the window. open() \({ }^{\mathrm{p} 827}\) method.

\section*{The sandboxed top-level navigation without user activation browsing context flag}

This flag prevents content from navigating their top-level browsing context \({ }^{\text {p866 }}\) and prevents content from closing their top-level browsing context \({ }^{\text {p829 }}\). It is consulted only when the sandboxed browsing context's active window \({ }^{\text {p811 }}\) does not have transient activation \({ }^{\text {p767 }}\).

When the sandboxed top-level navigation without user activation browsing context flag \({ }^{\text {p842 }}\) is not set, content can navigate its toplevel browsing context \({ }^{\text {p814 }}\), but other browsing contexts \({ }^{\text {p811 }}\) are still protected by the sandboxed navigation browsing context flag \({ }^{\text {p842 }}\) and possibly the sandboxed auxiliary navigation browsing context flag \({ }^{\text {p842 }}\).

\section*{The sandboxed top-level navigation with user activation browsing context flag}

This flag prevents content from navigating their top-level browsing context \({ }^{\mathrm{p} 866}\) and prevents content from closing their top-level browsing context \({ }^{\mathrm{p} 829}\). It is consulted only when the sandboxed browsing context's active window \({ }^{\mathrm{p} 811}\) has transient activation \({ }^{\mathrm{p} 767}\).

As with the sandboxed top-level navigation without user activation browsing context flag \({ }^{\mathrm{p} 842}\), this flag only affects the top-level browsing context \({ }^{\mathrm{p814}}\); if it is not set, other browsing contexts \({ }^{\mathrm{p} 811}\) might still be protected by other flags.

\section*{The sandboxed plugins browsing context flag}

This flag prevents content from instantiating plugins \({ }^{\text {p45 }}\), whether using the embed element \({ }^{\text {p372 }}\), the object element \({ }^{\text {p377 }}\), or through navigation \({ }^{\text {p879 }}\) of their nested browsing context \({ }^{\text {p814 }}\), unless those plugins \({ }^{\text {p45 }}\) can be secured \({ }^{\text {p45 }}\).

\section*{The sandboxed origin browsing context flag}

This flag forces content into a unique origin \({ }^{\text {p812 }}\), thus preventing it from accessing other content from the same origin \({ }^{\text {p837 }}\).
This flag also prevents script from reading from or writing to the document. cookie IDL attribute \({ }^{\text {p116 }}\), and blocks access to localStorage \({ }^{\text {p1063 }}\).

\section*{The sandboxed forms browsing context flag}

This flag blocks form submission \({ }^{\text {p596 }}\).

\section*{The sandboxed pointer lock browsing context flag}

This flag disables the Pointer Lock API. [POINTERLOCK] \({ }^{\text {p1290 }}\)

\section*{The sandboxed scripts browsing context flag}

This flag blocks script execution \({ }^{\text {p924 }}\).

\section*{The sandboxed automatic features browsing context flag}

This flag blocks features that trigger automatically, such as automatically playing a video \({ }^{\text {p407 }}\) or automatically focusing a form control \({ }^{\text {p782 }}\).

\section*{The sandboxed document. domain browsing context flag}

This flag prevents content from using the document. domain \({ }^{\text {p84日 }}\) setter.

\section*{The sandbox propagates to auxiliary browsing contexts flag}

This flag prevents content from escaping the sandbox by ensuring that any auxiliary browsing context \({ }^{\text {p814 }}\) it creates inherits the content's active sandboxing flag set \({ }^{\text {p844 }}\).

\section*{The sandboxed modals flag}

This flag prevents content from using any of the following features to produce modal dialogs:
- window.alert() \({ }^{\text {p977 }}\)
- window.confirm( () \({ }^{\text {p978 }}\)
- window.print() \({ }^{\text {p978 }}\)
- window.prompt() \()^{\text {p978 }}\)
- the beforeunload \({ }^{\text {p1281 }}\) event

\section*{The sandboxed orientation lock browsing context flag}

This flag disables the ability to lock the screen orientation. [SCREENORIENTATION] \({ }^{\text {p1291 }}\)

\section*{The sandboxed presentation browsing context flag}

This flag disables the Presentation API. [PRESENTATION] \({ }^{11290}\)

\section*{The sandboxed downloads browsing context flag}

This flag prevents content from initiating or instantiating downloads, whether through downloading hyperlinks \({ }^{\text {p291 }}\) or through navigation \({ }^{\mathrm{p} 871}\) that gets handled as a download \({ }^{\mathrm{p} 291}\).

When the user agent is to parse a sandboxing directive, given a string input, a sandboxing flag set \({ }^{p 842}\) output, it must run the following steps:
1. Split input on ASCII whitespace, to obtain tokens.
2. Let output be empty.
3. Add the following flags to output:
- The sandboxed navigation browsing context flag \({ }^{\text {p842 }}\).
- The sandboxed auxiliary navigation browsing context flag \({ }^{\text {p842 }}\), unless tokens contains the allow-popups keyword.
- The sandboxed top-level navigation without user activation browsing context flag \({ }^{\text {p842 }}\), unless tokens contains the allow-top-navigation keyword.
- The sandboxed top-level navigation with user activation browsing context flag \({ }^{\text {p842 }}\), unless tokens contains either the allow-top-navigation-by-user-activation keyword or the allow-top-navigation \({ }^{\text {p843 }}\) keyword.

\section*{Note}

This means that if the allow-top-navigation \({ }^{p 843}\) is present, the allow-top-navigation-by-user-
activation \({ }^{\text {p843 }}\) keyword will have no effect. For this reason, specifying both is a document conformance error.
- The sandboxed plugins browsing context flag \({ }^{\text {p842 }}\).
- The sandboxed origin browsing context flag \({ }^{\text {p842 }}\), unless the tokens contains the allow-same-origin keyword.

\section*{Note}

The allow-same-origin \({ }^{\text {p843 }}\) keyword is intended for two cases.
First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.

Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening popups, etc, without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.
- The sandboxed forms browsing context flag \({ }^{\text {p842 }}\), unless tokens contains the allow-forms keyword.
- The sandboxed pointer lock browsing context flag \({ }^{\text {p842 }}\), unless tokens contains the allow-pointer-lock keyword.
- The sandboxed scripts browsing context flag \({ }^{\text {p842 }}\), unless tokens contains the allow-scripts keyword.
- The sandboxed automatic features browsing context flag \({ }^{\text {p842 }}\), unless tokens contains the allow-scripts \({ }^{\text {p844 }}\) keyword (defined above).

\section*{Note}

This flag is relaxed by the same keyword as scripts, because when scripts are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use script to do them when sandboxed rather than allowing them to use the declarative features.
- The sandboxed document. domain browsing context flag \({ }^{\text {p843 }}\).
- The sandbox propagates to auxiliary browsing contexts flag \({ }^{\text {p843 }}\), unless tokens contains the allow-popups-to-escape-sandbox keyword.
- The sandboxed modals flag \({ }^{\text {p843 }}\), unless tokens contains the allow-modals keyword.
- The sandboxed orientation lock browsing context flag \({ }^{\text {p843 }}\), unless tokens contains the allow-orientation-lock keyword.
- The sandboxed presentation browsing context flag \({ }^{\mathrm{p} 83}\), unless tokens contains the allow-presentation keyword.
- The sandboxed downloads browsing context flag \({ }^{\text {p843 }}\), unless tokens contains the allow-downloads keyword.

Every top-level browsing context \({ }^{\text {p814 }}\) has a popup sandboxing flag set, which is a sandboxing flag set \({ }^{p 842}\). When a browsing context \({ }^{\text {p811 }}\) is created, its popup sandboxing flag set \({ }^{\text {p844 }}\) must be empty. It is populated by the rules for choosing a browsing context \({ }^{\text {p820 }}\) and the obtain a browsing context to use for a navigation response \({ }^{\text {p846 }}\) algorithm.

Every iframe \({ }^{\text {p361 }}\) element has an iframe sandboxing flag set, which is a sandboxing flag set \({ }^{p 842}\). Which flags in an iframe sandboxing flag set \({ }^{\mathrm{p} 844}\) are set at any particular time is determined by the iframe \({ }^{\mathrm{p} 361}\) element's sandbox \({ }^{\mathrm{p} 365}\) attribute.

Every Document \({ }^{\text {p114 }}\) has an active sandboxing flag set, which is a sandboxing flag set \({ }^{\text {p842 }}\). When the Document \({ }^{\text {p114 }}\) is created, its active sandboxing flag set \({ }^{\mathrm{p} 844}\) must be empty. It is populated by the navigation algorithm \({ }^{\mathrm{p} 866}\).

Every resource that is obtained by the navigation algorithm \({ }^{\text {p866 }}\) has a forced sandboxing flag set, which is a sandboxing flag set \({ }^{\mathrm{p} 842}\). A resource by default has no flags set in its forced sandboxing flag set \({ }^{\mathrm{p} 84}\), but other specifications can define that certain flags are set.

\section*{Note}

In particular, the forced sandboxing flag set \({ }^{p 844}\) is used by Content Security Policy. [CSP] \({ }^{p 1285}\)

To determine the creation sandboxing flags for a browsing context \({ }^{\text {p811 }}\) browsing context, given null or an element embedder, return the union of the flags that are present in the following sandboxing flag sets \({ }^{\text {p842 }}\) :
- If embedder is null, then: the flags set on browsing context's popup sandboxing flag set \({ }^{\text {p844 }}\).
- If embedder is an element, then: the flags set on embedder's iframe sandboxing flag set \({ }^{\text {p844 }}\).
- If embedder is an element, then: the flags set on embedder's node document's active sandboxing flag set \({ }^{\text {p844 }}\).

After creation, the sandboxing flags for a browsing context \({ }^{p 811}\) browsing context are the result of determining the creation sandboxing flags \({ }^{\text {p844 }}\) given browsing context and browsing context's container \({ }^{\mathrm{p814}}\).

\subsection*{7.7 Cross-origin opener policies \(\S^{p 84}\)}

A cross-origin opener policy allows a document which is navigated to in a top-level browsing context \({ }^{\text {p814 }}\) to force the creation of a new top-level browsing context \({ }^{\text {p814 }}\), and a corresponding group \({ }^{\text {p814 }}\). It has one of the following values:
"unsafe-none"
This is the (current) default and means that the document will occupy the same top-level browsing context \({ }^{\text {p814 }}\) as its predecessor, unless that document specified a different cross-origin opener policy \({ }^{\text {p844 }}\).
"same-origin-allow-popups"
This forces the creation of a new top-level browsing context \({ }^{p 814}\) for the document, unless its predecessor specified the same crossorigin opener policy \({ }^{\text {p844 }}\) and they are same origin \({ }^{\text {p838 }}\).
"same-origin"
This behaves the same as "same-origin-allow-popups \({ }^{\text {p845" }}\), with the addition that any auxiliary browsing context \({ }^{p 814}\) created needs to contain same origin \({ }^{\text {p838 }}\) documents that also have the same cross-origin opener policy \({ }^{\text {p844 }}\) or it will appear closed to the opener.
"same-origin-plus-COEP"
This behaves the same as "same-origin \({ }^{p 845}\) ", with the addition that it sets the (new) top-level browsing context \({ }^{\text {p814' }} \mathrm{sgroup}^{\text {p814. }}\). cross-origin isolated \({ }^{\mathrm{p} 818}\) to true.

\section*{Note}
"same-origin-plus-C0EP \({ }^{p 845}\) " cannot be directly set via the `Cross-0rigin-0pener-Policy \({ }^{\text {p1257. }}\) 'header, but results from a combination of setting both `Cross-Origin-Opener-Policy \({ }^{\mathrm{p1257}}\) : same-origin \({ }^{\mathrm{p845}}\) ` and `Cross-Origin-EmbedderPolicy \({ }^{\text {p1257 }}\) : require-corp` together.

To match cross-origin opener policies, given a cross-origin opener policy \({ }^{\mathrm{p} 844} A\), an origin \({ }^{\mathrm{p} 837}\) originA, a cross-origin opener policy \({ }^{\mathrm{p} 844}\) \(B\), and an origin \({ }^{\mathrm{p} 837}\) originB:
1. If \(A\) is "unsafe-none \({ }^{\text {p845" }}\) and \(B\) is "unsafe-none \({ }^{\text {p845" }}\) " then return true.
2. If \(A\) is "unsafe-none \({ }^{p 845 "}\) or \(B\) is "unsafe-none \({ }^{p 845}\) ", then return false.
3. If \(A\) is \(B\) and origin \(A\) is same origin \({ }^{\mathrm{p} 838}\) with origin \(B\), then return true.
4. Return false.

\subsection*{7.7.1 The `Cross-Origin-Opener-Policy \({ }^{\text {p1257, }}\) header \(\S_{5}^{\text {p84 }}\)}

A Document \({ }^{p 114}\) 's cross-origin opener policy \({ }^{\text {p115 }}\) is derived from the `Cross-0rigin-0pener-Policy \({ }^{\text {p1257. }}\) HTTP response header. This header is a structured header whose value must be a token. [STRUCTURED-FIELDS] \({ }^{\text {p1291 }}\)

The valid token values are "unsafe-none \({ }^{\text {p845" }}\), "same-origin-allow-popups \({ }^{\text {p845" } ", ~ a n d ~ " s a m e-o r i g i n ~}{ }^{\text {p845". }}\)

\section*{Note}

Per the processing model described below, user agents will ignore this header if it contains an invalid value. Likewise, user agents will ignore this header if the value cannot be parsed as a token.

To obtain a cross-origin opener policy given a response response and an environment \({ }^{\text {p916 }}\) reservedEnvironment:
1. If reservedEnvironment is a non-secure context \({ }^{\mathrm{p925}}\), then return "unsafe-none \({ }^{\mathrm{p} 845 \mathrm{n}}\).
2. Let value be the result of getting a structured field value given "Cross-0rigin-0pener-Policy \({ }^{\text {p1257. }}\) and "item" from response's header list.
3. If value is null, then return "unsafe-none \({ }^{p 845}\) ".
4. If value[0] is not "same-origin \({ }^{\text {p845" }}\) or "same-origin-allow-popups \({ }^{\text {p845" }}\) ", then return "unsafe-none \({ }^{\text {p845" ". }}\)
5. If value[0] is "same-origin \({ }^{\mathrm{p} 845}\) ", then:
1. Let coep be the result of obtaining an embedder policy \({ }^{\mathrm{p847}}\) from response.
2. If coep's value \({ }^{\text {p847 }}\) is "require-corp", then return "same-origin-plus-C0EP \({ }^{p 845 "}\).
6. Return value[0].

\subsection*{7.7.2 Browsing context group switches due to cross-origin opener policy \(\S^{\text {p84 }}\)}

To check if a response requires a browsing context group switch, given a browsing context \({ }^{\text {p811 }}\) browsingContext, an origin \({ }^{\text {p837 }}\) responseOrigin and a cross-origin opener policy \({ }^{\text {p844 }}\) responseCOOP:
1. Let activeDocumentNavigationOrigin be browsingContext's active document \({ }^{\mathrm{p811}}\) ' s origin \({ }^{\mathrm{p837}}\).
2. Let activeDocumentCOOP be browsingContext's active document \({ }^{\text {p811 }}\) 's cross-origin opener policy \({ }^{\text {p115 }}\).
3. Let isInitialAboutBlank be false.
4. If browsingContext's only entry in its session history \({ }^{\text {p849 }}\) is the about:blank \({ }^{p 51}\) Document \({ }^{p 114}\) that was added when browsingContext was created \({ }^{\text {p812 }}\), then set isInitialAboutBlank to true.
5. If the result of matching \({ }^{\text {p845 }}\) activeDocumentCOOP, activeDocumentNavigationOrigin, responseCOOP and responseOrigin is true, then return false.
6. If all of the following are true:
- isInitialAboutBlank
- activeDocumentCOOP is "same-origin-allow-popups \({ }^{\text {p845". }}\).
- responseCOOP is "unsafe-none \({ }^{\text {p845". }}\).
then return false.
7. Return true.

To obtain a browsing context to use for a navigation response, given a browsing context \({ }^{\text {p811 }}\) browsingContext, a sandboxing flag set \({ }^{\text {p842 }}\) sandboxFlags, and a cross-origin opener policy \({ }^{\text {p844 }}\) navigationCOOP:
1. Assert: browsingContext is a top-level browsing context \({ }^{p 814}\).
2. Let newBrowsingContext be the result of creating a new top-level browsing context \({ }^{\mathrm{p} 813}\).
3. If navigationCOOP is "same-origin-plus-COEP \({ }^{p 845 "}\) ", then set newBrowsingContext's group \({ }^{\text {p814 's }} \mathrm{s}\) cross-origin isolated \({ }^{\text {p818 }}\) to true.
4. If sandboxFlags is not empty, then:
1. Assert: navigationCOOP is "unsafe-none \({ }^{\text {p845" }}\).
2. Assert: newBrowsingContext's popup sandboxing flag set \({ }^{\mathrm{p} 844}\) is empty.
3. Set newBrowsingContext's popup sandboxing flag set \({ }^{\mathrm{p844}}\) to a clone of sandboxFlags.
5. Discard \({ }^{\mathrm{p831}}\) browsingContext.

\section*{Note}

This has no effect on browsingContext's group \({ }^{p 814}\), unless browsingContext was its sole top-level browsing context \({ }^{p 814}\). In that case, the user agent might delete the browsing context group \({ }^{p 818}\) which no longer contains any browsing contexts \({ }^{p 811}\).
6. Return newBrowsingContext.

The impact of swapping browsing context groups following a navigation is not fully defined. It is currently under discussion in issue \#5350.

\subsection*{7.8 Cross-origin embedder policies \(\S^{\text {p84 }}\)}

An embedder policy value controls the fetching of cross-origin resources without explicit permission from resource owners. There are two such values:
"unsafe-none"
This is the default value. When this value is used, cross-origin resources can be fetched without giving explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.
"require-corp"
When this value is used, fetching cross-origin resources requires the server's explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

An embedder policy consists of:
- A value, which is an embedder policy value \({ }^{\text {p847 }}\), initially "unsafe-none \({ }^{\text {p847" }}\).
- A reporting endpoint string, initially the empty string.
- A report only value, which is an embedder policy value \({ }^{\text {p847 }}\), initially "unsafe-none \({ }^{\text {p847" }}\).
- A report only reporting endpoint string, initially the empty string.

The "coep" report type is a report type whose value is "coep". It is visible to Reporting0bservers.

\subsection*{7.8.1 The headers \(\S_{{ }_{7}}^{\text {p84 }}\)}

The `Cross-Origin-Embedder-Policy \({ }^{\text {p1257. }}\) and `Cross-Origin-Embedder-Policy-Report-Only \({ }^{\text {p1257. }}\) - HTTP response header fields allow a server to declare an embedder policy \({ }^{\mathrm{p847}}\) for an environment settings object \({ }^{\mathrm{p917}}\). These headers are structured headers whose values must be token. [STRUCTURED-FIELDS] \({ }^{p 1291}\)

The valid token values are the embedder policy values \({ }^{\text {p847 }}\). The token may also have attached parameters; of these, the "report-to" parameter can have a valid URL string identifying an appropriate reporting endpoint. [REPORTING] \({ }^{p 1289}\)

\section*{Note}

The processing model \({ }^{p 847}\) fails open (by defaulting to "unsafe-none \({ }^{\text {p847" }}\) ) in the presence of a header that cannot be parsed as a token. This includes inadvertent lists created by combining multiple instances of the `Cross-Origin-Embedder-Policy \({ }^{\text {p1257. }}\) header present in a given response:
\begin{tabular}{|c|c|}
\hline `Cross-Origin-Embedder-Policy \({ }^{\text {p1257, }}\) & Final embedder policy value \({ }^{\text {p847 }}\) \\
\hline No header delivered & "unsafe-none \({ }^{\text {p847." }}\) \\
\hline 'require-corp' & "require-corp \({ }^{\text {p847 }}\) " \\
\hline `unknown-value` & "unsafe-none \({ }^{\text {p847." }}\) \\
\hline 'require-corp, unknown-value' & "unsafe-none \({ }^{\text {p847." }}\) \\
\hline `unknown-value, unknown-value` & "unsafe-none \({ }^{\text {p847." }}\) \\
\hline `unknown-value, require-corp' & "unsafe-none \({ }^{\text {p847." }}\) \\
\hline 'require-corp, require-corp' & "unsafe-none \({ }^{\text {p847." }}\) \\
\hline
\end{tabular}
(The same applies to `Cross-Origin-Embedder-Policy-Report-Only \({ }^{\text {p1257 }}\).)

To obtain an embedder policy from a response response:
1. Let policy be a new embedder policy \({ }^{\mathrm{p847}}\).
2. Let parsedltem be the result of getting a structured field value with `Cross-Origin-Embedder-Policy \({ }^{\text {p1257. }}\) and "item" from response's header list.
3. If parsedltem is non-null and parsedltem[0] is "require-corp":
1. Set policy's value \({ }^{\text {p847 }}\) to "require-corp \({ }^{\text {p847" }}\).
2. If parsedltem[1]["report-to \({ }^{\text {p847" }}\) ] exists, then set policy's endpoint \({ }^{\text {p847 }}\) to parsedltem[1]["report-to \({ }^{\text {p847" "]. }}\)
4. Set parsedltem to the result of getting a structured field value with `Cross-Origin-Embedder-Policy-Report-Only \({ }^{\text {p1257. }}\) and "item" from response's header list.
5. If parsedltem is non-null and parsedltem[0] is "require-corp":
1. Set policy's report only value \({ }^{\mathrm{p847}}\) to "require-corp \({ }^{\mathrm{p} 847}\) ".
 parsedltem[1]["report-to \({ }^{\text {8847" }}\) ].
6. Return policy.

\subsection*{7.8.2 Embedder policy checks \(\S^{\text {p84 }}\)}

To check a navigation response's adherence to its embedder policy given a response response and a browsing context \({ }^{\text {p811 }}\) target:
1. If target is not a child browsing context \({ }^{p 814}\), then return true.
2. Let responsePolicy be the result of obtaining an embedder policy \({ }^{p 847}\) from response.
3. Let parentPolicy be target's container document \({ }^{\mathrm{p} 814}\) 's embedder policy \({ }^{\mathrm{p} 115}\).
4. If parentPolicy's report only value \({ }^{\text {p847 }}\) is "require-corp \({ }^{\text {p847" }}\) and responsePolicy's value \({ }^{\text {p847 }}\) is "unsafe-none \({ }^{\text {p847" }}\), then queue a cross-origin embedder policy inheritance violation \({ }^{\text {p848 }}\) with response, "navigation", parentPolicy's report only reporting endpoint \({ }^{\mathrm{p} 847}\), "reporting", and target's container document \({ }^{\text {p814 }}\) 's relevant settings object \({ }^{\text {p924 }}\).
5. If parentPolicy's value \({ }^{p 847}\) is "unsafe-none \(e^{p 887}\) " or responsePolicy's value \({ }^{\text {p847 }}\) is "require-corp \(p^{p 847 ", ~ t h e n ~ r e t u r n ~ t r u e . ~}\)
6. Queue a cross-origin embedder policy inheritance violation \({ }^{\text {p848 }}\) with response, "navigation", parentPolicy's reporting endpoint \({ }^{\text {p847 }}\), "enforce", and target's container document \({ }^{\text {p814 }}\) 's relevant settings object \({ }^{\text {p924 }}\).
7. Return false.

To check a global object's embedder policy given a WorkerGlobalScope \({ }^{\text {p1044 }}\) workerGlobalScope, an environment settings object \({ }^{\text {p917 }}\) owner, and a response response:
1. If workerGlobalScope is not a DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object, then return true.
2. Let policy be workerGlobalScope's embedder policy \({ }^{\text {p1045 }}\).
3. Let ownerPolicy be owner's embedder policy \({ }^{\text {p917 }}\).
4. If ownerPolicy's report only value \({ }^{\text {p847 }}\) is "require-corp \({ }^{p 847 "}\) and policy's value \({ }^{\text {p847 }}\) is "unsafe-none \(e^{p 847 ", ~ t h e n ~ q u e u e ~ a ~ c r o s s-~}\) origin embedder policy inheritance violation \({ }^{\text {p848 }}\) with response, "worker initialization", owner's policy's report only reporting endpoint \({ }^{\text {p847 }}\), "reporting", and owner.
5. If ownerPolicy's value \({ }^{\text {p847 }}\) is "unsafe-none \({ }^{\text {p847" }}\) or policy's value \({ }^{\text {p847 }}\) is "require-corp \({ }^{\text {p847" }}\), then return true.
6. Queue a cross-origin embedder policy inheritance violation \({ }^{\text {p848 }}\) with response, "worker initialization", owner's policy's reporting endpoint \({ }^{\text {p847 }}\), "enforce", and owner.
7. Return false.

To queue a cross-origin embedder policy inheritance violation given a response response, a string type, a string endpoint, a string disposition, and an environment settings object \({ }^{\text {p917 }}\) settings:
1. Let serialized be the result of serializing a response URL for reporting with response.
2. Let body be a new object containing the following properties:
\begin{tabular}{l|l}
\multicolumn{1}{c|}{ key } & \multicolumn{1}{c}{ value } \\
\hline type & type \\
\hline blockedURL & serialized \\
\hline
\end{tabular}
\begin{tabular}{c|c} 
key & value \\
\hline disposition & disposition \\
\hline
\end{tabular}
3. Queue body as the "coep" report type \({ }^{\mathrm{p} 847}\) for endpoint on settings.

\subsection*{7.9 Session history and navigation \(\S^{p 84}\)}

\subsection*{7.9.1 Browsing sessions \(\S^{p 84}\)}

A browsing session is .... See whatwg/html issue \#4782 and whatwg/html issue \#5350 for defining browsing session \({ }^{\text {p849 }}\). It is roughly analogous to a top-level browsing context \({ }^{\text {p814 }}\) except that it cannot be replaced due to a `Cross-0rigin-0penerPolicy \({ }^{\text {p1257. }}\) header or navigation.

A top-level browsing context \({ }^{\text {p814 }}\) has an associated browsing session which is a browsing session \({ }^{\text {p849 }}\).
The browsing session of an environment settings object \({ }^{\text {p917 }}\) environment is the result of running these steps:
1. Assert: environment has a responsible document \({ }^{\mathrm{p} 917}\).
2. Return environment's responsible document \({ }^{\text {p917 ' }}\) ' browsing context \({ }^{\text {p811 ' }}\) 's top-level browsing context \({ }^{\text {p814 ' }}\) s browsing session \({ }^{\text {p849 }}\).

\subsection*{7.9.2 The session history of browsing contexts \(\S_{9}^{\text {p84 }}\)}

The sequence of Document \({ }^{p 114} s\) in a browsing context \({ }^{p 811}\) is its session history. Each browsing context \({ }^{\text {p811 }}\), including child browsing
 Each session history entry consists, at a minimum, of a URL, and each entry may in addition have serialized state \({ }^{\text {p849 }}\), a title, a Document \({ }^{\text {p114 }}\) object, form data, a scroll restoration mode \({ }^{\text {p850 }}\), a scroll position, a browsing context name \({ }^{\text {p819 }}\), and other information associated with it.

\section*{Note}

Each entry, when first created, has a Document \({ }^{\text {p114 }}\). However, when a Document \({ }^{\text {p114 }}\) is not active \({ }^{\text {p815 }}\), it's possible for it to be \(\underline{\text { discarded }}{ }^{p 831}\) to free resources. The \(\underline{U R L}\) and other data in a session history entry \({ }^{p 849}\) is then used to bring a new Document \({ }^{p 114}\) into being to take the place of the original, in case the user agent finds itself having to reactivate that Document \({ }^{\mathrm{pl14}}\).

\section*{Note}

Titles associated with session history entries \({ }^{p 849}\) need not have any relation with the current title \({ }^{\text {p154 }}\) of the Document \({ }^{\text {p114 }}\). The title of a session history entry \({ }^{p 849}\) is intended to explain the state of the document at that point, so that the user can navigate the document's history.

URLs without associated serialized state \({ }^{\mathrm{p} 849}\) are added to the session history as the user (or script) navigates from page to page.

Each Document \({ }^{\text {p114 }}\) object in a browsing context \({ }^{\text {p811 }}\) 's session history \({ }^{\text {p849 }}\) is associated with a unique History \({ }^{\text {p851 }}\) object which must all model the same underlying session history \({ }^{\text {p849 }}\).

The history attribute of the Window \({ }^{p 824}\) interface must return the object implementing the History \({ }^{p 851}\) interface for this Window \({ }^{p 824}\) object's associated Document \({ }^{\text {p826 }}\).

Serialized state is a serialization (via StructuredSerializeForStorage \({ }^{\text {p108 }}\) ) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or
alternately the objects created by deserializing (via StructuredDeserialize \({ }^{\text {p108 }}\) ) serialized state.
Pages can add \({ }^{\mathrm{p} 854}\) serialized state \({ }^{\mathrm{p} 849}\) to the session history. These are then deserialized \({ }^{\mathrm{p} 108}\) and returned to the script \({ }^{\mathrm{p} 1282}\) when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

\section*{Note}

Serialized state \({ }^{\text {p849 }}\) is intended to be used for two main purposes: first, storing a preparsed description of the state in the URL so that in the simple case an author doesn't have to do the parsing (though one would still need the parsing for handling URLs passed around by users, so it's only a minor optimization). Second, so that the author can store state that one wouldn't store in the URL because it only applies to the current Document \({ }^{\text {p114 }}\) instance and it would have to be reconstructed if a new Document \({ }^{\text {p114 }}\) were opened.

An example of the latter would be something like keeping track of the precise coordinate from which a popup div \({ }^{p 237}\) was made to animate, so that if the user goes back, it can be made to animate to the same location. Or alternatively, it could be used to keep a pointer into a cache of data that would be fetched from the server based on the information in the URL, so that when going back and forward, the information doesn't have to be fetched again.

At any point, one of the entries in the session history is the current entry. This is the entry representing the active document \({ }^{\mathrm{p811}}\) of the browsing context \({ }^{\mathrm{p} 811}\). Which entry is the current entry \({ }^{\mathrm{p} 850}\) is changed by the algorithms defined in this specification, e.g. during session history traversal \({ }^{\text {p881 }}\).

\section*{Note}

The current entry \({ }^{\text {p850 }}\) is usually an entry for the URL of the Document \({ }^{\text {p114. }}\). However, it can also be one of the entries for serialized state \({ }^{\text {p849 }}\) added to the history by that document.

An entry with persisted user state is one that also has implementation-defined state. This specification does not specify what kind of state can be stored.

\section*{Example}

For example, some user agents might want to persist the scroll position, or the values of form controls.

\section*{Note}

User agents that persist the value of form controls are encouraged to also persist their directionality (the value of the element's dir \({ }^{p 142}\) attribute). This prevents values from being displayed incorrectly after a history traversal when the user had originally entered the values with an explicit, non-default directionality.

An entry's scroll restoration mode indicates whether the user agent should restore the persisted scroll position (if any) when traversing to it. The scroll restoration mode may be one of the following:
"auto"
The user agent is responsible for restoring the scroll position upon navigation.
"manual"
The page is responsible for restoring the scroll position and the user agent does not attempt to do so automatically
If unspecified, the scroll restoration mode \({ }^{\text {p850 }}\) of a new entry must be set to "auto \({ }^{\text {p850" }}\).
Entries that contain serialized state \({ }^{p 849}\) share the same Document \({ }^{p 114}\) as the entry for the page that was active when they were added.
Contiguous entries that differ just by their URLs' fragments also share the same Document \({ }^{\text {p114 }}\).

\section*{Note}

All entries that share the same Document \({ }^{\text {p114 }}\) (and that are therefore merely different states of one particular document) are contiguous by definition.

Each Document \({ }^{\text {p114 }}\) in a browsing context \({ }^{\text {p811 }}\) can also have a latest entry. This is the entry for that Document \({ }^{\text {p114 }}\) to which the browsing context \({ }^{\text {p811 }}\) 's session history \({ }^{\text {p849 }}\) was most recently traversed. When a Document \({ }^{\text {p114 }}\) is created, it initially has no latest entry \({ }^{\text {p850 }}\).

User agents may discard \({ }^{\mathrm{p} 831}\) the Document \({ }^{\text {p114 }}\) objects of entries other than the current entry \({ }^{\text {p850 }}\) that are not referenced from any 850
script, reloading the pages afresh when the user or script navigates back to such pages. This specification does not specify when user agents should discard Document \({ }^{\text {p114 }}\) objects and when they should cache them.

Entries that have had their Document \({ }^{\text {p114 }}\) objects discarded must, for the purposes of the algorithms given below, act as if they had not. When the user or script navigates back or forwards to a page which has no in-memory DOM objects, any other entries that shared the same Document \({ }^{\text {p114 }}\) object with it must share the new object as well.

\subsection*{7.9.3 The History \({ }^{\text {p851 }}\) interface \(\S^{\text {p85 }}\)}
```
IDL
```
```
enum ScrollRestoration { "auto", "manual" };
```
enum ScrollRestoration { "auto", "manual" };
[Exposed=Window]
[Exposed=Window]
interface History {
interface History {
    readonly attribute unsigned long length;
    readonly attribute unsigned long length;
    attribute ScrollRestoration scrollRestoration;
    attribute ScrollRestoration scrollRestoration;
    readonly attribute any state;
    readonly attribute any state;
    undefined go(optional long delta = 0);
    undefined go(optional long delta = 0);
    undefined back();
    undefined back();
    undefined forward();
    undefined forward();
    undefined pushState(any data, DOMString title, optional USVString? url = null);
    undefined pushState(any data, DOMString title, optional USVString? url = null);
    undefined replaceState(any data, DOMString title, optional USVString? url = null)
    undefined replaceState(any data, DOMString title, optional USVString? url = null)
};
```
};
```

\section*{For web developers (non-normative)}
window . history \({ }^{\text {p849 }}\) • length \({ }^{\text {p852 }}\)
Returns the number of entries in the joint session history \({ }^{\mathrm{p} 851}\).
window. history \({ }^{\text {p849 }}\). scrollRestoration \({ }^{\text {p852 }}\) [ = value ]
Returns the scroll restoration mode \({ }^{\mathrm{p8550}}\) of the current entry in the session history \({ }^{\mathrm{p849}}\).
Can be set, to change the scroll restoration mode \({ }^{\text {p850 }}\) of the current entry in the session history \({ }^{\text {p849 }}\).
window . history \({ }^{\text {p849 }}\). state \({ }^{\text {p852 }}\)
Returns the current serialized state \({ }^{\mathrm{p} 849}\), deserialized into an object.
window. history \({ }^{\text {p849 }} \cdot\) go \(^{\text {p852 }}\) ([ delta ])
Goes back or forward the specified number of steps in the joint session history \({ }^{\text {p851 }}\).
A zero delta will reload the current page.
If the delta is out of range, does nothing.
window . history \({ }^{\mathrm{p} 849} \cdot\) back \(^{\mathrm{p} 852}\) ()
Goes back one step in the joint session history \({ }^{\mathrm{p} 851}\).
If there is no previous page, does nothing.
window . history \({ }^{\text {p849 }} \cdot\) forward \(^{p 852}\) ()
Goes forward one step in the joint session history \({ }^{\text {p851 }}\).
If there is no next page, does nothing.
window . history \({ }^{\mathrm{p} 849}\). pushState \({ }^{\mathrm{p} 854}\) (data, title [, url ])
Pushes the given data onto the session history, with the given title, and, if provided and not null, the given URL.
window. history \({ }^{\text {p849 }}\) • replaceState \({ }^{\text {p854 }}\) (data, title [, url ] )
Updates the current entry in the session history to have the given data, title, and, if provided and not null, URL.

The joint session history of a top-level browsing context \({ }^{\text {p814 }}\) is the union of all the session histories \({ }^{\text {p849 }}\) of all browsing contexts \({ }^{\text {p811 }}\) of all the fully active \({ }^{\text {p815 }}\) Document \({ }^{\text {p114 }}\) objects that share that top-level browsing context \({ }^{\text {p814 }}\), with all the entries that are current entries \({ }^{\text {p850 }}\) in their respective session histories \({ }^{\text {p849 }}\) removed except for the current entry of the joint session history \({ }^{\text {p851 }}\).

The current entry of the joint session history is the entry that most recently became a current entry \({ }^{\text {p850 }}\) in its session history \({ }^{\text {p849 }}\).

Entries in the joint session history \({ }^{\text {p851 }}\) are ordered chronologically by the time they were added to their respective session histories \({ }^{\text {p849 }}\). Each entry has an index; the earliest entry has index 0 , and the subsequent entries are numbered with consecutively increasing integers (1, 2, 3, etc).

\section*{Note}

Since each Document \({ }^{p 114}\) in a browsing context \(t^{p 811}\) might have a different event loop \({ }^{p 944}\), the actual state of the joint session \(\underline{\text { history }}{ }^{p 851}\) can be somewhat nebulous. For example, two sibling iframe \({ }^{\text {p361 }}\) elements could both traverse \({ }^{\text {p881 }}\) from one unique origin to another at the same time, so their precise order might not be well-defined; similarly, since they might only find out about each other later, they might disagree about the length of the joint session history \({ }^{\text {p851 }}\).

The length attribute of the History \({ }^{\mathrm{p} 851}\) interface, on getting, must return the number of entries in the top-level browsing context \({ }^{\mathrm{p} 814}\) 's joint session history \({ }^{\text {p851 }}\). If this History \({ }^{\text {p851 }}\) object is associated with a Document \({ }^{\text {p114 }}\) that is not fully active \({ }^{\text {p815 }}\), getting must instead throw a "SecurityError" DOMException.

The actual entries are not accessible from script.
The scrollRestoration attribute of the History interface, on getting, must return the scroll restoration mode \({ }^{\text {p850 }}\) of the current entry in the session history \({ }^{\mathrm{p} 849}\). On setting, the scroll restoration mode \({ }^{\mathrm{p850}}\) of the current entry in the session history \({ }^{\text {p849 }}\) must be set to the new value. If this History \({ }^{\text {p851 }}\) object is associated with a Document \({ }^{\text {p114 }}\) that is not fully active \({ }^{\text {p815 }}\), both getting and setting must instead throw a "SecurityError" DOMException.

The state attribute of the History \({ }^{\text {p851 }}\) interface, on getting, must return the last value it was set to by the user agent. If this History \({ }^{p 851}\) object is associated with a Document \({ }^{\text {p114 }}\) that is not fully active \({ }^{\text {p815 }}\), getting must instead throw a "SecurityError" DOMException. Initially, its value must be null.

When the go(delta) method is invoked:
1. Let document be this History \({ }^{\mathrm{p} 851}\) object's associated Document \({ }^{\text {p114 }}\).
2. If document is not fully active \({ }^{\text {p815 }}\), then throw a "SecurityError" DOMException.
3. If delta is 0 , then act as if the location. \(\operatorname{reload}()^{p 863}\) method was called, and return.
4. Traverse the history by a delta \({ }^{\mathrm{p} 853}\) with delta and document's browsing context \({ }^{\mathrm{p} 811}\).

When the back() method is invoked:
1. Let document be this History \({ }^{\text {p851 }}\) object's associated Document \({ }^{\text {p114 }}\).
2. If document is not fully active \({ }^{\text {p815 }}\), then throw a "SecurityError" DOMException.
3. Traverse the history by a delta \({ }^{\mathrm{p} 853}\) with -1 and document's browsing context \({ }^{\mathrm{p} 811}\).

When the forward() method is invoked:
1. Let document be this History \({ }^{\mathrm{p} 851}\) object's associated Document \({ }^{\text {p114 }}\).
2. If document is not fully active \({ }^{\mathrm{p815}}\), then throw a "SecurityError" DOMException.
3. Traverse the history by a delta \({ }^{\mathrm{p} 853}\) with +1 and document's browsing context \({ }^{\mathrm{p} 811}\).

Each top-level browsing context \({ }^{\mathrm{p} 814}\) has a session history traversal queue, initially empty, to which tasks \({ }^{\text {p944 }}\) can be added.
Each top-level browsing context \({ }^{\text {p814 }}\), when created, must begin running the following algorithm, known as the session history event loop for that top-level browsing context \({ }^{\text {p814 }}\), in parallel \({ }^{\text {p42 }}\) :
1. Wait until this top-level browsing context \({ }^{\text {p814' }}\) 's session history traversal queue \({ }^{p 852}\) is not empty.
2. Pull the first task \({ }^{\text {p944 }}\) from this top-level browsing context \({ }^{\text {p814 }}\) ' \(s\) session history traversal queue \({ }^{\text {p852 }}\), and execute it.
3. Return to the first step of this algorithm.

The session history event loop \({ }^{\text {p852 }}\) helps coordinate cross-browsing-context transitions of the joint session history \({ }^{\text {p851 }}\) : since each browsing context \({ }^{\text {p811 }}\) might, at any particular time, have a different event loop \({ }^{\text {p944 }}\) (this can happen if the user navigates from example.com to shop. example), transitions would otherwise have to involve cross-event-loop synchronization.

To traverse the history by a delta given delta and browsing context \({ }^{\text {p811 }}\) source browsing context, the user agent must append a task \({ }^{\text {p944 }}\) to this top-level browsing context \({ }^{\text {p814 }}\) 's session history traversal queue \({ }^{\text {p852 }}\), the task \({ }^{\text {p944 }}\) consisting of running the following steps:
1. If the index of the current entry of the joint session history \({ }^{\text {p851 }}\) plus delta is less than zero or greater than or equal to the number of items in the joint session history \({ }^{\text {p851 }}\), then return.
2. Let specified entry be the entry in the joint session history \({ }^{\text {p851 }}\) whose index is the sum of delta and the index of the current entry of the joint session history \({ }^{\text {p851 }}\).
3. Let specified browsing context be the browsing context \({ }^{\text {p811 }}\) of the specified entry.
4. If source browsing context is not allowed to navigate \({ }^{\mathrm{p} 818}\) specified browsing context, then return.
5. If the specified browsing context's active document \({ }^{p 811}\) 's unload a document \({ }^{p 886}\) algorithm is currently running, return.
6. Queue a global task \({ }^{\text {p945 }}\) on the history traversal task source \({ }^{\text {p952 }}\) given specified browsing context's active window \({ }^{\text {p811 }}\) to perform the following steps:
1. If there is an ongoing attempt to navigate specified browsing context that has not yet matured \({ }^{\text {p876 }}\) (i.e. it has not passed the point of making its Document \({ }^{p 114}\) the active document \({ }^{p 811}\) ), then cancel that attempt to navigate the browsing context \({ }^{\text {p811 }}\).
2. If the specified browsing context's active document \({ }^{p 811}\) is not the same Document \({ }^{p 114}\) as the Document \({ }^{p 114}\) of the specified entry, then run these substeps:
1. Prompt to unload \({ }^{\mathrm{p} 885}\) the active document \({ }^{\mathrm{p811}}\) of the specified browsing context. If the user refused to allow the document to be unloaded \({ }^{\text {p886 }}\), then return.
2. Unload \({ }^{\mathrm{p} 886}\) the active document \({ }^{\mathrm{p} 811}\) of the specified browsing context.
3. Traverse the history \({ }^{\text {p881 }}\) of the specified browsing context to the specified entry with explicitHistoryNavigation \({ }^{p 881}\) set to true.

When the user navigates through a browsing context \({ }^{\text {p811 }}\), e.g. using a browser's back and forward buttons, the user agent must traverse the history by a delta \({ }^{\text {p853 }}\) with a delta equivalent to the action specified by the user and the browsing context being operated on.

The URL and history update steps, given a Document \({ }^{\text {p114 }}\) object document, a URL newURL, an optional serialized state \({ }^{\mathrm{p849}}\) serializedData, and an optional string title, optionally with a state push flag, are:
1. Let browsingContext be document's browsing context \({ }^{\mathrm{p} 811}\).
2. If the state push flag is set, then:
1. Remove all the entries in browsingContext's session history \({ }^{\mathrm{p} 849}\) after the current entry \({ }^{\mathrm{p} 850}\). If the current entry \({ }^{\mathrm{p} 850}\) is the last entry in the session history, then no entries are removed.

\section*{Note}

This doesn't necessarily have to affect \({ }^{p 856}\) the user agent's user interface.
2. Remove any tasks \({ }^{\text {p944 }}\) queued by the history traversal task source \({ }^{\text {p952 }}\) that are associated with any Document \({ }^{\text {p114 }}\) objects in the top-level browsing context \({ }^{p 814}\) 's document family \({ }^{\text {p815 }}\).
3. If appropriate, update the current entry \({ }^{\text {p850 }}\) to reflect any state that the user agent wishes to persist. The entry is then said to be an entry with persisted user state \({ }^{\text {p850 }}\).
4. Add a session history entry \({ }^{\mathrm{p} 849}\) entry to the session history, after the current entry \({ }^{\mathrm{p850}}\), with
- newURL as the URL;
- the scroll restoration mode \({ }^{\mathrm{p} 850}\) of the current entry in the session history \({ }^{\mathrm{p} 849}\) as the scroll restoration mode;
- serializedData as the serialized state \({ }^{\mathrm{p} 849}\), if it is given;
- title as the title, if it is given.
5. Update the current entry \({ }^{\text {p850 }}\) to be this newly added entry.
3. Otherwise, update the current entry \({ }^{\mathrm{p} 850}\) in browsingContext's session history \({ }^{\mathrm{p} 849}\) so that:
- newURL is the entry's new URL;
- serializedData is the entry's new serialized state \({ }^{\text {p849 }}\), if it is given; otherwise, the current entry \({ }^{\text {p850 ' } s ~ c u r r e n t ~}\) serialized state \({ }^{\text {p849 }}\) is kept;
- title is the entry's new title, if it is given; otherwise, the entry does not have a title;
- it represents a GET request, if it currently represents a non-GET request (e.g. it was the result of a POST submission).
4. Set document's URL to newURL.

\section*{Note}

Since this is neither a navigation \({ }^{p 866}\) of the browsing context \({ }^{p 811}\) nor a history traversal \({ }^{p 881}\), it does not cause a hashchange \({ }^{\text {p1281 }}\) event to be fired.

The pushState(data, title, url) method adds a state object entry to the history.
The replaceState(data, title, url) method updates the state object, title, and optionally the URL of the current entry \({ }^{\text {p850 }}\) in the history.

When either of these methods is invoked, the user agent must run the following steps:
1. Let document be the unique Document \({ }^{\text {p114 }}\) object this History \({ }^{\mathrm{p} 851}\) object is associated with.
2. If document is not fully active \({ }^{\text {p815 }}\), throw a "SecurityError" DOMException.
3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)
4. Let targetRealm be this History \({ }^{p 851}\) object's relevant Realm \({ }^{\text {p924 }}\).
5. Let serializedData be StructuredSerializeForStorage \({ }^{\mathrm{p} 108}\) (data). Rethrow any exceptions.
6. Let newURL be the URL of the current entry \({ }^{\mathrm{p} 850}\) in browsingContext's session history \({ }^{\mathrm{p} 849}\).
7. If \(u r l\) is not null, then:
1. Parse \({ }^{\mathrm{p} 89}\) url, relative to the relevant settings object \({ }^{\mathrm{p924}}\) of this History \({ }^{\mathrm{p} 851}\) object.
2. If that fails, then throw a "SecurityError" DOMException.
3. Set newURL to the resulting URL record \({ }^{\text {p89 }}\).
4. Compare newURL to document's URL. If any component of these two URL records differ other than the path, query, and fragment components, then throw a "SecurityError" DOMException.
5. If the origin of newURL is not same origin \({ }^{p 838}\) with the origin \({ }^{p 837}\) of document, and either the path or query components of the two URL records compared in the previous step differ, throw a "SecurityError" DOMException. (This prevents sandboxed content from spoofing other pages on the same origin.)
8. Run the URL and history update steps \({ }^{\text {p853 }}\) given document, newURL, serializedData, and title, with the state push flag set if the method invoked was the pushState( () \({ }^{\text {p854 }}\) method.
9. Let state be StructuredDeserialize \({ }^{\text {p108 }}\) (serializedData, targetRealm). If this throws an exception, catch it, ignore the exception, and set state to null.
10. Set history. state \({ }^{\mathrm{p} 852}\) to state.
11. Set the current entry \({ }^{\mathrm{p} 850} \mathrm{~s}\) Document \({ }^{\mathrm{p} 114}\) object's latest entry \({ }^{\mathrm{p} 850}\) to the current entry \({ }^{\mathrm{p} 850}\).

\section*{Note}

The title is purely advisory. User agents might use the title in the user interface.

User agents may limit the number of state objects added to the session history per page. If a page hits the implementation-defined limit, user agents must remove the entry immediately after the first entry for that Document \({ }^{p 114}\) object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

\section*{Example}

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the \(x=5\) position in such a game could look like the following:
```
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate 5 on the line.</p>
<p>
    <a href="?x=6">Advance to 6</a> or
    <a href="?x=4">retreat to 4</a>?
</p>
```

The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:
```
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<p>
    <a href="?x=6" onclick="go(1); return false;">Advance to 6</a> or
    <a href="?x=4" onclick="go(-1); return false;">retreat to 4</a>?
</p>
<script>
    var currentPage = 5; // prefilled by server
    function go(d) {
        setupPage(currentPage + d);
        history.pushState(currentPage, document.title, '?x=' + currentPage);
}
    onpopstate = function(event) {
        setupPage(event.state);
}
    function setupPage(page) {
        currentPage = page;
        document.title = 'Line Game - ' + currentPage;
        document.getElementById('coord').textContent = currentPage;
        document.links[0].href = '?x=' + (currentPage+1);
        document.links[0].textContent = 'Advance to ' + (currentPage+1);
        document.links[1].href = '?x=' + (currentPage-1);
        document.links[1].textContent = 'retreat to ' + (currentPage-1);
}
</script>
```

In systems without script, this still works like the previous example. However, users that do have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the data argument to the pushState() \({ }^{\text {p854 }}\) method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn't have to parse the URL each time the user navigates.

Applications might not use the same title for a session history entry \({ }^{\mathrm{p849}}\) as the value of the document's title \({ }^{p 154}\) element at that time. For example, here is a simple page that shows a block in the title \({ }^{p 154}\) element. Clearly, when navigating backwards to a previous state the user does not go back in time, and therefore it would be inappropriate to put the time in the session history title.
```
<!DOCTYPE HTML>
<HTML LANG=EN>
<TITLE>Line</TITLE>
<SCRIPT>
    setInterval(function () { document.title = 'Line - ' + new Date(); }, 1000);
    var i = 1;
    function inc() {
        set(i+1);
        history.pushState(i, 'Line - ' + i);
    }
    function set(newI) {
        i = newI;
        document.forms.F.I.value = newI;
    }
</SCRIPT>
<BODY ONPOPSTATE="set(event.state)">
<FORM NAME=F>
State: <OUTPUT NAME=I>1</OUTPUT> <INPUT VALUE="Increment" TYPE=BUTTON ONCLICK="inc()">
</FORM>
```

\section*{Example}

Most applications want to use the same scroll restoration mode \({ }^{\text {p850 }}\) value for all of their history entries. To achieve this they can set the scrollRestoration \({ }^{\text {p852 }}\) attribute as soon as possible (e.g., in the first script \({ }^{\text {p614 }}\) element in the document's head \({ }^{\text {p153 }}\) element) to ensure that any entry added to the history session gets the desired scroll restoration mode.
```
<head>
    <script>
        if ('scrollRestoration' in history)
            history.scrollRestoration = 'manual';
    </script>
</head>
```

\section*{}

This section is non-normative.
The History \({ }^{p 851}\) interface is not meant to place restrictions on how implementations represent the session history to the user.
For example, session history could be implemented in a tree-like manner, with each page having multiple "forward" pages. This specification doesn't define how the linear list of pages in the history \({ }^{\mathrm{p} 499}\) object are derived from the actual session history as seen from the user's perspective.

Similarly, a page containing two iframe \({ }^{p 361}\) s has a history \({ }^{p 849}\) object distinct from the iframe \({ }^{p 361} s^{\prime}\) history \({ }^{p 849}\) objects, despite the fact that typical web browsers present the user with just one "Back" button, with a session history that interleaves the navigation of the two inner frames and the outer page.

Security: It is suggested that to avoid letting a page "hijack" the history navigation facilities of a UA by abusing pushState() \({ }^{\text {p854 }}\), the UA provide the user with a way to jump back to the previous page (rather than just going back to the previous state). For example, the back button could have a drop down showing just the pages in the session history, and not showing any of the states. Similarly, an aural browser could have two "back" commands, one that goes back to the previous state, and one that jumps straight back to the previous page.

For both pushState( ) \({ }^{\text {p854 }}\) and replaceState( \()^{\text {p854 }}\), user agents are encouraged to prevent abuse of these APIs via too-frequent calls or 856
over-large state objects. As detailed above, the algorithm explicitly allows user agents to ignore any such calls when appropriate.

\subsection*{7.9.5 The Location \({ }^{\text {p857 }}\) interface \(\S^{\text {p85 }}\)}

Each Window \({ }^{p 824}\) object is associated with a unique instance of a Location \({ }^{p 857}\) object, allocated when the Window \({ }^{p 824}\) object is created.

\section*{\(\triangle\) Warning!}

The Location \({ }^{\text {p857 }}\) exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods postcreation, and overridden JavaScript internal methods. Coupled with its scary security policy, please take extra care while implementing this excrescence.

To create a Location \({ }^{\text {p857 }}\) object, run these steps:
1. Let location be a new Location \({ }^{\text {p857 }}\) platform object.
2. Let valueOf be location's relevant Realm \({ }^{\text {p924. }}\).[[Intrinsics]].[[\%Object.prototype.valueOf\%]].
3. Perform ! location.[[DefineOwnProperty]]("value0f", \{ [[Value]]: valueOf, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false \}).
4. Perform!location.[[DefineOwnProperty]](@@toPrimitive \({ }^{\text {p54 }}\), \{ [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false \}).
5. Set the value of the [[DefaultProperties \(]]^{\text {p863 }}\) internal slot of location to location.[[OwnPropertyKeys]]().
6. Return location.

\section*{Note}

The addition of value0f and @@toPrimitive \({ }^{\text {p54 }}\) own data properties, as well as the fact that all of Location \({ }^{\text {p857' }}\) 's IDL attributes are marked [LegacyUnforgeable], is required by legacy code that consulted the Location \({ }^{\text {p857 }}\) interface, or stringified it, to determine the document URL, and then used it in a security-sensitive way. In particular, the value0f, @@toPrimitive \({ }^{\text {p54 }}\), and [LegacyUnforgeable] stringifier mitigations ensure that code such as foo[location] = bar or location + "" cannot be misdirected.

\section*{For web developers (non-normative)}
document . location \({ }^{\text {p857 }}\) [ = value ]
window . location \({ }^{\text {p857 }}\) [ = value ]
Returns a Location \({ }^{\text {p857 }}\) object with the current page's location.
Can be set, to navigate to another page.

The Document \({ }^{\text {p114 }}\) object's location attribute's getter must return this Document \({ }^{\text {p114 }}\) object's relevant global object \({ }^{\text {p924 }}\) 's Location \({ }^{\text {p857 }}\) object, if this Document \({ }^{\text {p114 }}\) object is fully active \({ }^{\mathrm{p} 815}\), and null otherwise.

The Window \({ }^{\text {p824 }}\) object's location attribute's getter must return this Window \({ }^{\text {p824 }}\) object's Location \({ }^{\text {p857 }}\) object.
Location \({ }^{\text {p857 }}\) objects provide a representation of the URL of the active document \({ }^{\text {p811 }}\) of their Document \({ }^{\text {p114' }} \mathbf{s} \underline{\text { browsing context }^{\mathrm{p} 811}}\), and allow the current entry \({ }^{\text {p850 }}\) of the browsing context \({ }^{\text {p811' }}\) 's session history to be changed, by adding or replacing entries in the history \({ }^{\text {p849 }}\) object.

IDL
```
[Exposed=Window]
interface Location { // but see also additional creation steps and overridden internal methods
    [LegacyUnforgeable] stringifier attribute USVString href;
    [LegacyUnforgeable] readonly attribute USVString origin;
    [LegacyUnforgeable] attribute USVString protocol;
    [LegacyUnforgeable] attribute USVString host;
    [LegacyUnforgeable] attribute USVString hostname;
    [LegacyUnforgeable] attribute USVString port;
    [LegacyUnforgeable] attribute USVString pathname;
```
```
    [LegacyUnforgeable] attribute USVString search;
[LegacyUnforgeable] attribute USVString hash;
[LegacyUnforgeable] undefined assign(USVString url);
[LegacyUnforgeable] undefined replace(USVString url);
[LegacyUnforgeable] undefined reload();
[LegacyUnforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
};
```

\section*{For web developers (non-normative)}

\section*{location . toString()}
location. href \({ }^{\text {p859 }}\)
Returns the Location \({ }^{\text {p857 }}\) object's URL.
Can be set, to navigate to the given URL.

\section*{location . origin \({ }^{\text {p859 }}\)}

Returns the Location \({ }^{\text {p857 }}\) object's URL's origin.
location . protocol \({ }^{\text {p860 }}\)
Returns the Location \({ }^{\text {p857 }}\) object's URL's scheme.
Can be set, to navigate to the same URL with a changed scheme.

\section*{location . host \({ }^{\text {p860 }}\)}

Returns the Location \({ }^{\text {p857 }}\) object's URL's host and port (if different from the default port for the scheme).
Can be set, to navigate to the same URL with a changed host and port.

\section*{location . hostname \({ }^{\text {p860 }}\)}

Returns the Location \({ }^{\text {p857 }}\) object's URL's host.
Can be set, to navigate to the same URL with a changed host.

\section*{location . port \({ }^{\text {p861 }}\)}

Returns the Location \({ }^{\text {p857 }}\) object's URL's port.
Can be set, to navigate to the same URL with a changed port.
location . pathname \({ }^{\text {p861 }}\)
Returns the Location \({ }^{\text {p857 }}\) object's URL's path.
Can be set, to navigate to the same URL with a changed path.
location. search \({ }^{\text {p862 }}\)
Returns the Location \({ }^{\text {p857 }}\) object's URL's query (includes leading "?" if non-empty).
Can be set, to navigate to the same URL with a changed query (ignores leading "?").
location . hash \({ }^{\text {p862 }}\)
Returns the Location \({ }^{\text {p857 }}\) object's URL's fragment (includes leading "\#" if non-empty).
Can be set, to navigate to the same URL with a changed fragment (ignores leading "\#").
location . assign \({ }^{\text {p862 }}\) (url)
Navigates to the given URL.
location . replace \({ }^{\text {p863 }}\) (url)
Removes the current page from the session history and navigates to the given URL.

\section*{location . reload \({ }^{\text {p863 }}\) ()}

Reloads the current page.
location . ancestor0rigins \({ }^{\text {p863 }}\)
Returns a DOMStringList \({ }^{\text {p101 }}\) object listing the origins of the ancestor browsing contexts \({ }^{\text {p811 }}\), from the parent browsing context \({ }^{\mathrm{p} 814}\) to the top-level browsing context \({ }^{\mathrm{p} 814}\).

A Location \({ }^{\text {p857 }}\) object has an associated relevant Document, which is this Location \({ }^{\text {p857 }}\) object's relevant global object \({ }^{\text {p924 }}\) 's browsing
context \({ }^{\text {p826 }}\) 's active document \({ }^{\text {p811 }}\), if this Location \({ }^{\text {p857 }}\) object's relevant global object \({ }^{\text {p924 }}\) 's browsing context \({ }^{\text {p826 }}\) is non-null, and null otherwise.

A Location \({ }^{\text {p857 }}\) object has an associated url, which is this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858' }} \mathbf{s} \underline{U R L}\), if this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\mathrm{p} 858}\) is non-null, and about:blank \({ }^{\mathrm{p51}}\) otherwise.

A Location \({ }^{\text {p857 }}\) object has an associated ancestor origins list. When a Location \({ }^{\text {p857 }}\) object is created, its ancestor origins list \({ }^{8859}\) must be set to a DOMStringList \({ }^{\text {p101 }}\) object whose associated list is the list of strings that the following steps would produce:
1. Let output be a new list of strings.
2. Let current be the browsing context \({ }^{\mathrm{p811}}\) of the Document \({ }^{\mathrm{p114}}\) with which this Location \({ }^{\mathrm{p857}}\) object is associated.
3. Loop: If current has no parent browsing context \({ }^{\text {p814 }}\), jump to the step labeled end.
4. Let current be current's parent browsing context \({ }^{\mathrm{p} 814}\).
5. Append the serialization \({ }^{\text {p838 }}\) of current's active document \({ }^{\mathrm{p} 811}\) 's origin \({ }^{\mathrm{p} 837}\) to output.
6. Return to the step labeled loop.
7. End: Return output.

A Location \({ }^{\text {p857 }}\) object has an associated Location-object-setter navigate algorithm, which given a url, runs these steps:
1. Let historyHandling be "replace \({ }^{\text {p866" }}\).
2. If any of the following conditions are met, then set historyHandling to "default \({ }^{\mathrm{p8666}}\) ":
- This Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) has completely loaded \({ }^{\text {p885 }}\), or
- In the task \({ }^{9944}\) in which the algorithm is running, an activation behavior is currently being processed whose click event's isTrusted attribute is true, or
- In the task \({ }^{\text {p944 }}\) in which the algorithm is running, the event listener for a click event, whose isTrusted attribute is true, is being handled.
3. Location-object navigate \({ }^{\mathrm{p} 859}\), given url and historyHandling.

To Location-object navigate, given a url and historyHandling:
1. Let browsingContext be the current global object \({ }^{\mathrm{p} 924}\) 's browsing context \({ }^{\mathrm{p} 826}\).
2. Let sourceBrowsingContext be the incumbent global object \({ }^{\text {p922 }}\) 's browsing context \({ }^{\text {p826 }}\).
3. If browsingContext's session history \({ }^{\text {p849 }}\) contains only one Document \({ }^{p 114}\), and that was the about:blank \({ }^{p 51}\) Document \(^{p 114}\) created when the browsing context \({ }^{\text {p811 }}\) was created, then set historyHandling to "replace \({ }^{\text {p866" }}\).
4. Navigate \({ }^{p 866}\) browsingContext to url, with exceptionsEnabled \({ }^{p 866}\) set to true, historyHandling \({ }^{p 866}\) set to historyHandling, and the source browsing context \({ }^{\text {p866 }}\) set to sourceBrowsingContext.

The href attribute's getter must run these steps:
1. If this Location \({ }^{p 857}\) object's relevant Document \({ }^{p 858}\) is non-null and its origin \({ }^{p 837}\) is not same origin-domain \({ }^{p 838}\) with the entry settings object \({ }^{\text {p921 's }}\) origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. Return this Location \({ }^{p 857}\) object's url \({ }^{p 859}\), serialized.

The href \({ }^{\mathrm{p859}}\) attribute's setter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. Parse \({ }^{\mathrm{p} 89}\) the given value relative to the entry settings object \({ }^{\mathrm{p921}}\). If that failed, throw a TypeError exception.
3. Location-object-setter navigate \({ }^{\mathrm{p} 859}\) given the resulting URL record \({ }^{\mathrm{p89}}\).

\section*{Note}

The href \({ }^{p 859}\) attribute setter intentionally has no security check.

The origin attribute's getter must run these steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\mathrm{p} 858}\) is non-null and its origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. Return the serialization \({ }^{p 838}\) of this Location \({ }^{p 857}\) object's url \({ }^{p 859}\) 's origin.

The protocol attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is non-null and its origin \({ }^{\text {p837 }}\) is not same origin-domain \({ }^{\text {p838 }}\) with the entry settings object \({ }^{\text {p921 ' 's origin }}{ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. Return this Location \({ }^{\mathrm{p} 857}\) object's url \({ }^{\mathrm{p859}}\) 's scheme, followed by ": ".

The protocol \({ }^{\text {p860 }}\) attribute's setter must run these steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) 's origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p} 838}\) with the entry settings object \({ }^{\text {p921 ' }} \mathrm{s}\) origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's ur| \({ }^{p 859}\).
4. Let possibleFailure be the result of basic URL parsing the given value, followed by ":", with copyURL as url and scheme start state as state override.

\section*{Note}

Because the URL parser ignores multiple consecutive colons, providing a value of "https:" (or even "https: :: :") is the same as providing a value of "https".
5. If possibleFailure is failure, then throw a "SyntaxError" DOMException.
6. If copyURL's scheme is not an HTTP(S) scheme, then terminate these steps.
7. Location-object-setter navigate \({ }^{\mathrm{p} 859}\) to copyURL.

The host attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is non-null and its origin \({ }^{p 837}\) is not same origin-domain \({ }^{\text {p838 }}\) with the entry settings object \({ }^{\text {p921 's }}\) sorigin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. Let \(u r l\) be this Location \({ }^{p 857}\) object's url \({ }^{p 859}\).
3. If url's host is null, return the empty string.
4. If url's port is null, return url's host, serialized.
5. Return url's host, serialized, followed by " : " and url's port, serialized.

The host \({ }^{\text {p860 }}\) attribute's setter must run these steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\mathrm{p} 858}\) is null, then return.
2. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\mathrm{p858}}\) 's origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p} 838}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's \(\underline{u r l^{1859}}\).
4. If copyURL's cannot-be-a-base-URL flag is set, terminate these steps.
5. Basic URL parse the given value, with copyURL as url and host state as state override.
6. Location-object-setter navigate \({ }^{\mathrm{p} 859}\) to copyURL.

The hostname attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is non-null and its origin \({ }^{\text {p837 }}\) is not same origin-domain \({ }^{\text {p838 }}\) with the entry settings object \({ }^{\text {p921 's }}\) origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. If this Location \({ }^{\mathrm{p} 857}\) object's url \({ }^{\mathrm{p} 859}\) 's host is null, return the empty string.

The hostname \({ }^{\text {p860 }}\) attribute's setter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) 's origin \({ }^{\mathrm{p} 837}\) is not same origin-domain \({ }^{\mathrm{p} 838}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's uri \({ }^{1859}\).
4. If copyURL's cannot-be-a-base-URL flag is set, terminate these steps.
5. Basic URL parse the given value, with copyURL as url and hostname state as state override.
6. Location-object-setter navigate \({ }^{\text {p859 }}\) to copyURL.

The port attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\mathrm{p858}}\) is non-null and its origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. If this Location \({ }^{p 857}\) object's url \({ }^{\text {p859's }} \mathrm{s}\) port is null, return the empty string.
3. Return this Location \({ }^{\text {p857 }}\) object's url \({ }^{1859}\) 's port, serialized.

The port \({ }^{\text {p861 }}\) attribute's setter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) 's origin \({ }^{\mathrm{p} 837}\) is not same origin-domain \({ }^{\mathrm{p} 838}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's ur| \({ }^{p 859}\).
4. If copyURL cannot have a username/password/port, then return.
5. If the given value is the empty string, then set copyURL's port to null.
6. Otherwise, basic URL parse the given value, with copyURL as url and port state as state override.
7. Location-object-setter navigate \({ }^{\text {p859 }}\) to copyURL.

The pathname attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\mathrm{p858}}\) is non-null and its origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. Let \(u r l\) be this Location \({ }^{p 857}\) object's url \({ }^{1859}\).
3. If url's cannot-be-a-base-URL flag is set, return the first string in url's path.
4. If url's path is empty, then return the empty string.
5. Return "/", followed by the strings in url's path (including empty strings), separated from each other by "/".

The pathname \({ }^{\text {p861 }}\) attribute's setter must run these steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\mathrm{p} 858}\) is null, then return.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) 's origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's ur| \({ }^{p 859}\).
4. If copyURL's cannot-be-a-base-URL flag is set, terminate these steps.
5. Set copyURL's path to the empty list.
6. Basic URL parse the given value, with copyURL as url and path start state as state override.
7. Location-object-setter navigate \({ }^{\text {p859 }}\) to copyURL.

The search attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is non-null and its origin \({ }^{\text {p837 }}\) is not same origin-domain \({ }^{\text {p838 }}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. If this Location \({ }^{\mathrm{p} 857}\) object's url \({ }^{\text {p859' }} \mathrm{s}\) query is either null or the empty string, return the empty string.
3. Return "?", followed by this Location \({ }^{\text {p857 }}\) object's ur| \({ }^{p 859}\) 's query.

The search \({ }^{\text {p862 }}\) attribute's setter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) ' s origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's ur| \({ }^{p 859}\).
4. If the given value is the empty string, set copyURL's query to null.
5. Otherwise, run these substeps:
1. Let input be the given value with a single leading "?" removed, if any.
2. Set copyURL's query to the empty string.
3. Basic URL parse input, with copyURL as url and query state as state override, and the relevant Document \({ }^{\mathrm{p} 558}\) 's document's character encoding as encoding override.
6. Location-object-setter navigate \({ }^{\mathrm{p859}}\) to copyURL.

The hash attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{p 858}\) is non-null and its origin \({ }^{p 837}\) is not same origin-domain \({ }^{p 838}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
2. If this Location \({ }^{p 857}\) object's url \({ }^{p 859}\) 's fragment is either null or the empty string, return the empty string.
3. Return "\#", followed by this Location \({ }^{\text {p857 }}\) object's url \({ }^{p 859}\) 's fragment.

The hash \({ }^{\mathrm{p} 862}\) attribute's setter must run these steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\mathrm{p858}}\) ' s origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Let copyURL be a copy of this Location \({ }^{\text {p857 }}\) object's ur| \({ }^{p 859}\).
4. Let input be the given value with a single leading "\#" removed, if any.
5. Set copyURL's fragment to the empty string.
6. Basic URL parse input, with copyURL as url and fragment state as state override.
7. Location-object-setter navigate \({ }^{\mathrm{p} 859}\) to copyURL.

\section*{Note}

Unlike the equivalent API for the \(a^{p 238}\) and area \({ }^{p 443}\) elements, the hash \({ }^{p 862}\) attribute's setter does not special case the empty string to remain compatible with deployed scripts.

When the assign(url) method is invoked, the user agent must run the following steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) 's origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p} 838}\) with the entry settings
object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Parse \({ }^{\text {p89 }} u r /\) relative to the entry settings object \({ }^{\text {p921 }}\). If that failed, throw a "SyntaxError" DOMException.
4. Location-object navigate \({ }^{\text {p859 }}\) given the resulting URL record \({ }^{p 89}\) and "default \({ }^{\mathrm{p} 866 \text { ". }}\)

When the replace (url) method is invoked, the user agent must run the following steps:
1. If this Location \({ }^{\mathrm{p} 857}\) object's relevant Document \({ }^{\mathrm{p} 858}\) is null, then return.
2. Parse \({ }^{\text {p89 }}\) url relative to the entry settings object \({ }^{\text {p921 }}\). If that failed, throw a "SyntaxError" DOMException.
3. Location-object navigate \({ }^{\text {p859 }}\) given the resulting URL record \({ }^{\text {p89 }}\) and "replace \({ }^{\text {p866" }}\).

\section*{Note}

The replace() \({ }^{\text {p863 }}\) method intentionally has no security check.

When the reload () method is invoked, the user agent must run the appropriate steps from the following list:
\(\hookrightarrow\) If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is null Return.
\(\hookrightarrow\) If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858's }}\) origin \({ }^{\text {p837 }}\) is not same origin-domain \({ }^{\text {p838 }}\) with the entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\)

Throw a "SecurityError" DOMException.
\(\rightarrow\) If the currently executing task \({ }^{\text {p944 }}\) is the dispatch of a resize event in response to the user resizing the browsing context \({ }^{\text {p811 }}\)

Repaint the browsing context \({ }^{\text {p811 }}\) and return.
\(\rightarrow\) If the browsing context \({ }^{\text {p811 }}\) 's active document \({ }^{\text {p811 }}\) is an iframe srcdoc document \({ }^{\text {p362 }}\) Reprocess the iframe attributes \({ }^{\mathrm{p} 363}\) of the browsing context \({ }^{\mathrm{p} 811}\) 's container \({ }^{\mathrm{p} 814}\).

\section*{\(\leftrightarrow\) Otherwise}

Navigate \({ }^{\text {p866 }}\) the browsing context \({ }^{\text {p811 }}\) to this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 ' }}\) URL, with exceptionsEnabled \({ }^{\text {p866 }}\) set to true, historyHandling \({ }^{p 866}\) set to "reload \({ }^{\text {p866" }}\), and the source browsing context \({ }^{\text {p866 }}\) set to the browsing context \({ }^{\text {p811 }}\) being navigated.

When a user requests that the active document \({ }^{\text {p811 }}\) of a browsing context \({ }^{p 811}\) be reloaded through a user interface element, the user agent should navigate \({ }^{\text {p866 }}\) the browsing context \({ }^{\text {p811 }}\) to the same resource as that Document \({ }^{\text {p114 }}\), with historyHandling \({ }^{\text {p866 }}\) set to "reload \({ }^{8866}\) ". In the case of non-idempotent methods (e.g., HTTP POST), the user agent should prompt the user to confirm the operation first, since otherwise transactions (e.g., purchases or database modifications) could be repeated. User agents may allow the user to explicitly override any caches when reloading.

The ancestor0rigins attribute's getter must run these steps:
1. If this Location \({ }^{\text {p857 }}\) object's relevant Document \({ }^{\text {p858 }}\) is null, then return an empty list.
2. If this Location \({ }^{\mathrm{p857}}\) object's relevant Document \({ }^{\mathrm{p858}}\) ' s origin \({ }^{\mathrm{p837}}\) is not same origin-domain \({ }^{\mathrm{p838}}\) with the entry settings object \({ }^{\text {p921 's }}\) origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
3. Otherwise, return this Location \({ }^{\mathrm{p} 857}\) object's ancestor origins list \({ }^{\mathrm{p} 859}\).

\section*{\(\triangle\) Warning!}

The details of how the ancestor0rigins \({ }^{p 863}\) attribute works are still controversial and might change. See issue \#1918 for more information.

As explained earlier, the Location \({ }^{\text {p857 }}\) exotic object requires additional logic beyond IDL for security purposes. The Location \({ }^{\text {p857 }}\) object must use the ordinary internal methods except where it is explicitly specified otherwise below.

Also, every Location \({ }^{\text {p857 }}\) object has a [[DefaultProperties]] internal slot representing its own properties at time of its creation.

\subsection*{7.9.5.1 [[GetPrototypeOf]] ( ) \(\$^{\text {p86 }}\)}
1. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (this) is true, then return! OrdinaryGetPrototypeOf(this).
2. Return null.

\subsection*{7.9.5.2 [[SetPrototypeOf]] (V) \({ }_{4}^{\text {p86 }}\)}
1. Return! SetImmutablePrototype(this, \(V\) ).

\subsection*{7.9.5.3 [[IsExtensible]] ( ) \({ }^{\text {p86 }}\)}
1. Return true.

\subsection*{7.9.5.4 [[PreventExtensions]] ( ) \(\S_{4}^{\text {p86 }}\)}
1. Return false.

\subsection*{7.9.5.5 [[GetOwnProperty]] (P ) \(\S^{p 86}\)}
1. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (this) is true, then:
1. Let desc be! OrdinaryGetOwnProperty(this, \(P\) ).
2. If the value of the [[DefaultProperties]] \({ }^{\text {p863 }}\) internal slot of this contains \(P\), then set desc.[[Configurable]] to true.
3. Return desc.
2. Let property be! CrossOriginGetOwnPropertyHelper \({ }^{\text {p823 }}\) (this, \(P\) ).
3. If property is not undefined, then return property.
4. Return ? CrossOriginPropertyFallback \({ }^{\text {p822 }}(P)\).

\subsection*{7.9.5.6 [[DefineOwnProperty]] ( P, Desc ) \(\S_{4}^{\text {p86 }}\)}
1. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (this) is true, then:
1. If the value of the [[DefaultProperties]] \({ }^{\text {p863 }}\) internal slot of this contains \(P\), then return false.
2. Return ? OrdinaryDefineOwnProperty(this, P, Desc).
2. Throw a "SecurityError" DOMException.

\subsection*{7.9.5.7 [[Get]] ( P, Receiver) ) \({ }_{4}^{\text {p86 }}\)}
1. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (this) is true, then return ? OrdinaryGet(this, \(P\), Receiver).
2. Return ? CrossOriginGet \({ }^{\mathrm{p} 824}\) (this, \(P\), Receiver).
7.9.5.8 [[Set]] ( P, V, Receiver) \(\AA_{5}^{\text {p86 }}\)
1. If! IsPlatformObjectSameOrigin \({ }^{\mathrm{p} 822}\) (this) is true, then return ? OrdinarySet(this, \(P\), Receiver).
2. Return ? CrossOriginSet \({ }^{\mathrm{p} 824}\) (this, \(P, V\), Receiver).

\subsection*{7.9.5.9 [[Delete]] ( P ) \({ }^{\text {p86 }}\)}
1. If! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (this) is true, then return ? OrdinaryDelete(this, \(P\) ).
2. Throw a "SecurityError" DOMException.

\subsection*{7.9.5.10 [[OwnPropertyKeys]] () § § \(^{p 86}\)}
1. If ! IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\) (this) is true, then return! OrdinaryOwnPropertyKeys(this).
2. Return! CrossOriginOwnPropertyKeys \({ }^{\text {p824 }}\) (this).

\subsection*{7.10 Browsing the web \(\S_{5}^{886}\)}

\subsection*{7.10.1 Navigating across documents \(\S^{p 86}\)}

Certain actions cause the browsing context \({ }^{p 811}\) to navigate \({ }^{p 866}\) to a new resource. A user agent may provide various ways for the user to explicitly cause a browsing context to navigate, in addition to those defined in this specification.

\section*{Example}

For example, following a hyperlink \({ }^{\text {p290 }}\), form submission \({ }^{\text {p596 }}\), and the window. open( () \({ }^{\text {p827 }}\) and location. assign( \()^{\text {p862 }}\) methods can all cause a browsing context to navigate.

\section*{Note}

A resource has a URL, but that might not be the only information necessary to identify it. For example, a form submission that uses HTTP POST would also have the HTTP method and payload. Similarly, an iframe srcdoc document \({ }^{p 362}\) needs to know the data it is to use.

Much of the navigation process is concerned with determining how to create a new Document \({ }^{p 114}\), which ultimately happens in the create and initialize a Document object \({ }^{\text {p873 }}\) algorithm. The parameters to this algorithm are tracked via a navigation params struct, which has the following items:

\section*{request}
null or a request that started the navigation

\section*{response}
a response that ultimately was navigated to (potentially a network error)

\section*{origin}
an origin \({ }^{\text {p837 }}\) to use for the new Document \({ }^{\text {p114 }}\)
final sandboxing flag set
a sandboxing flag set \({ }^{\text {p842 }}\) to impose on the new Document \({ }^{\text {p114 }}\)

\section*{cross-origin opener policy}
a cross-origin opener policy \({ }^{\text {p844 }}\) to use for the new Document \({ }^{p 114}\)

\section*{reserved environment}
null or an environment \({ }^{\text {p916 }}\) reserved for the new Document \({ }^{\text {p114 }}\)

\section*{browsing context}
the browsing context \({ }^{\text {p811 }}\) to be navigated (but see below)

\section*{browsing context switch needed}
a boolean indicating whether or not the navigation should conclude by discarding \({ }^{\text {p831 }}\) the given browsing context \({ }^{\text {p866 }}\) and creating a new one

\section*{history handling}
a history handling behavior \({ }^{\text {p866 }}\)

\section*{Note}

Once a navigation params \({ }^{\text {p865 }}\) struct is created, this standard does not mutate any of its items. They are only passed onward to other algorithms.

After Document \({ }^{\text {p114 }}\) creation, the session history \({ }^{\text {p849 }}\) gets updated. A history handling behavior is used to track the desired type of session history update throughout the navigation process. It is one of the following:
"default"
A regular navigation which adds a new entry to the session history.
"entry update"
A navigation to an existing session history entry \({ }^{\text {p849 }}\) to recreate that entry's Document \({ }^{p 114}\), which was previously discarded \({ }^{p 831}\).
"reload"
A navigation intended to reload the current page and replace the current session history entry \({ }^{\mathrm{p} 850}\).
"replace"
A non-reload navigation that will replace the current session history entry \({ }^{\text {p850 }}\).
Navigation always involves source browsing context, which is the browsing context which was responsible for starting the navigation.

As explained in issue \#1130 the use of a browsing context as source might not be the correct architecture.

To navigate a browsing context browsingContext to a resource resource, with an optional boolean exceptionsEnabled (default false) and an optional history handling behavior \({ }^{p 866}\) historyHandling (default "default \({ }^{\text {p866" }}\) ):
1. If resource is a URL, then set resource to a new request whose url is resource.
2. If resource is a request and historyHandling is "reload \({ }^{\mathrm{p866}}\) ", then set resource's reload-navigation flag.
3. If the source browsing context \({ }^{\text {p866 }}\) is not allowed to navigate \({ }^{\text {p818 }}\) browsingContext, then:
1. If exceptionsEnabled is given and is true, then throw a "SecurityError" DOMException.
2. Otherwise, the user agent may instead offer to open resource in a new top-level browsing context \({ }^{\text {p814 }}\) or in the toplevel browsing context \({ }^{\text {p814 }}\) of the source browsing context \({ }^{8866}\), at the user's option, in which case the user agent must navigate \({ }^{\text {p866 }}\) that designated top-level browsing context \({ }^{\text {p814 }}\) to resource as if the user had requested it independently.

\section*{Note}

Doing so, however, can be dangerous, as it means that the user is overriding the author's explicit request to sandbox the content.
4. If there is a preexisting attempt to navigate browsingContext, and the source browsing context \({ }^{\mathrm{p} 866}\) is the same as browsingContext, and that attempt is currently running the unload a document \({ }^{p 886}\) algorithm, then return without affecting the preexisting attempt to navigate browsingContext.
5. If the prompt to unload \({ }^{\mathrm{p} 885}\) algorithm is being run for the active document \({ }^{\mathrm{p} 811}\) of browsingContext, then return without affecting the prompt to unload \({ }^{\text {p885 }}\) algorithm.
6. If historyHandling is not "reload \({ }^{\text {p866" }}\), resource is a request, resource's url equals browsingContext's active document \({ }^{\mathrm{p} 811}\) 's URL with exclude fragments flag set, and resource's url's fragment is non-null, then:
1. Navigate to that fragment \({ }^{\mathrm{p880}}\) given historyHandling.
2. Return.
7. Let activeDocumentNavigationOrigin be the origin \({ }^{\mathrm{p} 837}\) of the active document \({ }^{\mathrm{p811}}\) of browsingContext.
8. Let incumbentNavigationOrigin be the origin \({ }^{\text {p837 }}\) of the incumbent settings object \({ }^{\mathrm{p} 921}\), or if no script \({ }^{\mathrm{p} 614}\) was involved, the origin \({ }^{\text {p837 }}\) of the node document of the element that initiated the navigation \({ }^{\text {p866 }}\).
9. Cancel any preexisting but not yet mature \({ }^{\mathrm{p876}}\) attempt to navigate browsingContext, including canceling any instances of the fetch algorithm started by those attempts. If one of those attempts has already created and initialized a new Document object \({ }^{\mathrm{p} 873}\), abort \({ }^{\mathrm{p887}}\) that Document \({ }^{\mathrm{p114}}\) also. (Navigation attempts that have matured \({ }^{\mathrm{p} 876}\) already have session history entries, and are therefore handled during the update the session history with the new page \({ }^{\text {p875 }}\) algorithm, later.)
10. Prompt to unload \({ }^{\mathrm{p} 885}\) the active document \({ }^{\mathrm{p} 811}\) of browsingContext. If the user refused to allow the document to be unloaded \({ }^{\text {p886 }}\), then return.

If this instance of the navigation \({ }^{\text {p866 }}\) algorithm gets canceled while this step is running, the prompt to unload \({ }^{\text {p885 }}\) algorithm must nonetheless be run to completion.
11. Abort \({ }^{\mathrm{p887}}\) the active document \({ }^{\mathrm{p811}}\) of browsingContext.
12. If browsingContext is a child browsing context \({ }^{\mathrm{p} 814}\), then put it in the delaying load events mode \({ }^{\mathrm{p} 815}\).

The user agent must take this child browsing context \({ }^{\mathrm{p} 814}\) out of the delaying load events mode \({ }^{\text {p815 }}\) when this navigation \({ }^{\text {p866 }}\) algorithm later matures \({ }^{\text {p876 }}\), or when it terminates (whether due to having run all the steps, or being canceled, or being aborted), whichever happens first.
13. Let navigationType be "form-submission" if the navigation algorithm \({ }^{\text {p866 }}\) was invoked as a result of the form submission algorithm \({ }^{\text {p596 }}\), and "other" otherwise.
14. Let sandboxFlags be the result of determining the creation sandboxing flags \({ }^{\text {p844 }}\) given browsingContext and browsingContext's container \({ }^{p 814}\).
15. Return to whatever algorithm invoked the navigation steps and continue running these steps in parallel \(l^{\text {p42 }}\).
16. This is the step that attempts to obtain resource, if necessary. Jump to the first appropriate substep:

\section*{If resource is a response}
1. Assert: browsingContext is not a top-level browsing context \({ }^{\mathrm{p814}}\).
2. Let finalSandboxFlags be the union of browsingContext's sandboxing flags \({ }^{\mathrm{p} 844}\) and resource's forced sandboxing flag set \({ }^{\text {p844 }}\).
3. Let responseOrigin be the result of determining the origin \({ }^{\text {p812 }}\) given browsingContext, resource's url, finalSandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin.
4. Let navigationParams be a new navigation params \({ }^{p 865}\) whose request \({ }^{p 865}\) is null, response \({ }^{\text {p865 }}\) is resource, origin \({ }^{\text {p865 }}\) is responseOrigin, final sandboxing flag set \({ }^{\text {p865 }}\) is finalSandboxFlags, cross-origin opener policy \({ }^{\text {p865 }}\) is "unsafe-none \({ }^{\mathrm{p845}}\) ", reserved environment \({ }^{\mathrm{p865}}\) is null, browsing context \({ }^{\mathrm{p866}}\) is browsingContext, browsing context switch needed \({ }^{\mathrm{p866}}\) is false, and history handling \({ }^{\text {p866 }}\) is historyHandling.
5. Run process a navigate response \({ }^{\mathrm{p} 871}\) with navigationType, the source browsing context \({ }^{\mathrm{p} 866}\), and navigationParams.

If resource is a request whose url's scheme is "javascript \({ }^{\mathrm{p} 872 \text { " }}\)
Queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given browsingContext's active window \({ }^{\text {p811 }}\) to run these steps:
1. Let response be the result of executing a javascript: URL request \({ }^{\mathrm{p} 872}\) given resource, the source browsing context \({ }^{\mathrm{p866}}\), and browsingContext.
2. Let finalSandboxFlags be the union of browsingContext's sandboxing flags \({ }^{\mathrm{p844}}\) and response's forced sandboxing flag set \({ }^{\text {p844 }}\).
3. Let navigationParams be a new navigation params \({ }^{\mathrm{p865}}\) whose request \({ }^{\mathrm{p} 865}\) is resource, response \({ }^{\mathrm{p865}}\) is response, origin \({ }^{\text {p865 }}\) is activeDocumentNavigationOrigin, final sandboxing flag set \({ }^{\mathrm{p} 865}\) is finalSandboxFlags, cross-origin opener policy \({ }^{\text {p865 }}\) is browsingContext's active document \({ }^{\text {p811 }}\) 's cross-origin opener policy \({ }^{\text {p115 }}\), reserved
environment \({ }^{p 865}\) is null, browsing context \({ }^{p 866}\) is browsingContext, browsing context switch needed \({ }^{\text {p866 }}\) is false, and history handling \({ }^{\text {p866 }}\) is historyHandling.
4. Run process a navigate response \({ }^{\mathrm{p871}}\) with navigationType, the source browsing context \({ }^{\mathrm{p866}}\), and navigationParams.

\section*{Example}

So for example a javascript: URL \({ }^{p 872}\) in an href \(f^{p 284}\) attribute of an \(\underline{a}^{p 238}\) element would only be evaluated when the link was followed \({ }^{\mathrm{p} 290}\), while such a URL in the \(\mathrm{src}^{\mathrm{p} 362}\) attribute of an iframe \({ }^{\mathrm{p} 361}\) element would be evaluated in the context of the iframe \({ }^{\mathrm{p} 361}\) 's nested browsing context \({ }^{\mathrm{p} 814}\) when the iframe \({ }^{\mathrm{p} 361}\) is being set up. Once evaluated, its return value (if it was a string) would replace that browsing context \({ }^{\text {p811 }}\) 's active document \({ }^{p 811}\), thus also changing the corresponding Window \({ }^{\text {p824 }}\) object.

If resource is to be fetched using `GET`, and there are relevant application caches \({ }^{\text {p893 }}\) that are identified by a URL with the same origin \({ }^{p 838}\) as the URL in question, and that have this URL as one of their entries, excluding entries marked as foreign \({ }^{p 893}\), and whose mode \({ }^{\mathrm{p893}}\) is fast \({ }^{\mathrm{p893}}\), and the user agent is not in a mode where it will avoid using application caches \({ }^{\text {p892 }}\)

Fetch resource from the most appropriate application cache \({ }^{p 894}\) of those that match.

\section*{Example}

For example, imagine an HTML page with an associated application cache displaying an image and a form, where the image is also used by several other application caches. If the user right-clicks on the image and chooses "View Image", then the user agent could decide to show the image from any of those caches, but it is likely that the most useful cache for the user would be the one that was used for the aforementioned HTML page. On the other hand, if the user submits the form, and the form does a POST submission, then the user agent will not use an application cache at all; the submission will be made to the network.
\[
\text { This still needs to be integrated with the Fetch standard. [FETCH] }{ }^{\text {p1287 }}
\]

\section*{If resource is a request whose url's scheme is a fetch scheme}

Run process a navigate fetch \({ }^{\text {p868 }}\) given resource, the source browsing context \({ }^{\mathrm{p} 866}\), browsingContext, navigationType, sandboxFlags, incumbentNavigationOrigin, activeDocumentNavigationOrigin, and historyHandling.

Otherwise, resource is a request whose url's scheme is neither "javascript \({ }^{\mathrm{p} 872}\) " nor a fetch scheme
Run process a navigate URL scheme \({ }^{\text {p872 }}\) given resource's url and browsingContext.
To process a navigate fetch, given a request request, two browsing contexts \({ }^{\text {p811 }}\) sourceBrowsingContext and browsingContext, a string navigationType, a sandboxing flag set \({ }^{\mathrm{p} 842}\) sandboxFlags, two origins \({ }^{\mathrm{p837}}\) incumbentNavigationOrigin and activeDocumentNavigationOrigin, and a history handling behavior \({ }^{\mathrm{p} 866}\) historyHandling:
1. Let response be null.
2. Set request's client to sourceBrowsingContext's active document \({ }^{\text {p811 }}\) 's relevant settings object \({ }^{\text {p924 }}\), destination to "document", mode to "navigate", credentials mode to "include", use-URL-credentials flag, redirect mode to "manual", and replaces client id to browsingContext's active document \({ }^{\text {p811 }}\) 's relevant settings object \({ }^{\text {p924 }}\) 's id \(^{\text {p916 }}\).
3. If browsingContext's container \({ }^{\mathrm{p} 814}\) is non-null:
1. If the browsingContext's container \({ }^{\text {p814 }}\) has a browsing context scope origin \({ }^{\text {p818 }}\), then set request's origin to that browsing context scope origin \({ }^{\text {p818 }}\).
2. Set request's destination to browsingContext's container \({ }^{\text {p814' }}\) 's local name.
4. Let reservedEnvironment be null.
5. Let responseOrigin be null.
6. Let browsingContextSwitchNeeded be false.
7. Let finalSandboxFlags be an empty sandboxing flag set \({ }^{\mathrm{p} 842}\).
8. Let responseCOOP be "unsafe-none \({ }^{\text {p845" }}\).
9. While true:
1. Let currentURL be response's location URL, if response is not null, and request's current URL otherwise.
2. If reservedEnvironment is not null and currentURL's origin is not the same \({ }^{p 838}\) as reservedEnvironment's creation URL \({ }^{\text {p916 }}\) 's origin, then:
1. Run the environment discarding steps \({ }^{\text {p917 }}\) for reservedEnvironment.
2. Set reservedEnvironment to null.
3. If reservedEnvironment is null, then:
1. Let topLeveICreationURL be currentURL.
2. Let topLeveIOrigin be null.
3. If browsingContext is not a top-level browsing context \({ }^{\mathrm{p814}}\), then:

2. Set topLeveICreationURL to parentEnvironment's top-level creation URL \({ }^{\text {p916 }}\) and topLevelOrigin to parentEnvironment's top-level origin \({ }^{\text {p916 }}\).
4. Set reservedEnvironment to a new environment \({ }^{\text {p916 }}\) whose \(\underline{i d}^{\text {p916 }}\) is a unique opaque string, target browsing context \({ }^{\text {p917 }}\) is browsingContext, creation URL \({ }^{\text {p916 }}\) is currentURL, top-level creation URL \({ }^{\text {p916 }}\) is topLeveICreationURL, and top-level origin \({ }^{\text {p916 }}\) is topLevelOrigin.

\section*{Note}

The created environment's active service worker \({ }^{p 917}\) is set in the Handle Fetch algorithm during the fetch if the request URL matches a service worker registration. [SW] \({ }^{p 1291}\)
4. Set request's reserved client to reservedEnvironment.
5. If the Should navigation request of type from source in target be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon request, navigationType, sourceBrowsingContext, and browsingContext, then set response to a network error and break. [CSP] \({ }^{\text {p1285 }}\)
6. Otherwise:
1. If response is null, fetch request.
2. Otherwise, perform HTTP-redirect fetch using request and response.
3. Wait for the task \({ }^{\text {p944 }}\) on the networking task source \({ }^{\text {p952 }}\) to process response and set response to the result.
4. Set finalSandboxFlags to the union of browsingContext's sandboxing flags \({ }^{\text {p844 }}\) and response's forced sandboxing flag set \({ }^{\text {p844 }}\).
5. Set responseOrigin to the result of determining the origin \({ }^{\text {p812 }}\) given browsingContext, request's url, finalSandboxFlags, incumbentNavigationOrigin, and activeDocumentNavigationOrigin.
6. If browsingContext is a top-level browsing context \({ }^{\text {8814 }}\), then:
1. Set responseCOOP to the result of obtaining a cross-origin opener policy \({ }^{\text {p845 }}\) given response and reservedEnvironment.
2. If sandboxFlags is not empty and responseCOOP is not "unsafe-none \({ }^{\text {p845" }}\), then set response to an appropriate network error and break.

\section*{Note}

This results in a network error as one cannot simultaneously provide a clean slate to a response using cross-origin opener policy and sandbox the result of navigating to that response.
3. Let responseRequiresBrowsingContexGroupSwitch be the result of checking if the response requires a browsing context group switch \({ }^{\text {p846 }}\) given browsingContext, responseOrigin, and responseCOOP.
4. If responseRequiresBrowsingContextGroupSwitch is true, set browsingContextSwitchNeeded to true.
7. If response is not a network error, browsingContext is a child browsing context \({ }^{\mathrm{p} 814}\), and the result of performing a cross-origin resource policy check with browsingContext's container document \({ }^{\text {p814 }}\) 's origin \({ }^{\text {p837 }}\), browsingContext's container document \({ }^{\text {p814' }}\) 's relevant settings object \({ }^{\text {p924 }}\), request's destination, response, and true is blocked, then set response to a network error and break.

\section*{Note}

Here we're running the cross-origin resource policy check against the parent browsing context \({ }^{\text {p814 }}\) rather than sourceBrowsingContext. This is because we care about the same-originness of the embedded content against the parent context, not the navigation source.
8. If response does not have a location URL or the location URL is not a URL whose scheme is an HTTP(S) scheme, then break.

\section*{Note}

Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to mailto: URLs and such.
10. If response has a location URL that is failure, then set response to a network error.
11. Otherwise, if response has a location URL that is a URL whose scheme is "blob", "file", "filesystem", or "javascript", then set response to a network error.
12. Otherwise, if response has a location URL that is a URL whose scheme is a fetch scheme, then run process a navigate fetch \({ }^{\text {p868 }}\) with a new request whose url is response's location URL, sourceBrowsingContext, browsingContext, navigationType, sandboxFlags, incumbentNavigationOrigin, activeDocumentNavigationOrigin, and historyHandling, and return.
13. Otherwise, if response has a location URL that is a URL, run the process a navigate URL scheme \({ }^{\text {p872 }}\) given response's location URL and browsingContext, and return.
14. Fallback in prefer-online mode: If response was not fetched from an application cache \({ }^{\text {p892 }}\), and was to be fetched using `GET`, and there are relevant application caches \({ }^{\text {p893 }}\) that are identified by a URL with the same origin \({ }^{\text {p838 }}\) as the URL in question, and that have this URL as one of their entries, excluding entries marked as foreign \({ }^{\text {p893 }}\), and whose mode \({ }^{\text {p893 }}\) is prefer-online \({ }^{\text {p893 }}\), and the user didn't cancel the navigation attempt during the earlier step, and response is either a network error or its status is not an ok status, then:

Let candidate be the response identified by the URL in question from the most appropriate application cache \({ }^{\text {p894 }}\) of those that match.

If candidate is not marked as foreign \({ }^{\text {p893 }}\), then the user agent must discard the failed load and instead continue along these steps using candidate as response. The user agent may indicate to the user that the original page load failed, and that the page used was a previously cached response.
15. Fallback for fallback entries: If response was not fetched from an application cache \({ }^{\text {p892 }}\), and was to be fetched using 'GET`, and its URL matches the fallback namespace \({ }^{\text {p894 }}\) of one or more relevant application caches \({ }^{\text {p893 }}\), and the most appropriate application cache \({ }^{\text {p894 }}\) of those that match does not have an entry in its online safelist \({ }^{p 893}\) that has the same origin \({ }^{\text {p838 }}\) as response's URL and that is a prefix match \({ }^{p 67}\) for response's URL, and the user didn't cancel the navigation attempt during the earlier step, and response is either a network error or its status is not an ok status, then:

Let candidate be the fallback response \({ }^{\text {p893 }}\) specified for the fallback namespace \({ }^{\text {p893 }}\) in question. If multiple application caches match, the user agent must use the fallback of the most appropriate application cache \({ }^{\text {p894 }}\) of those that match.

If candidate is not marked as foreign \({ }^{\text {p893 }}\), then the user agent must discard the failed load and instead continue along these steps using candidate as response. The document's URL, if appropriate, will still be the originally requested URL, not the fallback URL, but the user agent may indicate to the user that the original page load failed, that the page used was a fallback response, and what the URL of the fallback response actually is.
16. Let navigationParams be a new navigation params \({ }^{\mathrm{p} 865}\) whose request \({ }^{\mathrm{p} 865}\) is request, response \({ }^{\mathrm{p} 865}\) is response, origin \({ }^{\mathrm{p865}}\) is responseOrigin, final sandboxing flag set \({ }^{\text {p865 }}\) is finalSandboxFlags, cross-origin opener policy \({ }^{\text {p865 }}\) is responseCOOP, reserved environment \({ }^{\mathrm{p} 865}\) is reservedEnvironment, browsing context \({ }^{\mathrm{p} 866}\) is browsingContext, browsing context switch needed \({ }^{\text {p866 }}\) is browsingContextSwitchNeeded, and history handling \({ }^{\text {p866 }}\) is historyHandling.
17. Run process a navigate response \({ }^{\mathrm{p} 871}\) with navigationType, the source browsing context \({ }^{\mathrm{p866}}\), and navigationParams.

To process a navigate response, given a string navigationType, a browsing context \({ }^{\mathrm{p} 811}\) source, and a navigation params \({ }^{\text {p865 }}\) navigationParams:
1. Let response be navigationParams's response \({ }^{\mathrm{p} 865}\).
2. Let browsingContext be navigationParams's browsing context \({ }^{\mathrm{p} 866}\).
3. Let failure be false.
4. If response is a network error, then set failure to true.

Otherwise, if the result of should navigation response to navigation request of type from source in target be blocked by Content Security Policy? given navigationParams's request \({ }^{\text {p865 }}\), response, navigationType, source, and browsingContext is "Blocked", then set failure to true. [CSP] \({ }^{\text {p1285 }}\)

Otherwise, if the result of checking a navigation response's adherence to its embedder policy \({ }^{\text {p848 }}\) given response and browsingContext is false, then set failure to true.

Otherwise, if the result of checking a navigation response's adherence to `X-Frame-Options`p888 given response, browsingContext, and navigationParams's origin \({ }^{\text {p865 }}\) is false, then set failure to true.
5. If failure is true, then:
1. Display the inline content with an appropriate error shown to the user \({ }^{\mathrm{p} 879}\) given browsingContext.
2. Run the environment discarding steps \({ }^{p 917}\) for navigationParams's reserved environment \({ }^{p 865}\).
3. Return.

\section*{Note}

This is where the network errors defined and propagated by Fetch, such as DNS or TLS errors, end up being displayed to users. \([\text { FETCH }]^{p 1287}\)
6. If response's status is 204 or 205, then return.
7. If response has a `Content-Disposition` header specifying the attachment disposition type, then:
1. If the result of running the allowed to download \({ }^{\text {p290 }}\) given source and browsingContext is true, then handle response as a download \({ }^{\mathrm{p} 291}\).
2. Return.
8. Let type be the computed type of response.
9. If the user agent has been configured to process resources of the given type using some mechanism other than rendering the content in a browsing context \({ }^{\text {p811 }}\), then skip this step. Otherwise, if the type is one of the following types, jump to the appropriate entry in the following list, and process response as described there:

\section*{\(\rightarrow\) an HTML MIME type}

Follow the steps given in the HTML document \({ }^{\text {p876 }}\) section providing navigationParams. Once the steps have completed, return.

\section*{\(\rightarrow\) an XML MIME type that is not an explicitly supported XML MIME type \({ }^{\text {p872 }}\)}

Follow the steps given in the XML document \({ }^{\mathrm{p} 877}\) section providing navigationParams and type. Once the steps have completed, return.

\section*{\(\rightarrow\) a JavaScript MIME type}
\(\rightarrow\) a JSON MIME type that is not an explicitly supported JSON MIME type \({ }^{\text {p872 }}\)
\(\rightarrow\) "text/cache-manifest \({ }^{\text {p1253 }}{ }^{\prime \prime}\)
\(\rightarrow\) "text/css \({ }^{\text {p1283" }}\)
\(\rightarrow\) "text/plain"
\(\rightarrow\) "text/vtt \({ }^{\text {p1284" }}\)
Follow the steps given in the plain text file \({ }^{\mathrm{p877}}\) section providing navigationParams and type. Once the steps have completed, return.
\(\rightarrow\) "multipart/x-mixed-replace \({ }^{\text {p1251" }}\)
Follow the steps given in the multipart/x-mixed-replace \({ }^{\text {p878 }}\) section providing navigationParams. Once the steps have
completed, return.
\(\hookrightarrow\) A supported image, video, or audio type
Follow the steps given in the media \({ }^{p 878}\) section providing navigationParams and type. Once the steps have completed, return.
\(\rightarrow\) A type that will use an external application to render the content in browsingContext
Follow the steps given in the plugin \({ }^{\text {p879 }}\) section providing navigationParams and type. Once the steps have completed, return.

An explicitly supported XML MIME type is an XML MIME type for which the user agent is configured to use an external application to render the content (either a plugin \({ }^{\text {p45 }}\) rendering directly in browsingContext, or a separate application), or one for which the user agent has dedicated processing rules (e.g., a web browser with a built-in Atom feed viewer would be said to explicitly support the application/atom+xml \({ }^{\text {p1282 }}\) MIME type), or one for which the user agent has a dedicated handler.

An explicitly supported JSON MIME type is a JSON MIME type for which the user agent is configured to use an external application to render the content (either a plugin \({ }^{\text {p45 }}\) rendering directly in browsingContext, or a separate application), or one for which the user agent has dedicated processing rules, or one for which the user agent has a dedicated handler.
10. Non-document content: If, given type, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the content or an error message because the specified type is not supported, then display the inline content \({ }^{\text {p879 }}\) given browsingContext, and then return.
11. Otherwise, the document's type is such that the resource will not affect browsingContext, e.g., because the resource is to be handed to an external application or because it is an unknown type that will be processed as a download \({ }^{\text {p291 }}\). Process the resource appropriately \({ }^{\text {p872 }}\).

To process a navigate URL scheme, given a URL url and browsing context \({ }^{\text {p811 }}\) browsingContext, run these steps:
1. If \(u r l\) is to be handled using a mechanism that does not affect browsingContext, e.g., because url's scheme is handled externally, then proceed with that mechanism instead \({ }^{\mathrm{p} 872}\).
2. Otherwise, url is to be handled by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select a registered handler \({ }^{\text {p983 }}\) for the given scheme. Display the inline content \({ }^{\mathrm{p879}}\) given browsingContext.

Note
In the case of a registered handler being used, navigate \({ }^{p 866}\) will be invoked with a new URL.

When a resource is handled by passing its URL or data to an external software package separate from the user agent (e.g. handing a mailto: URL to a mail client, or a Word document to a word processor), user agents should attempt to mitigate the risk that this is an attempt to exploit the target software, e.g. by prompting the user to confirm that the source browsing context \({ }^{\text {p866/'s }}{ }^{\text {active }}\) document \({ }^{\text {p811 }}\) 's origin \({ }^{\text {p837 }}\) is to be allowed to invoke the specified software. In particular, if the navigate \({ }^{\text {p866 }}\) algorithm was invoked when source browsing context \({ }^{\mathrm{p866}}\) 's active window \({ }^{\mathrm{p} 811}\) does not have transient activation \({ }^{\mathrm{p767}}\), the user agent should not invoke the external software package without prior user confirmation.

\section*{Example}

For example, there could be a vulnerability in the target software's URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.

To execute a javascript: URL request, given a request request and two browsing contexts \({ }^{\text {p811 }}\) source and browsingContext, run these steps:
1. Let response be a response whose status is 204 .
2. If both of the following are true:
- source's active document \({ }^{\text {p811' }}\) 's origin \({ }^{\text {p837 }}\) is same origin \({ }^{\text {p838 }}\) with browsingContext's active document \({ }^{\text {p811' }}\) 's origin \({ }^{\text {p837 }}\).

> As explained in issue \#2591 this step does not work and presents a security issue.
- The Should navigation request of type from source in target be blocked by Content Security Policy? algorithm returns "Allowed" when executed upon request, "other", source, and browsingContext. [CSP] \({ }^{\text {p1285 }}\)
then:
1. Let urlString be the result of running the URL serializer on request's url.
2. Let encodedScriptSource be the result of removing the leading "javascript:" from urlString
3. Let scriptSource be the UTF-8 decoding of the percent-decoding of encodedScriptSource.
4. Append browsingContext's active document \({ }^{p 811}\) 's URL to request's URL list.
5. Let settings be browsingContext's active document \({ }^{\mathrm{p} 811}\) 's relevant settings object \({ }^{\mathrm{p} 924}\).
6. Let baseURL be settings's API base URL \({ }^{\text {p917 }}\).
7. Let script be the result of creating a classic script \({ }^{\text {p933 }}\) given scriptSource, settings, baseURL, and the default classic script fetch options \({ }^{\text {p926 }}\).
8. Let evaluationStatus be the result of running the classic script \({ }^{\text {p934 }}\) script.
9. Let result be undefined if evaluationStatus is an abrupt completion or evaluationStatus.[[Value]] is empty, or evaluationStatus.[[Value]] otherwise.
10. If Type(result) is String, then set response to a response whose header list consists of `Content-Type \({ }^{\text {p90 ` }}\) 「text/ html \({ }^{\text {p1259`` }}\) and `Referrer-Policy`/settings's referrer policy, and whose body is result.

The exact conversion between the string result and the bytes that comprise a response body is not yet specified, pending further investigation into user agent behavior. See issue \#1129.
3. Return response.

In addition to the specific issues linked above, javascript: \({ }^{8872}\) URLs have a dedicated label on the issue tracker documenting various problems with their specification.

Some of the sections below, to which the above algorithm defers in certain cases, use the following steps to create and initialize a Document object, given a type type, content type contentType, and navigation params \({ }^{\text {p865 }}\) navigationParams:
1. Let browsingContext be navigationParams's browsing context \({ }^{p 866}\).
2. If navigationParams's browsing context switch needed \({ }^{p 866}\) is true, then set browsingContext to the result of the obtain a browsing context to use for a navigation response \({ }^{\text {p846 }}\) algorithm, given browsingContext, navigationParams's final sandboxing flag set \({ }^{\text {p865 }}\), and navigationParams's cross-origin opener policy \({ }^{\text {p865 }}\).
3. Let permissionsPolicy be the result of creating a permissions policy from a response given browsingContext, navigationParams's origin \({ }^{\text {p865 }}\), and navigationParams's response \({ }^{\text {p865 }}\). [PERMISSIONSPOLICY] \({ }^{\text {p1289 }}\)

\section*{Note}

The creating a permissions policy from a response algorithm makes use of the passed origin \({ }^{p 837}\). If document. domain \({ }^{\text {p840 }}\) has been used for browsingContext's container document \({ }^{p 814}\), then its origin \({ }^{p 837}\) cannot be same origin-domain \({ }^{p 838}\) with the passed origin, because these steps run before the document is created, so it cannot itself yet have used document. domain \({ }^{\text {p840 }}\). Note that this means that Permissions Policy checks are less permissive compared to doing a same origin \({ }^{\text {p838 }}\) check instead.

See below for some examples of this in action.
4. Let creationURL be navigationParams's response \({ }^{p 865}\) 's URL.
5. If navigationParams's request \({ }^{\text {p865 }}\) is non-null, then set creationURL to navigationParams's request \({ }^{p 865}\) 's current URL.
6. If browsingContext's only entry in its session history \({ }^{\text {p849 }}\) is the initial about:blank \({ }^{p 51}\) Document \({ }^{\text {p114 }}\) that was added when that browsing context \({ }^{\text {p811 }}\) was created \({ }^{\text {p812 }}\), and navigationParams's history handling \({ }^{\text {p866 }}\) is "replace \({ }^{\text {p866" }}\) ", and that Document \({ }^{p 114 \text { 's } s}\) origin \({ }^{\text {p837 }}\) is same origin-domain \({ }^{p 838}\) with navigationParams's origin \({ }^{\text {p865 }}\), then do nothing.
7. Otherwise:
1. Let oiHeader be the result of getting a structured field value given `origin-Isolation \({ }^{\text {p1258`` }}\) and "item" from response's header list.
2. Let requestsOl be true if oiHeader is not null and oiHeader[0] is the boolean true; otherwise false.
3. If reservedEnvironment is a non-secure context \({ }^{\mathrm{p} 925}\), then set requestsOI to false.
4. Let agent be the result of obtaining a similar-origin window agent \({ }^{\text {p914 }}\) given navigationParams's origin \({ }^{\text {p865 }}\), browsingContext's group \({ }^{\text {p814 }}\), and requestsOI.
5. Let realm execution context be the result of creating a new JavaScript realm \({ }^{\text {p918 }}\) given agent and the following customizations:
- For the global object, create a new Window \({ }^{p 824}\) object.
- For the global this binding, use browsingContext's WindowProxy \({ }^{\text {p834 }}\) object.
6. Let topLeveICreationURL be creationURL.
7. Let topLevelOrigin be navigationParams's origin \({ }^{\text {p865 }}\).
8. If browsingContext is not a top-level browsing context \({ }^{\mathrm{p} 814}\), then:
1. Let parentEnvironment be browsingContext's container \({ }^{\mathrm{p} 814 \text { 's }} \mathrm{s}\) relevant settings object \({ }^{\mathrm{p} 924}\).
2. Set topLevelCreationURL to parentEnvironment's top-level creation URL \({ }^{\text {p916 }}\).
3. Set topLevelOrigin to parentEnvironment's top-level origin \({ }^{\text {p916 }}\).
9. Set up a window environment settings object \({ }^{\text {p833 }}\) with realm execution context, navigationParams's reserved environment \({ }^{\text {p865 }}\), topLeve/CreationURL, and topLeveIOrigin.
8. Let document be a new Document \({ }^{\text {p114 }}\), whose type is type, content type is contentType, origin \({ }^{\text {p837 }}\) is navigationParams's origin \({ }^{\text {p865 }}\), permissions policy \({ }^{\text {p115 }}\) is permissionsPolicy, active sandboxing flag set \({ }^{\mathrm{p} 844}\) is navigationParams's final sandboxing flag set \({ }^{\text {p865 }}\), and cross-origin opener policy \({ }^{\text {p115 }}\) is navigationParams's cross-origin opener policy \({ }^{\text {p865 }}\).
9. Set document's URL to creationURL.
10. Set document's referrer policy \({ }^{\text {p115 }}\) to the result of parsing the `Referrer-Policy` header of navigationParams's response \({ }^{\text {p865 }}\). [REFERRERPOLICY] \({ }^{\text {p1290 }}\)
11. Set document's embedder policy \({ }^{\text {p115 }}\) to the result of obtaining an embedder policy \({ }^{\text {p847 }}\) from navigationParams's response \({ }^{\text {p865 }}\).
12. Initialize a Document's CSP list given document, navigationParams's response \({ }^{\mathrm{p865}}\), and navigationParams's request \({ }^{\mathrm{p} 865}\). [CSP] \({ }^{\text {p1285 }}\)
13. If navigationParams's request \({ }^{\text {p865 }}\) is non-null, then:
1. Set document's referrer \({ }^{p 114}\) to the empty string.
2. Let referrer be navigationParams's request \({ }^{\mathrm{p} 865}\) ' \(s\) referrer.
3. If referrer is a URL record, then set document's referrer \({ }^{p 114}\) to the serialization of referrer.

\section*{Note}

Per Fetch, referrer will be either a URL record or "no-referrer" at this point.
14. If navigationParams's response \({ }^{\text {p865 }}\) has a `Refresh \({ }^{\text {p1259` }}\). header, then:
1. Let value be the isomorphic decoding of the value of the header.
2. Run the shared declarative refresh steps \({ }^{\text {p171 }}\) with document and value.
```
We do not currently have a spec for how to handle multiple `Refresh \({ }^{\text {p1259` }}\) headers. This is tracked as issue \#2900.
```
15. Return document.

\section*{Example}

In this example, the child document is not allowed to use PaymentRequest, despite being same origin-domain \({ }^{\text {p838 }}\) at the time the child document tries to use it. At the time the child document is initialized, only the parent document has set document. domain \({ }^{\text {p840 }}\),
and the child document has not.
```
<!-- https://foo.example.com/a.html -->
<!doctype html>
<script>
document.domain = 'example.com';
</script>
<iframe src=b.html></iframe>
<!-- https://bar.example.com/b.html -->
<!doctype html>
<script>
document.domain = 'example.com'; // This happens after the document is initialized
new PaymentRequest(...); // Not allowed to use
</script>
```

\section*{Example}

In this example, the child document is allowed to use PaymentRequest, despite not being same origin-domain \({ }^{\text {p838 }}\) at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set document. domain \({ }^{\text {p840 }}\) yet so same origin-domain \({ }^{\text {p838 }}\) falls back to a normal same origin \({ }^{p 838}\) check.
```
<!-- https://example.com/a.html -->
<!doctype html>
<iframe src=b.html></iframe>
<!-- The child document is now initialized, before the script below is run. -->
<script>
document.domain = 'example.com';
</script>
<!-- https://example.com/b.html -->
<!doctype html>
<script>
new PaymentRequest(...); // Allowed to use
</script>
```

Some of the sections below, to which the above algorithm defers in certain cases, require the user agent to update the session history with the new page, given some navigation params \({ }^{p 865}\) navigationParams. When a user agent is required to do this, it must queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\), given the relevant global object \({ }^{\text {p924 }}\) of the Document \({ }^{\text {p114 }}\) object of the current entry \({ }^{\text {p850 }}\) (not the new one), to run the following steps:
1. Unload \({ }^{\mathrm{p} 886}\) the Document \({ }^{\text {p114 }}\) object of the current entry \({ }^{\mathrm{p} 850}\).

If this instance of the navigation \({ }^{\text {p866 }}\) algorithm is canceled while this step is running the unload a document \({ }^{\text {p886 }}\) algorithm, then the unload a document \({ }^{\text {p886 }}\) algorithm must be allowed to run to completion, but this instance of the navigation \({ }^{\text {p866 }}\) algorithm must not run beyond this step. (In particular, for instance, the cancelation of this algorithm does not abort any event dispatch or script execution occurring as part of unloading the document or its descendants.)
2. If navigationParams's history handling \({ }^{\text {p866 }}\) is "reload \({ }^{\text {p866" }}\) or "entry update \({ }^{\text {p866" }}\)
1. Replace the Document \({ }^{\text {p114 }}\) of the entry being updated, and any other entries that referenced the same document as that entry, with the new Document \({ }^{\text {p114 }}\).
2. Traverse the history \({ }^{\mathrm{p} 881}\) to the new entry.

If the navigation was initiated with a URL that equals the browsing context \({ }^{\text {p811 }}\) 's active document \({ }^{p 811}\) 's URL
1. Replace the current entry \({ }^{\mathrm{p} 850}\) with a new entry representing the new resource and its Document \({ }^{\mathrm{p} 114}\) object, related state, and the default scroll restoration mode \({ }^{\text {p850 }}\) of "auto \({ }^{\text {p850 " }}\).
2. Traverse the history \({ }^{\text {p881 }}\) to the new entry.

\section*{Otherwise}
1. Remove all the entries in the browsing context \({ }^{\mathrm{p} 811}\) 's session history \({ }^{\text {p849 }}\) after the current entry \({ }^{\mathrm{p850}}\). If the current entry \({ }^{p 850}\) is the last entry in the session history, then no entries are removed.

\section*{Note}

This doesn't necessarily have to affect \({ }^{8856}\) the user agent's user interface.
2. Append a new entry at the end of the History \({ }^{\mathrm{P851}}\) object representing the new resource and its Document \({ }^{\text {p114 }}\) object, related state, and the default scroll restoration mode \({ }^{\text {p850 }}\) of "auto \({ }^{\text {p850 " }}\).
3. Traverse the history \({ }^{\text {p881 }}\) to the new entry, with historyHandling \({ }^{p 881}\) set to navigationParams's history handling \({ }^{\text {p866 }}\).
3. The navigation algorithm \({ }^{\text {p866 }}\) has now matured.
4. Try to scroll to the fragment \({ }^{\text {p876 }}\) for the Document \({ }^{\text {p114 }}\).

To try to scroll to the fragment for a Document \({ }^{p 114}\) document, perform the following steps in parallel \({ }^{\mathrm{p} 42}\) :
1. Wait for an implementation-defined amount of time. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)
2. Queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) given document's relevant global object \({ }^{\text {p924 }}\) to run these steps:
1. If document has no parser, or its parser has stopped parsing \({ }^{\text {p1165 }}\), or the user agent has reason to believe the user is no longer interested in scrolling to the fragment, then abort these steps.
2. Scroll to the fragment \({ }^{p 880}\) given in document's \(\underline{U R L}\). If this does not find an indicated part of the document \({ }^{p 880}\), then try to scroll to the fragment \({ }^{\mathrm{p} 876}\) for document.

\subsection*{7.10.2 Page load processing model for HTML files \(\S^{p 87}\)}

When an HTML document is to be loaded, given navigation params \({ }^{\text {p865 }}\) navigationParams, the user agent must queue a task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) to:
1. Let document be the result of creating and initializing a Document object \({ }^{\text {p873 }}\) given "html", "text/html", and navigationParams.
2. Create an HTML parser \({ }^{\text {p1079 }}\) and associate it with the document. Each task \({ }^{\text {p944 }}\) that the networking task source \({ }^{\text {p952 }}\) places on the task queue \({ }^{\text {p944 }}\) while fetching runs must then fill the parser's input byte stream \({ }^{\text {p1085 }}\) with the fetched bytes and cause the HTML parser \({ }^{\text {p1079 }}\) to perform the appropriate processing of the input stream.

\section*{Note}

The input byte stream \({ }^{\text {p1085 }}\) converts bytes into characters for use in the tokenizer \({ }^{p 1097}\). This process relies, in part, on character encoding information found in the real Content-Type metadata \({ }^{p 90}\) of the resource; the computed type is not used for this purpose.

When no more bytes are available, the user agent must queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) given the newlycreated Document \({ }^{\text {p114 }}\) 's relevant global object \({ }^{\text {p924 }}\) for the parser to process the implied EOF character, which eventually causes a load \(^{\text {p1282 }}\) event to be fired.

After creating the Document \({ }^{\text {p114 }}\) object, but before any script execution, certainly before the parser stops \({ }^{\text {p1165 }}\), the user agent must update the session history with the new page \({ }^{\mathrm{p} 875}\) given navigationParams.

\section*{Note}

Application cache selection \({ }^{p 907}\) happens in the HTML parser \({ }^{p 1134}\).

\subsection*{7.10.3 Page load processing model for XML files \(\S^{p 87}\)}

When faced with displaying an XML file inline, provided navigation params \({ }^{\text {p865 }}\) navigationParams and a string type, user agents must follow the requirements defined in XML and Namespaces in XML, XML Media Types, DOM, and other relevant specifications to create and initialize a Document object \({ }^{\mathrm{p} 873}\) given "xml", type, and navigationParams. They must also create a corresponding XML parser \({ }^{\text {p1188 }}\). \([\text { XML }]^{\text {p1293 }}[\text { XMLNS }]^{\text {p1293 }}[\text { RFC } 7303]^{\text {p1291 }}[D O M]^{\text {p1287 }}\)

\section*{Note}

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the document's character encoding must be set to that character encoding.

If the document element, as parsed according to \(X M L\) cited above, is found to be an html \({ }^{p 152}\) element with an attribute manifest \({ }^{p 152}\) whose value is not the empty string, then, as soon as the element is inserted into the document \({ }^{\text {p44 }}\), the user agent must parse \({ }^{\text {p89 }}\) the value of that attribute relative to that element's node document, and if that is successful, must apply the URL serializer algorithm to the resulting URL record \({ }^{p 89}\) with the exclude fragment flag set to obtain manifest URL, and then run the application cache selection algorithm \({ }^{\text {p907 }}\) with manifest URL as the manifest URL, passing in the newly-created Document \({ }^{\text {p114 }}\). Otherwise, if the attribute is absent, its value is the empty string, or parsing its value fails, then as soon as the document element is inserted into the document \({ }^{\text {p44 }}\), the user agent must run the application cache selection algorithm \({ }^{\text {p907 }}\) with no manifest, and passing in the Document \({ }^{\text {p1144 }}\).

\section*{Note}

Because the processing of the manifest \({ }^{\text {p152 }}\) attribute happens only once the document element is parsed, any URLs referenced by processing instructions before the document element (such as <?xml-stylesheet?> PIs) will be fetched from the network and cannot be cached.

Then, with the newly created Document \({ }^{\text {p114 }}\), the user agent must update the session history with the new page \({ }^{\text {p875 }}\) given navigationParams. User agents may do this before the complete document has been parsed (thus achieving incremental rendering), and must do this before any scripts are to be executed.

Error messages from the parse process (e.g., XML namespace well-formedness errors) may be reported inline by mutating the Document \({ }^{\text {p114 }}\).

\subsection*{7.10.4 Page load processing model for text files \(\S^{\text {p87 }}\)}

When a plain text document is to be loaded, provided navigation params \({ }^{\text {p865 }}\) navigationParams and a string type, the user agent must queue a task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) to:
1. Let document be the result of creating and initializing a Document object \({ }^{\mathrm{p} 873}\) given "html", type, and navigationParams.
2. Create an HTML parser \({ }^{\text {p1079 }}\) and associate it with the document. Act as if the tokenizer had emitted a start tag token with the tag name "pre" followed by a single U+000A LINE FEED (LF) character, and switch the HTML parser \({ }^{\text {p1079 ' }}\) 's tokenizer to the PLAINTEXT state \({ }^{\text {p1099 }}\). Each task \({ }^{\text {p944 }}\) that the networking task source \({ }^{\text {p952 }}\) places on the task queue \({ }^{\text {p944 }}\) while fetching runs must then fill the parser's input byte stream \({ }^{\text {p1085 }}\) with the fetched bytes and cause the HTML parser \({ }^{\text {p1079 }}\) to perform the appropriate processing of the input stream.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the computed MIME type of the resource (i.e., type).

The document's character encoding must be set to the character encoding used to decode the document.
Upon creation of the Document \({ }^{\text {p114 }}\) object, the user agent must run the application cache selection algorithm \({ }^{\text {p907 }}\) with no manifest, and passing in the newly-created Document \({ }^{\text {p114 }}\).

When no more bytes are available, the user agent must queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) given the newlycreated Document \({ }^{\text {p114' }}\) 's relevant global object \({ }^{\text {p924 }}\) for the parser to process the implied EOF character, which eventually causes a \(\underline{\text { load }^{p 1282}}\) event to be fired.

After creating the Document \({ }^{\text {p114 }}\) object, but potentially before the page has finished parsing, the user agent must update the session
history with the new page \({ }^{\text {p875 }}\) given navigationParams.
User agents may add content to the head \({ }^{p 153}\) element of the Document \({ }^{\text {p114 }}\), e.g., linking to a style sheet, providing script, or giving the document a title \({ }^{\text {p154 }}\).

\section*{Note}

In particular, if the user agent supports the Format=Flowed feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.

\subsection*{7.10.5 Page load processing model for multipart/x-mixed-replace resources \(\S_{8}^{\mathrm{p} 87}\)}

When a resource with the type multipart/x-mixed-replace \({ }^{p 1251}\) is to be loaded in a browsing context \({ }^{\text {p811 }}\), the user agent must parse the resource using the rules for multipart types. [RFC2046] \({ }^{\text {p1290 }}\)

This algorithm is passed navigation params \({ }^{\text {p865 }}\), but it's unclear how exactly to use them.

For each body part obtained from the resource, the user agent must run process a navigate response \({ }^{\text {p871 }}\) using the new body part and the same browsing context \({ }^{\text {p811 }}\), with history handling \({ }^{\text {p866 }}\) set to "replace \({ }^{\text {p866" }}\) if a previous body part from the same resource resulted in a creating and initializing a Document object \({ }^{p 873}\), and otherwise using the same setup as the navigate \({ }^{\text {p866 }}\) attempt that caused this section to be invoked in the first place.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary following the body part is reached.

Note
Thus, load \({ }^{\text {p1282 }}\) events (and for that matter unload \({ }^{\text {p1282 }}\) events) do fire for each body part loaded.

\subsection*{7.10.6 Page load processing model for media \({\underset{8}{\text { p }}}_{8}^{\text {p7 }}\)}

When an image, video, or audio resource is to be loaded, provided navigation params \({ }^{\text {p865 }}\) navigationParams and a string type, the user agent should:
1. Let document be the result of creating and initializing a Document object \({ }^{\text {p873 }}\) given "html", type, and navigationParams.
2. Append an html \({ }^{\text {p152 }}\) element to document.
3. Append a head \({ }^{\text {p153 }}\) element to the html \({ }^{\text {p152 }}\) element.
4. Append a body \({ }^{p 178}\) element to the html \({ }^{\text {p152 }}\) element.
5. Append an element host element for the media, as described below, to the body \({ }^{\text {p178 }}\) element.
6. Set the appropriate attribute of the element host element, as described below, to the address of the image, video, or audio resource.

The element host element to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.
\begin{tabular}{|c|c|c|}
\hline Type of media & Element for the media & Appropriate attribute \\
\hline Image & img \({ }^{\text {p320 }}\) & \(s r c^{\text {p321 }}\) \\
\hline Video & video \({ }^{\text {p380 }}\) & \(s r c^{\text {p399 }}\) \\
\hline Audio & audio \({ }^{\text {p384 }}\) & \(s r c^{\text {p390 }}\) \\
\hline
\end{tabular}

Then, the user agent must act as if it had stopped parsing \({ }^{\text {p1165 }}\).
Upon creation of the Document \({ }^{\text {p114 }}\) object, the user agent must run the application cache selection algorithm \({ }^{\text {p907 }}\) with no manifest, and passing in the newly-created Document \({ }^{\text {p114 }}\).

After creating the Document \({ }^{p 114}\) object, but potentially before the page has finished fully loading, the user agent must update the session history with the new page \({ }^{\mathrm{p} 875}\) given navigationParams.

User agents may add content to the head \({ }^{\text {p153 }}\) element of the Document \({ }^{p 114}\), or attributes to the element host element, e.g., to link to a style sheet, to provide a script, to give the document a title \({ }^{\text {p154 }}\), or to make the media autoplay \({ }^{\text {p407 }}\).

\subsection*{7.10.7 Page load processing model for content that uses plugins \(\S_{9}^{887}\)}

When a resource that requires an external resource to be rendered is to be loaded, provided navigation params \({ }^{\text {p865 }}\) navigationParams and a string type, the user agent should:
1. Let document be the result of creating and initializing a Document object \({ }^{\mathrm{p} 873}\) given "html", type, and navigationParmas.
2. Mark document as being a plugin document
3. Append an html \({ }^{p 152}\) element to document.
4. Append a head \({ }^{p 153}\) element to the html \({ }^{p 152}\) element.
5. Append a body \({ }^{p 178}\) element to the html \({ }^{p 152}\) element.
6. Append an embed \({ }^{p 369}\) to the body \({ }^{p 178}\) element
7. Set the \(s r c^{\rho 369}\) attribute of the embed \({ }^{\mathrm{p} 369}\) element to the address of the resource.

\section*{Note}

The term plugin document \({ }^{p 879}\) is used by Content Security Policy as part of the mechanism that ensures iframe \({ }^{p 361} s\) can't be used to evade plugin-types directives. \([C S P]^{p 1285}\)

Then, the user agent must act as if it had stopped parsing \({ }^{\text {p1165 }}\).
Upon creation of the Document \({ }^{\text {p114 }}\) object, the user agent must run the application cache selection algorithm \({ }^{\text {p907 }}\) with no manifest, and passing in the newly-created Document \({ }^{\text {p114 }}\).

After creating the Document \({ }^{p 114}\) object, but potentially before the page has finished fully loading, the user agent must update the session history with the new page \({ }^{\text {p875 }}\) given navigationParams.

User agents may add content to the head \({ }^{p 153}\) element of the Document \({ }^{\text {p114 }}\), or attributes to the embed \({ }^{\text {p369 }}\) element, e.g. to link to a style sheet or to give the document a title \({ }^{p 154}\).

\section*{Note}

If the Document \({ }^{\text {p114' }}\) 's active sandboxing flag set \({ }^{p 844}\) has its sandboxed plugins browsing context flag \({ }^{p 842}\) set, the synthesized embed \(^{\text {p369 }}\) element will fail to render the content \({ }^{p 372}\) if the relevant plugin \({ }^{\text {p45 }}\) cannot be secured \({ }^{\text {p45 }}\).

\subsection*{7.10.8 Page load processing model for inline content that doesn't have a DOM \(\S_{9}^{\text {p87 }}\)}

When the user agent is to display a user agent page inline, provided a browsing context \({ }^{\text {p811 }}\) browsingContext, the user agent should:
1. Let navigationParams be a new navigation params \({ }^{p 865}\) whose request \({ }^{p 865}\) is null, response \({ }^{\text {p865 }}\) is null, origin \({ }^{p 865}\) is a new opaque origin \({ }^{\text {p837 }}\), final sandboxing flag set \({ }^{\text {p865 }}\) is an empty set, cross-origin opener policy \({ }^{\text {p865 }}\) is "unsafe-none \({ }^{\text {p845" } \text { ", reserved }}\) environment \({ }^{\text {p865 }}\) is null, browsing context \({ }^{\text {p866 }}\) is browsingContext, and browsing context switch needed \({ }^{\text {p866 }}\) is false.
\[
\text { The algorithm called in the next step is not prepared to deal with a null response }{ }^{\text {p865 }} \text {. Probably we should synthesize one }
\] instead.
2. Let document be the result of creating and initializing a Document object \({ }^{p 873}\) given "html", "text/html", and navigationParams.
3. Either associate document with a custom rendering that is not rendered using the normal Document \({ }^{\text {p114 }}\) rendering rules, or
mutate document until it represents the content the user agent wants to render.
Once the page has been set up, the user agent must act as if it had stopped parsing \({ }^{\text {p1165 }}\).
Upon creation of the Document \({ }^{\text {p114 }}\) object, the user agent must run the application cache selection algorithm \({ }^{\text {p907 }}\) with no manifest, passing in the newly-created Document \({ }^{\text {p114 }}\).

After creating the Document \({ }^{\text {p114 }}\) object, but potentially before the page has been completely set up, the user agent must update the session history with the new page \({ }^{p 875}\) given navigationParams.

\subsection*{7.10.9 Navigating to a fragment \(\S^{p 88}\)}

To navigate to a fragment, with a history handling behavior \({ }^{\mathrm{p866}}\) historyHandling:
1. If historyHandling is not "replace \({ }^{\text {p866" }}\), then remove all the entries in the browsing context \({ }^{p 811}\) 's session history \({ }^{\text {p849 }}\) after the current entry \({ }^{p 850}\). (If the current entry \({ }^{\text {p850 }}\) is the last entry in the session history, then no entries are removed.)

Note
This doesn't necessarily have to affect \({ }^{p 856}\) the user agent's user interface.
2. Remove any tasks \({ }^{\text {p944 }}\) queued by the history traversal task source \({ }^{\text {p952 }}\) that are associated with any Document \({ }^{\text {p114 }}\) objects in the top-level browsing context \({ }^{\text {p814 }}\) 's document family \({ }^{\text {p815 }}\).
3. Append a new entry at the end of the History \({ }^{\text {p851 }}\) object representing the new resource and its Document \({ }^{\text {p114 }}\) object, related state, and current entry \({ }^{\text {p850' }}\) 's scroll restoration mode \({ }^{\text {p850 }}\). Its URL must be set to the address to which the user agent was navigating \({ }^{\text {p866 }}\). The title must be left unset.
4. Traverse the history \({ }^{p 881}\) to the new entry, with historyHandling \({ }^{p 881}\) set to historyHandling and with nonBlockingEvents \({ }^{p 881}\) set to true. This will scroll to the fragment \({ }^{p 880}\) given in what is now the document's URL.

\section*{Note}

If the scrolling fails because the relevant ID has not yet been parsed, then the original navigation \({ }^{p 866}\) algorithm will take care of the scrolling instead, as the last few steps of its update the session history with the new page \({ }^{\text {p875 }}\) algorithm.

When the user agent is required to scroll to the fragment and the indicated part of the document \({ }^{\text {p880 }}\), if any, is being rendered \({ }^{\text {p1192 }}\), the user agent must either change the scrolling position of the document using the following algorithm, or perform some other action such that the indicated part of the document \({ }^{\mathrm{p880}}\) is brought to the user's attention. If there is no indicated part, or if the indicated part is not being rendered \({ }^{\text {p1192 }}\), then the user agent must do nothing. The aforementioned algorithm is as follows:
1. If there is no indicated part of the document \({ }^{\mathrm{p880}}\), set the Document \({ }^{\mathrm{p} 114}\) 's target element \({ }^{\mathrm{p} 881}\) to null.
2. If the indicated part of the document \({ }^{p 880}\) is the top of the document, then:
1. Set the Document \({ }^{\text {p114 }}\) 's target element \({ }^{\mathrm{p} 881}\) to null.
2. Scroll to the beginning of the document for the Document \({ }^{\text {p114 }}\). [CSSOMVIEW] \({ }^{\text {p1286 }}\)
3. Otherwise:
1. Let target be element that is the indicated part of the document \({ }^{\mathrm{p} 880}\).
2. Set the Document \({ }^{\text {p114 }}\) 's target element \({ }^{\mathrm{p} 881}\) to target.
3. Scroll target into view, with behavior set to "auto", block set to "start", and inline set to "nearest". [CSSOMVIEW] \({ }^{\text {p1286 }}\)
4. Run the focusing steps \({ }^{p 776}\) for target, with the Document \({ }^{\mathrm{p114}}\) 's viewport as the fallback target.
5. Move the sequential focus navigation starting point \({ }^{\mathrm{p} 779}\) to target.

The indicated part of the document is the one that the fragment, if any, identifies. The semantics of the fragment in terms of mapping it to a node is defined by the specification that defines the MIME type used by the Document \({ }^{\text {pl14 }}\) (for example, the processing
of fragments for XML MIME types is the responsibility of RFC7303). [RFC7303] \({ }^{\text {p1291 }}\)
There is also a target element for each Document \({ }^{\text {p114 }}\), which is used in defining the :target \({ }^{\mathrm{p} 726}\) pseudo-class and is updated by the above algorithm. It is initially null.

For HTML documents (and HTML MIME types), the following processing model must be followed to determine what the indicated part of the document \({ }^{p 880}\) is.
1. Let fragment be the document's URL's fragment.
2. If fragment is the empty string, then the indicated part of the document \({ }^{\mathrm{p} 880}\) is the top of the document; return.
3. If find a potential indicated element \({ }^{\text {p881 }}\) with fragment returns non-null, then the return value is the indicated part of the document \({ }^{\text {p880}}\); return.
4. Let fragmentBytes be the result of percent-decoding fragment.
5. Let decodedFragment be the result of running UTF-8 decode without BOM on fragmentBytes.
6. If find a potential indicated element \({ }^{\mathrm{p} 881}\) with decodedFragment returns non-null, then the return value is the indicated part of the document \({ }^{\mathrm{p} 880}\); return.
7. If decodedFragment is an ASCII case-insensitive match for the string top, then the indicated part of the document \({ }^{\text {p880 }}\) is the top of the document; return.
8. There is no indicated part of the document \({ }^{p 880}\).

To find a potential indicated element given a string fragment, run these steps:
1. If there is an element in the document tree that has an ID equal to fragment, then return the first such element in tree order.
2. If there is an \(a^{p 238}\) element in the document tree that has a name \({ }^{p 1233}\) attribute whose value is equal to fragment, then return the first such element in tree order.
3. Return null.

\subsection*{7.10.10 History traversal \(\S_{1}^{\text {p88 }}\)}

To traverse the history to a session history entry \({ }^{\text {p849 }}\) entry, with an optional history handling behavior \({ }^{p 866}\) historyHandling (default "default \({ }^{\mathrm{p} 866 "}\) "), an optional boolean nonBlockingEvents (default false), and an optional boolean explicitHistoryNavigation (default false):

\section*{Note}

This algorithm is not just invoked when explicitly going back or forwards in the session history \({ }^{\text {p853 }}\) - it is also invoked in other situations, for example when navigating a browsing context \({ }^{p 866}\), as part of updating the session history with the new page \({ }^{p 875}\).
1. If entry no longer holds a Document \({ }^{\text {p114 }}\) object, then:
1. Let request be a new request whose url is entry's URL.
2. If explicitHistoryNavigation is true, then set request's history-navigation flag.
3. Assert: historyHandling is not "replace \({ }^{\text {p866". }}\)
4. Navigate \({ }^{\text {p866 }}\) the browsing context \({ }^{\text {p811 }}\) to request with historyHandling \({ }^{\text {p866 }}\) set to "entry update \({ }^{\text {p866". The navigation }}\) must be done using the same source browsing context \({ }^{\text {p866 }}\) as was used the first time entry was created.

\section*{Note}

The "navigate \({ }^{p 866 "}\) algorithm reinvokes this "traverse" algorithm to complete the traversal, at which point entry holds a Document \({ }^{\text {p114 }}\) object.

\section*{Note}

If the resource was obtained using a non-idempotent action, for example a POST form submission, or if the
resource is no longer available, for example because the computer is now offline and the page wasn't cached, navigating to it again might not be possible. In this case, the navigation will result in a different page than previously; for example, it might be an error message explaining the problem or offering to resubmit the form.
5. Return.
2. If the current entry \({ }^{p 850}\) 's title was not set by the pushState( ( \()^{\mathrm{p} 854}\) or replaceState( \()^{\mathrm{p} 854}\) methods, then set its title to the value returned by the document. title \({ }^{\text {p117 }}\) IDL attribute.
3. If appropriate, update the current entry \({ }^{\mathrm{p} 850}\) in the browsing context \({ }^{\mathrm{p811}}\) 's Document \({ }^{\mathrm{p114}}\) object's History \({ }^{\mathrm{p} 851}\) object to reflect any state that the user agent wishes to persist. The entry is then said to be an entry with persisted user state \({ }^{\text {p850 }}\).
4. If entry has a different Document \({ }^{\text {p114 }}\) object than the current entry \({ }^{\text {p850 }}\), then run the following substeps:
1. Remove any tasks \({ }^{\text {p944 }}\) queued by the history traversal task source \({ }^{\text {p952 }}\) that are associated with any Document \({ }^{\text {p114 }}\) objects in the top-level browsing context \({ }^{\mathrm{p} 814}\) 's document family \({ }^{\mathrm{p} 815}\).
2. If the origin \({ }^{\mathrm{p} 837}\) of entry's Document \({ }^{\mathrm{p} 114}\) object is not the same \({ }^{\mathrm{p} 838}\) as the origin \({ }^{\mathrm{p837}}\) of the current entry \({ }^{\mathrm{p} 850}\) 's Document \({ }^{\text {p114 }}\) object, then run the following subsubsteps:
1. The current browsing context name \({ }^{\text {p819 }}\) must be stored with all the entries in the history that are associated with Document \({ }^{\text {p114 }}\) objects with the same origin \({ }^{\text {p838 }}\) as the active document \({ }^{\text {p811 }}\) and that are contiguous with the current entry \({ }^{\text {p850 }}\).
2. If the browsing context is a top-level browsing context \({ }^{\text {p814 }}\), but not an auxiliary browsing context \({ }^{\text {p814 }}\), then set the browsing context's name \({ }^{\text {p819 }}\) to the empty string.
3. Set the active document \({ }^{\text {p812 }}\) of the browsing context \({ }^{\text {p811 }}\) to entry's Document \({ }^{\text {p114 }}\) object.
4. If entry has a browsing context name \({ }^{\text {p819 }}\), then run the following subsubsteps:
1. Set the browsing context's browsing context name \({ }^{\mathrm{p} 819}\) to entry's browsing context name \({ }^{\mathrm{p} 819}\).
2. Clear any browsing context names \({ }^{\text {p819 }}\) of all entries in the history that are associated with Document \({ }^{\text {p114 }}\) objects with the same origin \({ }^{\text {p838 }}\) as the new active document \({ }^{\text {p811 }}\) and that are contiguous with entry.
5. If entry's Document \({ }^{\text {p114 }}\) object has any form controls whose autofill field name \({ }^{\text {p579 }}\) is "off \({ }^{p 574}{ }^{\text {" }}\), invoke the reset algorithm \({ }^{\text {p604 }}\) of each of those elements.
6. If the current document readiness \({ }^{\text {p117 }}\) of entry's Document \({ }^{\text {p114 }}\) object is "complete", then queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given entry's Document \({ }^{\text {p114' }}\) 's relevant global object \({ }^{\text {p924 }}\) to run the following subsubsteps:
1. If the Document \({ }^{\text {p114 }}\) 's page showing \({ }^{\text {p885 }}\) flag is true, then abort these steps.
2. Set the Document \({ }^{\text {p114' }}\) 's page showing \({ }^{\text {p885 }}\) flag to true.
3. Run any session history document visibility change steps for Document \({ }^{p 114}\) that are defined by other applicable specifications \({ }^{\text {p65 }}\).

Note
This is specifically intended for use by Page Visibility. [PAGEVIS] \({ }^{p 1289}\)
4. Fire an event named pageshow \({ }^{p 1282}\) at the Document \({ }^{p 114}\) object's relevant global object \({ }^{p 924}\), using PageTransitionEvent \({ }^{\text {p884 }}\), with the persisted \({ }^{\text {p885 }}\) attribute initialized to true, and legacy target override flag set.
5. Set the document's URL to entry's URL.
6. If entry has a URL whose fragment is not identical to that of the current entry \({ }^{\mathrm{p} 850} \mathrm{~s}\) s, and the two share the same Document \({ }^{\mathrm{p} 114}\) object, then let hash changed be true, and let old URL be the current entry \({ }^{\text {p850 ' } s ~} \mathrm{URL}\) and new URL be entry's URL. Otherwise, let hash changed be false.
7. If historyHandling is "replace \({ }^{\text {p866" ", then remove the entry immediately before the specified entry in the session history. }}\)
8. If entry is not an entry with persisted user state \({ }^{p 850}\), but its URL's fragment is non-null, then scroll to the fragment \({ }^{p 880}\).
9. Set the current entry \({ }^{\text {p850 }}\) to entry.
10. Let targetRealm be the current Realm Record.
11. If entry has serialized state \({ }^{\mathrm{p} 849}\), then let state be StructuredDeserialize \({ }^{\mathrm{p} 108}\) (entry's serialized state \({ }^{\mathrm{p849}}\), targetRealm). If this throws an exception, catch it, ignore the exception, and let state be null.
12. Otherwise, let state be null.
13. Set history. state \({ }^{p 852}\) to state.
14. Let state changed be true if entry's Document \({ }^{\text {p114 }}\) object has a latest entry \({ }^{\text {p850 }}\), and that entry is not entry; otherwise let it be false.
15. Set entry's Document \({ }^{\text {p114 }}\) object's latest entry \({ }^{\text {p850 }}\) to entry.
16. If nonBlockingEvents is false, then run the following substeps immediately \({ }^{\text {p42 }}\). Otherwise, queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given entry's Document \({ }^{\text {p114 }}\) 's relevant global object \({ }^{\text {p924 }}\) to run the following substeps instead.
1. If state changed is true, then fire an event named popstate \({ }^{\text {p1282 }}\) at the Document \({ }^{\text {p1144 }}\) object's relevant global object \({ }^{\text {p924 }}\), using PopStateEvent \({ }^{\text {p883 }}\), with the state \({ }^{\text {p884 }}\) attribute initialized to state.
2. If entry is an entry with persisted user state \({ }^{\text {p850 }}\), then the user agent may restore persisted user state \({ }^{\text {p883 }}\) and update aspects of the document and its rendering.
3. If hash changed is true, then fire an event named hashchange \({ }^{p 1281}\) at the browsing context \({ }^{p 811}\) 's active window \({ }^{p 811}\), using HashChangeEvent \({ }^{\text {p884 }}\), with the oldURL \({ }^{\text {p884 }}\) attribute initialized to old URL and the newURL \({ }^{\text {p884 }}\) attribute initialized to new URL.

\subsection*{7.10.10.1 Persisted user state restoration \({ }_{3}^{888}\)}

When the user agent is to restore persisted user state from a history entry, it must run the following steps immediately:
1. If the entry has a scroll restoration mode \({ }^{\mathrm{p855}}\), let scrollRestoration be that. Otherwise let scrollRestoration be "auto \({ }^{\mathrm{p} 850 \text { " }}\)
2. If scrollRestoration is "manual \({ }^{\text {p850" }}\), then the user agent should not restore the scroll position for the Document \({ }^{\text {p114 }}\) or any of its scrollable regions, with the exception of any child browsing contexts \({ }^{\text {p814 }}\) of Document \({ }^{\text {p114 }}\) s browsing context \({ }^{\text {p811 }}\) whose scroll restoration is controlled by their own history entry's scroll restoration mode \({ }^{\mathrm{p855}}\), otherwise, it may do so.
3. Optionally, update other aspects of the document and its rendering, for instance values of form fields, that the user agent had previously recorded.

\section*{Note}

This can even include updating the dir \(r^{p 142}\) attribute of textarea \({ }^{\text {p548 }}\) elements or input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attribute is in either the Text \({ }^{\text {p499 }}\) state or the Search \({ }^{\text {p499 }}\) state, if the persisted state includes the directionality of user input in such controls.

\section*{Note}

Not restoring the scroll position by user agent does not imply that the scroll position will be left at any particular value (e.g., ( 0,0 )). The actual scroll position depends on the navigation type and the user agent's particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.

\subsection*{7.10.10.2 The PopStateEvent \({ }^{p 883}\) interface \(\begin{gathered}\S_{3}^{p 88} \\ 3\end{gathered}\)}
```
[Exposed=Window]
interface PopStateEvent : Event {
    constructor(DOMString type, optional PopStateEventInit eventInitDict = {});
    readonly attribute any state;
};
```
```
dictionary PopStateEventInit : EventInit {
    any state = null;
};
```

\section*{For web developers (non-normative)}

\section*{event . state \({ }^{\text {p884 }}\)}

Returns a copy of the information that was provided to pushState() \({ }^{\text {p854 }}\) or replaceState() \()^{\text {p854 }}\).

The state attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the Document \({ }^{\text {p114 }}\).
7.10.10.3 The HashChangeEvent \({ }^{\text {p884 }}\) interface \(\S_{4}^{\text {p88 }}\)

IDL [Exposed=Window]
```
interface HashChangeEvent : Event {
    constructor(DOMString type, optional HashChangeEventInit eventInitDict = {});
    readonly attribute USVString oldURL;
    readonly attribute USVString newURL;
};
dictionary HashChangeEventInit : EventInit {
    USVString oldURL = "";
    USVString newURL = "";
};
```

\section*{For web developers (non-normative)}

\section*{event. oldURL \({ }^{\text {p884 }}\)}

Returns the URL of the session history entry \({ }^{\text {p849 }}\) that was previously current.
event. newURL \({ }^{\text {p884 }}\)
Returns the URL of the session history entry \({ }^{\text {p849 }}\) that is now current.

The oldURL attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the session history entry \({ }^{\text {p899 }}\) that was traversed from.

The newURL attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the session history entry \({ }^{\text {p849 }}\) that was traversed to.

\subsection*{7.10.10.4 The PageTransitionEvent \({ }^{\text {p884 }}\) interface \(\S_{4}^{\text {p88 }}\)}

IDL [Exposed=Window]
```
interface PageTransitionEvent : Event {
    constructor(DOMString type, optional PageTransitionEventInit eventInitDict = {});
    readonly attribute boolean persisted;
};
dictionary PageTransitionEventInit : EventInit {
    boolean persisted = false;
};
```

\section*{For web developers (non-normative)}

For the pageshow \({ }^{\text {p1282 }}\) event, returns false if the page is newly being loaded (and the load \({ }^{\text {p1282 }}\) event will fire). Otherwise, returns true.

For the pagehide \({ }^{p 1282}\) event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that (if nothing conspires to make the page unsalvageable) the page might be reused if the user navigates back to this page.

Things that can cause the page to be unsalvageable include:
- Listening for beforeunload \({ }^{p 1281}\) events
- Listening for unload \({ }^{\text {p1282 }}\) events
- Having iframe \({ }^{p 361} s\) that are not salvageable
- Active WebSocket \({ }^{\text {p1008 }}\) objects
- Aborting a Document \({ }^{\text {p887 }}\)

The persisted attribute must return the value it was initialized to. It represents the context information for the event.

\subsection*{7.10.11 Loading documents \(\S^{p 88}\)}

A Document \({ }^{\text {p114 }}\) has a completely loaded time (a time or null), which is initially null.
A Document \({ }^{\text {p114 }}\) is considered completely loaded if its completely loaded time \({ }^{\text {p885 }}\) is non-null.

To completely finish loading a Document \({ }^{\text {p114 }}\) document:
1. Assert: document's browsing context \({ }^{\mathrm{p} 811}\) is non-null.
2. Set document's completely loaded time \({ }^{\text {p885 }}\) to the current time.
3. Let container be document's browsing context \({ }^{\mathrm{p} 811}\) 's container \({ }^{\mathrm{p} 814}\).
4. If container is an iframe \({ }^{p 361}\) element, then queue an element task \({ }^{p 946}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given container to run the iframe load event steps \({ }^{\text {p364 }}\) given container.
5. Otherwise, if container is non-null, then queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{p 952}\) given container to fire an event named load \({ }^{p 1282}\) at container.

\subsection*{7.10.12 Unloading documents \(\S_{5}^{p 88}\)}

A Document \({ }^{p 114}\) has a salvageable state, which must initially be true, a fired unload flag, which must initially be false, and a page showing flag, which must initially be false. The page showing \({ }^{\text {p885 }}\) flag is used to ensure that scripts receive pageshow \({ }^{\text {p1282 }}\) and pagehide \({ }^{p 1282}\) events in a consistent manner (e.g. that they never receive two pagehide \({ }^{\text {p1282 }}\) events in a row without an intervening pageshow \({ }^{p 1282}\), or vice versa).

Event loops \({ }^{\text {p944 }}\) have a termination nesting level counter, which must initially be 0.

To prompt to unload, given a Document \({ }^{p 114}\) object document and optionally a recursiveFlag, run these steps:
1. Increase the event loop \({ }^{\text {p944 }}\) 's termination nesting level \({ }^{\text {p885 }}\) by 1.
2. Increase the document's ignore-opens-during-unload counter \({ }^{p 968}\) by 1.
3. Let event be the result of creating an event using BeforeUnloadEvent \({ }^{\text {p887 }}\).
4. Initialize event's type attribute to beforeunload \({ }^{p 1281}\) and its cancelable attribute true.
5. Dispatch: Dispatch event at document's relevant global object \({ }^{\text {p924 }}\).
6. Decrease the event loop \({ }^{\text {p944 }}\) 's termination nesting level \({ }^{\text {p885 }}\) by 1.
7. If any event listeners were triggered by the earlier dispatch step, then set document's salvageable \({ }^{p 885}\) state to false.
8. If document's active sandboxing flag set \({ }^{\text {p844 }}\) does not have its sandboxed modals flag \({ }^{\text {p843 }}\) set, and the returnValue \({ }^{\text {p887 }}\) attribute of the event object is not the empty string, or if the event was canceled, then the user agent may ask the user to confirm that they wish to unload the document.

Note
The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the returnValue \({ }^{\mathrm{p} 887}\) attribute is ignored.

The user agent is encouraged to avoid asking the user for confirmation if it judges that doing so would be annoying, deceptive, or pointless. A simple heuristic might be that if the user has not interacted with the document, the user agent would not ask for confirmation before unloading it.

If the user agent asks the user for confirmation, it must pause \({ }^{\text {p951 }}\) while waiting for the user's response.
If the user did not confirm the page navigation, then the user agent refused to allow the document to be unloaded.
9. If the recursiveFlag is not set, then:
1. Let descendants be the list of the descendant browsing contexts \({ }^{\text {p814 }}\) of document.
2. For each browsingContext in descendants:
1. Prompt to unload \({ }^{\mathrm{p} 885}\) browsingContext's active document \({ }^{\mathrm{p} 811}\) with the recursiveFlag set. If the user refused to allow the document to be unloaded \({ }^{\text {p886 }}\), then the user implicitly also refused to allow document to be unloaded \({ }^{\text {p886; }}\) break.
2. If the salvageable \({ }^{p 885}\) state of browsingContext's active document \({ }^{p 811}\) is false, then set the salvageable \({ }^{p 885}\) state of document to false.
10. Decrease the document's ignore-opens-during-unload counter \({ }^{\mathrm{p} 968}\) by 1 .

To unload a Document \({ }^{\text {p114 }}\) document, optionally given a recursiveFlag:
1. Increase the event loop \({ }^{\text {p944' }} \mathrm{s}\) termination nesting level \({ }^{\text {p885 }}\) by one.
2. Increase document's ignore-opens-during-unload counter \({ }^{\text {p968 }}\) by one.
3. If document's page showing \({ }^{\text {p885 }}\) flag is false, then jump to the step labeled unload event below (i.e. skip firing the pagehide \({ }^{\text {p1282 }}\) event and don't rerun the unloading document visibility change steps \({ }^{\text {p886 }}\) ).
4. Set document's page showing \({ }^{\text {p885 }}\) flag to false.
5. Fire an event named pagehide \({ }^{\text {p1282 }}\) at document's relevant global object \({ }^{\text {p924 }}\), using PageTransitionEvent \({ }^{\text {p884 }}\), with the persisted \({ }^{p 885}\) attribute initialized to true if document's salvageable \({ }^{p 885}\) state is true, and false otherwise, and legacy target override flag set.
6. Run any unloading document visibility change steps for document that are defined by other applicable specifications \({ }^{\text {p65 }}\).

\section*{Note}

This is specifically intended for use by Page Visibility. [PAGEVIS] \({ }^{\text {p1289 }}\)
7. Unload event: If document's fired unload \({ }^{\text {p885 }}\) flag is false, then fire an event named unload \({ }^{\text {p1282 }}\) at document's relevant global object \({ }^{\text {p924 }}\), with legacy target override flag set.
8. Decrease the event loop \({ }^{\text {p944' }}\) 'stermination nesting level \({ }^{\text {p885 }}\) by one.
9. If any event listeners were triggered by the earlier unload event step, then set document's salvageable \({ }^{p 885}\) state to false and set document's fired unload \({ }^{\text {p885 }}\) flag to true.
10. Run any unloading document cleanup steps \({ }^{\text {p887 }}\) for document that are defined by this specification and other applicable specifications \({ }^{\text {p65 }}\).
11. If the recursiveFlag is not set, then:
1. Let descendants be the list of the descendant browsing contexts \({ }^{\text {p814 }}\) of document.
2. For each browsingContext in descendants:
1. Unload \({ }^{\mathrm{p} 886}\) the active document \({ }^{\mathrm{p} 811}\) of browsingContext with the recursiveFlag set.
2. If the salvageable \({ }^{p 885}\) state of the active document \({ }^{p 811}\) of browsingContext is false, then set the salvageable \({ }^{\text {p885 }}\) state of document to false also.
3. If document's salvageable \({ }^{\text {p885 }}\) state is false, then discard \({ }^{\text {p831 }}\) document.
12. Decrease document's ignore-opens-during-unload counter \({ }^{\text {p968 }}\) by one.

This specification defines the following unloading document cleanup steps. Other specifications can define more. Given a Document \({ }^{\text {p114 }}\) document:
1. Let window be document's relevant global object \({ }^{\text {p924 }}\).
2. For each WebSocket \({ }^{\text {p1008 }}\) object webSocket whose relevant global object \({ }^{\mathrm{p} 924}\) is window, make disappear \({ }^{\text {p1015 }}\) webSocket. If this affected any WebSocket \({ }^{\text {p1008 }}\) objects, then set document's salvageable \({ }^{\text {p885 }}\) state to false.
3. If document's salvageable \({ }^{p 885}\) state is false, then:
1. For each EventSource \({ }^{\text {p1000 }}\) object eventSource whose relevant global object \({ }^{\text {p924 }}\) is equal to window, forcibly close \({ }^{\text {p1007 }}\) eventSource.
2. Empty window's list of active timers \({ }^{\text {p973 }}\).
7.10.12.1 The BeforeUnloadEvent \({ }^{\text {p887 }}\) interface \(\S_{7}^{\text {p88 }}\)

IDL [Exposed=Window]
interface BeforeUnloadEvent : Event \{ attribute DOMString returnValue; \};

\section*{Note}

There are no BeforeUnloadEvent \({ }^{\text {p887 }}\)-specific initialization methods.

The BeforeUnloadEvent \({ }^{\text {p887 }}\) interface is a legacy interface which allows prompting to unload \({ }^{\text {p885 }}\) to be controlled not only by canceling the event, but by setting the returnValue \({ }^{\text {p887 }}\) attribute to a value besides the empty string. Authors should use the preventDefault () method, or other means of canceling events, instead of using returnValue \({ }^{\text {p887 }}\).

The returnValue attribute controls the process of prompting to unload \({ }^{p 885}\). When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.

\section*{Note}

This attribute is a DOMString only for historical reasons. Any value besides the empty string will be treated as a request to ask the user for confirmation.

\subsection*{7.10.13 Aborting a document load \(\S^{p 88}\)}

To abort a Document \({ }^{\text {p114 }}\) document:
1. Abort \({ }^{\mathrm{p} 887}\) the active documents \({ }^{\mathrm{p} 811}\) of every child browsing context \({ }^{\mathrm{p} 814}\). If this results in any of those Document \({ }^{p 114}\) objects having their salvageable \({ }^{p 885}\) state set to false, then set document's salvageable \({ }^{p 885}\) state to false also.
2. Cancel any instances of the fetch algorithm in the context of document, discarding any tasks \({ }^{\text {p944 }}\) queued \({ }^{\text {p945 }}\) for them, and discarding any further data received from the network for them. If this resulted in any instances of the fetch algorithm being canceled or any queued \({ }^{\text {p945 }}\) tasks \(^{\text {p944 }}\) or any network data getting discarded, then set document's salvageable \({ }^{\text {p885 }}\) state to false.
3. If document has an active parser \({ }^{\text {p117 }}\), then:
1. Set document's active parser was aborted \({ }^{\text {p968 }}\) to true.
2. Abort that parser \({ }^{\text {p1165 }}\).
3. Set document's salvageable \({ }^{p 885}\) state to false.

User agents may allow users to explicitly invoke the abort a document \({ }^{\mathrm{p} 887}\) algorithm for a Document \({ }^{\mathrm{p} 114}\). If the user does so, then, if that Document \({ }^{\text {p114 }}\) is an active document \({ }^{\text {p811 }}\), the user agent should queue a task \({ }^{\text {p945 }}\) to fire an event named abort \({ }^{\text {p1281 }}\) at that Document \({ }^{\text {p114 }}\) object's relevant global object \({ }^{\text {p924 }}\) before invoking the abort \({ }^{\text {p887 }}\) algorithm.

To stop document loading given a Document \({ }^{p 114}\) object document, run these steps:
1. If document is not an active document \({ }^{\text {p811 }}\), then return.
2. Let browsingContext be document's browsing context \({ }^{\mathrm{p} 811}\).
3. If there is an existing attempt to navigate \({ }^{\text {p866 }}\) browsingContext and that attempt is not currently running the unload a document \({ }^{\mathrm{p886}}\) algorithm, then cancel that navigation \({ }^{\text {p866 }}\).
4. Abort \({ }^{\mathrm{p887}}\) document.

\subsection*{7.10.14 The `X-Frame-Options \({ }^{\text {p1260` }}\) header \(\S_{8}^{\text {p88 }}\)}

The `X-Frame-Options \({ }^{\text {p1260` }}\) HTTP response header is a legacy way of controlling whether and how a Document \({ }^{\text {p114 }}\) may be loaded inside of a child browsing context \({ }^{\text {p814 }}\). It is obsoleted by the frame-ancestors CSP directive, which provides more granular control over the same situations. It was originally defined in HTTP Header Field X-Frame-Options, but the definition and processing model here supersedes that document. [CSP] \({ }^{\text {p1285 }}[\text { RFC7034] }]^{\text {p1291 }}\)

\section*{Note}

In particular, HTTP Header Field X-Frame-Options specified an `ALLOW-FROM` variant of the header, but that is not to be implemented.

\section*{Note}

Per the below processing model, if both a CSP frame-ancestors directive and an `X-Frame-0ptions \({ }^{\text {p1260 }}\) ' header are used in the same response, then `X-Frame-Options \({ }^{\text {p1260 ` }}\) ' is ignored.

For web developers and conformance checkers, its value ABNF is:
```
X-Frame-Options = "DENY" / "SAMEORIGIN"
```

To check a navigation response's adherence to `X-Frame-Options`, given a response response, a browsing context \({ }^{\text {p811 }}\) browsingContext, and an origin \({ }^{\mathrm{p837}}\) destinationOrigin:
1. If browsingContext is not a child browsing context \({ }^{\text {p814 }}\), then return true.
2. For each policy of response's CSP list:
1. If policy's disposition is not "enforce", then continue.
2. If policy's directive set contains a frame-ancestors directive, then return true.
3. Let rawXFrameOptions be the result of getting, decoding, and splitting `X-Frame-Options \({ }^{\text {p1260`` }}\) from response's header list.
4. Let \(x\) FrameOptions be a new set.
5. For each value of rawXFrameOptions, append value, converted to ASCII lowercase, to xFrameOptions.
6. If \(x\) FrameOptions's size is greater than 1, and \(x\) FrameOptions contains any of "deny", "allowall", or "sameorigin", then return false.
but appear confused.

\section*{Note}

This is the only impact of the legacy `ALLOWALL` value on the processing model.
7. If \(x\) FrameOptions's size is greater than 1 , then return true.

\section*{Note}

This means it contains multiple invalid values, which we treat the same way as if the header was omitted entirely.
8. If \(x\) FrameOptions[0] is "deny", then return false.
9. If \(x\) FrameOptions[0] is "sameorigin", then:
1. Let containerDocument be browsingContext's container document \({ }^{\mathrm{p} 814}\).
2. While containerDocument is not null:
1. If containerDocument's origin \({ }^{\text {p837 }}\) is not same origin \({ }^{\text {p838 }}\) with destinationOrigin, then return false.
2. Let containerBC be containerDocument's browsing context \({ }^{\mathrm{p} 811}\).
3. Set containerDocument to containerBC's container document \({ }^{\mathrm{p814}}\), if containerBC is non-null; otherwise, null.
10. Return true.

\section*{Note}

> If we've reached this point then we have a lone invalid value (which could potentially be one the legacy `ALLOWALL` or `ALLOW- FROM` forms). These are treated as if the header were omitted entirely.

\section*{Example}

The following table illustrates the processing of various values for the header, including non-conformant ones:
\begin{tabular}{|c|c|c|}
\hline \({ }^{\text {® }}\) X-Frame-0ptions \({ }^{\text {p1260, }}\) & Valid & Result \\
\hline 'DENY' & \(\checkmark\) & embedding disallowed \\
\hline 'SAMEORIGIN` & \(\checkmark\) & same-origin embedding allowed \\
\hline `INVALID` & \(\times\) & embedding allowed \\
\hline `ALLOWALL' & \(\times\) & embedding allowed \\
\hline `ALLOW-FROM=https://example.com/` & \(\times\) & embedding allowed (from anywhere) \\
\hline
\end{tabular}

\section*{Example}

The following table illustrates how various non-conformant cases involving multiple values are processed:
\begin{tabular}{|c|c|}
\hline ` X-Frame-Options \({ }^{\text {p1260, }}\) & Result \\
\hline `SAMEORIGIN, SAMEORIGIN` & same-origin embedding allowed \\
\hline `SAMEORIGIN, DENY` & embedding disallowed \\
\hline `SAMEORIGIN,` & embedding disallowed \\
\hline `SAMEORIGIN, ALLOWALL` & embedding disallowed \\
\hline `SAMEORIGIN, INVALID` & embedding disallowed \\
\hline `ALLOWALL, INVALID` & embedding disallowed \\
\hline `ALLOWALL,' & embedding disallowed \\
\hline `INVALID, INVALID` & embedding allowed \\
\hline
\end{tabular}

The same results are obtained whether the values are delivered in a single header whose value is comma-delimited, or in multiple headers.

\subsection*{7.11 Offline web applications \(\S^{\text {p8s }}\)}

This feature is in the process of being removed from the web platform. (This is a long process that takes many years.) Using any of the offline web application features at this time is highly discouraged. Use service workers instead. [SW] \({ }^{\text {p1291 }}\)

\subsection*{7.11.1 Introduction \(\S^{\text {p89 }}\)}

This section is non-normative.
In order to enable users to continue interacting with web applications and documents even when their network connection is unavailable - for instance, because they are traveling outside of their ISP's coverage area - authors can provide a manifest which lists the files that are needed for the web application to work offline and which causes the user's browser to keep a copy of the files for use offline.

To illustrate this, consider a simple clock applet consisting of an HTML page "clock1.html", a CSS style sheet "clock. css", and a JavaScript script "clock.js".

Before adding the manifest, these three files might look like this:
```
<!-- clock1.html -->
<!DOCTYPE HTML>
<html lang="en">
    <head>
        <meta charset="utf-8">
        <title>Clock</title>
        <script src="clock.js"></script>
        <link rel="stylesheet" href="clock.css">
    </head>
    <body>
        <p>The time is: <output id="clock"></output></p>
    </body>
</html>
```

CSS
```

/* clock.css */
output { font: 2em sans-serif; }

```
```

/* clock.js */
setInterval(function () {
document.getElementById('clock').value = new Date();
}, 1000);

```

If the user tries to open the "clockl.html" page while offline, though, the user agent (unless it happens to have it still in the local cache) will fail with an error.

The author can instead provide a manifest of the three files, say "clock. appcache":
CACHE MANIFEST
clock2.html
clock.css
clock.js
With a small change to the HTML file, the manifest (served as text/cache-manifest \({ }^{p 1253}\) ) is linked to the application:
```

<!-- clock2.html -->
<!DOCTYPE HTML>

<html lang="en" manifest="clock.appcache">
    <head>
    <meta charset="utf-8">
    <title>Clock</title>
```
```
    <script src="clock.js"></script>
    <link rel="stylesheet" href="clock.css">
</head>
<body>
    <p>The time is: <output id="clock"></output></p>
</body>
</html>
```

Now, if the user goes to the page, the browser will cache the files and make them available even when the user is offline.

\section*{Note}

Authors are encouraged to include the main page in the manifest also, but in practice the page that referenced the manifest is automatically cached even if it isn't explicitly mentioned.

\section*{Note}

With the exception of "no-store" directive, HTTP cache headers and restrictions on caching pages served over TLS (encrypted, using https:) are overridden by manifests. Thus, pages will not expire from an application cache before the user agent has updated it, and even applications served over TLS can be made to work offline.

\section*{View this example online.}

\subsection*{7.11.1.1 Supporting offline caching for legacy applications \(\S^{\text {p89 }}\)}

This section is non-normative.

The application cache feature works best if the application logic is separate from the application and user data, with the logic (markup, scripts, style sheets, images, etc) listed in the manifest and stored in the application cache, with a finite number of static HTML pages for the application, and with the application and user data stored in Web Storage or a client-side Indexed Database, updated dynamically using Web Sockets, XMLHttpRequest, server-sent events, or some other similar mechanism.

This model results in a fast experience for the user: the application immediately loads, and fresh data is obtained as fast as the network will allow it (possibly while stale data shows).

Legacy applications, however, tend to be designed so that the user data and the logic are mixed together in the HTML, with each operation resulting in a new HTML page from the server.

\section*{Example}

For example, consider a news application. The typical architecture of such an application, when not using the application cache feature, is that the user fetches the main page, and the server returns a dynamically-generated page with the current headlines and the user interface logic mixed together.

A news application designed for the application cache feature, however, would instead have the main page just consist of the logic, and would then have the main page fetch the data separately from the server, e.g. using XMLHttpRequest.

The mixed-content model does not work well with the application cache feature: since the content is cached, it would result in the user always seeing the stale data from the previous time the cache was updated.

While there is no way to make the legacy model work as fast as the separated model, it can at least be retrofitted for offline use using the prefer-online \({ }^{\text {p893 }}\) application cache mode \({ }^{\text {p893 }}\). To do so, list all the static resources used by the HTML page you want to have work offline in an application cache manifest \({ }^{\text {p892 }}\), use the manifest \({ }^{\text {p152 }}\) attribute to select that manifest from the HTML file, and then add the following line at the bottom of the manifest:
```

SETTINGS:
prefer-online
NETWORK:
*

```

This causes the application cache \({ }^{\text {p892 }}\) to only be used for primary entries \({ }^{\text {p892 }}\) when the user is offline, and causes the application cache to be used as an atomic HTTP cache (essentially pinning resources listed in the manifest), while allowing all resources not listed in the
manifest to be accessed normally when the user is online.

\subsection*{7.11.1.2 Events summary \({ }_{8}^{\text {§ }}{ }_{2}^{89}\)}

This section is non-normative.

When the user visits a page that declares a manifest, the browser will try to update the cache. It does this by fetching a copy of the manifest and, if the manifest has changed since the user agent last saw it, redownloading all the resources it mentions and caching them anew.

As this is going on, a number of events get fired on the ApplicationCache \({ }^{\text {p999 }}\) object to keep the script updated as to the state of the cache update, so that the user can be notified appropriately. The events are as follows:
\begin{tabular}{|c|c|c|c|}
\hline Event name & Interface & Fired when... & Next events \\
\hline checking & Event & The user agent is checking for an update, or attempting to download the manifest for the first time. This is always the first event in the sequence. & noupdate \({ }^{\text {p892 }}\), downloading \({ }^{\text {p892 }}\), obsolete \({ }^{\text {p892 }}\), error \({ }^{\text {p892 }}\) \\
\hline noupdate & Event & The manifest hadn't changed. & Last event in sequence. \\
\hline downloading & Event & The user agent has found an update and is fetching it, or is downloading the resources listed by the manifest for the first time. & \[
\begin{aligned}
& \text { progress }^{\mathrm{p} 892} \text {, error }{ }^{\mathrm{p892}}, \\
& \text { cached } \\
& \text { updateready } \\
& \text { upg2 }
\end{aligned}
\] \\
\hline progress & ProgressEvent & The user agent is downloading resources listed by the manifest. The event object's total attribute returns the total number of files to be downloaded. The event object's loaded attribute returns the number of files processed so far. & \begin{tabular}{l}
progress \({ }^{\text {p892 }}\), error \({ }^{\text {p892 }}\), \\
cached \({ }^{\text {p892 }}\), \\
updateready \({ }^{\text {p892 }}\)
\end{tabular} \\
\hline cached & Event & The resources listed in the manifest have been downloaded, and the application is now cached. & Last event in sequence. \\
\hline updateready & Event & The resources listed in the manifest have been newly redownloaded, and the script can use swapCache() \({ }^{\text {p911 }}\) to switch to the new cache. & Last event in sequence. \\
\hline obsolete & Event & The manifest was found to have become a 404 or 410 page, so the application cache is being deleted. & Last event in sequence. \\
\hline \multirow[t]{4}{*}{error} & \multirow[t]{4}{*}{Event} & The manifest was a 404 or 410 page, so the attempt to cache the application has been aborted. & \multirow[t]{3}{*}{Last event in sequence.} \\
\hline & & The manifest hadn't changed, but the page referencing the manifest failed to download properly. & \\
\hline & & A fatal error occurred while fetching the resources listed in the manifest. & \\
\hline & & The manifest changed while the update was being run. & The user agent will try fetching the files again momentarily. \\
\hline
\end{tabular}

These events are cancelable; their default action is for the user agent to show download progress information. If the page shows its own update UI, canceling the events will prevent the user agent from showing redundant progress information.

\subsection*{7.11.2 Application caches \(\S^{p 89}\)}

An application cache is a set of cached resources consisting of:
- One or more resources (including their out-of-band metadata, such as HTTP headers, if any), identified by URLs, each falling into one (or more) of the following categories:

\section*{Primary entries}

Note
These are documents that were added to the cache because a browsing context \({ }^{p 811}\) was navigated \({ }^{\text {p866 }}\) to that document and the document indicated that this was its cache, using the manifest \({ }^{\mathrm{p} 152}\) attribute.

\section*{The manifest}

Note
This is the resource corresponding to the URL that was given in a primary entry's html \({ }^{\text {p152 }}\) element's manifest \({ }^{\text {p152 }}\) attribute. The manifest is fetched and processed during the application cache download process \({ }^{\text {p900 }}\). All the primary entries \({ }^{p 892}\) have the same origin \({ }^{p 838}\) as the manifest.

\section*{Explicit entries}

\section*{Note}
\[
\text { These are the resources that were listed in the cache's manifest }{ }^{p 892} \text { in an explicit section }{ }^{p 896} \text {. }
\]

\section*{Fallback entries}

\section*{Note}

These are the resources that were listed in the cache's manifest \({ }^{p 892}\) in a fallback section \({ }^{p 896}\).

Explicit entries \({ }^{\mathrm{p893}}\) and Fallback entries \({ }^{\mathrm{p} 893}\) can be marked as foreign, which means that they have a manifest \({ }^{p 152}\) attribute but that it doesn't point at this cache's manifest \({ }^{\text {p892 }}\).
```

Note
A URL in the list can be flagged with multiple different types, and thus an entry can end up being categorized as multiple
entries. For example, an entry can be a manifest entry and an explicit entry at the same time, if the manifest is listed
within the manifest.

```
- Zero or more fallback namespaces, each of which is mapped to a fallback entry \({ }^{\text {p893 }}\).

\section*{Note}

These are URLs used as prefix match patterns \({ }^{p 894}\) for resources that are to be fetched from the network if possible, or to be replaced by the corresponding fallback entry \({ }^{\text {p893 }}\) if not. Each namespace URL has the same origin \({ }^{\text {p838 }}\) as the manifest \({ }^{p 892}\).
- Zero or more URLs that form the online safelist namespaces.

\section*{Note}

These are used as prefix match patterns, and declare URLs for which the user agent will ignore the application cache, instead fetching them normally (i.e. from the network or local HTTP cache as appropriate).
- An online safelist wildcard flag, which is either open or blocking.

\section*{Note}

The open state indicates that any URL not listed as cached is to be implicitly treated as being in the online safelist namespaces \({ }^{p 893}\); the blocking state indicates that URLs not listed explicitly in the manifest are to be treated as unavailable.
- A cache mode flag, which is either in the fast state or the prefer-online state.

Each application cache \({ }^{\text {p892 }}\) has a completeness flag, which is either complete or incomplete.

An application cache group is a group of application caches \({ }^{\text {p892 }}\), identified by the absolute URL of a resource manifest \({ }^{\text {p892 }}\) which is used to populate the caches in the group.

An application cache \({ }^{\mathrm{p} 892}\) is newer than another if it was created after the other (in other words, application caches \({ }^{\mathrm{p} 892}\) in an application cache group \({ }^{\text {p893 }}\) have a chronological order).

Only the newest application cache \({ }^{\mathrm{p892}}\) in an application cache group \({ }^{\mathrm{p} 893}\) can have its completeness flag \({ }^{\mathrm{p} 893}\) set to incomplete; the others are always all complete.

Each application cache group \({ }^{\text {p893 }}\) has an update status, which is one of the following: idle, checking, downloading.
A relevant application cache is an application cache \({ }^{\text {p892 }}\) that is the newest \({ }^{\text {p893 }}\) in its group \({ }^{\text {p893 }}\) to be complete.
Each application cache group \({ }^{p 893}\) has a list of pending primary entries. Each entry in this list consists of a resource and a corresponding Document \({ }^{\text {p114 }}\) object. It is used during the application cache download process \({ }^{\text {p900 }}\) to ensure that new primary entries are cached even if the application cache download process \({ }^{\text {p900 }}\) was already running for their application cache group \({ }^{\text {p893 }}\) when they were loaded.

An application cache group \({ }^{p 893}\) can be marked as obsolete, meaning that it must be ignored when looking at what application cache groups \({ }^{\text {p893 }}\) exist.

A cache host is a Document \({ }^{\text {p114 }}\) object.
Each cache host \({ }^{\text {p894 }}\) has an associated ApplicationCache \({ }^{\text {p999 }}\) object.
Each cache host \({ }^{\mathrm{p} 894}\) initially is not associated with an application cache \({ }^{\text {p892 }}\), but can become associated with one early during the page load process, when steps in the parser \({ }^{\text {p1134 }}\) and in the navigation \({ }^{\text {p866 }}\) sections cause cache selection \({ }^{\text {p907 }}\) to occur.

Multiple application caches \({ }^{\text {p892 }}\) in different application cache groups \({ }^{\text {p893 }}\) can contain the same resource, e.g. if the manifests all reference that resource. If the user agent is to select an application cache from a list of relevant application caches \({ }^{\text {p893 }}\) that contain a resource, the user agent must use the application cache that the user most likely wants to see the resource from, taking into account the following:
- which application cache was most recently updated,
- which application cache was being used to display the resource from which the user decided to look at the new resource, and
- which application cache the user prefers.

A URL matches a fallback namespace if there exists a relevant application cache \({ }^{\text {p893 }}\) whose manifest \({ }^{\mathrm{p892}} \mathrm{I}^{\mathrm{s}} \mathrm{s}\) URL has the same origin \({ }^{\text {p838 }}\) as the URL in question, and that has a fallback namespace \({ }^{\text {p893 }}\) that is a prefix match \({ }^{\text {p67 }}\) for the URL being examined. If multiple fallback namespaces match the same URL, the longest one is the one that matches. A URL looking for a fallback namespace can match more than one application cache at a time, but only matches one namespace in each cache.

\section*{Example}

If a manifest https://example.com/appl/manifest declares that https://example.com/resources/images is a fallback namespace, and the user navigates to https://example.com:80/resources/images/cat.png, then the user agent will decide that the application cache identified by https://example.com/appl/manifest contains a namespace with a match for that URL.

\subsection*{7.11.3 The cache manifest syntax \(\S^{p 89}\)}

\subsection*{7.11.3.1 Some sample manifests \(\mathbb{\S}_{4}{ }_{4}^{889}\)}

This section is non-normative.

\section*{Example}

This example manifest requires two images and a style sheet to be cached and safelists a CGI script.
```

CACHE MANIFEST

# the above line is required

# this is a comment

# there can be as many of these anywhere in the file

# they are all ignored

        # comments can have spaces before them
        # but must be alone on the line
    
# blank lines are ignored too

# these are files that need to be cached they can either be listed

# first, or a "CACHE:" header could be put before them, as is done

# lower down.

images/sound-icon.png
images/background.png

# note that each file has to be put on its own line

```
```

# here is a file for the online safelist -- it isn't cached, and

# references to this file will bypass the cache, always hitting the

# network (or trying to, if the user is offline).

NETWORK:
comm.cgi

# here is another set of files to cache, this time just the CSS file.

CACHE:
style/default.css

```

It could equally well be written as follows:
```

CACHE MANIFEST
NETWORK:
comm.cgi
CACHE:
style/default.css
images/sound-icon.png
images/background.png

```

\section*{Example}

Offline application cache manifests can use absolute paths or even absolute URLs:

\section*{CACHE MANIFEST}
```

/main/home
/main/app.js
/settings/home
/settings/app.js
https://img.example.com/logo.png
https://img.example.com/check.png
https://img.example.com/cross.png

```

\section*{Example}

The following manifest defines a catch-all error page that is displayed for any page on the site while the user is offline. It also specifies that the online safelist wildcard flag \({ }^{\text {p893 }}\) is open, meaning that accesses to resources on other sites will not be blocked. (Resources on the same site are already not blocked because of the catch-all fallback namespace.)

So long as all pages on the site reference this manifest, they will get cached locally as they are fetched, so that subsequent hits to the same page will load the page immediately from the cache. Until the manifest is changed, those pages will not be fetched from the server again. When the manifest changes, then all the files will be redownloaded.

Subresources, such as style sheets, images, etc, would only be cached using the regular HTTP caching semantics, however.
```

CACHE MANIFEST
FALLBACK:
/ /offline.html
NETWORK:
*

```

\subsection*{7.11.3.2 Writing cache manifests \(\S^{889}\)}

Manifests must be served using the text/cache-manifest \({ }^{\text {p1253 }}\) MIME type. All resources served using the text/cache-manifest \({ }^{\text {p1253 }}\) MIME type must follow the syntax of application cache manifests, as described in this section.

An application cache manifest is a text file, whose text is encoded using UTF-8. Data in application cache manifests is line-based. Newlines must be represented by U+000A LINE FEED (LF) characters, U+000D CARRIAGE RETURN (CR) characters, or U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) pairs. [ENCODING] \({ }^{\text {p1287 }}\)

This is a willful violation \({ }^{p 27}\) of RFC 2046, which requires all text/* types to only allow CRLF line breaks. This requirement, however, is outdated; the use of CR, LF, and CRLF line breaks is commonly supported and indeed sometimes CRLF is not supported by text editors. [RFC2046] \({ }^{\text {p1290 }}\)

The first line of an application cache manifest must consist of the string "CACHE", a single U+0020 SPACE character, the string "MANIFEST", and either a U+0020 SPACE character, a U+0009 CHARACTER TABULATION (tab) character, a U+000A LINE FEED (LF) character, or a U+000D CARRIAGE RETURN (CR) character. The first line may optionally be preceded by a U+FEFF BYTE ORDER MARK (BOM) character. If any other text is found on the first line, it is ignored.

Subsequent lines, if any, must all be one of the following:

\section*{A blank line}

Blank lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters only.

\section*{A comment}

Comment lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, followed by a single U+0023 NUMBER SIGN character (\#), followed by zero or more characters other than U+000A LINE FEED (LF) and U+000D CARRIAGE RETURN (CR) characters.

\section*{Note}

> Comments need to be on a line on their own. If they were to be included on a line with a URL, the "\#" would be mistaken for part of a fragment.

\section*{A section header}

Section headers change the current section. There are four possible section headers:
CACHE:
Switches to the explicit section.
FALLBACK:
Switches to the fallback section.
NETWORK:
Switches to the online safelist section.
SETTINGS:
Switches to the settings section.
Section header lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, followed by one of the names above (including the U+003A COLON character (:)) followed by zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

Ironically, by default, the current section is the explicit section \({ }^{\text {p896 }}\).

\section*{Data for the current section}

The format that data lines must take depends on the current section.
When the current section is the explicit section \({ }^{\text {p896 }}\), data lines must consist of zero or more \(U+0020\) SPACE and U+0009 CHARACTER TABULATION (tab) characters, a valid URL string identifying a resource other than the manifest itself, and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

When the current section is the fallback section \({ }^{\text {p896 }}\), data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, a valid URL string identifying a resource other than the manifest itself, one or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, another valid URL string identifying a resource other than the manifest itself, and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

When the current section is the online safelist section \({ }^{\text {p896 }}\), data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, either a single U+002A ASTERISK character (*) or a valid URL string identifying a resource other than the manifest itself, and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

When the current section is the settings section \({ }^{\text {p896 }}\), data lines must consist of zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters, a setting \({ }^{\text {p897 }}\), and then zero or more U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters.

Currently only one setting is defined:

\section*{The cache mode setting}

This consists of the string "prefer-online". It sets the cache mode \({ }^{\text {p893 }}\) to prefer-online \({ }^{\text {p893 }}\). (The cache mode \({ }^{\text {p893 }}\) defaults to fast \({ }^{8893}\).)

Within a settings section \({ }^{\text {p896 }}\), each setting \({ }^{\text {p897 }}\) must occur no more than once.
Manifests may contain sections more than once. Sections may be empty
URLs that are to be fallback pages associated with fallback namespaces \({ }^{\text {p893 }}\), and those namespaces themselves, must be given in fallback sections \({ }^{\text {p896 }}\), with the namespace being the first URL of the data line, and the corresponding fallback page being the second URL. All the other pages to be cached must be listed in explicit sections \({ }^{\text {p896 }}\).

Fallback namespaces \({ }^{\mathrm{p} 893}\) and fallback entries \({ }^{\mathrm{p893}}\) must have the same origin \({ }^{\mathrm{p838}}\) as the manifest itself. Fallback namespaces \({ }^{\mathrm{p893}}\) must also be in the same path as the manifest's URL.

A fallback namespace \({ }^{\text {p893 }}\) must not be listed more than once.
Namespaces that the user agent is to put into the online safelist \({ }^{\text {p893 }}\) must all be specified in online safelist sections \({ }^{\text {p896 }}\). (This is needed for any URL that the page is intending to use to communicate back to the server.) To specify that all URLs are automatically safelisted in this way, a U+002A ASTERISK character (*) may be specified as one of the URLs.

Authors should not include namespaces in the online safelist \({ }^{\text {p893 }}\) for which another namespace in the online safelist \({ }^{\text {p893 }}\) is a prefix match \({ }^{\mathrm{p} 67}\).

Relative URLs must be given relative to the manifest's own URL. All URLs in the manifest must have the same scheme as the manifest itself (either explicitly or implicitly, through the use of relative URLs). [URL] \({ }^{\text {p1292 }}\)

URLs in manifests must not have fragments (i.e. the U+0023 NUMBER SIGN character isn't allowed in URLs in manifests).
Fallback namespaces \({ }^{\text {p893 }}\) and namespaces in the online safelist \({ }^{\text {p893 }}\) are matched by prefix match \({ }^{\text {p67 }}\).

\subsection*{7.11.3.3 Parsing cache manifests \(\S^{p 89}\)}

When a user agent is to parse a manifest, it means that the user agent must run the following steps:
1. UTF-8 decode the byte stream corresponding with the manifest to be parsed.
```

Note
The UTF-8 decode algorithm strips a leading BOM, if any.

```
2. Let base URL be the absolute URL representing the manifest.
3. Apply the URL parser to base URL, and let manifest path be the path component thus obtained.
4. Remove all the characters in manifest path after the last U+002F SOLIDUS character (/), if any. (The first character and the last character in manifest path after this step will both be slashes, the URL path separator character.)
5. Apply the URL parser steps to the base URL, so that the components from its URL record can be used by the subsequent steps of this algorithm.
6. Let explicit URLs be an initially empty list of absolute URLs for explicit entries \({ }^{\text {p893 }}\).
7. Let fallback URLs be an initially empty mapping of fallback namespaces \({ }^{\text {p893 }}\) to absolute URLs for fallback entries \({ }^{\text {p893 }}\).
8. Let online safelist namespaces be an initially empty list of absolute URLs for an online safelist \({ }^{p 893}\).
9. Let online safelist wildcard flag be blocking.
10. Let cache mode flag be fast.
11. Let input be the decoded text of the manifest's byte stream.
12. Let position be a pointer into input, initially pointing at the first character.
13. If the characters starting from position are "CACHE", followed by a U+0020 SPACE character, followed by "MANIFEST", then advance position to the next character after those. Otherwise, this isn't a cache manifest; return with a failure while checking for the magic signature.
14. If the character at position is neither a U+0020 SPACE character, a U+0009 CHARACTER TABULATION (tab) character, U+000A LINE FEED (LF) character, nor a U+000D CARRIAGE RETURN (CR) character, then this isn't a cache manifest; return with a failure while checking for the magic signature.
15. This is a cache manifest. The algorithm cannot fail beyond this point (though bogus lines can get ignored).
16. Collect a sequence of code points that are not U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters from input given position, and ignore those characters. (Extra text on the first line, after the signature, is ignored.)
17. Let mode be "explicit".
18. Start of line: If position is past the end of input, then jump to the last step. Otherwise, collect a sequence of code points that are U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, or U+0009 CHARACTER TABULATION (tab) characters from input given position.
19. Now, collect a sequence of code points that are not \(\mathrm{U}+000 \mathrm{~A}\) LINE FEED (LF) or U+000D CARRIAGE RETURN (CR) characters from input given position, and let the result be line.
20. Drop any trailing U+0020 SPACE and U+0009 CHARACTER TABULATION (tab) characters at the end of line.
21. If line is the empty string, then jump back to the step labeled start of line.
22. If the first character in line is a U+0023 NUMBER SIGN character (\#), then jump back to the step labeled start of line.
23. If line equals "CACHE:" (the word "CACHE" followed by a U+003A COLON character (:)), then set mode to "explicit" and jump back to the step labeled start of line.
24. If line equals "FALLBACK:" (the word "FALLBACK" followed by a U+003A COLON character (:)), then set mode to "fallback" and jump back to the step labeled start of line.
25. If line equals "NETWORK:" (the word "NETWORK" followed by a U+003A COLON character (:)), then set mode to "online safelist" and jump back to the step labeled start of line.
26. If line equals "SETTINGS:" (the word "SETTINGS" followed by a U+003A COLON character (:)), then set mode to "settings" and jump back to the step labeled start of line.
27. If line ends with a U+003A COLON character (:), then set mode to "unknown" and jump back to the step labeled start of line.
28. This is either a data line or it is syntactically incorrect.
29. Let position be a pointer into line, initially pointing at the start of the string
30. Let tokens be a list of strings, initially empty.
31. While position doesn't point past the end of line:
1. Let current token be an empty string.
2. While position doesn't point past the end of line and the character at position is neither a U+0020 SPACE nor a U+0009 CHARACTER TABULATION (tab) character, add the character at position to current token and advance position to the next character in input.
3. Add current token to the tokens list.
4. While position doesn't point past the end of line and the character at position is either a U+0020 SPACE or a U+0009 CHARACTER TABULATION (tab) character, advance position to the next character in input.
32. Process tokens as follows:

\section*{\(\rightarrow\) If mode is "explicit"}

Let urlRecord be the result of parsing the first item in tokens with base URL; ignore the rest.
If urlRecord is failure, then jump back to the step labeled start of line.

If urIRecord has a different scheme component than base URL (the manifest's URL), then jump back to the step labeled start of line.

Let new URL be the result of applying the URL serializer algorithm to urlRecord, with the exclude fragment flag set.
Add new URL to the explicit URLs.

\section*{\(\hookrightarrow\) If mode is "fallback"}

Let part one be the first token in tokens, and let part two be the second token in tokens.
Let urlRecordOne be the result of parsing part one with base URL.
Let urIRecordTwo be the result of parsing part two with base URL.
If either urlRecordOne or urlRecordTwo are failure, then jump back to the step labeled start of line.
If the origin of either urIRecordOne or urIRecordTwo is not same origin \({ }^{\text {p838 }}\) with the manifest's URL origin, then jump back to the step labeled start of line.

Let part one path be the path component of urlRecordOne.
If manifest path is not a prefix match \({ }^{\text {p67 }}\) for part one path, then jump back to the step labeled start of line.
Let part one be the result of applying the URL serializer algorithm to urlRecordOne, with the exclude fragment flag set.

Let part two be the result of applying the URL serializer algorithm to urIRecordTwo, with the exclude fragment flag set.
If part one is already in the fallback URLs mapping as a fallback namespace \({ }^{\text {p893 }}\), then jump back to the step labeled start of line.

Otherwise, add part one to the fallback URLs mapping as a fallback namespace \({ }^{\text {p893 }}\), mapped to part two as the fallback entry \({ }^{\text {p893 }}\).
\(\rightarrow\) If mode is "online safelist"
If the first item in tokens is a U+002A ASTERISK character (*), then set online safelist wildcard flag to open and jump back to the step labeled start of line.

Otherwise, let urlRecord be the result of parsing the first item in tokens with base URL.
If urlRecord is failure, then jump back to the step labeled start of line.

If urIRecord has a different scheme component than base URL (the manifest's URL), then jump back to the step labeled start of line.

Let new URL be the result of applying the URL serializer algorithm to urlRecord, with the exclude fragment flag set.
Add new URL to the online safelist namespaces.
\(\rightarrow\) If mode is "settings"
If tokens contains a single token, and that token is "prefer-online", then set cache mode flag to prefer-online and jump back to the step labeled start of line.

Otherwise, the line is an unsupported setting: do nothing; the line is ignored.

\section*{\(\hookrightarrow\) If mode is "unknown"}

Do nothing. The line is ignored.
33. Jump back to the step labeled start of line. (That step jumps to the next, and last, step when the end of the file is reached.)
34. Return the explicit URLs list, the fallback URLs mapping, the online safelist namespaces, the online safelist wildcard flag, and the cache mode flag.

\section*{Note}

The resource that declares the manifest (with the manifest \({ }^{p 152}\) attribute) will always get taken from the cache, whether it is listed in the cache or not, even if it is listed in an online safelist namespace \({ }^{\text {p893 }}\).

If a resource is listed in the explicit section \({ }^{p 896}\) or as a fallback entry \({ }^{p 893}\) in the fallback section \({ }^{p 896}\), the resource will always be taken from the cache, regardless of any other matching entries in the fallback namespaces \({ }^{\text {p893 }}\) or online safelist namespaces \({ }^{\text {p893 }}\).

When a fallback namespace \({ }^{p 893}\) and an online safelist namespace \({ }^{p 893}\) overlap, the online safelist namespace \({ }^{p 893}\) has priority.
The online safelist wildcard flag \({ }^{p 893}\) is applied last, only for URLs that match neither the online safelist namespace \({ }^{\text {p893 }}\) nor the fallback namespace \({ }^{\text {p893 }}\) and that are not listed in the explicit section \({ }^{\text {p896 }}\).

\subsection*{7.11.4 Downloading or updating an application cache \(\S^{\text {p90 }}\)}

When the user agent is required (by other parts of this specification) to start the application cache download process for an absolute URL purported to identify a manifest \({ }^{\text {p892 }}\), or for an application cache group \({ }^{\text {p893 }}\), potentially given a particular cache host \({ }^{\text {p894 }}\), and potentially given a primary \({ }^{\text {p892 }}\) resource, the user agent must run the steps below. These steps are always run in parallel \({ }^{\text {p42 }}\) with the event loop \({ }^{\text {p944 }}\) tasks \({ }^{\text {p944 }}\).

Some of these steps have requirements that only apply if the user agent shows caching progress. Support for this is optional. Caching progress UI could consist of a progress bar or message panel in the user agent's interface, or an overlay, or something else. Certain events fired during the application cache download process \({ }^{p 900}\) allow the script to override the display of such an interface. (Such events are delayed until after the load \({ }^{p 1282}\) event has fired.) The goal of this is to allow web applications to provide more seamless update mechanisms, hiding from the user the mechanics of the application cache mechanism. User agents may display user interfaces independent of this, but are encouraged to not show prominent update progress notifications for applications that cancel the relevant events.

The application cache download process \({ }^{\text {p900 }}\) steps are as follows:
1. Optionally, wait until the permission to start the application cache download process \({ }^{\text {p900 }}\) has been obtained from the user and until the user agent is confident that the network is available. This could include doing nothing until the user explicitly opts-in to caching the site, or could involve prompting the user for permission. The algorithm might never get past this point. (This step is particularly intended to be used by user agents running on severely space-constrained devices or in highly privacysensitive environments).
2. Atomically, so as to avoid race conditions, perform the following substeps:
1. Pick the appropriate substeps:
\(\rightarrow\) If these steps were invoked with an absolute URL purported to identify a manifest \({ }^{\text {p892 }}\)
Let manifest URL be that absolute URL.
If there is no application cache group \({ }^{\text {p893 }}\) identified by manifest \(U R L\), then create a new application cache group \({ }^{\text {p893 }}\) identified by manifest URL. Initially, it has no application caches \({ }^{\text {p892 }}\). One will be created later in this algorithm.
\(\leftrightarrow\) If these steps were invoked with an application cache group \({ }^{\text {p893 }}\)
Let manifest URL be the absolute URL of the manifest \({ }^{p 892}\) used to identify the application cache group \({ }^{p 893}\) to be updated.

If that application cache group \({ }^{p 893}\) is obsolete \({ }^{\text {p894 }}\), then abort this instance of the application cache download process \({ }^{\text {p900 }}\). This can happen if another instance of this algorithm found the manifest to be 404 or 410 while this algorithm was waiting in the first step above.
2. Let cache group be the application cache group \({ }^{\text {p893 }}\) identified by manifest URL.
3. If these steps were invoked with a primary \({ }^{\text {p892 }}\) resource, then add the resource, along with the resource's Document \({ }^{\text {p114 }}\), to cache group's list of pending primary entries \({ }^{\text {p893 }}\).
4. If these steps were invoked with a cache host \({ }^{\mathrm{p} 894}\), and the status \({ }^{\mathrm{p893}}\) of cache group is checking or downloading, then queue a post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named checking \({ }^{8892}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of that cache host \({ }^{\text {p894 }}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the user agent is checking to see if it can download the application.
5. If these steps were invoked with a cache host \({ }^{\text {p894 }}\), and the status \({ }^{8893}\) of cache group is downloading, then also queue a post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named downloading \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of that cache host \({ }^{\mathrm{p} 894}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user the application is being downloaded.
6. If the status \({ }^{\text {p893 }}\) of the cache group is either checking or downloading, then abort this instance of the application cache download process \({ }^{\text {p900 }}\), as an update is already in progress.
7. Set the status \({ }^{8893}\) of cache group to checking.
8. For each cache host \({ }^{\mathrm{p} 894}\) associated with an application cache \({ }^{\text {p892 }}\) in cache group, queue a post-load task \({ }^{\text {p906 }}\) run these steps:
1. Let showProgress be the result of firing an event named checking \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{p 894}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the user agent is checking for the availability of updates.
```

Note The remainder of the steps run in parallel ${ }^{p 42}$.

```

If cache group already has an application cache \({ }^{p 892}\) in it, then this is an upgrade attempt. Otherwise, this is a cache attempt.
3. If this is a cache attempt \({ }^{\text {p901 }}\), then this algorithm was invoked with a cache host \({ }^{\text {p894 }}\); queue a post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named checking \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of that cache host \({ }^{\mathrm{p} 894}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the user agent is checking for the availability of updates.
4. Let request be a new request whose url is manifest URL, client is null, destination is the empty string, referrer is "noreferrer", synchronous flag is set, credentials mode is "include", and whose use-URL-credentials flag is set.
5. Fetching the manifest: Let manifest be the result of fetching request. HTTP caching semantics should be honored for this request.

Parse manifest's body according to the rules for parsing manifests \({ }^{\text {p897 }}\), obtaining a list of explicit entries \({ }^{\text {p893 }}\), fallback entries \({ }^{\text {p893 }}\) and the fallback namespaces \({ }^{\text {p893 }}\) that map to them, entries for the online safelist \({ }^{\text {p893 }}\), and values for the online safelist wildcard flag \({ }^{\text {p893 }}\) and the cache mode flag \({ }^{\text {p893 }}\).

Note
The MIME type of the resource is ignored - it is assumed to be text/cache-manifest \({ }^{\text {p1253 }}\). In the future, if new manifest formats are supported, the different types will probably be distinguished on the basis of the file signatures (for the current format, that is the "CACHE MANIFEST" string at the top of the file).
6. If fetching the manifest fails due to a 404 or 410 response status, then run these substeps:
1. Mark cache group as obsolete \({ }^{\text {p894. }}\). This cache group no longer exists for any purpose other than the processing of Document \({ }^{\text {p114 }}\) objects already associated with an application cache \({ }^{\text {p892 }}\) in the cache group.
2. Let task list be an empty list of tasks \({ }^{\text {p944 }}\).
3. For each cache host \({ }^{\text {p894 }}\) associated with an application cache \({ }^{\text {p892 }}\) in cache group, create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named obsolete \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p9e9 }}\) singleton of the cache host \({ }^{\mathrm{p894}}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the application is no longer available for offline use.
4. For each entry in cache group's list of pending primary entries \({ }^{\text {p893 }}\), create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named error \({ }^{\text {p892 }}\) (not obsolete \(e^{\text {p892 }!\text { ) at the }}\) ApplicationCache \({ }^{\text {p999 }}\) singleton of the Document \({ }^{\text {p114 }}\) for this entry, if there still is one, with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
5. If cache group has an application cache \({ }^{\mathrm{p} 892}\) whose completeness flag \({ }^{\mathrm{p} 893}\) is incomplete, then discard that application cache \({ }^{\text {p892 }}\).
6. If appropriate, remove any user interface indicating that an update for this cache is in progress.
7. Let the status \({ }^{\text {p893 }}\) of cache group be idle.
8. For each task \({ }^{\text {p944 }}\) in task list, queue that task as a post-load task \({ }^{\text {p906 }}\).
9. Abort the application cache download process \({ }^{\text {p900 }}\).
7. Otherwise, if fetching the manifest fails in some other way (e.g. the server returns another 4 xx or 5 xx response, or there is a DNS error, or the connection times out, or the user cancels the download, or the parser for manifests fails when checking the magic signature), or if the server returned a redirect, then run the cache failure steps \({ }^{\text {p906 }}\). \([\mathrm{HTTP}]^{\text {p1288 }}\)
8. If this is an upgrade attempt \({ }^{\text {p901 }}\) and the newly downloaded manifest is byte-for-byte identical to the manifest found in the newest \({ }^{\mathrm{p893}}\) application cache \({ }^{\mathrm{p892}}\) in cache group, or the response status is 304 , then run these substeps:
1. Let cache be the newest \({ }^{\mathrm{p} 893}\) application cache \({ }^{\mathrm{p} 892}\) in cache group.
2. Let task list be an empty list of tasks \({ }^{9944}\).
3. For each entry in cache group's list of pending primary entries \({ }^{\mathrm{p893}}\), wait for the resource for this entry to have either completely downloaded or failed.

If the download failed (e.g. the server returns a \(4 x x\) or \(5 x x\) response, or there is a DNS error, the connection times out, or the user cancels the download), or if the resource is labeled with the "no-store" cache directive, then create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named error \({ }^{p 892}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the Document \({ }^{p 114}\) for this entry, if there still is one, with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.

Otherwise, associate the Document \({ }^{\text {p114 }}\) for this entry with cache; store the resource for this entry in cache, if it isn't already there, and categorize its entry as a primary entry \({ }^{\text {p892 }}\). If applying the URL parser algorithm to the resource's URL results in a URL record that has a non-null fragment component, the URL used for the entry in cache must instead be the absolute URL obtained from applying the URL serializer algorithm to the URL record with the exclude fragment flag set (application caches never include fragments).
4. For each cache host \({ }^{\mathrm{p} 894}\) associated with an application cache \({ }^{\mathrm{p} 892}\) in cache group, create a task \({ }^{\mathrm{p} 944}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named noupdate \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{\mathrm{p894}}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the application is up to date.
5. Empty cache group's list of pending primary entries \({ }^{\text {p893 }}\).
6. If appropriate, remove any user interface indicating that an update for this cache is in progress.
7. Let the status \({ }^{\text {p893 }}\) of cache group be idle.
8. For each task \({ }^{\text {p944 }}\) in task list, queue that task as a post-load task \({ }^{\text {p906 }}\).
9. Abort the application cache download process \({ }^{\text {p900 }}\).
9. Let new cache be a newly created application cache \({ }^{\text {p892 }}\) in cache group. Set its completeness flag \({ }^{\text {p893 }}\) to incomplete.
10. For each entry in cache group's list of pending primary entries \({ }^{\text {p893 }}\), associate the Document \({ }^{\text {p114 }}\) for this entry with new cache.
11. Set the status \({ }^{8893}\) of cache group to downloading.
12. For each cache host \({ }^{p 894}\) associated with an application cache \({ }^{\text {p892 }}\) in cache group, queue a post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named downloading \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{p 894}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that a new version is being downloaded.
13. Let file list be an empty list of URLs with flags.
14. Add all the URLs in the list of explicit entries \({ }^{\text {p893 }}\) obtained by parsing manifest to file list, each flagged with "explicit entry".
15. Add all the URLs in the list of fallback entries \({ }^{\text {p893 }}\) obtained by parsing manifest to file list, each flagged with "fallback entry".
16. If this is an upgrade attempt \({ }^{\mathrm{p} 901}\), then add all the URLs of primary entries \({ }^{\mathrm{p} 892}\) in the newest \({ }^{\mathrm{p893}}\) application cache \({ }^{\mathrm{p} 892}\) in cache group whose completeness flag \({ }^{\text {p893 }}\) is complete to file list, each flagged with "primary entry".
17. If any URL is in file list more than once, then merge the entries into one entry for that URL, that entry having all the flags that the original entries had.
18. For each URL in file list, run the following steps. These steps may be run in parallel for two or more of the URLs at a time. If, while running these steps, the ApplicationCache \({ }^{\text {p999 }}\) object's abort ( ) \({ }^{\text {p911 }}\) method sends a signal \({ }^{\text {p911 }}\) to this instance of the application cache download process \({ }^{\text {p900 }}\) algorithm, then run the cache failure steps \({ }^{\text {p906 }}\) instead.
1. If the resource URL being processed was flagged as neither an "explicit entry" nor or a "fallback entry", then the user agent may skip this URL.

\section*{Note}

This is intended to allow user agents to expire resources not listed in the manifest from the cache. Generally, implementers are urged to use an approach that expires lesser-used resources first.
2. For each cache host \({ }^{8894}\) associated with an application cache \({ }^{p 892}\) in cache group, queue a progress post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named progress \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p9e9 }}\) singleton of the cache host \({ }^{\text {p894 }}\), using ProgressEvent, with the cancelable attribute initialized to true, the lengthComputable attribute initialized to true, the total attribute initialized to the number of files in file list, and the loaded attribute initialized to the number of files in file list that have been either downloaded or skipped so far. \([\mathrm{XHR}]^{p 1292}\)
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that a file is being downloaded in preparation for updating the application.
3. Let request be a new request whose url is URL, client is null, destination is the empty string, origin is manifest URL's origin \({ }^{\text {p837 }}\), referrer is "no-referrer", synchronous flag is set, credentials mode is "include", use-URLcredentials flag is set, and redirect mode is "manual".
4. Fetch request. If this is an upgrade attempt \({ }^{\text {p901 }}\), then use the newest \({ }^{\mathrm{p} 893}\) application cache \({ }^{\text {p892 }}\) in cache group as an HTTP cache, and honor HTTP caching semantics (such as expiration, ETags, and so forth) with respect to that cache. User agents may also have other caches in place that are also honored.
5. If the previous step fails (e.g. the server returns a \(4 x x\) or \(5 x x\) response, or there is a DNS error, or the connection times out, or the user cancels the download), or if the server returned a redirect, or if the resource is labeled with the "no-store" cache directive, then run the first appropriate step from the following list: \([H T P]^{p 1288}\)
\(\rightarrow\) If the URL being processed was flagged as an "explicit entry" or a "fallback entry"
If these steps are being run in parallel for any other URLs in file list, then abort this algorithm for those other URLs. Run the cache failure steps \({ }^{\text {p906 }}\).

Redirects are fatal because they are either indicative of a network problem (e.g. a captive portal); or would allow resources to be added to the cache under URLs that differ from any URL that the networking model will allow access to, leaving orphan entries; or would allow resources to be stored under URLs different than their true URLs. All of these situations are bad.

\section*{\(\hookrightarrow\) If the error was a 404 or 410 HTTP response}
\(\leftrightarrow\) If the resource was labeled with the "no-store" cache directive
Skip this resource. It is dropped from the cache.

\section*{\(\leftrightarrow\) Otherwise}

Copy the resource and its metadata from the newest \({ }^{\mathrm{p893}}\) application cache \({ }^{\mathrm{p} 892}\) in cache group whose completeness flag \({ }^{\text {p893 }}\) is complete, and act as if that was the fetched resource, ignoring the resource obtained from the network.

User agents may warn the user of these errors as an aid to development.

\section*{Note}

These rules make errors for resources listed in the manifest fatal, while making it possible for other resources to be removed from caches when they are removed from the server, without errors, and making non-manifest resources survive server-side errors.

\section*{Note}

Except for the "no-store" directive, HTTP caching rules that would cause a file to be expired or otherwise not cached are ignored for the purposes of the application cache download process \({ }^{p 900}\).
6. Otherwise, the fetching succeeded. Store the resource in the new cache.

If the user agent is not able to store the resource (e.g. because of quota restrictions), the user agent may prompt the user or try to resolve the problem in some other manner (e.g. automatically pruning content in other caches). If the problem cannot be resolved, the user agent must run the cache failure steps \({ }^{\mathrm{p} 906}\).
7. If the URL being processed was flagged as an "explicit entry" in file list, then categorize the entry as an explicit entry \({ }^{\text {p893 }}\).
8. If the URL being processed was flagged as a "fallback entry" in file list, then categorize the entry as a fallback entry \({ }^{\text {p893 }}\).
9. If the URL being processed was flagged as a "primary entry" in file list, then categorize the entry as a primary entry \({ }^{\text {p892 }}\).
10. As an optimization, if the resource is an HTML or XML file whose document element is an html \({ }^{p 152}\) element with a manifest \({ }^{p 152}\) attribute whose value doesn't match the manifest URL of the application cache being processed, then the user agent should mark the entry as being foreign \({ }^{\text {p893 }}\).
19. For each cache host \({ }^{\mathrm{p} 894}\) associated with an application cache \({ }^{\mathrm{p} 892}\) in cache group, queue a progress post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named progress \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{\text {p894 }}\), using ProgressEvent, with the cancelable attribute initialized to true, the lengthComputable attribute initialized to true, and the total and loaded attributes initialized to the number of files in file list. [XHR] \({ }^{\text {p1292 }}\)
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that all the files have been downloaded.
20. Store the list of fallback namespaces \({ }^{\text {p893 }}\), and the URLs of the fallback entries \({ }^{\text {p893 }}\) that they map to, in new cache.
21. Store the URLs that form the new online safelist \({ }^{\mathrm{p} 933}\) in new cache.
22. Store the value of the new online safelist wildcard flag \({ }^{\text {p893 }}\) in new cache.
23. Store the value of the new cache mode flag \({ }^{\text {p893 }}\) in new cache.
24. For each entry in cache group's list of pending primary entries \({ }^{\text {p893 }}\), wait for the resource for this entry to have either
completely downloaded or failed.
If the download failed (e.g. the server returns a \(4 x x\) or \(5 x x\) response, or there is a DNS error, the connection times out, or the user cancels the download), or if the resource is labeled with the "no-store" cache directive, then run these substeps:
1. Unassociate the Document \({ }^{\text {p114 }}\) for this entry from new cache.
2. Queue a post-load task \({ }^{\text {p906 }}\) to run these steps:
1. Let showProgress be the result of firing an event named error \({ }^{p 892}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the Document \({ }^{\text {p114 }}\) for this entry, if there still is one, with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{p 900}\), then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
3. If this is a cache attempt \({ }^{\text {p901 }}\) and this entry is the last entry in cache group's list of pending primary entries \({ }^{\text {p893 }}\), then run these further substeps:
1. Discard cache group and its only application cache \({ }^{\text {p892 }}\), new cache.
2. If appropriate, remove any user interface indicating that an update for this cache is in progress.
3. Abort the application cache download process \({ }^{\text {p900 }}\).
4. Otherwise, remove this entry from cache group's list of pending primary entries \({ }^{\mathrm{p893}}\).

Otherwise, store the resource for this entry in new cache, if it isn't already there, and categorize its entry as a primary entry \({ }^{\text {p892 }}\).
25. Let request be a new request whose url is manifest URL, client is null, destination is the empty string, referrer is "noreferrer", synchronous flag is set, credentials mode is "include", and whose use-URL-credentials flag is set.
26. Let second manifest be the result of fetching request. HTTP caching semantics should again be honored for this request.

\section*{Note}

Since caching can be honored, authors are encouraged to avoid setting the cache headers on the manifest in such a way that the user agent would simply not contact the network for this second request; otherwise, the user agent would not notice if the cache had changed during the cache update process.
27. If the previous step failed for any reason, or if the fetching attempt involved a redirect, or if second manifest and manifest are not byte-for-byte identical, then schedule a rerun of the entire algorithm with the same parameters after a short delay, and run the cache failure steps \({ }^{p 906}\).
28. Otherwise, store manifest in new cache, if it's not there already, and categorize its entry as the manifest \({ }^{\mathrm{p892}}\).
29. Set the completeness flag \({ }^{\text {p893 }}\) of new cache to complete.
30. Let task list be an empty list of tasks \({ }^{\text {p944 }}\).
31. If this is a cache attempt \({ }^{\text {p901 }}\), then for each cache host \({ }^{\mathrm{p} 894}\) associated with an application cache \({ }^{\mathrm{p} 892}\) in cache group, create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named cached \({ }^{8892}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{\text {p894 }}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{\text {p900 }}\), then display some sort of user interface indicating to the user that the application has been cached and that they can now use it offline.

Otherwise, it is an upgrade attempt \({ }^{\mathrm{p} 901}\). For each cache host \({ }^{\mathrm{p} 894}\) associated with an application cache \({ }^{\text {p892 }}\) in cache group, create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named updateready \({ }^{\text {p892 }}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{p 894}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{p 900}\), then display some sort of user interface indicating to the user that a new version is available and that they can activate it by reloading the page.
32. If appropriate, remove any user interface indicating that an update for this cache is in progress.
33. Set the update status \({ }^{\text {p893 }}\) of cache group to idle.
34. For each task \({ }^{\text {p944 }}\) in task list, queue that task as a post-load task \({ }^{\text {p906 }}\).

The cache failure steps are as follows:
1. Let task list be an empty list of tasks \({ }^{\text {p944 }}\).
2. For each entry in cache group's list of pending primary entries \({ }^{\text {p893 }}\), run the following further substeps. These steps may be run in parallel for two or more entries at a time.
1. Wait for the resource for this entry to have either completely downloaded or failed.
2. Unassociate the Document \({ }^{\text {p114 }}\) for this entry from its application cache \({ }^{\mathrm{p} 892}\), if it has one.
3. Create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named error \({ }^{p 892}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the Document \({ }^{\text {p114 }}\) for this entry, if there still is one, with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{p 900}\), then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
3. For each cache host \({ }^{\mathrm{p} 894}\) still associated with an application cache \({ }^{\mathrm{p} 892}\) in cache group, create a task \({ }^{\text {p944 }}\) to run these steps and append it to task list:
1. Let showProgress be the result of firing an event named error \({ }^{p 892}\) at the ApplicationCache \({ }^{\text {p999 }}\) singleton of the cache host \({ }^{\text {p894 }}\), with the cancelable attribute initialized to true.
2. If showProgress is true and the user agent shows caching progress \({ }^{p 900}\), then display some sort of user interface indicating to the user that the user agent failed to save the application for offline use.
4. Empty cache group's list of pending primary entries \({ }^{\mathrm{p} 893}\).
5. If cache group has an application cache \({ }^{\text {p892 }}\) whose completeness flag \({ }^{\text {p893 }}\) is incomplete, then discard that application cache \({ }^{\text {p892 }}\).
6. If appropriate, remove any user interface indicating that an update for this cache is in progress.
7. Let the status \({ }^{\mathrm{p} 893}\) of cache group be idle.
8. If this was a cache attempt \({ }^{\text {p901 }}\), discard cache group altogether.
9. For each task \({ }^{\text {p944 }}\) in task list, queue that task as a post-load task \({ }^{\text {p906 }}\).
10. Abort the application cache download process \({ }^{\text {p900 }}\).

Attempts to fetch resources as part of the application cache download process \({ }^{\text {p900 }}\) may be done with cache-defeating semantics, to avoid problems with stale or inconsistent intermediary caches.

User agents may invoke the application cache download process \({ }^{\text {p900 }}\), in the background, for any application cache group \({ }^{\text {p893 }}\), at any time (with no cache host \({ }^{p 894}\) ). This allows user agents to keep caches primed and to update caches even before the user visits a site.

Each Document \({ }^{\text {p114 }}\) has a list of pending application cache download process tasks that is used to delay events fired by the algorithm above until the document's load \({ }^{p 1282}\) event has fired. When the Document \({ }^{\text {p114 }}\) is created, the list must be empty.

When the steps above say to queue a post-load task task, where task is a task \({ }^{\text {p944 }}\) that dispatches an event on a target ApplicationCache \({ }^{\text {p909 }}\) object target, the user agent must run the appropriate steps from the following list:

If target's node document is ready for post-load tasks \({ }^{\text {p1165 }}\)
Queue \({ }^{\text {p945 }}\) the task task.

\section*{Otherwise}

Add task to target's node document's list of pending application cache download process tasks \({ }^{\text {p906 }}\).
When the steps above say to queue a progress post-load task task, where task is a task \({ }^{\text {p944 }}\) that dispatches an event on a target ApplicationCache \({ }^{\text {p999 }}\) object target, the user agent must run the following steps:
1. If there is a task in target's node document's list of pending application cache download process tasks \({ }^{\text {p906 }}\) that is labeled as a progress task, then remove that task from the list.
2. Label task as a progress task.
3. Queue a post-load task \({ }^{\text {p906 }}\) task.

The task source \({ }^{\text {p945 }}\) for these tasks \({ }^{\text {p944 }}\) is the networking task source \({ }^{\text {p952 }}\).

\subsection*{7.11.5 The application cache selection algorithm \(\S^{\text {p90 }}\)}

When the application cache selection algorithm algorithm is invoked with a Document \({ }^{\text {p114 }}\) document and optionally a manifest URL manifest URL, the user agent must run the first applicable set of steps from the following list:

\section*{\(\hookrightarrow\) If there is a manifest URL, and document was loaded from an application cache \({ }^{\text {p892 }}\), and the URL of the manifest \({ }^{\text {p892 }}\) of that cache's application cache group \({ }^{\text {p893 }}\) is not the same as manifest URL}

Mark the entry for the resource from which document was taken in the application cache \({ }^{\mathrm{p} 892}\) from which it was loaded as foreign \({ }^{\text {p893 }}\).

Restart the current navigation from the top of the navigation algorithm \({ }^{\mathrm{p866}}\), undoing any changes that were made as part of the initial load (changes can be avoided by ensuring that the step to update the session history with the new page \({ }^{\text {p875 }}\) is only ever completed after this application cache selection algorithm \({ }^{\text {p907 }}\) is run, though this is not required).

\section*{Note}

The navigation will not result in the same resource being loaded, because "foreign" entries are never picked during navigation.

User agents may notify the user of the inconsistency between the cache manifest and the document's own metadata, to aid in application development.
\(\leftrightarrow\) If document was loaded from an application cache \({ }^{\text {p892 }}\), and that application cache \({ }^{\text {p892 }}\) still exists (it is not now obsolete \({ }^{\text {p894 }}\) )

Associate document with the application cache \({ }^{\text {p892 }}\) from which it was loaded. Invoke, in the background, the application cache download process \({ }^{\text {p900 }}\) for that application cache \({ }^{\text {p892 }}\) 's application cache group \({ }^{\text {p893 }}\), with document as the cache host \({ }^{\text {p894 }}\).

\section*{\(\leftrightarrow\) If document was loaded using `GET`, and, there is a manifest URL, and manifest URL has the same origin \({ }^{\text {p838 }}\) as document}

Invoke, in the background, the application cache download process \({ }^{\text {p900 }}\) for manifest URL, with document as the cache host \({ }^{\text {p894 }}\) and with the resource from which document was parsed as the primary \({ }^{\text {p892 }}\) resource.

If there are relevant application caches \({ }^{\text {p893 }}\) that are identified by a URL with the same origin \({ }^{\text {p838 }}\) as the URL of document, and that have this URL as one of their entries, excluding entries marked as foreign \({ }^{\text {p893 }}\), then the user agent should use the most appropriate application cache \({ }^{\text {p894 }}\) of those that match as an HTTP cache for any subresource loads. User agents may also have other caches in place that are also honored.
\(\rightarrow\) Otherwise
The Document \({ }^{p 114}\) is not associated with any application cache \({ }^{\mathrm{p} 892}\).
If there was a manifest \(U R L\), the user agent may report to the user that it was ignored, to aid in application development.

\subsection*{7.11.6 Changes to the networking model \(\S^{\text {p90 }}\)}

If "AppCache" is not removed as a feature this section needs to be integrated into the Fetch standard.

When a cache host \({ }^{\text {p894 }}\) is associated with an application cache \({ }^{\text {p892 }}\) whose completeness flag \({ }^{\text {p893 }}\) is complete, any and all loads for resources related to that cache host \({ }^{\text {p894 }}\) other than those for child browsing contexts \({ }^{\text {p814 }}\) must go through the following steps instead of immediately invoking the mechanisms appropriate to that resource's scheme:
1. If the resource is not to be fetched using the GET method, or if applying the URL parser algorithm to both its URL and the application cache \({ }^{\text {p892 ' 's manifest }}{ }^{\text {p892 's }}\) URL results in two URL records with different scheme components, then fetch the resource normally and return.
2. If the resource's URL is a primary entry \({ }^{\mathrm{p892}}\), the manifest \({ }^{\mathrm{p} 892}\), an explicit entry \({ }^{\mathrm{p893}}\), or a fallback entry \({ }^{\mathrm{p893}}\) in the application cache \({ }^{\text {p892 }}\), then get the resource from the cache (instead of fetching it), and return.
3. If there is an entry in the application cache \({ }^{\mathrm{p} 892}\) 's online safelist \({ }^{\mathrm{p} 893}\) that has the same origin \({ }^{\mathrm{p} 838}\) as the resource's URL and that is a prefix match \({ }^{\text {p67 }}\) for the resource's URL, then fetch the resource normally and return.
4. If the resource's URL has the same origin \({ }^{\text {p838 }}\) as the manifest's URL, and there is a fallback namespace \({ }^{\text {p893 }} f\) in the application cache \({ }^{\text {p892 }}\) that is a prefix match \({ }^{\text {p67 }}\) for the resource's URL, then:

Fetch the resource normally. If this results in a redirect to a resource with another origin \({ }^{\text {p837 }}\) (indicative of a captive portal), or a \(4 x x\) or \(5 x x\) status code, or if there were network errors (but not if the user canceled the download), then instead get, from the cache, the resource of the fallback entry \({ }^{\text {p893 }}\) corresponding to the fallback namespace \({ }^{\text {p893 }} f\). Return.
5. If the application cache \({ }^{\text {p892 ' }} \mathrm{s}\) online safelist wildcard flag \({ }^{\text {p893 }}\) is open, then fetch the resource normally and return.
6. Fail the resource load as if there had been a generic network error.

\section*{Note}

The above algorithm ensures that so long as the online safelist wildcard flag \({ }^{p 893}\) is blocking, resources that are not present in the manifest \({ }^{p 892}\) will always fail to load (at least, after the application cache \({ }^{p 892}\) has been primed the first time), making the testing of offline applications simpler.

\subsection*{7.11.7 Expiring application caches \(\S_{8}^{\text {p90 }}\)}

As a general rule, user agents should not expire application caches, except on request from the user, or after having been left unused for an extended period of time.

Application caches and cookies have similar implications with respect to privacy (e.g. if the site can identify the user when providing the cache, it can store data in the cache that can be used for cookie resurrection). Implementors are therefore encouraged to expose application caches in a manner related to HTTP cookies, allowing caches to be expunged together with cookies and other originspecific data.

\section*{Example}

For example, a user agent could have a "delete site-specific data" feature that clears all cookies, application caches, local storage, databases, etc, from an origin all at once.

\subsection*{7.11.8 Disk space \({ }_{\S}{ }_{8}^{p 90}\)}

User agents should consider applying constraints on disk usage of application caches \({ }^{\text {p892 }}\), and care should be taken to ensure that the restrictions cannot be easily worked around using subdomains.

User agents should allow users to see how much space each domain is using, and may offer the user the ability to delete specific application caches \({ }^{\text {p892 }}\).

For predictability, quotas should be based on the uncompressed size of data stored.

\section*{Note}

How quotas are presented to the user is not defined by this specification. User agents are encouraged to provide features such as allowing a user to indicate that certain sites are trusted to use more than the default quota, e.g. by presenting a non-modal user interface while a cache is being updated, or by having an explicit safelist in the user agent's configuration interface.

\subsection*{7.11.9 Security concerns with offline applications caches \(\S^{p 90}\)}

This section is non-normative.
The main risk introduced by offline application caches is that an injection attack can be elevated into persistent site-wide page replacement. This attack involves using an injection vulnerability to upload two files to the victim site. The first file is an application cache manifest consisting of just a fallback entry pointing to the second file, which is an HTML page whose manifest is declared as that first file. Once the user has been directed to that second file, all subsequent accesses to any file covered by the given fallback namespace while either the user or the site is offline will instead show that second file. Targeted denial-of-service attacks or cookie bombing attacks (where the client is made to send so many cookies that the server refuses to process the request) can be used to ensure that the site appears offline.

To mitigate this, manifests can only specify fallbacks that are in the same path as the manifest itself. This means that a content injection upload vulnerability in a particular directory on a server can only be escalated to a take-over of that directory and its subdirectories. If there is no way to inject a file into the root directory, the entire site cannot be taken over.

If a site has been attacked in this way, simply removing the offending manifest might eventually clear the problem, since the next time the manifest is updated, a 404 error will be seen, and the user agent will clear the cache. "Eventually" is the key word here, however; while the attack on the user or server is ongoing, such that connections from an affected user to the affected site are blocked, the user agent will simply assume that the user is offline and will continue to use the hostile manifest. Unfortunately, if a cookie bombing attack has also been used, merely removing the manifest is insufficient; in addition, the server has to be configured to return a 404 or 410 response instead of the 413 "Request Entity Too Large" response.

TLS does not inherently protect a site from this attack, since the attack relies on content being served from the server itself. Not using application caches also does not prevent this attack, since the attack relies on an attacker-provided manifest.

\subsection*{7.11.10 Application cache API \(\S^{p 90}\)}
```

[SecureContext,
Exposed=Window]
interface ApplicationCache : EventTarget {
// update status
const unsigned short UNCACHED = 0;
const unsigned short IDLE = 1;
const unsigned short CHECKING = 2;
const unsigned short DOWNLOADING = 3;
const unsigned short UPDATEREADY = 4;
const unsigned short OBSOLETE = 5;
readonly attribute unsigned short status;
// updates
undefined update();
undefined abort();
undefined swapCache();
// events
attribute EventHandler onchecking;
attribute EventHandler onerror;
attribute EventHandler onnoupdate;
attribute EventHandler ondownloading;
attribute EventHandler onprogress;
attribute EventHandler onupdateready;
attribute EventHandler oncached;
attribute EventHandler onobsolete;
};

```

For web developers (non-normative)

\section*{cache \(=\) window . applicationCache \({ }^{\text {p910 }}\)}

Returns the ApplicationCache \({ }^{\text {p989 }}\) object that applies to the active document \({ }^{\mathrm{p} 811}\) of that Window \({ }^{\mathrm{p} 824}\).

\section*{cache. status \({ }^{\text {p910 }}\)}

Returns the current status of the application cache, as given by the constants defined below.
cache. update \({ }^{\text {p911 }}\) ()
Invokes the application cache download process \({ }^{\text {p900 }}\).
Throws an "InvalidStateError" DOMException if there is no application cache to update.
Calling this method is not usually necessary, as user agents will generally take care of updating application caches \({ }^{\text {p892 }}\) automatically.
The method can be useful in situations such as long-lived applications. For example, a web mail application might stay open in a browser tab for weeks at a time. Such an application could want to test for updates each day.
cache. abort \({ }^{\text {p911 }}\) ()
Cancels the application cache download process \({ }^{\text {p900 }}\).
This method is intended to be used by web application showing their own caching progress UI, in case the user wants to stop the update (e.g. because bandwidth is limited).
cache. swapCache \({ }^{\text {p911 }}\) ()
Switches to the most recent application cache, if there is a newer one. If there isn't, throws an "InvalidStateError"
DOMException.
This does not cause previously-loaded resources to be reloaded; for example, images do not suddenly get reloaded and style sheets and scripts do not get reparsed or reevaluated. The only change is that subsequent requests for cached resources will obtain the newer copies.
The updateready \({ }^{8892}\) event will fire before this method can be called. Once it fires, the web application can, at its leisure, call this method to switch the underlying cache to the one with the more recent updates. To make proper use of this, applications have to be able to bring the new features into play; for example, reloading scripts to enable new features.
An easier alternative to swapCache () \({ }^{\text {p911 }}\) is just to reload the entire page at a time suitable for the user, using location. reload() \({ }^{\text {p863 }}\).

There is a one-to-one mapping from cache hosts \({ }^{\text {p894 }}\) to ApplicationCache \({ }^{\text {p999 }}\) objects. The applicationCache attribute on Window \({ }^{\text {p824 }}\) objects must return the ApplicationCache \({ }^{\text {p999 }}\) object associated with the Window \({ }^{\text {p824 }}\) object's active document \({ }^{\text {p881 }}\).

\section*{Note}

A Document \({ }^{\text {p114 }}\) has an associated ApplicationCache \({ }^{\text {p909 }}\) object even if that cache host \({ }^{p 894}\) has no actual application cache \({ }^{\text {p892 }}\).

The status attribute, on getting, must return the current state of the application cache \({ }^{\text {p892 }}\) that the ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\mathrm{p} 894}\) is associated with, if any. This must be the appropriate value from the following list:

\section*{UNCACHED (numeric value 0)}

The ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is not associated with an application cache \({ }^{\text {p892 }}\) at this time.
IDLE (numeric value 1)
The ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is associated with an application cache \({ }^{\text {p892 }}\) whose application cache group \({ }^{\text {p893' }} \mathrm{s}\) update status \({ }^{\mathrm{p} 893}\) is idle, and that application cache \({ }^{\mathrm{p} 892}\) is the newest \({ }^{\mathrm{p} 893}\) cache in its application cache group \({ }^{\mathrm{p893}}\), and the application cache group \({ }^{\text {p893 }}\) is not marked as obsolete \({ }^{\text {p894 }}\).

CHECKING (numeric value 2)
The ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{8894}\) is associated with an application cache \({ }^{\text {p892 }}\) whose application cache group \({ }^{\text {p893' }} \mathrm{S}\) update status \({ }^{p 893}\) is checking.

\section*{DOWNLOADING (numeric value 3)}

The ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is associated with an application cache \({ }^{\text {p892 }}\) whose application cache group \({ }^{\text {p893' }} \mathrm{s}\) update status \({ }^{\text {p893 }}\) is downloading.

The ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is associated with an application cache \({ }^{\text {p892 }}\) whose application cache group \({ }^{\text {p893's }}\). update status \({ }^{\text {p893 }}\) is idle, and whose application cache group \({ }^{\text {p893 }}\) is not marked as obsolete \({ }^{\text {p894 }}\), but that application cache \({ }^{\text {p892 }}\) is not the newest \({ }^{\text {p893 }}\) cache in its group.

\section*{OBSOLETE (numeric value 5)}

The ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is associated with an application cache \({ }^{\text {p892 }}\) whose application cache group \({ }^{\text {p893 }}\) is marked as obsolete \({ }^{\text {p894 }}\).

If the update() method is invoked, the user agent must invoke the application cache download process \({ }^{\text {p900 }}\), in the background, for the application cache group \({ }^{\text {p893 }}\) of the application cache \({ }^{\text {p892 }}\) with which the ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is associated, but without giving that cache host \({ }^{\text {p894 }}\) to the algorithm. If there is no such application cache \({ }^{\text {p892 }}\), or if its application cache group \({ }^{\text {p893 }}\) is marked as obsolete \({ }^{\text {p894 }}\), then the method must throw an "InvalidStateError" DOMException instead.

If the abort () method is invoked, the user agent must send a signal to the current application cache download process \({ }^{\text {p900 }}\) for the application cache group \({ }^{\text {p893 }}\) of the application cache \({ }^{\text {p892 }}\) with which the ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) is associated, if any. If there is no such application cache \({ }^{\mathrm{p} 892}\), or it does not have a current application cache download process \({ }^{\mathrm{p900}}\), then do nothing.

If the swapCache() method is invoked, the user agent must run the following steps:
1. Check that ApplicationCache \({ }^{\text {p909 }}\) object's cache host \({ }^{\text {p894 }}\) is associated with an application cache \({ }^{\text {p892 }}\). If it is not, then throw an "InvalidStateError" DOMException.
2. Let cache be the application cache \({ }^{\text {p892 }}\) with which the ApplicationCache \({ }^{\text {p909 }}\) object's cache host \({ }^{\text {p894 }}\) is associated. (By definition, this is the same as the one that was found in the previous step.)
3. If cache's application cache group \({ }^{\text {p893 }}\) is marked as obsolete \({ }^{\text {p894 }}\), then unassociate the ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {p894 }}\) from cache and return. (Resources will now load from the network instead of the cache.)
4. Check that there is an application cache in the same application cache group \({ }^{p 893}\) as cache whose completeness flag \({ }^{\text {p893 }}\) is complete and that is newer \({ }^{p 893}\) than cache. If there is not, then throw an "InvalidStateError" DOMException exception.
5. Let new cache be the newest \({ }^{\text {p893 }}\) application cache \({ }^{\text {p892 }}\) in the same application cache group \({ }^{\text {p893 }}\) as cache whose completeness flag \({ }^{\text {p893 }}\) is complete.
6. Unassociate the ApplicationCache \({ }^{\text {p999 }}\) object's cache host \({ }^{\text {8894 }}\) from cache and instead associate it with new cache.

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by all objects implementing the ApplicationCache \({ }^{\text {p999 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\mathrm{p954}}\) & Event handler event type \({ }^{\mathrm{p957}}\) \\
\hline onchecking & checking \(^{\mathrm{p892}}\) \\
\hline onerror & error \(^{\mathrm{p892}}\) \\
\hline onnoupdate & noupdate \(^{\mathrm{p} 892}\) \\
\hline ondownloading & downloading \({ }^{\mathrm{p892}}\) \\
\hline onprogress & progress \({ }^{\mathrm{p892}}\) \\
\hline onupdateready & \(\underline{\text { updateready }} \mathrm{p892}\) \\
\hline oncached & \(\underline{\text { cached }{ }^{\mathrm{p} 892}}\) \\
\hline onobsolete & \(\underline{\text { obsolete }} \mathrm{p} 892\) \\
\hline
\end{tabular}

\subsection*{7.11.11 Browser state \(\S^{\text {p91 }}\)}
```

IDL interface mixin NavigatorOnLine {
readonly attribute boolean onLine;
};

```

For web developers (non-normative)

Returns false if the user agent is definitely offline (disconnected from the network). Returns true if the user agent might be online.
The events online \({ }^{p 1282}\) and offline \({ }^{p 1282}\) are fired when the value of this attribute changes.

The navigator. onLine attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the navigator. onLine \({ }^{p 912}\) attribute of a Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) global changes from true to false, the user agent must queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) given global to fire an event named offline \({ }^{\text {p1282 }}\) at global.

On the other hand, when the value that would be returned by the navigator. onLine \({ }^{p 912}\) attribute of a Window \({ }^{p 824}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) global changes from false to true, the user agent must queue a global task \({ }^{\text {p945 }}\) on the networking task source \({ }^{\text {p952 }}\) given global to fire an event named online \({ }^{\text {p1282 }}\) at the Window \({ }^{p 824}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object.

\section*{Note}

This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.

\section*{Example}

In this example, an indicator is updated as the browser goes online and offline.
```

<!DOCTYPE HTML>

<html lang="en">
    <head>
    <title>Online status</title>
    <script>
        function updateIndicator() {
            document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
        }
        </script>
        </head>
        <body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
        <p>The network is: <span id="indicator">(state unknown)</span>
        </body>
</html>
```

\section*{8 Web application APIs \(\S^{p 91}\)}

\subsection*{8.1 Scripting \(\S^{\text {p91 }}\)}

\subsection*{8.1.1 Introduction \({ }_{3}^{\text {pp1 }}\)}

Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:
- Processing of script \({ }^{\text {p614 }}\) elements.
- Navigating to javascript: URLs \({ }^{\text {p872 }}\).
- Event handlers, whether registered through the DOM using addEventListener(), by explicit event handler content attributes \({ }^{\text {p955 }}\), by event handler IDL attributes \({ }^{\text {p955 }}\), or otherwise.
- Processing of technologies like SVG that have their own scripting features.

\subsection*{8.1.2 Agents and agent clusters \(\mathbb{§}^{\text {p91 }}\)}

\subsection*{8.1.2.1 Integration with the JavaScript agent formalism \(\S^{\text {p91 }}\)}

JavaScript defines the concept of an agent. This section gives the mapping of that language-level concept on to the web platform.

\section*{Note}

Conceptually, the agent concept is an architecture-independent, idealized "thread" in which JavaScript code runs. Such code can involve multiple globals/realms \({ }^{p 918}\) that can synchronously access each other, and thus needs to run in a single execution thread.

Two Window \({ }^{p 824}\) objects having the same agent does not indicate they can directly access all objects created in each other's realms. They would have to be same origin-domain \({ }^{\text {p838 }}\); see IsPlatformObjectSameOrigin \({ }^{\text {p822 }}\).

The following types of agents exist on the web platform:

\section*{Similar-origin window agent}

Contains various Window \({ }^{p 824}\) objects which can potentially reach each other, either directly or by using document. domain \({ }^{\text {p84e }}\).
If the encompassing agent cluster's cross-origin isolated \({ }^{\text {p914 }}\) is true, then all the Window \({ }^{\text {p824 }}\) objects will be same origin \({ }^{\text {p838 }}\), can reach each other directly, and document. domain \({ }^{\text {p849 }}\) will no-op.

\section*{Note}

Two Window \({ }^{p 824}\) objects that are same origin \({ }^{p 838}\) can be in different similar-origin window agents \({ }^{p 913}\), for instance if they are each in their own browsing context group \({ }^{\text {p818 }}\).

\section*{Dedicated worker agent}

Contains a single DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\).

\section*{Shared worker agent}

Contains a single SharedWorkerGlobalScope \({ }^{\text {p1047 }}\).

\section*{Service worker agent}

Contains a single ServiceWorkerGlobalScope.

\section*{Worklet agent}

Contains a single WorkletGlobalScope object.

Although a given worklet can have multiple realms, each such realm needs its own agent, as each realm can be executing code independently and at the same time as the others.

Only shared \({ }^{\text {p913 }}\) and dedicated worker agents \({ }^{\text {p913 }}\) allow the use of JavaScript Atomics APIs to potentially block.
To create an agent, given a boolean canBlock:
1. Let signifier be a new unique internal value.
2. Let candidateExecution be a new candidate execution.
3. Let agent be a new agent whose [[CanBlock]] is canBlock, [[Signifier]] is signifier, [[CandidateExecution]] is candidateExecution, and [[IsLockFree1]], [[IsLockFree2]], and [[LittleEndian]] are set at the implementation's discretion.
4. Set agent's event loop \({ }^{\text {p944 }}\) to a new event loop \({ }^{\text {p944 }}\).
5. Return agent.

The relevant agent for a platform object platformObject is platformObject's relevant Realm \({ }^{\text {p924 ' }}\) 's agent. This pointer is not yet defined in the JavaScript specification; see tc39/ecma262\#1357.

\section*{Note}

The agent equivalent of the current Realm Record is the surrounding agent.

\subsection*{8.1.2.2 Integration with the JavaScript agent cluster formalism \(\S_{4}^{\text {p91 }}\)}

JavaScript also defines the concept of an agent cluster, which this standard maps to the web platform by placing agents appropriately when they are created using the obtain a similar-origin window agent \({ }^{\text {p914 }}\) or obtain a worker/worklet agent \({ }^{\text {p915 }}\) algorithms.

The agent cluster concept is crucial for defining the JavaScript memory model, and in particular among which agents the backing data of SharedArrayBuffer objects can be shared.

\section*{Note}

Conceptually, the agent cluster concept is an architecture-independent, idealized "process boundary" that groups together multiple "threads" (agents). The agent clusters defined by the specification are generally more restrictive than the actual process boundaries implemented in user agents. By enforcing these idealized divisions at the specification level, we ensure that web developers see interoperable behavior with regard to shared memory, even in the face of varying and changing user agent process models.

An agent cluster has an associated cross-origin isolated (a boolean), which is initially false.
An agent cluster has an associated origin-isolated (a boolean), which is initially false.

The following defines the allocation of the agent clusters of similar-origin window agents \({ }^{\text {p913 }}\).
An agent cluster key is a site \({ }^{\text {p839 }}\) or tuple origin \({ }^{\text {p837 }}\) whose host \({ }^{\mathrm{p837}}\) 's registrable domain is non-null. I.e., an agent cluster key \({ }^{\text {p914 }}\) can be a scheme-and-registrable-domain \({ }^{\text {p839 }}\) or any origin \({ }^{\text {p837 }}\).

To obtain a similar-origin window agent, given an origin \({ }^{\text {p837 }}\) origin, a browsing context group \({ }^{\text {p818 }}\) group, and a boolean requestsOI, run these steps:
1. Let site be the result of obtaining a site \({ }^{\mathrm{p} 839}\) with origin.
2. Let key be site.
3. If group's cross-origin isolated \({ }^{\mathrm{p} 818}\) is true, then set key to origin.
4. Otherwise, if group's historical agent cluster key map \({ }^{\text {p818 }}\) [origin] exists, then set key to group's historical agent cluster key map \({ }^{\text {p818 }}\) [origin].
5. Otherwise:
1. If requestsOl is true, then set key to origin.
2. Set group's historical agent cluster key map \({ }^{\text {p818 }}\) [origin] to key.
6. If group's agent cluster map \({ }^{p 818}[k e y]\) does not exist, then:
1. Let agentCluster be a new agent cluster.
2. Set agentCluster's cross-origin isolated \({ }^{\text {p914 }}\) to group's cross-origin isolated \({ }^{\text {p818 }}\).
3. Set agentCluster's origin-isolated \({ }^{\text {p914 }}\) to true if key equals origin; otherwise false.
4. Add the result of creating an agent \({ }^{p 914}\), given false, to agentCluster.
5. Set group's agent cluster map \({ }^{p 818}[k e y]\) to agentCluster.
7. Return the single similar-origin window agent \({ }^{\text {p913 }}\) contained in group's agent cluster map \({ }^{\text {p818 }}\) [key].

\section*{Note}

This means that there is only one similar-origin window agent \({ }^{p 913}\) per browsing context agent cluster. (However, dedicated worker \(^{p 913}\) and worklet agents \({ }^{p 913}\) might be in the same cluster.)

The following defines the allocation of the agent clusters of all other types of agents.
To obtain a worker/worklet agent, given an environment settings object \({ }^{\text {p917 }}\) or null outside settings, a boolean isTopLevel, and a boolean canBlock, run these steps:
1. Let agentCluster be null.
2. If isTopLevel is true, then:
1. Set agentCluster to a new agent cluster.
2. Set agentCluster's origin-isolated \({ }^{\text {p914 }}\) to true.

\section*{Note}

These workers can be considered to be origin-isolated. However, this is not exposed through any APIs (in the way that originIsolated \({ }^{\mathrm{p} 841}\) exposes the origin-isolation state for windows).
3. Otherwise:
1. Assert: outside settings is not null.
2. Let ownerAgent be outside settings's Realm \({ }^{\text {p918 's }}\) 's agent.
3. Set agentCluster to the agent cluster which contains ownerAgent.
4. Let agent be the result of creating an agent \({ }^{\text {p914 }}\) given canBlock.
5. Add agent to agentCluster.
6. Return agent.

To obtain a dedicated/shared worker agent, given an environment settings object \({ }^{\text {p917 }}\) outside settings and a boolean isShared, return the result of obtaining a worker/worklet agent \({ }^{\text {p915 }}\) given outside settings, isShared, and true.

To obtain a worklet agent, given an environment settings object \({ }^{\text {p917 }}\) outside settings, return the result of obtaining a worker/worklet agent \({ }^{\text {p915 }}\) given outside settings, false, and false.

To obtain a service worker agent, return the result of obtaining a worker/worklet agent \({ }^{\text {p915 }}\) given null, true, and false.

The following pairs of global objects are each within the same agent cluster, and thus can use SharedArrayBuffer instances to share memory with each other:
- A Window \({ }^{p 824}\) object and a dedicated worker that it created.
- A worker (of any type) and a dedicated worker it created.
- A Window \({ }^{\text {p824 }}\) object \(A\) and the Window \({ }^{\text {p824 }}\) object of an iframe \({ }^{\text {p361 }}\) element that \(A\) created that could be same origindomain \({ }^{\text {p838 }}\) with \(A\).
- A Window \({ }^{\text {p824 }}\) object and a same origin-domain \({ }^{p 838}\) Window \({ }^{p 824}\) object that opened it.
- A Window \({ }^{\text {p824 }}\) object and a worklet that it created.

The following pairs of global objects are not within the same agent cluster, and thus cannot share memory:
- A Window \({ }^{\text {p824 }}\) object and a shared worker it created.
- A worker (of any type) and a shared worker it created.
- A Window \({ }^{\text {p824 }}\) object and a service worker it created.
- A Window \({ }^{\text {p824 }}\) object and the Window \({ }^{\text {p824 }}\) object of an iframe \({ }^{\text {p361 }}\) element that \(A\) created that cannot be same origindomain \({ }^{\mathrm{p} 838}\) with \(A\).
- Any two Window \({ }^{p 824}\) objects whose browsing contexts \({ }^{p 811}\) do not have a non-null opener \({ }^{p 811}\) or ancestor \({ }^{\mathrm{p814}}\) relationship. This holds even if the two Window \({ }^{\text {p824 }}\) objects are same origin \({ }^{\text {p838 }}\).

\subsection*{8.1.3 Realms and their counterparts \(\S^{\text {p9 }}\)}

The JavaScript specification introduces the realm concept, representing a global environment in which script is run. Each realm comes with an implementation-defined global object \({ }^{\text {p918 }}\); much of this specification is devoted to defining that global object and its properties.

For web specifications, it is often useful to associate values or algorithms with a realm/global object pair. When the values are specific to a particular type of realm, they are associated directly with the global object in question, e.g., in the definition of the Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) interfaces. When the values have utility across multiple realms, we use the environment settings object \({ }^{\text {p917 }}\) concept.

Finally, in some cases it is necessary to track associated values before a realm/global object/environment settings object even comes into existence (for example, during navigation \({ }^{\text {p866 }}\) ). These values are tracked in the environment \({ }^{\text {p916 }}\) concept.

\subsection*{8.1.3.1 Environments \(\S^{\text {p91 }}\)}

An environment is an object that identifies the settings of a current or potential execution environment. An environment \({ }^{\text {p916 }}\) has the following fields:

\section*{An id}

An opaque string that uniquely identifies this environment \({ }^{p 916}\).

\section*{A creation URL}

A URL that represents the location of the resource with which this environment \({ }^{\text {p916 }}\) is associated.

\section*{Note}

In the case of an environment settings object \({ }^{p 917}\), this URL might be distinct from the environment settings object \({ }^{p 917}\) 's responsible document \({ }^{p 917}\) 's URL, due to mechanisms such as history.pushState() \({ }^{\text {p854 }}\).

\section*{A top-level creation URL}

Null or a URL that represents the creation URL" \({ }^{\text {p916 }}\) of the "top-level" environment \({ }^{\text {p916 }}\). It is null for workers and worklets.

\section*{A top-level origin}

A for now implementation-defined value, null, or an origin \({ }^{\text {p837 }}\). For a "top-level" potential execution environment it is null (i.e., when there is no response yet); otherwise it is the "top-level" environment \({ }^{\text {p916 }}\) 's origin \({ }^{\text {p917 }}\). For a dedicated worker or worklet it is the top-level origin \({ }^{p 916}\) of its creator. For a shared or service worker it is an implementation-defined value.

\section*{A target browsing context}

Null or a target browsing context \({ }^{\text {p811 }}\) for a navigation request.

\section*{An active service worker}

Null or a service worker that controls the environment \({ }^{\text {p916 }}\).

\section*{An execution ready flag}

A flag that indicates whether the environment setup is done. It is initially unset.
Specifications may define environment discarding steps for environments. The steps take an environment \({ }^{\text {p916 }}\) as input.
```

Note
The environment discarding steps }\mp@subsup{}{}{p917}\mathrm{ are run for only a select few environments: the ones that will never become execution ready
because, for example, they failed to load.

```

\subsection*{8.1.3.2 Environment settings objects \(\S^{\text {p91 }}\)}

An environment settings object is an environment \({ }^{\text {p916 }}\) that additionally specifies algorithms for:

\section*{A realm execution context}

A JavaScript execution context shared by all scripts \({ }^{\text {p614 }}\) that use this settings object, i.e. all scripts in a given JavaScript realm. When we run a classic script \({ }^{\text {p934 }}\) or run a module script \({ }^{\text {p935 }}\), this execution context becomes the top of the JavaScript execution context stack, on top of which another execution context specific to the script in question is pushed. (This setup ensures ParseScript and Source Text Module Record's Evaluate know which Realm to use.)

\section*{A module map}

A module map \({ }^{\text {p941 }}\) that is used when importing JavaScript modules.

\section*{A responsible document}

A Document \({ }^{\text {p114 }}\) that is assigned responsibility for actions taken by the scripts that use this environment settings object \({ }^{\text {p917 }}\).

\section*{Example}

For example, the URL of the responsible document \({ }^{\text {p917 }}\) is used to set the URL of the Document \({ }^{\text {p114 }}\) after it has been reset using document. open() \({ }^{\text {p969. }}\).

If the responsible event loop \({ }^{\text {p918 }}\) is not a window event loop \({ }^{\text {p944 }}\), then the environment settings object \({ }^{\text {p917 }}\) has no responsible document \({ }^{\text {p917 }}\).

\section*{An API URL character encoding}

A character encoding used to encode URLs by APIs called by scripts that use this environment settings object \({ }^{\text {p917 }}\).

\section*{An API base URL}

A URL used by APIs called by scripts that use this environment settings object \({ }^{p 917}\) to parse URLs \({ }^{\text {p89 }}\).

\section*{An origin}

An origin \({ }^{\text {p837 }}\) used in security checks.

\section*{A referrer policy}

The default referrer policy for fetches performed using this environment settings object \({ }^{\text {p917 }}\) as a request client. [REFERRERPOLICY] \({ }^{\text {p1290 }}\)

\section*{An embedder policy}

An embedder policy \({ }^{\text {p847 }}\) used by cross-origin resource policy checks for fetches performed using this environment settings object \({ }^{\text {p917 }}\) as a request client.

\section*{A cross-origin isolated capability}

A boolean representing whether scripts that use this environment settings object \({ }^{p 917}\) are allowed to use APIs that require crossorigin isolation.

An environment settings object \({ }^{\text {p917 }}\) also has an outstanding rejected promises weak set and an about-to-be-notified rejected promises list, used to track unhandled promise rejections \({ }^{\text {p938. }}\). The outstanding rejected promises weak set \({ }^{\text {p918 }}\) must not create strong references to any of its members, and implementations are free to limit its size, e.g. by removing old entries from it when new ones are added.

An environment settings object \({ }^{\text {p977' }}\) 's responsible event loop is its global object \({ }^{\text {p988 }}\) 's relevant agent \({ }^{\text {p914' }}\) 's event loop \({ }^{\text {p9944 }}\).

\subsection*{8.1.3.3 Realms, settings objects, and global objects \(\underset{8}{\AA^{\text {p91 }}}\)}

A global object is a JavaScript object that is the [[GlobalObject]] field of a JavaScript realm.

\section*{Note}

In this specification, all JavaScript realms are created \({ }^{p 918}\) with global objects \({ }^{p 918}\) that are either Window \({ }^{p 824}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) objects.

There is always a 1-to-1-to-1 mapping between JavaScript realms, global objects \({ }^{\text {p918 }}\), and environment settings objects \({ }^{\text {p917 }}\) :
- A JavaScript realm has a [[HostDefined]] field, which contains the Realm's settings object.
- A JavaScript realm has a [[GlobalObject]] field, which contains the Realm's global object.
- Each global object \({ }^{\text {p918 }}\) in this specification is created during the creation \({ }^{\text {p918 }}\) of a corresponding JavaScript realm, known as the global object's Realm.
- Each global object \({ }^{\mathrm{p} 918}\) in this specification is created alongside a corresponding environment settings object \({ }^{\text {p917 }}\), known as its relevant settings object \({ }^{\text {p924 }}\).
- An environment settings object \({ }^{\text {p917' }} \mathrm{s}\) realm execution context \({ }^{\text {p917 ' 's Realm component is the environment settings object's }}\) Realm.
- An environment settings object \({ }^{\text {p917 }}\) 's Realm \({ }^{\text {p918 }}\) then has a [[GlobalObject]] field, which contains the environment settings object's global object.

To create a new JavaScript realm in an agent agent, optionally with instructions to create a global object or a global this binding (or both), the following steps are taken:
1. Perform InitializeHostDefinedRealm() with the provided customizations for creating the global object and the global this binding.
2. Let realm execution context be the running JavaScript execution context.

Note
This is the JavaScript execution context created in the previous step.
3. Remove realm execution context from the JavaScript execution context stack.
4. Let realm be realm execution context's Realm component.
5. Set realm's agent to agent. This pointer is not yet defined in the JavaScript specification; see tc39/ecma262\#1357.
6. If agent's agent cluster's cross-origin isolated \({ }^{p 914}\) is false, then:
1. Let global be realm's global object \({ }^{\text {p918 }}\).
2. Let status be! global.[[Delete]]("SharedArrayBuffer").
3. Assert: status is true.

\section*{Note}

> This is done for compatibility with web content and there is some hope that this can be removed in the future. Web developers can still get at the constructor through new WebAssembly.Memory(\{ shared:true, initial:0, maximum:0 \}). buffer. constructor.
7. Return realm execution context.

When defining algorithm steps throughout this specification, it is often important to indicate what 〕avaScript realm is to be used-or, equivalently, what global object \({ }^{\text {p918 }}\) or environment settings object \({ }^{p 917}\) is to be used. In general, there are at least four possibilities:

\section*{Entry}

This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

\section*{Incumbent}

This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally scheduled the currently-running callback.

\section*{Current}

This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the current JavaScript realm.)

\section*{Relevant}

Every platform object has a relevant Realm \({ }^{\text {p924 }}\), which is roughly the JavaScript realm in which it was created. When writing algorithms, the most prominent platform object whose relevant Realm \({ }^{\text {p924 }}\) might be important is the this value of the currentlyrunning function object. In some cases, there can be other important relevant Realms \({ }^{\text {p924 }}\), such as those of any arguments.

Note how the entry \({ }^{\text {p919 }}\), incumbent \({ }^{\text {p919 }}\), and current \({ }^{\text {p919 }}\) concepts are usable without qualification, whereas the relevant \({ }^{\text {p919 }}\) concept must be applied to a particular platform object.

\section*{\(\triangle\) Warning!}

The incumbent \({ }^{p 919}\) and entry \({ }^{\text {p919 }}\) concepts should not be used by new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see issue \#1430 for incumbent \({ }^{\text {p919 }}\), and issue \#1431 for entry \({ }^{\text {p919 }}\).

In general, web platform specifications should use the relevant \({ }^{\text {p919 }}\) concept, applied to the object being operated on (usually the this value of the current method). This mismatches the JavaScript specification, where current \({ }^{\text {p919 }}\) is generally used as the default (e.g. in determining the JavaScript realm whose Array constructor should be used to construct the result in Array. prototype.map). But this inconsistency is so embedded in the platform that we have to accept it going forward.

\section*{Example}

Consider the following pages, with a.html being loaded in a browser window, b.html being loaded in an iframe \({ }^{\text {p361 }}\) as shown, and c. html and d.html omitted (they can simply be empty documents):
```

<!-- a.html -->
<!DOCTYPE html>

<html lang="en">
<title>Entry page</title>
<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>
<!--b.html -->
<!DOCTYPE html>
<html lang="en">
<title>Incumbent page</title>
<iframe src="c.html" id="c"></iframe>
<iframe src="d.html" id="d"></iframe>
<script>
    const c = document.querySelector("#c").contentWindow;
    const d = document.querySelector("#d").contentWindow;
    window.hello = () => {
        c.print.call(d);
    };
</script>
```

Each page has its own browsing context \({ }^{\mathrm{p} 811}\), and thus its own JavaScript realm, global object \({ }^{\mathrm{p918}}\), and environment settings object \({ }^{\text {p917 }}\).

When the print() \()^{\text {p978 }}\) method is called in response to pressing the button in a.html, then:
- The entry Realm \({ }^{\text {p921 }}\) is that of a.html.
- The incumbent Realm \({ }^{\text {p922 }}\) is that of b.html.
- The current Realm is that of \(\mathrm{c} . \mathrm{html}\) (since it is the print () \({ }^{\text {p978 }}\) method from c.html whose code is running).
- The relevant Realm \({ }^{\text {p924 }}\) of the object on which the print () \()^{\text {p978 }}\) method is being called is that of d.html.

\section*{Example}

One reason why the relevant \({ }^{\text {p919 }}\) concept is generally a better default choice than the current \({ }^{\text {p919 }}\) concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the navigator. getBattery() method creates promises in the relevant Realm \({ }^{\text {p924 }}\) for the Navigator \({ }^{\text {p979 }}\) object on which it is invoked. This has the following impact:
[BATTERY] \({ }^{p 1285}\)
```
<!-- outer.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: outer page</title>
<script>
    function doTest() {
        const promise = navigator.getBattery.call(frames[0].navigator);
        console.log(promise instanceof Promise); // logs false
        console.log(promise instanceof frames[0].Promise); // logs true
        frames[0].hello();
    }
</script>
<iframe src="inner.html" onload="doTest()"></iframe>
<!-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant Realm demo: inner page</title>
<script>
    function hello() {
        const promise = navigator.getBattery();
        console.log(promise instanceof Promise); // logs true
        console.log(promise instanceof parent.Promise); // logs false
    }
</script>
```

If the algorithm for the getBattery() method had instead used the current Realm, all the results would be reversed. That is, after the first call to getBattery () in outer. html, the Navigator \({ }^{\text {p979 }}\) object in inner. html would be permanently storing a Promise object created in outer.html's JavaScript realm, and calls like that inside the hello() function would thus return a promise from the "wrong" realm. Since this is undesirable, the algorithm instead uses the relevant Realm \({ }^{\text {p924 }}\), giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the entry \({ }^{\text {p919 }}\), incumbent \({ }^{\text {p919 }}\), current \({ }^{\text {p919 }}\), and relevant \({ }^{\text {p919 }}\) concepts.

\subsection*{8.1.3.3.1 Entry \(\S^{p 92}\)}

The process of calling scripts \({ }^{\text {p934 }}\) will push or pop realm execution contexts \({ }^{\text {p917 }}\) onto the JavaScript execution context stack, interspersed with other execution contexts.

With this in hand, we define the entry execution context to be the most recently pushed item in the JavaScript execution context stack that is a realm execution context \({ }^{\text {p917 }}\). The entry Realm is the entry execution context \({ }^{\text {p921 }}\) 's Realm component.

Then, the entry settings object is the environment settings object \({ }^{\text {p918 }}\) of the entry Realm \({ }^{\text {p921 }}\).
Similarly, the entry global object is the global object \({ }^{\text {p918 }}\) of the entry Realm \({ }^{\text {p921 }}\).

\subsection*{8.1.3.3.2 Incumbent \(\$^{\text {p92 }}\)}

All JavaScript execution contexts must contain, as part of their code evaluation state, a skip-when-determining-incumbent
counter value, which is initially zero. In the process of preparing to run a callback \({ }^{\text {p921 }}\) and cleaning up after running a callback \({ }^{\text {p921 }}\), this value will be incremented and decremented.

Every event loop \({ }^{\text {p944 }}\) has an associated backup incumbent settings object stack, initially empty. Roughly speaking, it is used to determine the incumbent settings object \({ }^{\text {p921 }}\) when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of preparing to run a callback \({ }^{\text {p921 }}\) and cleaning up after running a callback \({ }^{\text {p921 }}\) manipulate this stack. [WEBIDL] \({ }^{\text {p1292 }}\)

When Web IDL is used to invoke author code, or when HostEnqueuePromiseJob \({ }^{\text {p939 }}\) invokes a promise job, they use the following algorithms to track relevant data for determining the incumbent settings object \({ }^{\mathrm{p} 921}\) :

To prepare to run a callback with an environment settings object \({ }^{\text {p917 }}\) settings:
1. Push settings onto the backup incumbent settings object stack \({ }^{\text {p921 }}\).
2. Let context be the topmost script-having execution context \({ }^{\text {p921 }}\).
3. If context is not null, increment context's skip-when-determining-incumbent counter \({ }^{\mathrm{p} 921}\).

To clean up after running a callback with an environment settings object \({ }^{\text {p917 }}\) settings:
1. Let context be the topmost script-having execution context \({ }^{\text {p921 }}\).

Note
This will be the same as the topmost script-having execution context \({ }^{p 921}\) inside the corresponding invocation of prepare to run a callback \({ }^{\text {p921 }}\).
2. If context is not null, decrement context's skip-when-determining-incumbent counter \({ }^{\text {p921 }}\).
3. Assert: the topmost entry of the backup incumbent settings object stack \({ }^{\text {p921 }}\) is settings.
4. Remove settings from the backup incumbent settings object stack \({ }^{\text {p921 }}\).

Here, the topmost script-having execution context is the topmost entry of the JavaScript execution context stack that has a nonnull ScriptOrModule component, or null if there is no such entry in the JavaScript execution context stack.

With all this in place, the incumbent settings object is determined as follows:
1. Let context be the topmost script-having execution context \({ }^{\mathrm{p} 921}\).
2. If context is null, or if context's skip-when-determining-incumbent counter \({ }^{\text {p921 }}\) is greater than zero, then:
1. Assert: the backup incumbent settings object stack \({ }^{\text {p921 }}\) is not empty.

\section*{Note}

This assert would fail if you try to obtain the incumbent settings object \({ }^{p 921}\) from inside an algorithm that was triggered neither by calling scripts \({ }^{p 934}\) nor by Web IDL invoking a callback. For example, it would trigger if you tried to obtain the incumbent settings object \({ }^{p 921}\) inside an algorithm that ran periodically as part of the event loop \({ }^{p 944}\), with no involvement of author code. In such cases the incumbent \({ }^{p 919}\) concept cannot be used.
2. Return the topmost entry of the backup incumbent settings object stack \({ }^{\text {p921 }}\).
3. Return context's Realm component's settings object \({ }^{\text {p918 }}\).

Then, the incumbent Realm is the Realm \({ }^{\text {p918 }}\) of the incumbent settings object \({ }^{\text {p921 }}\).
Similarly, the incumbent global object is the global object \({ }^{\text {p918 }}\) of the incumbent settings object \({ }^{\text {p921 }}\).

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the incumbent \({ }^{\text {p921 }}\) concept:

\section*{Example}

Consider the following starter example:
```
<!DOCTYPE html>
<iframe></iframe>
<script>
    frames[0].postMessage("some data", "*");
</script>
```

There are two interesting environment settings objects \({ }^{\text {p917 }}\) here: that of window, and that of frames [0]. Our concern is: what is the incumbent settings object \({ }^{\text {p921 }}\) at the time that the algorithm for postMessage( \()^{\text {p1018 }}\) executes?

It should be that of window, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in window, not frames [0]. This makes sense: the window post message steps \({ }^{\text {p1017 }}\) use the incumbent settings object \({ }^{\text {p921 }}\) to determine the source \({ }^{\text {p999 }}\) property of the resulting MessageEvent \({ }^{\text {p998 }}\), and in this case window is definitely the source of the message.

Let us now explain how the steps given above give us our intuitively-desired result of window's relevant settings object \({ }^{\text {p924 }}\).
When the window post message steps \({ }^{\text {p1017 }}\) look up the incumbent settings object \({ }^{\text {p921 }}\), the topmost script-having execution context \({ }^{\text {p921 }}\) will be that corresponding to the script \({ }^{\text {p614 }}\) element: it was pushed onto the JavaScript execution context stack as part of ScriptEvaluation during the run a classic script \({ }^{\text {p934 }}\) algorithm. Since there are no Web IDL callback invocations involved, the context's skip-when-determining-incumbent counter \({ }^{\text {p921 }}\) is zero, so it is used to determine the incumbent settings object \({ }^{\text {p921 }}\); the result is the environment settings object \({ }^{\text {p917 }}\) of window.
(Note how the environment settings object \({ }^{\text {p917 }}\) of frames [0] is the relevant settings object \({ }^{\text {p924 }}\) of this at the time the postMessage( ) \({ }^{\text {p1018 }}\) method is called, and thus is involved in determining the target of the message. Whereas the incumbent is used to determine the source.)

\section*{Example}

Consider the following more complicated example:
```
<!DOCTYPE html>
<iframe></iframe>
<script>
    const bound = frames[0].postMessage.bind(frames[0], "some data", "*");
    window.setTimeout(bound);
</script>
```

This example is very similar to the previous one, but with an extra indirection through Function. prototype. bind as well as setTimeout () \({ }^{\text {p973 }}\). But, the answer should be the same: invoking algorithms asynchronously should not change the incumbent \({ }^{\text {p919 }}\) concept.

This time, the result involves more complicated mechanisms:
When bound is converted to a Web IDL callback type, the incumbent settings object \({ }^{\text {p921 }}\) is that corresponding to window (in the same manner as in our starter example above). Web IDL stores this as the resulting callback value's callback context.

When the task \({ }^{\text {p944 }}\) posted by setTimeout ( ) \({ }^{\text {p973 }}\) executes, the algorithm for that task uses Web IDL to invoke the stored callback
value. Web IDL in turn calls the above prepare to run a callback \({ }^{\text {p921 }}\) algorithm. This pushes the stored callback context onto the backup incumbent settings object stack \({ }^{\text {p921 }}\). At this time (inside the timer task) there is no author code on the stack, so the topmost script-having execution context \({ }^{\text {p921 }}\) is null, and nothing gets its skip-when-determining-incumbent counter \({ }^{\text {p921 }}\) incremented.

Invoking the callback then calls bound, which in turn calls the postMessage() \()^{\text {p1018 }}\) method of frames [0]. When the postMessage ( ) \({ }^{\text {p1018 }}\) algorithm looks up the incumbent settings object \({ }^{\text {p921 }}\), there is still no author code on the stack, since the bound function just directly calls the built-in method. So the topmost script-having execution context \({ }^{\text {p921 }}\) will be null: the JavaScript execution context stack only contains an execution context corresponding to postMessage() \({ }^{\text {p1018 }}\), with no ScriptEvaluation context or similar below it.

This is where we fall back to the backup incumbent settings object stack \({ }^{\text {p921 }}\). As noted above, it will contain as its topmost entry the relevant settings object \({ }^{\text {p924 }}\) of window. So that is what is used as the incumbent settings object \({ }^{\text {p921 }}\) while executing the postMessage() \({ }^{\text {p1018 }}\) algorithm.

\section*{Example}

Consider this final, even more convoluted example:
```
<!-- a.html -->
<!DOCTYPE html>
<button>click me</button>
<iframe></iframe>
<script>
const bound = frames[0].location.assign.bind(frames[0].location, "https://example.com/");
document.querySelector("button").addEventListener("click", bound);
</script>
<!-- b.html -->
<!DOCTYPE html>
<iframe src="a.html"></iframe>
<script>
    const iframe = document.querySelector("iframe");
    iframe.onload = function onLoad() {
        iframe.contentWindow.document.querySelector("button").click();
    };
</script>
```

Again there are two interesting environment settings objects \({ }^{p 917}\) in play: that of a.html, and that of b. html. When the location. assign ( ) \({ }^{p 862}\) method triggers the Location-object navigate \({ }^{\text {p859 }}\) algorithm, what will be the incumbent settings object \({ }^{\mathrm{p921}}\) ? As before, it should intuitively be that of a.html: the click listener was originally scheduled by a.html, so even if something involving b.html causes the listener to fire, the incumbent \({ }^{\text {p919 }}\) responsible is that of a.html.

The callback setup is similar to the previous example: when bound is converted to a Web IDL callback type, the incumbent settings object \({ }^{\text {p921 }}\) is that corresponding to a.html, which is stored as the callback's callback context.

When the click() \({ }^{\text {p769 }}\) method is called inside b.html, it dispatches a click event on the button that is inside a.html. This time, when the prepare to run a callback \({ }^{\text {p921 }}\) algorithm executes as part of event dispatch, there is author code on the stack; the topmost script-having execution context \({ }^{\text {p921 }}\) is that of the onLoad function, whose skip-when-determining-incumbent counter \({ }^{\text {p921 }}\) gets incremented. Additionally, a.html's environment settings object \({ }^{\text {p917 }}\) (stored as the EventHandler \({ }^{\text {p958 's callback context) is pushed }}\) onto the backup incumbent settings object stack \({ }^{\text {p921 }}\).

Now, when the Location-object navigate \({ }^{\mathrm{p} 859}\) algorithm looks up the incumbent settings object \({ }^{\text {p921 }}\), the topmost script-having execution context \({ }^{p 921}\) is still that of the onLoad function (due to the fact we are using a bound function as the callback). Its skip-when-determining-incumbent counter \({ }^{\text {p921 }}\) value is one, however, so we fall back to the backup incumbent settings object stack \({ }^{\text {p921 }}\). This gives us the environment settings object \({ }^{\text {p917 }}\) of a.html, as expected.

Note that this means that even though it is the iframe \({ }^{\mathrm{p} 361}\) inside a.html that navigates, it is a.html itself that is used as the source browsing context \({ }^{\text {p866 }}\), which determines among other things the request client. This is perhaps the only justifiable use of the incumbent concept on the web platform; in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use current \({ }^{\text {p919 }}\) or relevant \({ }^{\text {p919 }}\) as appropriate.

\subsection*{8.1.3.3.3 Current \({ }^{5}{ }_{4}^{p 92}\)}

The JavaScript specification defines the current Realm Record, sometimes abbreviated to the "current Realm". [JAVASCRIPT] \({ }^{\text {p1288 }}\)
Then, the current settings object is the environment settings object \({ }^{\text {p918 }}\) of the current Realm Record.
Similarly, the current global object is the global object \({ }^{\text {p918 }}\) of the current Realm Record.

\subsection*{8.1.3.3.4 Relevant \({ }^{\text {p992 }}\)}

The relevant Realm for a platform object is the value of its [[Realm]] field.
Then, the relevant settings object for a platform object \(o\) is the environment settings object \({ }^{\text {p918 }}\) of the relevant Realm \({ }^{\text {p924 }}\) for \(o\). Similarly, the relevant global object for a platform object \(o\) is the global object \({ }^{\text {p918 }}\) of the relevant Realm \({ }^{\text {p924 }}\) for 0 .

\subsection*{8.1.3.4 Enabling and disabling scripting \({\underset{4}{892}}^{\text {p92 }}\)}

Scripting is enabled for an environment settings object \({ }^{\text {p917 }}\) settings when all of the following conditions are true:
- The user agent supports scripting.
- The user has not disabled scripting for settings at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g., on a per-origin basis, down to the level of individual environment settings objects \({ }^{\text {p917 }}\).)
- Either settings's global object \({ }^{p 918}\) is not a Window \({ }^{p 824}\) object, or settings's global object \({ }^{p 918}\) 's associated Document \({ }^{p 826}\) 's active sandboxing flag set \({ }^{\text {p844 }}\) does not have its sandboxed scripts browsing context flag \({ }^{\text {p842 }}\) set.

Scripting is disabled for an environment settings object \({ }^{\text {p917 }}\) when scripting is not enabled \({ }^{\text {p924 }}\) for it, i.e., when any of the above conditions are false.

Scripting is enabled for a node node if node's node document's browsing context \({ }^{\text {p811 }}\) is non-null, and scripting is enabled \({ }^{\text {p924 }}\) for node's relevant settings object \({ }^{\text {p924 }}\).

Scripting is disabled for a node when scripting is not enabled \({ }^{\text {p924 }}\), i.e., when its node document's browsing context \({ }^{\text {p811 }}\) is null or when scripting is disabled \({ }^{\text {p924 }}\) for its relevant settings object \({ }^{\text {p924 }}\).

\subsection*{8.1.3.5 Secure contexts \(\S^{1992}\)}

An environment \({ }^{\text {p916 }}\) environment is a secure context if the following algorithm returns true:
1. If environment is an environment settings object \({ }^{\text {p917 }}\), then:
1. Let global be environment's global object \({ }^{\text {p918 }}\).
2. If global is a WorkerGlobalScope \({ }^{\text {p1044 }}\), then:
1. If global's owner set \({ }^{\mathrm{p} 1045}[0]\) 's relevant settings object \({ }^{\mathrm{p} 924}\) is a secure context \({ }^{\mathrm{p} 924}\), then return true.

\section*{Note}

We only need to check the Oth item since they will necessarily all be consistent.
2. Return false.
3. If global is a WorkletGlobalScope, then:
1. If global's owner document's relevant settings object \({ }^{\mathrm{p} 924}\) is a secure context \({ }^{\mathrm{p} 924}\), then return true.
2. Return false.
2. If the result of Is url potentially trustworthy? given environment's top-level creation URL \({ }^{\text {p916 }}\) is "Potentially Trustworthy", then return true.
3. Return false.

An environment \({ }^{\mathrm{p} 916}\) is a non-secure context if it is not a secure context \({ }^{\mathrm{p} 924}\).

\subsection*{8.1.4 Script processing model \(\S_{5}^{\text {p92 }}\)}

\subsection*{8.1.4.1 Scripts \(\S^{\text {p92 }}\)}

A script is one of two possible structs. All scripts have:

\section*{A settings object}

An environment settings object \({ }^{\text {p917 }}\), containing various settings that are shared with other scripts \({ }^{\text {p925 }}\) in the same context.

\section*{A record}

Either a Script Record, for classic scripts \({ }^{\text {p925 }}\); a Source Text Module Record, for module scripts \({ }^{\text {p925 }}\); or null. In the former two cases, it represents a parsed script; null represents a failure parsing.

\section*{A parse error}

A JavaScript value, which has meaning only if the record \({ }^{p 925}\) is null, indicating that the corresponding script source text could not be parsed.

\section*{Note}

This value is used for internal tracking of immediate parse errors when creating scripts \({ }^{p 933}\), and is not to be used directly. Instead, consult the error to rethrow \({ }^{\text {p925 }}\) when determining "what went wrong" for this script.

\section*{An error to rethrow}

A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to run \({ }^{\text {p934 }}\) the script.

\section*{Note}

This could be the script's parse error \({ }^{p 925}\), but in the case of a module script \({ }^{p 925}\) it could instead be the parse error \({ }^{p 925}\) from one of its dependencies, or an error from resolve a module specifier \({ }^{\text {p941 }}\).

\section*{Note}

Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.

\section*{Fetch options}

A script fetch options \({ }^{\text {p926 }}\), containing various options related to fetching this script or module scripts \({ }^{\text {p925 }}\) that it imports.

\section*{A base URL}

A base URL used for resolving module specifiers \({ }^{p 941}\). This will either be the URL from which the script was obtained, for external scripts, or the document base URL \({ }^{\text {p88 }}\) of the containing document, for inline scripts.

A classic script is a type of script \({ }^{\text {p925 }}\) that has the following additional item:

\section*{A muted errors boolean}

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

A module script is another type of script \({ }^{p 925}\). It has no additional items.
The active script is determined by the following algorithm:
1. Let record be GetActiveScriptOrModule().
2. If record is null, return null.
3. Return record.[[HostDefined]].

\section*{Note}

The active script \({ }^{p 925}\) concept is so far only used by the import() feature, to determine the \(\underline{b a s e ~ U R L}{ }^{p 925}\) to use for resolving relative module specifiers.

\subsection*{8.1.4.2 Fetching scripts \(\S_{{ }_{6}^{p 92}}^{\text {pr }}\)}

This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in classic \({ }^{\text {p925 }}\) or module scripts \({ }^{\text {p925 }}\).

Script fetch options is a struct with the following items:

\section*{cryptographic nonce}

The cryptographic nonce metadata used for the initial fetch and for fetching any imported modules

\section*{integrity metadata}

The integrity metadata used for the initial fetch

\section*{parser metadata}

The parser metadata used for the initial fetch and for fetching any imported modules

\section*{credentials mode}

The credentials mode used for the initial fetch (for module scripts \({ }^{\text {p925 }}\) ) and for fetching any imported modules (for both module scripts \({ }^{\text {p925 }}\) and classic scripts \({ }^{\text {p925 }}\) )

\section*{referrer policy}

The referrer policy used for the initial fetch and for fetching any imported modules

\section*{Note}

Recall that via the import () feature, classic scripts \({ }^{p 925}\) can import module scripts \({ }^{p 925}\).

The default classic script fetch options are a script fetch options \({ }^{\text {p926 }}\) whose cryptographic nonce \({ }^{\text {p926 }}\) is the empty string, integrity metadata \({ }^{\text {p926 }}\) is the empty string, parser metadata \({ }^{\text {p926 }}\) is "not-parser-inserted", credentials mode \({ }^{\text {p926 }}\) is "same-origin", and referrer policy \({ }^{\text {p926 }}\) is the empty string.

Given a request request and a script fetch options \({ }^{\text {p926 }}\) options, we define:

\section*{set up the classic script request}

Set request's cryptographic nonce metadata to options's cryptographic nonce \({ }^{\text {p926 }}\), its integrity metadata to options's integrity metadata \({ }^{\text {p926 }}\), its parser metadata to options's parser metadata \({ }^{\text {p926 }}\), and its referrer policy to options's referrer policy \({ }^{\text {p926 }}\).

\section*{set up the module script request}

Set request's cryptographic nonce metadata to options's cryptographic nonce \({ }^{\text {p926 }}\), its integrity metadata to options's integrity metadata \(^{\text {p926 }}\), its parser metadata to options's parser metadata \({ }^{\text {p926 }}\), its credentials mode to options's credentials mode \({ }^{\text {p926 }}\), and its referrer policy to options's referrer policy \({ }^{\text {p926 }}\).

For any given script fetch options \({ }^{\text {p926 }}\) options, the descendant script fetch options are a new script fetch options \({ }^{\text {p926 }}\) whose items all have the same values, except for the integrity metadata \({ }^{\text {p926 }}\), which is instead the empty string.

The algorithms below can be customized by optionally supplying a custom perform the fetch hook, which takes a request and an is top-level flag. The algorithm must complete with a response (which may be a network error), either synchronously (when using fetch a classic worker-imported script \({ }^{\text {p928 }}\) ) or asynchronously (otherwise). The is top-level \({ }^{\text {p926 }}\) flag will be set for all classic script \({ }^{\text {p925 }}\) fetches, and for the initial fetch when fetching an external module script graph \({ }^{\text {p929 }}\), fetching a module worker script graph \({ }^{\text {p930 }}\), or fetching an import() module script graph \({ }^{\text {p929 }}\), but not for the fetches resulting from import statements encountered throughout the graph.

By default, not supplying the perform the fetch \({ }^{p 926}\) will cause the below algorithms to simply fetch the given request, with algorithm-specific customizations to the request and validations of the resulting response.

To layer your own customizations on top of these algorithm-specific ones, supply a perform the fetch \({ }^{\text {p926 }}\) hook that modifies the given request, fetches it, and then performs specific validations of the resulting response (completing with a network error if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of responses and avoiding performing a fetch at all.

\section*{Note}

Service Workers is an example of a specification that runs these algorithms with its own options for the hook. [SW] \({ }^{p 1291}\)

Now for the algorithms themselves.
To fetch a classic script given a url, a settings object, some options, a CORS setting, and a character encoding, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new classic script \({ }^{\text {p925 }}\) (on success).
1. Let request be the result of creating a potential-CORS request \({ }^{p 90}\) given url, "script", and CORS setting.
2. Set request's client to settings object.
3. Set up the classic script request \({ }^{\mathrm{p} 926}\) given request and options.
4. If the caller specified custom steps to perform the fetch \({ }^{\text {p926 }}\), perform them on request, with the is top-level \({ }^{\text {p926 }}\) flag set. Return from this algorithm, and when the custom perform the fetch \({ }^{\text {p926 }}\) steps complete with response response, run the remaining steps.

Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response response.

\section*{Note}
response can be either CORS-same-origin \({ }^{p 90}\) or CORS-cross-origin \({ }^{p 90}\). This only affects how error reporting happens.
5. Set response to response's unsafe response \({ }^{\text {p90 }}\).
6. If response's type is "error", or response's status is not an ok status, then asynchronously complete this algorithm with null, and return.

\section*{Note}

For historical reasons, this algorithm does not include MIME type checking, unlike the other script-fetching algorithms in this section.
7. If response's Content Type metadata \({ }^{\text {p90 }}\), if any, specifies a character encoding, and the user agent supports that encoding, then set character encoding to that encoding (ignoring the passed-in value).
8. Let source text be the result of decoding response's body to Unicode, using character encoding as the fallback encoding.

\section*{Note}

The decode algorithm overrides character encoding if the file contains a BOM.
9. Let muted errors be true if response was CORS-cross-origin \({ }^{\text {p90 }}\), and false otherwise.
10. Let script be the result of creating a classic script \({ }^{\text {p933 }}\) given source text, settings object, response's url, options, and muted errors.
11. Asynchronously complete this algorithm with script.

To fetch a classic worker script given a url, a fetch client settings object, a destination, and a script settings object, run these steps. The algorithm will asynchronously complete with either null (on failure) or a new classic script \({ }^{\text {p925 }}\) (on success).
1. Let request be a new request whose url is url, client is fetch client settings object, destination is destination, mode is "same-
origin", credentials mode is "same-origin", parser metadata is "not parser-inserted", and whose use-URL-credentials flag is set.
2. If the caller specified custom steps to perform the fetch \({ }^{\text {p926 }}\), perform them on request, with the is top-level \({ }^{\text {p926 }}\) flag set. Return from this algorithm, and when the custom perform the fetch \({ }^{\text {p926 }}\) steps complete with response response, run the remaining steps.

Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response response.
3. Set response to response's unsafe response \({ }^{\text {p90 }}\).
4. If either of the following conditions are met:
- response's type is "error"; or
- response's status is not an ok status,
then asynchronously complete this algorithm with null, and return.
5. If both of the following conditions are met:
- response's url's scheme is an HTTP(S) scheme; and
- the result of extracting a MIME type from response's header list is not a JavaScript MIME type,
then asynchronously complete this algorithm with null, and return.
Note
Other fetch schemes are exempted from MIME type checking for historical web-compatibility reasons. We might be able to tighten this in the future; see issue \#3255.
6. Let source text be the result of UTF-8 decoding response's body.
7. Let script be the result of creating a classic script \({ }^{\text {p933 }}\) using source text, script settings object, response's url, and the default classic script fetch options \({ }^{\text {p926 }}\).
8. Asynchronously complete this algorithm with script.

To fetch a classic worker-imported script given a url and a settings object, run these steps. The algorithm will synchronously complete with a classic script \({ }^{\text {p925 }}\) on success, or throw an exception on failure.
1. Let request be a new request whose url is url, client is settings object, destination is "script", parser metadata is "not parser-inserted", synchronous flag is set, and whose use-URL-credentials flag is set.
2. If the caller specified custom steps to perform the fetch \({ }^{\text {p926 }}\), perform them on request, with the is top-level \({ }^{p 926}\) flag set. Let response be the result.

Otherwise, fetch request, and let response be the result.

\section*{Note}

Unlike other algorithms in this section, the fetching process is synchronous here. Thus any perform the fetch \({ }^{p 926}\) steps will also finish their work synchronously.
3. Set response to response's unsafe response \({ }^{\text {p90 }}\).
4. If any of the following conditions are met:
- response's type is "error"; or
- response's status is not an ok status; or
- the result of extracting a MIME type from response's header list is not a JavaScript MIME type,
then throw a "NetworkError" DOMException.
5. Let source text be the result of UTF-8 decoding response's body.
6. Let muted errors be true if response was CORS-cross-origin \({ }^{\text {p90 }}\), and false otherwise.
7. Let script be the result of creating a classic script \({ }^{p 933}\) given source text, settings object, response's url, the default classic script fetch options \({ }^{\text {p926 }}\), and muted errors.
8. Return script.

To fetch an external module script graph given a url, a settings object, and some options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\text {p925 }}\) (on success).
1. Fetch a single module script \({ }^{\text {p931 }}\) given url, settings object, "script", options, settings object, "client", and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch \({ }^{\text {p926 }}\) steps, pass those along as well. Wait until the algorithm asynchronously completes with result.
2. If result is null, asynchronously complete this algorithm with null, and return.
3. Let visited set be «url».
4. Fetch the descendants of and link \({ }^{\text {p930 }}\) result given settings object, destination, and visited set. When this asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch an import() module script graph given a specifier, a base URL, a settings object, and some options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\mathrm{p} 925}\) (on success).
1. Let \(u r l\) be the result of resolving a module specifier \({ }^{\text {p941 }}\) given base URL and specifier.
2. If \(u r l\) is failure, then asynchronously complete this algorithm with null, and return.
3. Fetch a single module script \({ }^{\text {p931 }}\) given url, settings object, "script", options, settings object, "client", and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch \({ }^{\text {p926 }}\) steps, pass those along as well. Wait until the algorithm asynchronously completes with result.
4. If result is null, asynchronously complete this algorithm with null, and return.
5. Let visited set be «url».
6. Fetch the descendants of and link \({ }^{\text {p930 }}\) result given settings object, destination, and visited set. When this asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch a modulepreload module script graph given a url, a destination, a settings object, and some options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\text {p925 }}\) (on success), although it will perform optional steps even after completing.
1. Fetch a single module script \({ }^{\text {p931 }}\) given url, settings object, destination, options, settings object, "client", and with the toplevel module fetch flag set. Wait until algorithm asynchronously completes with result.
2. Asynchronously complete this algorithm with result, but do not return.
3. If result is not null, optionally perform the following steps:
1. Let visited set be «url».
2. Fetch the descendants of and link \({ }^{\text {p930 }}\) result given settings object, destination, and visited set.

\section*{Note}

Generally, performing these steps will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, via algorithms such as fetch an external module script graph \({ }^{p 929}\) that fetch the entire graph. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.

To fetch an inline module script graph given a source text, base URL, settings object, and options, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\mathrm{p} 925}\) (on success).
1. Let script be the result of creating a module script \({ }^{\text {p933 }}\) using source text, settings object, base URL, and options.
2. If script is null, asynchronously complete this algorithm with null, and return.
3. Let visited set be an empty set.
4. Fetch the descendants of and link \({ }^{\text {p930 }}\) script, given settings object, the destination "script", and visited set. When this
asynchronously completes with final result, asynchronously complete this algorithm with final result.
To fetch a module worker script graph given a url, a fetch client settings object, a destination, a credentials mode, and a module map settings object, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\mathrm{p925}}\) (on success).
1. Let options be a script fetch options \({ }^{\text {p926 }}\) whose cryptographic nonce \({ }^{\text {p926 }}\) is the empty string, integrity metadata \({ }^{\text {p926 }}\) is the empty string, parser metadata \({ }^{\text {p926 }}\) is "not-parser-inserted", credentials mode \({ }^{\text {p926 }}\) is credentials mode, and referrer policy \({ }^{\text {p926 }}\) is the empty string.
2. Fetch a single module script \({ }^{\text {p931 }}\) given url, fetch client settings object, destination, options, module map settings object, "client", and with the top-level module fetch flag set. If the caller of this algorithm specified custom perform the fetch \({ }^{\text {p926 }}\) steps, pass those along as well. Wait until the algorithm asynchronously completes with result.
3. If result is null, asynchronously complete this algorithm with null, and return.
4. Let visited set be «url».
5. Fetch the descendants of and link \({ }^{\text {p930 }}\) result given fetch client settings object, destination, and visited set. When this asynchronously completes with final result, asynchronously complete this algorithm with final result.

The following algorithms are meant for internal use by this specification only as part of fetching an external module script graph \({ }^{\text {p929 }}\) or other similar concepts above, and should not be used directly by other specifications.

This diagram illustrates how these algorithms relate to the ones above, as well as to each other:

To fetch the descendants of and link a module script module script, given a fetch client settings object, a destination, and a visited set, run these steps. The algorithm will asynchronously complete with either null (on failure) or with module script (on success).
1. Fetch the descendants of \({ }^{\text {p931 }}\) module script, given fetch client settings object, destination, and visited set.
2. Return from this algorithm, and run the following steps when fetching the descendants of a module script \({ }^{\text {p931 }}\) asynchronously completes with result.
3. If result is null, then asynchronously complete this algorithm with result.

Note
In this case, there was an error fetching one or more of the descendants. We will not attempt to link.
4. Let parse error be the result of finding the first parse error \({ }^{\text {p932 }}\) given result.
5. If parse error is null, then:
1. Let record be result's record \({ }^{\mathrm{p925}}\).
2. Perform record.Link().

Note
This step will recursively call Link on all of the module's unlinked dependencies.
If this throws an exception, set result's error to rethrow \({ }^{\text {p925 }}\) to that exception.
6. Otherwise, set result's error to rethrow \({ }^{\text {p925 }}\) to parse error.
7. Asynchronously complete this algorithm with result.

To fetch the descendants of a module script module script, given a fetch client settings object, a destination, and a visited set, run these steps. The algorithm will asynchronously complete with either null (on failure) or with module script (on success).
1. If module script's record \({ }^{\mathrm{p} 925}\) is null, then asynchronously complete this algorithm with module script and return.
2. Let record be module script's record \({ }^{\text {p925 }}\).
3. If record is not a Cyclic Module Record, or if record.[[RequestedModules]] is empty, asynchronously complete this algorithm with module script.
4. Let urls be a new empty list.
5. For each string requested of record.[[RequestedModules]],
1. Let \(u r l\) be the result of resolving a module specifier \({ }^{\text {p941 }}\) given module script's base URL \({ }^{\mathrm{p} 925}\) and requested.
2. Assert: url is never failure, because resolving a module specifier \({ }^{\text {p941 }}\) must have been previously successful \({ }^{\text {p934 }}\) with these same two arguments.
3. If visited set does not contain url, then:
1. Append url to urls.
2. Append url to visited set.
6. Let options be the descendant script fetch options \({ }^{\text {p926 }}\) for module script's fetch options \({ }^{\text {p925 }}\).
7. Assert: options is not null, as module script is a module script \({ }^{\text {p925 }}\).
8. For each url in urls, perform the internal module script graph fetching procedure \({ }^{\text {p931 }}\) given url, fetch client settings object, destination, options, module script's settings object \({ }^{\text {p925 }}\), visited set, and module script's base URL \({ }^{\text {p925 }}\). If the caller of this algorithm specified custom perform the fetch \({ }^{\text {p926 }}\) steps, pass those along while performing the internal module script graph fetching procedure \({ }^{\text {p931 }}\).

These invocations of the internal module script graph fetching procedure \({ }^{\text {p931 }}\) should be performed in parallel to each other.
If any of the invocations of the internal module script graph fetching procedure \({ }^{\text {p931 }}\) asynchronously complete with null, asynchronously complete this algorithm with null, and return.

Otherwise, wait until all of the internal module script graph fetching procedure \({ }^{\text {p931 }}\) invocations have asynchronously completed. Asynchronously complete this algorithm with module script.

To perform the internal module script graph fetching procedure given a url, a fetch client settings object, a destination, some options, a module map settings object, a visited set, and a referrer, perform these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\mathrm{p925}}\) (on success).
1. Assert: visited set contains url.
2. Fetch a single module script \({ }^{\text {p931 }}\) given url, fetch client settings object, destination, options, module map settings object, referrer, and with the top-level module fetch flag unset. If the caller of this algorithm specified custom perform the fetch \({ }^{\text {p926 }}\) steps, pass those along while fetching a single module script \({ }^{p 931}\).
3. Return from this algorithm, and run the following steps when fetching a single module script \({ }^{\text {p931 }}\) asynchronously completes with result:
4. If result is null, asynchronously complete this algorithm with null, and return.
5. Fetch the descendants of \({ }^{p 931}\) result given fetch client settings object, destination, and visited set.
6. When the appropriate algorithm asynchronously completes with final result, asynchronously complete this algorithm with final result.

To fetch a single module script, given a url, a fetch client settings object, a destination, some options, a module map settings object, a referrer, and a top-level module fetch flag, run these steps. The algorithm will asynchronously complete with either null (on failure) or a module script \({ }^{\text {p925 }}\) (on success).
1. Let moduleMap be module map settings object's module map \({ }^{\text {p917 }}\).
2. If moduleMap[url] is "fetching", wait in parallel \({ }^{\mathrm{p} 42}\) until that entry's value changes, then queue a task \({ }^{\mathrm{p} 945}\) on the networking task source \({ }^{\text {p952 }}\) to proceed with running the following steps.
3. If moduleMap[url] exists, asynchronously complete this algorithm with moduleMap[url], and return.
4. Set moduleMap[url] to "fetching".
5. Let request be a new request whose url is url, destination is destination, mode is "cors", referrer is referrer, and client is fetch client settings object.
6. If destination is "worker" or "sharedworker" and the top-level module fetch flag is set, then set request's mode to "sameorigin".
7. Set up the module script request \({ }^{\mathrm{p} 926}\) given request and options.
8. If the caller specified custom steps to perform the fetch \({ }^{\text {p926 }}\), perform them on request, setting the is top-level \({ }^{p 926}\) flag if the top-level module fetch flag is set. Return from this algorithm, and when the custom perform the fetch \({ }^{\text {p926 }}\) steps complete with response response, run the remaining steps.

Otherwise, fetch request. Return from this algorithm, and run the remaining steps as part of the fetch's process response for the response response.

\section*{Note}
response is always CORS-same-origin \({ }^{p 90}\)
9. If any of the following conditions are met:
- response's type is "error"; or
- response's status is not an ok status; or
- the result of extracting a MIME type from response's header list is not a JavaScript MIME type,
then set moduleMap[url] to null, asynchronously complete this algorithm with null, and return.
10. Let source text be the result of UTF-8 decoding response's body.
11. Let module script be the result of creating a module script \({ }^{\text {p933 }}\) given source text, module map settings object, response's url, and options.
12. Set moduleMap[url] to module script, and asynchronously complete this algorithm with module script.

\section*{Note}

It is intentional that the module map \({ }^{\text {p941 }}\) is keyed by the request URL, whereas the base URL \({ }^{\text {p925 }}\) for the module script \({ }^{\text {p925 }}\) is set to the response URL. The former is used to deduplicate fetches, while the latter is used for URL resolution.

To find the first parse error given a root moduleScript and an optional discoveredSet:
1. Let moduleMap be moduleScript's settings object \({ }^{\text {p925 ' }} \mathrm{s}\) module map \({ }^{\text {p917 }}\).
2. If discoveredSet was not given, let it be an empty set.
3. Append moduleScript to discoveredSet.
4. If moduleScript's record \({ }^{\text {p925 }}\) is null, then return moduleScript's parse error \({ }^{\mathrm{p925}}\).
5. Let childSpecifiers be the value of moduleScript's record \({ }^{\text {p925 }}\) ' s [[RequestedModules]] internal slot.
6. Let childURLs be the list obtained by calling resolve a module specifier \({ }^{p 941}\) once for each item of childSpecifiers, given moduleScript's base URL \({ }^{\text {p925 }}\) and that item. (None of these will ever fail, as otherwise moduleScript would have been marked as itself having a parse error.)
7. Let childModules be the list obtained by getting each value in moduleMap whose key is given by an item of childURLs.
8. For each childModule of childModules:
1. Assert: childModule is a module script \({ }^{\text {p925 }}\) (i.e., it is not "fetching" or null); by now all module scripts \({ }^{\text {p925 }}\) in the graph rooted at moduleScript will have successfully been fetched.
2. If discoveredSet already contains childModule, continue.
3. Let childParseError be the result of finding the first parse error \({ }^{\text {p932 }}\) given childModule and discoveredSet.
4. If childParseError is not null, return childParseError.
9. Return null.

\subsection*{8.1.4.3 Creating scripts \(\mathbb{8}_{3}^{\text {p93 }}\)}

To create a classic script, given a string source, an environment settings object \({ }^{\text {p917 }}\) settings, a URL baseURL, some script fetch options \({ }^{\text {p926 }}\) options, and an optional muted errors boolean:
1. If muted errors was not provided, let it be false.
2. If muted errors is true, then set baseURL to about:blank \({ }^{\mathrm{p51}}\).

\section*{Note}

When muted errors is true, baseURL is the script's CORS-cross-origin \({ }^{p 90}\) response's url, which shouldn't be exposed to JavaScript. Therefore, baseURL is sanitized here.
3. If scripting is disabled \({ }^{\text {p924 }}\) for settings, then set source to the empty string.
4. Let script be a new classic script \({ }^{\text {p925 }}\) that this algorithm will subsequently initialize.
5. Set script's settings object \({ }^{\mathrm{p925}}\) to settings.
6. Set script's base URL \({ }^{\text {p925 }}\) to baseURL.
7. Set script's fetch options \({ }^{p 925}\) to options.
8. Set script's muted errors \({ }^{\text {p925 }}\) to muted errors.
9. Set script's parse error \({ }^{\text {p925 }}\) and error to rethrow \({ }^{\text {p925 }}\) to null.
10. Let result be ParseScript(source, settings's Realm \({ }^{\text {p918 }}\), script).

Note
Passing script as the last parameter here ensures result.[[HostDefined]] will be script.
11. If result is a list of errors, then:
1. Set script's parse error \({ }^{\text {p925 }}\) and its error to rethrow \({ }^{\text {p925 }}\) to result[0].
2. Return script.
12. Set script's record \({ }^{\text {p925 }}\) to result.
13. Return script.

To create a module script, given a string source, an environment settings object \({ }^{p 917}\) settings, a URL baseURL, and some script fetch options \({ }^{\text {p926 }}\) options:
1. If scripting is disabled \({ }^{\text {p924 }}\) for settings, then set source to the empty string.
2. Let script be a new module script \({ }^{\text {p925 }}\) that this algorithm will subsequently initialize.
3. Set script's settings object \({ }^{\text {p925 }}\) to settings.
4. Set script's base URL \({ }^{\text {p925 }}\) to baseURL.
5. Set script's fetch options \({ }^{p 925}\) to options.
6. Set script's parse error \({ }^{\text {p925 }}\) and error to rethrow \({ }^{\text {p925 }}\) to null.
7. Let result be ParseModule(source, settings's Realm \({ }^{\text {p918 }}\), script).

\section*{Note}

Passing script as the last parameter here ensures result.[[HostDefined]] will be script.
8. If result is a list of errors, then:
1. Set script's parse error \({ }^{\text {p925 }}\) to result[0].
2. Return script.
9. For each string requested of result.[[RequestedModules]]:
1. Let url be the result of resolving a module specifier \({ }^{p 941}\) given script's base URL \({ }^{\text {p925 }}\) and requested.
2. If \(u r l\) is failure, then:
1. Let error be a new TypeError exception.
2. Set script's parse error \({ }^{\text {p925 }}\) to error.
3. Return script.

\section*{Note}

This step is essentially validating all of the requested module specifiers. We treat a module with unresolvable module specifiers the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate linking the module later.
10. Set script's record \({ }^{\text {p925 }}\) to result.
11. Return script.

\subsection*{8.1.4.4 Calling scripts \({ }_{4}{ }_{4}^{p 93}\)}

To run a classic script given a classic script \({ }^{\text {p925 }}\) script and an optional rethrow errors boolean:
1. If rethrow errors is not given, let it be false.
2. Let settings be the settings object \({ }^{\text {p925 }}\) of script.
3. Check if we can run script \({ }^{9935}\) with settings. If this returns "do not run" then return NormalCompletion(empty).
4. Prepare to run script \({ }^{\text {p935 }}\) given settings.
5. Let evaluationStatus be null.
6. If script's error to rethrow \({ }^{\text {p925 }}\) is not null, then set evaluationStatus to Completion \{ [[Type]]: throw, [[Value]]: script's error to rethrow \({ }^{\text {p925 }}\), [[Target]]: empty \}.
7. Otherwise, set evaluationStatus to ScriptEvaluation(script's record \({ }^{\text {p925 }}\) ).

If ScriptEvaluation does not complete because the user agent has aborted the running script \({ }^{\text {p936 }}\), leave evaluationStatus as null.
8. If evaluationStatus is an abrupt completion, then:
1. If rethrow errors is true and script's muted errors \({ }^{\text {p925 }}\) is false, then:
1. Clean up after running script \({ }^{\text {p935 }}\) with settings.
2. Rethrow evaluationStatus.[[Value]].
2. If rethrow errors is true and script's muted errors \({ }^{\mathrm{p} 925}\) is true, then:
1. Clean up after running script \({ }^{\text {p935 }}\) with settings.
2. Throw a "NetworkError" DOMException.
3. Otherwise, rethrow errors is false. Perform the following steps:
1. Report the exception \({ }^{\text {p937 }}\) given by evaluationStatus.[[Value]] for script.
2. Clean up after running script \({ }^{\mathrm{p935}}\) with settings.
3. Return evaluationStatus.
9. Clean up after running script \({ }^{\mathrm{p935}}\) with settings.
10. If evaluationStatus is a normal completion, then return evaluationStatus.
11. If we've reached this point, evaluationStatus was left as null because the script was aborted prematurely \({ }^{p 936}\) during evaluation. Return Completion \{ [[Type]]: throw, [[Value]]: a new "OuotaExceededError" DOMException, [[Target]]: empty \}.

To run a module script given a module script \({ }^{\text {p925 }}\) script, with an optional rethrow errors boolean:
1. If rethrow errors is not given, let it be false.
2. Let settings be the settings object \({ }^{\text {p925 }}\) of script.
3. Check if we can run script \({ }^{\text {p935 }}\) with settings. If this returns "do not run" then return NormalCompletion(empty).
4. Prepare to run script \({ }^{\text {p935 }}\) given settings.
5. Let evaluationStatus be null.
6. If script's error to rethrow \({ }^{\text {p925 }}\) is not null, then set evaluationStatus to Completion \{ [[Type]]: throw, [[Value]]: script's error to rethrow \({ }^{\text {p925 }}\), [[Target]]: empty \}.
7. Otherwise:
1. Let record be script's record \({ }^{\text {p925 }}\).
2. Set evaluationStatus to record.Evaluate().

\section*{Note}

This step will recursively evaluate all of the module's dependencies.
If Evaluate fails to complete as a result of the user agent aborting the running script \({ }^{\text {p936 }}\), then set evaluationStatus to Completion \{ [[Type]]: throw, [[Value]]: a new "OuotaExceededError" DOMException, [[Target]]: empty \}.
8. If evaluationStatus is an abrupt completion, then:
1. If rethrow errors is true, rethrow the exception given by evaluationStatus.[[Value]].
2. Otherwise, report the exception \({ }^{\text {p937 }}\) given by evaluationStatus.[[Value]] for script.
9. Clean up after running script \({ }^{\text {p935 }}\) with settings.
10. Return evaluationStatus.

The steps to check if we can run script with an environment settings object \({ }^{\text {p917 }}\) settings are as follows. They return either "run" or "do not run".
1. If the global object \({ }^{\mathrm{p918}}\) specified by settings is a Window \({ }^{\mathrm{p} 824}\) object whose Document \({ }^{\text {p114 }}\) object is not fully active \({ }^{\mathrm{p815}}\), then return "do not run".
2. If scripting is disabled \({ }^{\text {p924 }}\) for settings, then return "do not run".
3. Return "run".

The steps to prepare to run script with an environment settings object \({ }^{\text {p917 }}\) settings are as follows:
1. Push settings's realm execution context \({ }^{p 917}\) onto the JavaScript execution context stack; it is now the running JavaScript execution context.
2. Add settings to the currently running task \({ }^{\text {p944 ' }} \mathrm{s}\) script evaluation environment settings object set \({ }^{\mathrm{p945}}\).

The steps to clean up after running script with an environment settings object \({ }^{\text {p917 }}\) settings are as follows:
1. Assert: settings's realm execution context \({ }^{\mathrm{p} 917}\) is the running JavaScript execution context.
2. Remove settings's realm execution context \({ }^{\text {p917 }}\) from the JavaScript execution context stack.
3. If the JavaScript execution context stack is now empty, perform a microtask checkpoint \({ }^{\text {p949 }}\). (If this runs scripts, these algorithms will be invoked reentrantly.)

These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.

The running script is the script \({ }^{\text {p925 }}\) in the [[HostDefined]] field in the ScriptOrModule component of the running JavaScript execution context.

\subsection*{8.1.4.5 Killing scripts \({ }^{\S^{p 93}}\)}

Although the JavaScript specification does not account for this possibility, it's sometimes necessary to abort a running script. This causes any ScriptEvaluation or Source Text Module Record Evaluate invocations to cease immediately, emptying the JavaScript execution context stack without triggering any of the normal mechanisms like finally blocks. [JAVASCRIPT] \({ }^{\text {p1288 }}\)

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a "QuotaExceededError" DOMException, abort the script \({ }^{\text {p936 }}\) without an exception, prompt the user, or throttle script execution.

\section*{Example}

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.
```
<script>
    while (true) { /* loop */ }
</script>
```

User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the window. alert () \({ }^{\text {p977 }}\) API) or because of a script's actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.
User agents may allow users to specifically disable scripts just for the purposes of closing a browsing context \({ }^{8811}\).

\section*{Example}

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page entirely, without running any unload \({ }^{p 1282}\) event handlers.

\subsection*{8.1.4.6 Runtime script errors \(\S^{\text {p93 }}\)}

When the user agent is required to report an error for a particular script \({ }^{\text {p925 }}\) script with a particular position line:col, using a particular target target, it must run these steps, after which the error is either handled or not handled:
1. If target is in error reporting mode \({ }^{\text {p936 }}\), then return; the error is not handled \({ }^{p 936}\).

\section*{2. Let target be in error reporting mode.}
3. Let message be an implementation-defined string describing the error in a helpful manner.
4. Let errorValue be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an Error object. If there is no corresponding value, then the null value must be used instead.
5. Let urIString be the result of applying the URL serializer to the URL record that corresponds to the resource from which script was obtained.

\section*{Note}

The resource containing the script will typically be the file from which the Document \({ }^{p 114}\) was parsed, e.g. for inline script \({ }^{\text {p614 }}\) elements or event handler content attributes \({ }^{p 955}\); or the JavaScript file that the script was in, for external scripts. Even for dynamically-generated scripts, user agents are strongly encouraged to attempt to keep track of the
original source of a script. For example, if an external script uses the document. write() \({ }^{\text {p97e }}\) API to insert an inline script \({ }^{\text {p614 }}\) element during parsing, the URL of the resource containing the script would ideally be reported as being the external script, and the line number might ideally be reported as the line with the document.write() \({ }^{\text {p970 }}\) call or where the string passed to that call was first constructed. Naturally, implementing this can be somewhat non-trivial.

\section*{Note}

User agents are similarly encouraged to keep careful track of the original line numbers, even in the face of document.write() \()^{\text {p97e }}\) calls mutating the document as it is parsed, or event handler content attributes \({ }^{p 955}\) spanning multiple lines.
6. If script's muted errors \({ }^{\text {p925 }}\) is true, then set message to "Script error.", urlString to the empty string, line and col to 0 , and errorValue to null.
7. Let notHandled be the result of firing an event named error \({ }^{p 1281}\) at target, using ErrorEvent \({ }^{\text {p937 }}\), with the cancelable attribute initialized to true, the message \({ }^{\text {p937 }}\) attribute initialized to message, the filename \({ }^{p 937}\) attribute initialized to urlString, the lineno \({ }^{p 937}\) attribute initialized to line, the \(c o l n 0^{\text {p938 }}\) attribute initialized to col, and the error \({ }^{p 938}\) attribute initialized to errorValue.
8. Let target no longer be in error reporting mode \({ }^{\text {p936 }}\).
9. If notHandled is false, then the error is handled \({ }^{p 936}\). Otherwise, the error is not handled \({ }^{p 936}\).
```
Note
    Returning true in an event handler cancels the event per the event handler processing algorithm }\mp@subsup{}{}{p957}\mathrm{ .
```

When the user agent is to report an exception \(E\), the user agent must report the error \({ }^{\mathrm{p} 936}\) for the relevant script \({ }^{\mathrm{p} 925}\), with the problematic position (line number and column number) in the resource containing the script, using the global object \({ }^{\text {p918 }}\) specified by the script's settings object \({ }^{\text {p925 }}\) as the target. If the error is still not handled \({ }^{p 936}\) after this, then the error may be reported to a developer console.

The existence of both report an error \({ }^{\text {p936 }}\) and report an exception \({ }^{\text {p937 }}\) is confusing, and both algorithms have known problems. You can track future cleanup in this area in issue \#958.

The ErrorEvent \({ }^{\text {p937 }}\) interface is defined as follows:
```
IDL [Exposed=(Window,Worker)]
interface ErrorEvent : Event {
    constructor(DOMString type, optional ErrorEventInit eventInitDict = {});
    readonly attribute DOMString message;
    readonly attribute USVString filename;
    readonly attribute unsigned long lineno;
    readonly attribute unsigned long colno;
    readonly attribute any error;
};
dictionary ErrorEventInit : EventInit {
    DOMString message = "";
    USVString filename = "";
    unsigned long lineno = 0;
    unsigned long colno = 0;
    any error = null;
};
```

The message attribute must return the value it was initialized to. It represents the error message.
The filename attribute must return the value it was initialized to. It represents the URL of the script in which the error originally occurred.

The lineno attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The colno attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.
The error attribute must return the value it was initialized to. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught DOM exception).

\subsection*{8.1.4.7 Unhandled promise rejections \(\S^{\text {p9 }}\)}

In addition to synchronous runtime script errors \({ }^{\text {p936 }}\), scripts may experience asynchronous promise rejections, tracked via the unhandledrejection \({ }^{\text {p1282 }}\) and rejectionhandled \({ }^{\text {p1282 }}\) events. Tracking these rejections is done via the HostPromiseRejectionTracker \({ }^{\text {p940 }}\) abstract operation, but reporting them is defined here.

To notify about rejected promises on a given environment settings object \({ }^{\text {p917 }}\) settings object:
1. Let list be a copy of settings object's about-to-be-notified rejected promises list \({ }^{\text {p918 }}\).
2. If list is empty, return.
3. Clear settings object's about-to-be-notified rejected promises list \({ }^{\text {p918 }}\).
4. Let global be settings object's global object \({ }^{\text {p918 }}\).
5. Queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given global to run the following substep:
1. For each promise \(p\) in list:
1. If \(p\) 's [[PromiselsHandled]] internal slot is true, continue to the next iteration of the loop.
2. Let notHandled be the result of firing an event named unhandledrejection \({ }^{\text {p1282 }}\) at global , using PromiseRejectionEvent \({ }^{\text {p938 }}\), with the cancelable attribute initialized to true, the promise \({ }^{\text {p938 }}\) attribute initialized to \(p\), and the reason \({ }^{p 938}\) attribute initialized to the value of \(p^{\text {'s }}\) [[PromiseResult]] internal slot.
3. If notHandled is false, then the promise rejection is handled \({ }^{p 938}\). Otherwise, the promise rejection is not handled \({ }^{p 938}\).
4. If \(p\) 's [[PromiselsHandled]] internal slot is false, add \(p\) to settings object's outstanding rejected promises weak set \({ }^{\text {p918 }}\).

This algorithm results in promise rejections being marked as handled or not handled. These concepts parallel handled \({ }^{p 936}\) and not handled \({ }^{p 936}\) script errors. If a rejection is still not handled \({ }^{p 938}\) after this, then the rejection may be reported to a developer console.

The PromiseRejectionEvent \({ }^{\text {p938 }}\) interface is defined as follows:

IDL [Exposed=(Window, Worker)]
interface PromiseRejectionEvent : Event \{
constructor(DOMString type, PromiseRejectionEventInit eventInitDict);
readonly attribute Promise<any> promise;
readonly attribute any reason;
\};
dictionary PromiseRejectionEventInit : EventInit \{
required Promise<any> promise;
any reason;
\};

The promise attribute must return the value it was initialized to. It represents the promise which this notification is about.

The reason attribute must return the value it was initialized to. It represents the rejection reason for the promise.

\subsection*{8.1.5 JavaScript specification host hooks \({ }_{8}^{\text {p93 }}\)}

The JavaScript specification contains a number of implementation-defined abstract operations, that vary depending on the host 938
environment. This section defines them for user agent hosts.

\subsection*{8.1.5.1 HostEnqueuePromiseJob(job, realm) \(\S^{\text {p93 }}\)}

JavaScript contains an implementation-defined HostEnqueuePromiseJob(job, realm) abstract operation to schedule Promise-related operations. HTML schedules these operations in the microtask queue. User agents must use the following implementation:
[JAVASCRIPT] \({ }^{p 1288}\)
1. If realm is not null, then let job settings be the settings object \({ }^{\text {p918 }}\) for realm. Otherwise, let job settings be null.

\section*{Note}

If realm is not null, it is the Realm of the author code that will run. When job is returned by NewPromiseReactionjob, it is the realm of the promise's handler function. When job is returned by NewPromiseResolveThenableJob, it is the realm of the then function.

If realm is null, either no author code will run or author code is guaranteed to throw. For the former, the author may not have passed in code to run, such as in promise. then(null, null). For the latter, it is because a revoked Proxy was passed. In both cases, all the steps below that would otherwise use job settings get skipped.
2. Let incumbent settings be the incumbent settings object \({ }^{\text {p921 }}\).
3. Let active script be the active script \({ }^{\mathrm{p} 925}\).
4. Let script execution context be null.
5. If active script is not null, set script execution context to a new JavaScript execution context, with its Function field set to null, its Realm field set to active script's settings object \({ }^{\text {p925 ' }} \mathrm{s}\) Realm \({ }^{\text {p918 }}\), and its ScriptOrModule set to active script's record \({ }^{\text {p925 }}\).

\section*{Note}

As seen below, this is used in order to propagate the current active script \({ }^{p 925}\) forward to the time when the job is executed.

\section*{Example}

A case where active script is non-null, and saving it in this way is useful, is the following:
```
Promise.resolve('import(`./example.mjs`)').then(eval);
```

Without this step (and the steps below that use it), there would be no active script \({ }^{\mathrm{p} 925}\) when the import () expression is evaluated, since eval () is a built-in function that does not originate from any particular script \({ }^{\text {p925 }}\).

With this step in place, the active script is propagated from the above code into the job, allowing import () to use the original script's base URL \({ }^{\text {p925 }}\) appropriately.

\section*{Example}
active script can be null if the user clicks on the following button:
<button onclick="Promise.resolve('import(`./example.mjs`)').then(eval)">Click me</button>

In this case, the JavaScript function for the event handler \({ }^{p 954}\) will be created by the get the current value of the event handler \({ }^{\text {p959 }}\) algorithm, which creates a function with null [[ScriptOrModule]] value. Thus, when the promise machinery calls HostEnqueuePromiseJob \({ }^{\text {p939 }}\), there will be no active script \({ }^{\text {p925 }}\) to pass along.

As a consequence, this means that when the import () expression is evaluated, there will still be no active script \({ }^{\mathrm{p} 925}\). Fortunately that is handled by our implementations of HostResolvelmportedModule \({ }^{\text {p943 }}\) and HostImportModuleDynamically \({ }^{\text {p942 }}\), by falling back to using the current settings object \({ }^{\text {p924 }}\) 's API base URL \({ }^{\text {p917 }}\).
6. Queue a microtask \({ }^{\text {p946 }}\) on the surrounding agent's event loop \({ }^{\text {p944 }}\) to perform the following steps:
1. If job settings is not null, then check if we can run script \({ }^{\text {p935 }}\) with job settings. If this returns "do not run" then return.
2. If job settings is not null, then prepare to run script \({ }^{\text {p935 }}\) with job settings.

\section*{Note}

This affects the entry \({ }^{\text {p919 }}\) concept while the job runs.
3. Prepare to run a callback \({ }^{\text {p921 }}\) with incumbent settings.
```
Note
    This affects the incumbent }\mp@subsup{}{}{p919}\mathrm{ concept while the job runs.
```
4. If script execution context is not null, then push script execution context onto the JavaScript execution context stack.

\section*{Note}

As explained above, this affects the active script \({ }^{p 925}\) while the job runs.
5. Let result be job().
```
Note
    job is an abstract closure returned by NewPromiseReactionJob or NewPromiseResolveThenableJob.
```
6. If script execution context is not null, then pop script execution context from the JavaScript execution context stack.
7. Clean up after running a callback \({ }^{\text {p921 }}\) with incumbent settings.
8. If job settings is not null, then clean up after running script \({ }^{\text {p935 }}\) with job settings.
9. If result is an abrupt completion, then report the exception \({ }^{\text {p937 }}\) given by result.[[Value]].

\subsection*{8.1.5.2 HostEnsureCanCompileStrings(callerRealm, calleeRealm) \(\S^{194}\)}

JavaScript contains an implementation-defined HostEnsureCanCompileStrings(callerRealm, calleeRealm) abstract operation. User agents must use the following implementation: [JAVASCRIPT] \({ }^{\text {p1288 }}\)
1. Perform ? EnsureCSPDoesNotBlockStringCompilation(callerRealm, calleeRealm). [CSP] \({ }^{\text {p1285 }}\)

\subsection*{8.1.5.3 HostPromiseRejectionTracker(promise, operation) \(\$^{\text {p94 }}\)}

JavaScript contains an implementation-defined HostPromiseRejectionTracker(promise, operation) abstract operation. User agents must use the following implementation: [JAVASCRIPT] \({ }^{\text {p1288 }}\)
1. Let script be the running script \({ }^{\mathrm{p936}}\).
2. If script's muted errors \({ }^{\text {p925 }}\) is true, terminate these steps.
3. Let settings object be script's settings object \({ }^{\text {p925 }}\).
4. If operation is "reject",
1. Add promise to settings object's about-to-be-notified rejected promises list \({ }^{\text {p918 }}\).
5. If operation is "handle",
1. If settings object's about-to-be-notified rejected promises list \({ }^{\text {p918 }}\) contains promise, then remove promise from that list and return.
2. If settings object's outstanding rejected promises weak set \({ }^{\text {p918 }}\) does not contain promise, then return.
3. Remove promise from settings object's outstanding rejected promises weak set \({ }^{\text {p918 }}\).
4. Let global be settings object's global object \({ }^{\text {p918 }}\).
5. Queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given global to fire an event named rejectionhandled \({ }^{\text {p1282 }}\) at global, using PromiseRejectionEvent \({ }^{\text {p938 }}\), with the promise \({ }^{\text {p938 }}\) attribute initialized to promise, and the reason \({ }^{\text {p938 }}\) attribute initialized to the value of promise's [[PromiseResult]] internal slot.

\subsection*{8.1.5.4 Module-related host hooks \(\S_{1}^{\text {p94 }}\)}

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the script \({ }^{\text {p614 }}\) element with type \({ }^{\text {p615 }}\) attribute set to "module", and how modules are fetched, resolved, and executed. [JAVASCRIPT] \({ }^{\text {p1288 }}\)

Note
Although the JavaScript specification speaks in terms of "scripts" versus "modules", in general this specification speaks in terms of classic scripts \({ }^{p 925}\) versus module scripts \({ }^{p 925}\), since both of them use the script \({ }^{\text {p614 }}\) element.

\section*{For web developers (non-normative)}

\section*{modulePromise \(=\) import(specifier)}

Returns a promise for the module namespace object for the module script \({ }^{\text {p925 }}\) identified by specifier. This allows dynamic importing of module scripts at runtime, instead of statically using the import statement form. The specifier will be resolved \({ }^{\text {p941 }}\) relative to the active script \({ }^{\mathrm{p} 925}\) 's base URL \({ }^{\mathrm{p} 925}\).

The returned promise will be rejected if an invalid specifier is given, or if a failure is encountered while fetching \({ }^{\text {p929 }}\) or evaluating \({ }^{\text {p935 }}\) the resulting module graph.
This syntax can be used inside both classic \({ }^{\text {p925 }}\) and module scripts \({ }^{\text {p925 }}\). It thus provides a bridge into the module-script world, from the classic-script world.
```
url = import . meta . url
```

Returns the active module script \({ }^{\text {p925 ' }}\) 's base URL \({ }^{\text {p925 }}\).
This syntax can only be used inside module scripts \({ }^{\text {p925 }}\).

A module map is a map of URL records to values that are either a module script \({ }^{\text {p925 }}\), null (used to represent failed fetches), or a placeholder value "fetching". Module maps \({ }^{\text {p941 }}\) are used to ensure that imported JavaScript modules are only fetched, parsed, and evaluated once per Document \({ }^{p 114}\) or worker \({ }^{\text {p1028 }}\).

\section*{Example}

Since module maps \({ }^{\text {p941 }}\) are keyed by URL, the following code will create three separate entries in the module map \({ }^{\text {p941 }}\), since it results in three different URLs:
```
import "https://example.com/module.mjs";
import "https://example.com/module.mjs#map-buster";
import "https://example.com/module.mjs?debug=true";
```

That is, URL queries and fragments can be varied to create distinct entries in the module map \({ }^{\text {p941 }}\); they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the module map \({ }^{\text {p941 }}\), since after applying the URL parser to these inputs, the resulting URL records are equal:
```
import "https://example.com/module2.mjs";
import "https:example.com/module2.mjs";
import "https://///example.com\\module2.mjs";
import "https://example.com/foo/../module2.mjs";
```

So in this second example, only one fetch and one module evaluation will occur.
Note that this behavior is the same as how shared workers \({ }^{\text {p1054 }}\) are keyed by their parsed constructor url \({ }^{p 1047}\).

To resolve a module specifier given a URL base URL and a string specifier, perform the following steps. It will return either a URL record or failure.
1. Apply the URL parser to specifier. If the result is not failure, return the result.
2. If specifier does not start with the character U+002F SOLIDUS (/), the two-character sequence U+002E FULL STOP, U+002F SOLIDUS (./), or the three-character sequence U+002E FULL STOP, U+002E FULL STOP, U+002F SOLIDUS (. ./), return failure.

\section*{Note}

This restriction is in place so that in the future we can allow custom module loaders to give special meaning to "bare" import specifiers, like import "jquery" or import "web/crypto". For now any such imports will fail, instead of being treated as relative URLs.
3. Return the result of applying the URL parser to specifier with base URL as the base URL.

\section*{Example}

The following are valid module specifiers according to the above algorithm:
- https://example.com/apples.mjs
- http:example.com\pears.js (becomes http://example.com/pears.js as step 1 parses with no base URL)
- //example.com/bananas
- ./strawberries.mjs.cgi
- ../lychees
- /limes.jsx
- data:text/javascript,export default 'grapes';
- blob:https://whatwg.org/d0360e2f-caee-469f-9a2f-87d5b0456f6f

The following are valid module specifiers according to the above algorithm, but will invariably cause failures when they are fetched \({ }^{\text {p931 }}\) :
- javascript:export default 'artichokes';
- data:text/plain,export default 'kale';
- about:legumes
- wss://example.com/celery

The following are not valid module specifiers according to the above algorithm:
- https://eggplant:b/c
- pumpkins.js
- .tomato
- ..zucchini.mjs
- . \yam.es

\subsection*{8.1.5.4.1 HostGetImportMetaProperties(moduleRecord) \(\S^{994}\)}

JavaScript contains an implementation-defined HostGetlmportMetaProperties abstract operation. User agents must use the following implementation: [JAVASCRIPT] \({ }^{\text {p1288 }}\)
1. Let module script be moduleRecord.[[HostDefined]].
2. Let urIString be module script's base URL \({ }^{\text {p925 }}\), serialized.
3. Return «Record \{ [[Key]]: "url", [[Value]]: urlString \} ».

\subsection*{8.1.5.4.2 HostlmportModuleDynamically(referencingScriptOrModule, specifier, promiseCapability) \(\underbrace{p 99}_{2}\)}

JavaScript contains an implementation-defined HostImportModuleDynamically abstract operation. User agents must use the following implementation: [JAVASCRIPT] \({ }^{\text {p1288 }}\)
1. Let settings object be the current settings object \({ }^{\text {p924 }}\).
2. Let base URL be settings object's API base URL \({ }^{\text {p917 }}\).
3. Let fetch options be the default classic script fetch options \({ }^{\text {p926 }}\).
4. If referencingScriptOrModule is not null, then:
1. Let referencing script be referencingScriptOrModule.[[HostDefined]].
2. Set settings object to referencing script's settings object \({ }^{\text {p925 }}\).
3. Set base URL to referencing script's base URL \({ }^{\mathrm{p} 925}\).
4. Set fetch options to the descendant script fetch options \({ }^{\text {p926 }}\) for referencing script's fetch options \({ }^{\text {p925 }}\).

\section*{Note}

As explained above for HostResolvelmportedModule \({ }^{p 943}\), in the common case, referencingScriptOrModule is non-null.
5. Fetch an import() module script graph \({ }^{\text {p929 }}\) given specifier, base URL, settings object, and fetch options. Wait until the algorithm asynchronously completes with result.
6. If result is null, then:
1. Let completion be Completion \{ [[Type]]: throw, [[Value]]: a new TypeError, [[Target]]: empty \}.
2. Perform FinishDynamiclmport(referencingScriptOrModule, specifier, promiseCapability, completion).
3. Return.
7. Run the module script \({ }^{\text {p935 }}\) result, with the rethrow errors boolean set to true.
8. If running the module script throws an exception, then perform FinishDynamicImport(referencingScriptOrModule, specifier, promiseCapability, the thrown exception completion).
9. Otherwise, perform FinishDynamicImport(referencingScriptOrModule, specifier, promiseCapability, NormalCompletion(undefined)).
10. Return undefined.

\subsection*{8.1.5.4.3 HostResolvelmportedModule(referencingScriptOrModule, specifier) \(\S^{p 94}\)}

JavaScript contains an implementation-defined HostResolvelmportedModule abstract operation. User agents must use the following implementation: [JAVASCRIPT] \({ }^{\text {p1288 }}\)
1. Let settings object be the current settings object \({ }^{\text {p924 }}\).
2. Let base URL be settings object's API base URL \({ }^{\text {p917 }}\).
3. If referencingScriptOrModule is not null, then:
1. Let referencing script be referencingScriptOrModule.[[HostDefined]].
2. Set settings object to referencing script's settings object \({ }^{\text {p925 }}\).
3. Set base URL to referencing script's base URL \({ }^{\text {p925 }}\).

\section*{Example}
referencingScriptOrModule is not usually null, but will be so for event handlers per the get the current value of the event handler \({ }^{\mathrm{p} 959}\) algorithm. For example, given:
```
<button onclick="import('./foo.mjs')">Click me</button>
```

If a click event occurs, then at the time the import () expression runs, GetActiveScriptOrModule will return null, which will be passed to this abstract operation when HostResolvelmportedModule is called by FinishDynamiclmport.
4. Let moduleMap be settings object's module map \({ }^{\text {p917 }}\).
5. Let \(u r l\) be the result of resolving a module specifier \({ }^{p 941}\) given base URL and specifier.
6. Assert: url is never failure, because resolving a module specifier \({ }^{p 941}\) must have been previously successful with these same two arguments (either while creating the corresponding module script \({ }^{\text {p934 }}\), or in HostlmportModuleDynamically \({ }^{\text {p942 }}\) ).
7. Let resolved module script be moduleMap[url]. (This entry must exist for us to have gotten to this point.)
8. Assert: resolved module script is a module script \({ }^{\mathrm{p} 925}\) (i.e., is not null or "fetching").
9. Assert: resolved module script's record \({ }^{\text {p925 }}\) is not null.
10. Return resolved module script's record \({ }^{\text {p925 }}\).

\subsection*{8.1.6 Event loops \(\S^{\text {p94 }}\)}

\subsection*{8.1.6.1 Definitions \({ }_{5}{ }_{4}^{p 94}\)}

To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use event loops as described in this section. Each agent has an associated event loop, which is unique to that agent.

The event loop \({ }^{\text {p944 }}\) of a similar-origin window agent \({ }^{\text {p913 }}\) is known as a window event loop. The event loop \({ }^{\text {p944 }}\) of a dedicated worker agent \({ }^{\text {p913 }}\), shared worker agent \({ }^{\text {p913 }}\), or service worker agent \({ }^{\text {p913 }}\) is known as a worker event loop. And the event loop \({ }^{\text {p944 }}\) of a worklet agent \({ }^{\text {p913 }}\) is known as a worklet event loop.

\section*{Note}

Event loops \({ }^{p 944}\) do not necessarily correspond to implementation threads. For example, multiple window event loops \({ }^{\text {p944 }}\) could be cooperatively scheduled in a single thread.

However, for the various worker agents that are allocated with [[CanBlock]] set to true, the JavaScript specification does place requirements on them regarding forward progress, which effectively amount to requiring dedicated per-agent threads in those cases.

An event loop \({ }^{\text {p944 }}\) has one or more task queues. A task queue \({ }^{\text {p944 }}\) is a set of tasks \({ }^{\text {p944 }}\).

\section*{Note}

Task queues \({ }^{p 944}\) are sets, not queues, because step one of the event loop processing model \({ }^{p 946}\) grabs the first runnable \({ }^{p 945} \underline{t a s k}^{\text {p944 }}\) from the chosen queue, instead of dequeuing the first task.

\section*{Note}

The microtask queue \({ }^{p 945}\) is not a task queue \({ }^{p 944}\).

Tasks encapsulate algorithms that are responsible for such work as:

\section*{Events}

Dispatching an Event object at a particular EventTarget object is often done by a dedicated task.

\section*{Note}

Not all events are dispatched using the task queue \({ }^{\text {p944 }}\); many are dispatched during other tasks.

\section*{Parsing}

The HTML parser \({ }^{\text {p1079 }}\) tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

\section*{Callbacks}

Calling a callback is often done by a dedicated task.

\section*{Using a resource}

When an algorithm fetches a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

\section*{Reacting to DOM manipulation}

Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is inserted into the document \({ }^{\mathrm{p} 44}\).
Formally, a task is a struct which has:

\section*{Steps}

A series of steps specifying the work to be done by the task.

\section*{A source}

One of the task sources \({ }^{\text {p945 }}\), used to group and serialize related tasks.

\section*{A document}

A Document \({ }^{\text {p114 }}\) associated with the task, or null for tasks that are not in a window event loop \({ }^{\text {p944 }}\).

\section*{A script evaluation environment settings object set}

A set of environment settings objects \({ }^{\text {p917 }}\) used for tracking script evaluation during the task.
A task \({ }^{\text {p944 }}\) is runnable if its document \({ }^{\text {p945 }}\) is either null or fully active \({ }^{\text {p815 }}\).
Per its source \({ }^{\text {p945 }}\) field, each task \({ }^{\text {p944 }}\) is defined as coming from a specific task source. For each event loop \({ }^{\text {p944 }}\), every task source \({ }^{\text {p945 }}\) must be associated with a specific task queue \({ }^{\text {p944 }}\).

\section*{Note}

Essentially, task sources \({ }^{p 945}\) are used within standards to separate logically-different types of tasks, which a user agent might wish to distinguish between. Task queues \({ }^{p 944}\) are used by user agents to coalesce task sources within a given event loop \({ }^{p 944}\).

\section*{Example}

For example, a user agent could have one task queue \({ }^{\text {p944 }}\) for mouse and key events (to which the user interaction task source \({ }^{\text {p952 }}\) is associated), and another to which all other task sources \({ }^{\text {p945 }}\) are associated. Then, using the freedom granted in the initial step of the event loop processing model \({ }^{\text {p946 }}\), it could give keyboard and mouse events preference over other tasks three-quarters of the time, keeping the interface responsive but not starving other task queues. Note that in this setup, the processing model still enforces that the user agent would never process events from any one task source \({ }^{\text {p945 }}\) out of order.

Each event loop \({ }^{\text {p944 }}\) has a currently running task, which is either a task \({ }^{\text {p944 }}\) or null. Initially, this is null. It is used to handle reentrancy.

Each event loop \({ }^{\text {p944 }}\) has a microtask queue, which is a queue of microtasks \({ }^{\text {p945 }}\), initially empty. A microtask is a colloquial way of referring to a task \({ }^{\text {p944 }}\) that was created via the queue a microtask \({ }^{\text {p946 }}\) algorithm.

Each event loop \({ }^{\text {p944 }}\) has a performing a microtask checkpoint boolean, which is initially false. It is used to prevent reentrant invocation of the perform a microtask checkpoint \({ }^{\text {p949 }}\) algorithm.

\subsection*{8.1.6.2 Queuing tasks \({ }_{5}{ }_{5}^{\text {p94 }}\)}

To queue a task on a task source \({ }^{\text {p945 }}\) source, which performs a series of steps steps, optionally given an event loop event loop and a document document:
1. If event loop was not given, set event loop to the implied event loop \({ }^{\text {p946 }}\).
2. If document was not given, set document to the implied document \({ }^{\text {p946 }}\).
3. Let task be a new task \({ }^{\text {p944 }}\).
4. Set task's steps \({ }^{\text {p944 }}\) to steps.
5. Set task's source \({ }^{\text {p945 }}\) to source.
6. Set task's document \({ }^{\mathrm{p} 945}\) to the document.
7. Set task's script evaluation environment settings object set \({ }^{\text {p945 }}\) to an empty set.
8. Let queue be the task queue \({ }^{\text {p944 }}\) to which source is associated on event loop.
9. Append task to queue.

To queue a global task on a task source \({ }^{\mathrm{p} 945}\) source, with a global object \({ }^{\mathrm{p918}}\) global and a series of steps steps:
1. Let event loop be global's relevant agent \({ }^{\text {p914' }}\) 's event loop \({ }^{\text {p944 }}\).
2. Let document be global's associated Document \({ }^{p 826}\), if global is a Window \({ }^{p 824}\) object; otherwise null.
3. Queue a task \({ }^{\text {p945 }}\) given source, event loop, document, and steps.

To queue an element task on a task source \({ }^{\text {p945 }}\) source, with an element element and a series of steps steps:
1. Let global be element's relevant global object \({ }^{\text {p924 }}\).
2. Queue a global task \({ }^{\text {p945 }}\) given source, global, and steps.

To queue a microtask which performs a series of steps steps, optionally given an event loop event loop and a document document:
1. If event loop was not given, set event loop to the implied event loop \({ }^{\text {p946 }}\).
2. If document was not given, set document to the implied document \({ }^{\mathrm{p} 946}\).
3. Let microtask be a new task \({ }^{\text {p944 }}\).
4. Set microtask's steps \({ }^{\text {p944 }}\) to steps.
5. Set microtask's source \({ }^{\mathrm{p} 945}\) to the microtask task source.
6. Set microtask's document \({ }^{\text {p945 }}\) to document.
7. Set task's script evaluation environment settings object set \({ }^{\text {p945 }}\) to an empty set.
8. Enqueue task on event loop's microtask queue \({ }^{\text {p945 }}\).

\section*{Note}

It is possible for a microtask \({ }^{p 945}\) to be moved to a regular task queue \({ }^{\text {p944 }}\), if, during its initial execution, it spins the event loop \({ }^{\text {p949 }}\). This is the only case in which the source \({ }^{p 945}\), document \(t^{p 945}\), and script evaluation environment settings object set \({ }^{p 945}\) of the microtask are consulted; they are ignored by the perform a microtask checkpoint \({ }^{p 949}\) algorithm.

The implied event loop when queuing a task is the one that can deduced from the context of the calling algorithm. This is generally unambiguous, as most specification algorithms only ever involve a single agent (and thus a single event loop \({ }^{\text {p944 }}\) ). The exception is algorithms involving or specifying cross-agent communication (e.g., between a window and a worker); for those cases, the implied event loop \(^{\text {p946 }}\) concept must not be relied upon and specifications must explicitly provide an event loop \({ }^{\text {p944 }}\) when queuing a task \({ }^{\text {p945 }}\) or microtask \({ }^{\text {p946 }}\).

The implied document when queuing a task on an event loop \({ }^{\text {p944 }}\) event loop is determined as follows:
1. If event loop is not a window event loop \({ }^{\text {p944 }}\), then return null.
2. If the task is being queued in the context of an element, then return the element's node document.
3. If the task is being queued in the context of a browsing context \({ }^{p 811}\), then return the browsing context's active document \({ }^{\mathrm{p} 811}\).
4. If the task is being queued by or for a script \({ }^{\mathrm{p} 925}\), then return the script's settings object \({ }^{\mathrm{p} 925}\) 's responsible document \({ }^{\mathrm{p} 917}\).
5. Assert: this step is never reached, because one of the previous conditions must be true. Really?

Both implied event loop \({ }^{\text {p946 }}\) and implied document \({ }^{\text {p946 }}\) are vaguely-defined and have a lot of action-at-a-distance. Perhaps we can come up with a more explicit architecture, while still avoiding all callers needing to explicitly specify the event loop and document.

\subsection*{8.1.6.3 Processing model \(\underset{{ }_{6}^{\text {p94 }}}{ }{ }^{\text {P9 }}\)}

An event loop \({ }^{\text {p944 }}\) must continually run through the following steps for as long as it exists:
1. Let taskQueue be one of the event loop \({ }^{\text {p944' }}\) 's task queues \({ }^{\text {p944 }}\), chosen in an implementation-defined manner, with the constraint that the chosen task queue must contain at least one runnable \({ }^{\text {p945 }}\) task \(^{\text {p944. }}\). If there is no such task queue, then jump to the microtasks step below.

\section*{Note}

Remember that the microtask queue \({ }^{p 945}\) is not a task queue \({ }^{p 944}\), so it will not be chosen in this step. However, a task queue \({ }^{p 944}\) to which the microtask task source \({ }^{p 946}\) is associated might be chosen in this step. In that case, the task \({ }^{p 944}\)
\[
\text { chosen in the next step was originally a microtask }{ }^{p 945} \text {, but it got moved as part of spinning the event loop }{ }^{\text {p949 }} \text {. }
\]
2. Let oldestTask be the first runnable \({ }^{p 945}\) task \(^{\mathrm{p944}}\) in taskQueue, and remove it from taskQueue.
3. Set the event loop \({ }^{\text {p944' }} \mathrm{s}\) currently running task \({ }^{\text {p945 }}\) to oldestTask.
4. Let taskStartTime be the current high resolution time.
5. Perform oldestTask's steps \({ }^{\text {p944 }}\).
6. Set the event loop \({ }^{\text {p944 ' }}\) s currently running task \({ }^{\text {p945 }}\) back to null.
7. Microtasks: Perform a microtask checkpoint \({ }^{\text {p949 }}\).
8. Let hasARenderingOpportunity be false.
9. Let now be the current high resolution time. [HRT] \({ }^{\text {p1288 }}\)
10. Report the task \({ }^{\text {p944' }}\) 's duration by performing the following steps:
1. Let top-level browsing contexts be an empty set.
2. For each environment settings object \({ }^{p 917}\) settings of oldestTask's script evaluation environment settings object set \({ }^{\mathrm{p945}}\), append setting's top-level browsing context \({ }^{\mathrm{p} 814}\) to top-level browsing contexts.
3. Report long tasks, passing in taskStartTime, now (the end time of the task), top-level browsing contexts, and oldestTask.
11. Update the rendering: if this is a window event loop \({ }^{\text {p944 }}\), then:
1. Let docs be all Document \({ }^{\text {p114 }}\) objects whose relevant agent \({ }^{\text {p914' }}\) 's event loop \({ }^{\text {p944 }}\) is this event loop, sorted arbitrarily except that the following conditions must be met:
- Any Document \({ }^{\mathrm{p} 114} B\) whose browsing context \({ }^{\mathrm{p811}}\) 's container document \({ }^{\mathrm{p} 814}\) is \(A\) must be listed after \(A\) in the list.

■ If there are two documents \(A\) and \(B\) whose browsing contexts \({ }^{\text {p811 }}\) are both child browsing contexts \({ }^{\text {p814 }}\) whose container documents \({ }^{\text {p814 }}\) are another Document \({ }^{p 114} C\), then the order of \(A\) and \(B\) in the list must match the shadow-including tree order of their respective browsing context containers \({ }^{\text {p814 }}\) in \(C^{\prime}\) s node tree.

In the steps below that iterate over docs, each Document \({ }^{p 114}\) must be processed in the order it is found in the list.
2. Rendering opportunities: Remove from docs all Document \({ }^{\text {p114 }}\) objects whose browsing context \({ }^{\text {p811 }}\) do not have a rendering opportunity \({ }^{\text {p947 }}\).

A browsing context \({ }^{p 811}\) has a rendering opportunity if the user agent is currently able to present the contents of the browsing context \({ }^{\text {p811 }}\) to the user, accounting for hardware refresh rate constraints and user agent throttling for performance reasons, but considering content presentable even if it's outside the viewport.

Browsing context \({ }^{\mathrm{p} 811}\) rendering opportunities \({ }^{\mathrm{p947}}\) are determined based on hardware constraints such as display refresh rates and other factors such as page performance or whether the page is in the background. Rendering opportunities typically occur at regular intervals.

\section*{Note}

This specification does not mandate any particular model for selecting rendering opportunities. But for example, if the browser is attempting to achieve a 60 Hz refresh rate, then rendering opportunities occur at a maximum of every 60 th of a second (about 16.7 ms ). If the browser finds that a browsing context \({ }^{p 811}\) is not able to sustain this rate, it might drop to a more sustainable 30 rendering opportunities per second for that browsing context \({ }^{p 811}\), rather than occasionally dropping frames. Similarly, if a browsing context \({ }^{p 811}\) is not visible, the user agent might decide to drop that page to a much slower 4 rendering opportunities per second, or even less.
3. If docs is not empty, then set hasARenderingOpportunity to true.
4. Unnecessary rendering: Remove from docs all Document \({ }^{\text {p114 }}\) objects which meet both of the following conditions:

■ The user agent believes that updating the rendering of the Document \({ }^{\text {p114 ' }}\) 's browsing context \({ }^{\text {p811 }}\) would
- The Document \({ }^{\text {p114 }}\) 's map of animation frame callbacks \({ }^{p 996}\) is empty.
5. Remove from docs all Document \({ }^{\text {p114 }}\) objects for which the user agent believes that it's preferrable to skip updating the rendering for other reasons.

\section*{Note}

The step labeled Rendering opportunities prevents the user agent from updating the rendering when it is unable to present new content to the user (there's no rendering opportunity \({ }^{\text {p947 }}\) ).

The step labeled Unnecessary rendering prevents the user agent from updating the rendering when there's no new content to draw.

This step enables the user agent to prevent the steps below from running for other reasons, for example, to ensure certain tasks \({ }^{p 944}\) are executed immediately after each other, with only microtask checkpoints \({ }^{\text {p949 }}\) interleaved (and without, e.g., animation frame callbacks \({ }^{p 996}\) interleaved). Concretely, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.
6. For each fully active \({ }^{p 815}\) Document \({ }^{p 114}\) in docs, flush autofocus candidates \({ }^{p 782}\) for that Document \({ }^{\text {p114 }}\) if its browsing context \({ }^{\text {p811 }}\) is a top-level browsing context \({ }^{\text {p814 }}\).
7. For each fully active \({ }^{p 815}\) Document \({ }^{p 114}\) in docs, run the resize steps for that Document \({ }^{\text {p114 }}\), passing in now as the timestamp. [CSSOMVIEW] \({ }^{\text {p1286 }}\)
8. For each fully active \({ }^{\text {p815 }}\) Document \({ }^{\text {p114 }}\) in docs, run the scroll steps for that Document \({ }^{\text {p114 }}\), passing in now as the timestamp. [CSSOMVIEW] \({ }^{\text {p1286 }}\)
9. For each fully active \({ }^{\mathrm{p} 815}\) Document \({ }^{\mathrm{p} 114}\) in docs, evaluate media queries and report changes for that Document \({ }^{\mathrm{p} 114}\), passing in now as the timestamp. [CSSOMVIEW] \({ }^{\text {p1286 }}\)
10. For each fully active \({ }^{\text {p815 }}\) Document \({ }^{\text {p114 }}\) in docs, update animations and send events for that Document \({ }^{\text {p114 }}\), passing in now as the timestamp. [WEBANIMATIONS] \({ }^{\text {p1292 }}\)
11. For each fully active \({ }^{\text {p815 }}\) Document \({ }^{\text {p114 }}\) in docs, run the fullscreen steps for that Document \({ }^{\text {p114 }}\), passing in now as the timestamp. [FULLSCREEN] \({ }^{\text {p1287 }}\)
12. For each fully active \({ }^{\text {p815 }}\) Document \(^{\text {p114 }}\) in docs, run the animation frame callbacks \({ }^{\text {p996 }}\) for that Document \({ }^{\text {p114 }}\), passing in now as the timestamp.
13. For each fully active \({ }^{p 815}\) Document \({ }^{\text {p114 }}\) in docs, run the update intersection observations steps for that Document \({ }^{\text {p114 }}\), passing in now as the timestamp. [INTERSECTIONOBSERVER] \({ }^{\text {p1288 }}\)
14. Invoke the mark paint timing algorithm for each Document \({ }^{\text {p114 }}\) object in docs.
15. For each fully active \({ }^{p 815}\) Document \({ }^{p 114}\) in docs, update the rendering or user interface of that Document \({ }^{p 114}\) and its browsing context \({ }^{\text {p811 }}\) to reflect the current state.
12. If all of the following are true
- this is a window event loop \({ }^{\text {p944 }}\)
- there is no task \({ }^{\text {p944 }}\) in this event loop \({ }^{\text {p944 }}\) 's task queues \({ }^{\text {p944 }}\) whose document \({ }^{\text {p945 }}\) is fully active \({ }^{\text {p815 }}\)
- this event loop \({ }^{\text {p9444 }}\) 's microtask queue \({ }^{\text {p945 }}\) is empty
- hasARenderingOpportunity is false
then for each Window \({ }^{p 824}\) object whose whose relevant agent \({ }^{p 914}\) 's event loop \({ }^{p 944}\) is this event loop, run the start an idle period algorithm, passing the Window \({ }^{\text {p824 }}\). [REQUESTIDLECALLBACK] \({ }^{\text {p1290 }}\)
13. If this is a worker event loop \({ }^{\text {p944 }}\), then:
1. If this event loop \({ }^{\text {p944 }}\) 's agent's single realm's global object \({ }^{\text {p918 }}\) is a supported \({ }^{\text {p996 }}\) DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) and the user agent believes that it would benefit from having its rendering updated at this time, then:
1. Let now be the current high resolution time. [HRT] \({ }^{p 1288}\)
2. Run the animation frame callbacks \({ }^{\text {p996 }}\) for that DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\), passing in now as the timestamp.
3. Update the rendering of that dedicated worker to reflect the current state.

\section*{Note}

Similar to the notes for updating the rendering \({ }^{p 947}\) in a window event loop \({ }^{p 944}\), a user agent can determine the rate of rendering in the dedicated worker.
2. If there are no tasks \({ }^{\text {p944 }}\) in the event loop \({ }^{\text {p944' }}\) 's task queues \({ }^{\text {p944 }}\) and the WorkerGlobalScope \({ }^{\text {p1044 }}\) object's closing \({ }^{\text {p1047 }}\) flag is true, then destroy the event loop \({ }^{\text {p944 }}\), aborting these steps, resuming the run a worker \({ }^{\text {p1048 }}\) steps described in the Web workers \({ }^{\text {p1028 }}\) section below.

When a user agent is to perform a microtask checkpoint:
1. If the event loop \({ }^{\text {p944 }}\) 's performing a microtask checkpoint \({ }^{\text {p945 }}\) is true, then return.
2. Set the event loop \({ }^{\text {p944' }}\) 's performing a microtask checkpoint \({ }^{\text {p945 }}\) to true.
3. While the event loop \({ }^{\text {p944' }} \mathbf{s}\) microtask queue \({ }^{\text {p945 }}\) is not empty:
1. Let oldestMicrotask be the result of dequeuing from the event loop \({ }^{\text {p944's }} \mathrm{s}\) microtask queue \({ }^{\text {p945 }}\).
2. Set the event loop \({ }^{\text {p944 }}\) 's currently running task \({ }^{\text {p945 }}\) to oldestMicrotask.
3. Run oldestMicrotask.

\section*{Note \\ This might involve invoking scripted callbacks, which eventually calls the clean up after running script \({ }^{p 935}\) steps, which call this perform a microtask checkpoint \({ }^{p 949}\) algorithm again, which is why we use the performing a microtask checkpoint \({ }^{p 945}\) flag to avoid reentrancy.}
4. Set the event loop \({ }^{\text {p944 }}\) 's currently running task \({ }^{\text {p945 }}\) back to null.
4. For each environment settings object \({ }^{\text {p917 }}\) whose responsible event loop \({ }^{\text {p918 }}\) is this event loop \({ }^{\text {p944 }}\), notify about rejected promises \({ }^{\text {p938 }}\) on that environment settings object \({ }^{\text {p917 }}\).
5. Cleanup Indexed Database transactions.
6. Set the event loop \({ }^{\text {p944 }}\) 's performing a microtask checkpoint \({ }^{\text {p945 }}\) to false.

When an algorithm running in parallel \({ }^{\mathrm{p} 42}\) is to await a stable state, the user agent must queue a microtask \({ }^{\text {p946 }}\) that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):
1. Run the algorithm's synchronous section.
2. Resumes execution of the algorithm in parallel \({ }^{\text {p42 }}\), if appropriate, as described in the algorithm's steps.

\section*{Note}

Steps in synchronous sections \({ }^{\text {p949 }}\) are marked with \&.

Algorithm steps that say to spin the event loop until a condition goal is met are equivalent to substituting in the following algorithm steps:
1. Let task be the event loop \({ }^{\text {p944' }} \mathrm{s}\) currently running task \({ }^{\text {p945 }}\).
```
Note
    task could be a microtask p945.
```
2. Let task source be task's source \({ }^{\text {p945 }}\).
3. Let old stack be a copy of the JavaScript execution context stack.
4. Empty the JavaScript execution context stack.
5. Perform a microtask checkpoint \({ }^{\mathrm{p} 949}\).

If task is a microtask \({ }^{p 945}\) this step will be a no-op due to performing a microtask checkpoint \({ }^{p 945}\) being true.
6. In parallel \({ }^{\mathrm{p} 42}\) :
1. Wait until the condition goal is met.
2. Queue a task \({ }^{\text {p945 }}\) on task source to:
1. Replace the JavaScript execution context stack with old stack.
2. Perform any steps that appear after this spin the event loop \({ }^{\text {p949 }}\) instance in the original algorithm.

\section*{Note}

This resumes task.
7. Stop task, allowing whatever algorithm that invoked it to resume.

Note
This causes the event loop \({ }^{p 944}\) 's main set of steps or the perform a microtask checkpoint \({ }^{p 949}\) algorithm to continue.

\section*{Note}

Unlike other algorithms in this and other specifications, which behave similar to programming-language function calls, spin the event loop \({ }^{\text {p949 }}\) is more like a macro, which saves typing and indentation at the usage site by expanding into a series of steps and operations.

\section*{Example}

An algorithm whose steps are:
1. Do something.
2. Spin the event loop \({ }^{\text {p949 }}\) until awesomeness happens.
3. Do something else.
is a shorthand which, after "macro expansion", becomes
1. Do something.
2. Let old stack be a copy of the JavaScript execution context stack.
3. Empty the JavaScript execution context stack.
4. Perform a microtask checkpoint \({ }^{\text {p949 }}\).
5. In parallel \({ }^{\mathrm{p} 42}\) :
1. Wait until awesomeness happens.
2. Queue a task \({ }^{\text {p945 }}\) on the task source in which "do something" was done to:
1. Replace the JavaScript execution context stack with old stack.
2. Do something else.

\section*{Example}

Here is a more full example of the substitution, where the event loop is spun from inside a task that is queued from work in parallel. The version using spin the event loop \({ }^{\text {p949 }}\) :
1. In parallel \({ }^{\mathrm{p} 42}\) :
1. Do parallel thing 1.
2. Queue a task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) to:
1. Do task thing 1 .
2. Spin the event loop \({ }^{\text {p949 }}\) until awesomeness happens.
3. Do task thing 2.
3. Do parallel thing 2 .

The fully expanded version:
1. In parallel \({ }^{\mathrm{p} 42}\) :
1. Do parallel thing 1.
2. Let old stack be null.
3. Queue a task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) to:
1. Do task thing 1 .
2. Set old stack to a copy of the JavaScript execution context stack.
3. Empty the JavaScript execution context stack.
4. Perform a microtask checkpoint \({ }^{\text {p949 }}\).
4. Wait until awesomeness happens.
5. Queue a task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\mathrm{p952}}\) to:
1. Replace the JavaScript execution context stack with old stack.
2. Do task thing 2.
6. Do parallel thing 2.

Some of the algorithms in this specification, for historical reasons, require the user agent to pause while running a task \({ }^{\text {p944 }}\) until a condition goal is met. This means running the following steps:
1. If necessary, update the rendering or user interface of any Document \({ }^{\mathrm{p} 114}\) or browsing context \({ }^{\mathrm{p} 811}\) to reflect the current state.
2. Wait until the condition goal is met. While a user agent has a paused task \({ }^{\text {p944 }}\), the corresponding event loop \({ }^{\text {p944 }}\) must not run further tasks \({ }^{\text {p944 }}\), and any script in the currently running task \({ }^{\text {p944 }}\) must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the event loop \({ }^{\text {p944 }}\) will not be doing anything.

\section*{\(\triangle\) Warning!}

Pausing \({ }^{\text {p951 }}\) is highly detrimental to the user experience, especially in scenarios where a single event loop \({ }^{\text {p944 }}\) is shared among multiple documents. User agents are encouraged to experiment with alternatives to pausing \({ }^{\text {p951 }}\), such as spinning the event loop \({ }^{p 949}\) or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily change if a less-drastic alternative is discovered to be web-compatible.

In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of event loop \({ }^{p 944}\) behavior, including task \({ }^{p 944}\) and microtask \({ }^{\text {p945 }}\) timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the pause \({ }^{\text {p951 }}\) operation.

\subsection*{8.1.6.4 Generic task sources \(\S^{\text {p95 }}\)}

The following task sources \({ }^{\text {p945 }}\) are used by a number of mostly unrelated features in this and other specifications.

\section*{The DOM manipulation task source}

This task source \({ }^{\mathrm{p} 945}\) is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is inserted into the document \({ }^{\text {p44 }}\).

\section*{The user interaction task source}

This task source \({ }^{\text {p945 }}\) is used for features that react to user interaction, for example keyboard or mouse input.
Events sent in response to user input (e.g. click events) must be fired using tasks \({ }^{\text {p944 }}\) queued \({ }^{\text {p945 }}\) with the user interaction task source \({ }^{\text {p952 }}\). [UIEVENTS] \({ }^{\text {p1292 }}\)

\section*{The networking task source}

This task source \({ }^{\text {p945 }}\) is used for features that trigger in response to network activity.

\section*{The history traversal task source}

This task source \({ }^{\mathrm{p945}}\) is used to queue calls to history. back () \({ }^{\mathrm{p} 852}\) and similar APIs.

\subsection*{8.1.6.5 Dealing with the event loop from other specifications \(\S^{\text {p95 }}\)}

Writing specifications that correctly interact with the event loop \({ }^{\text {p944 }}\) can be tricky. This is compounded by how this specification uses
 model-specific terms like "main thread" or "on a background thread".

By default, specification text generally runs on the event loop \({ }^{\text {p944. }}\). This falls out from the formal event loop processing model \({ }^{\text {p946 }}\), in that you can eventually trace most algorithms back to a task \({ }^{\text {p944 }}\) queued \({ }^{\text {p945 }}\) there.

\section*{Example}

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the script processing model \({ }^{\text {p619 }}\).

From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the event \(l^{100 p^{\text {p944 }}}\) must instead be performed in parallel \({ }^{\text {p42 }}\) with it. This includes (but is not limited to):
- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. "going out of process").

The next complication is that, in algorithm sections that are in parallel \({ }^{\text {p42 }}\), you must not create or manipulate objects associated to a specific JavaScript realm, global \({ }^{\text {p918 }}\), or environment settings object \({ }^{\text {p917 }}\). (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running in parallel \(l^{p 42}\) to the JavaScript code.

You can, however, manipulate specification-level data structures and values from Infra, as those are realm-agnostic. They are never directly exposed to JavaScript without a specific conversion taking place (often via Web IDL). [INFRA] \({ }^{\text {p1288 }}\) [WEBIDL] \({ }^{\text {p1292 }}\)

To affect the world of observable JavaScript objects, then, you must queue a task \({ }^{\text {p945 }}\) to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the event loop \({ }^{\text {p944. }}\). Furthermore, you must choose a task source \({ }^{\text {p945 }}\) when queuing a task \({ }^{\text {p945 }}\); this governs the relative order of your steps versus others. If you are unsure which task source \({ }^{\text {p945 }}\) to use, pick one of the generic task sources \({ }^{\text {p951 }}\) that sounds most applicable.

Most invocations of queue a task \({ }^{\text {p945 }}\) use the implied event loop \({ }^{\text {p946 }}\), i.e., the one that is obvious from context. That is because it is very rare for algorithms to be invoked in contexts involving multiple event loops. (Unlike contexts involving multiple global objects, which happen all the time!) So unless you are writing a specification which, e.g., deals with manipulating workers \({ }^{\text {p1028 }}\), you can omit this argument when queuing a task \({ }^{\text {p945 }}\).

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:
1. Do any synchronous setup work, while still on the event loop \({ }^{\text {p944 }}\). This may include converting realm-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps in parallel \({ }^{\text {p42 }}\), operating entirely on realm-agnostic values, and producing a
realm-agnostic result.
3. Queue a task \({ }^{\text {p945 }}\), on a specified task source \({ }^{\text {p945 }}\), to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the event loop \({ }^{\text {p944 }}\).

\section*{Example}

The following is an algorithm that "encrypts" a passed-in list of scalar value strings input, after parsing them as URLs:
1. Let urls be an empty list.
2. For each string of input:
1. Let parsed be the result of parsing \({ }^{\mathrm{p} 89}\) string relative to the current settings object \({ }^{\mathrm{p} 924}\).
2. If parsed is failure, return a promise rejected with a "SyntaxError" DOMException.
3. Let serialized be the result of applying the URL serializer to parsed.
4. Append serialized to urls.
3. Let realm be the current Realm Record.
4. Let \(p\) be a new promise.
5. Run the following steps in parallel \({ }^{\mathrm{p} 42}\) :
1. Let encryptedURLs be an empty list.
2. For each url of urls:
1. Wait 100 milliseconds, so that people think we're doing heavy-duty encryption.
2. Let encrypted be a new string derived from url, whose \(n\)th code unit is equal to url's nth code unit plus 13.
3. Append encrypted to encryptedURLs.
3. Queue a task \({ }^{\text {p945 }}\), on the networking task source \({ }^{\text {p952 }}\), to perform the following steps:
1. Let array be the result of converting encryptedURLs to a JavaScript array, in realm.
2. Resolve \(p\) with array.
6. Return \(p\).

Here are several things to notice about this algorithm:
- It does its URL parsing up front, on the event loop \({ }^{\text {p944 }}\), before going to the in parallel \({ }^{\text {p42 }}\) steps. This is necessary, since parsing depends on the current settings object \({ }^{\text {p924 }}\), which would no longer be current after going in parallel \({ }^{\text {p42 }}\).
- Alternately, it could have saved a reference to the current settings object \({ }^{\text {p924 }}\) 's API base URL \({ }^{\text {p917 }}\) and used it during the in parallel \({ }^{\text {p42 }}\) steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we'd saved just the current settings object \({ }^{\text {p924 }}\), instead of its API base URL \({ }^{\text {p917 }}\), there would have been a potential race.
- It implicitly passes a list of strings from the initial steps to the in parallel \({ }^{\mathrm{p} 42}\) steps. This is OK, as both lists and strings are realm-agnostic.
- It performs "expensive computation" (waiting for 100 milliseconds per input URL) during the in parallel \({ }^{\text {p42 }}\) steps, thus not blocking the main event loop \({ }^{\text {p944 }}\).
- Promises, as observable JavaScript objects, are never created and manipulated during the in parallel \({ }^{p 42}\) steps. \(p\) is created before entering those steps, and then is manipulated during a task \({ }^{\text {p944 }}\) that is queued \({ }^{\text {p945 }}\) specifically for that purpose.
- The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.
(On these last two points, see also w3ctag/promises-guide issue \#52, heycam/webidl issue \#135, and heycam/webidl issue \#371,
where we are still mulling over the subtleties of the above promise-resolution pattern.)
Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a sequence<USVString>, there was an automatic conversion from realm-specific JavaScript objects provided by the author as input, into the realm-agnostic sequence<USVString> Web IDL type, which we then treat as a list of scalar value strings. So depending on how your specification is structured, there may be other implicit steps happening on the main event loop \({ }^{\text {p944 }}\) that play a part in this whole process of getting you ready to go in parallel \({ }^{\text {p42 }}\).

\subsection*{8.1.7 Events \({ }^{\text {p95 }}\)}

\subsection*{8.1.7.1 Event handlers \(\S^{\text {p95 }}\)}

Many objects can have event handlers specified. These act as non-capture event listeners for the object on which they are specified. [DOM] \({ }^{\text {p1287 }}\)

An event handler \({ }^{\text {p954 }}\) is a struct with two items:
- a value, which is either null, a callback object, or an internal raw uncompiled handler \({ }^{\text {p959 }}\). The EventHandler \({ }^{\text {p958 }}\) callback function type describes how this is exposed to scripts. Initially, an event handler \({ }^{\text {p954's }}\) value \({ }^{\text {p954 }}\) must be set to null.
- a listener, which is either null or an event listener responsible for running the event handler processing algorithm \({ }^{\text {p957 }}\). Initially, an event handler \({ }^{\text {p954' }} \mathrm{s}\) listener \({ }^{\text {p954 }}\) must be set to null.

Event handlers are exposed in two ways.
The first way, common to all event handlers, is as an event handler IDL attribute \({ }^{\text {p955 }}\).
The second way is as an event handler content attribute \({ }^{\text {p955 }}\). Event handlers on HTML elements \({ }^{\text {p44 }}\) and some of the event handlers on Window \({ }^{\text {p824 }}\) objects are exposed in this way.

For both of these two ways, the event handler \({ }^{\text {p954 }}\) is exposed through a name, which is a string that always starts with "on" and is followed by the name of the event for which the handler is intended.

Most of the time, the object that exposes an event handler \({ }^{\text {p954 }}\) is the same as the object on which the corresponding event listener is added. However, the body \({ }^{\text {p178 }}\) and frameset \({ }^{p 1239}\) elements expose several event handlers \({ }^{\text {p954 }}\) that act upon the element's Window \({ }^{\text {p824 }}\) object, if one exists. In either case, we call the object an event handler \({ }^{\text {p954 }}\) acts upon the target of that event handler \({ }^{\text {p954 }}\).

To determine the target of an event handler, given an EventTarget object eventTarget on which the event handler \({ }^{\text {p954 }}\) is exposed, and an event handler name \({ }^{\text {p954 }}\) name, the following steps are taken:
1. If eventTarget is not a body \({ }^{\text {p178 }}\) element or a frameset \({ }^{\text {p1239 }}\) element, then return eventTarget.
2. If name is not the name of an attribute member of the WindowEventHandlers \({ }^{\text {p964 }}\) interface mixin and the Window-reflecting body element event handler set \({ }^{\text {p962 }}\) does not contain name, then return eventTarget.
3. If eventTarget's node document is not an active document \({ }^{\mathrm{p} 811}\), then return null.

Note
This could happen if this object is a body \({ }^{p 178}\) element without a corresponding Window \({ }^{\mathrm{p} 824}\) object, for example.

\section*{Note}

This check does not necessarily prevent body \({ }^{\text {p178 }}\) and frameset \({ }^{p 1239}\) elements that are not the body element \({ }^{p 118}\) of their node document from reaching the next step. In particular, a body \({ }^{\text {p178 }}\) element created in an active document \({ }^{p 811}\) (perhaps with document. createElement ()) but not connected will also have its corresponding Window \({ }^{\text {p824 }}\) object as the target \({ }^{\text {p954 }}\) of several event handlers \({ }^{\text {p954 }}\) exposed through it.
4. Return eventTarget's node document's relevant global object \({ }^{\text {p924 }}\).

Each EventTarget object that has one or more event handlers \({ }^{\text {p954 }}\) specified has an associated event handler map, which is a map of strings representing names \({ }^{\mathrm{p954}}\) of event handlers \({ }^{\mathrm{p954}}\) to event handlers \({ }^{\mathrm{p954}}\).

When an EventTarget object that has one or more event handlers \({ }^{\text {p954 }}\) specified is created, its event handler map \({ }^{\text {p955 }}\) must be initialized such that it contains an entry for each event handler \({ }^{\text {p954 }}\) that has that object as target \({ }^{\text {p954 }}\), with items in those event handlers \({ }^{\text {p954 }}\) set to their initial values.

\section*{Note}

The order of the entries of event handler map \({ }^{p 955}\) could be arbitrary. It is not observable through any algorithms that operate on the map.

\section*{Note}

Entries are not created in the event handler map \({ }^{\text {p955 }}\) of an object for event handlers \({ }^{\text {p954 }}\) that are merely exposed on that object, but have some other object as their targets \({ }^{p 954}\).

An event handler IDL attribute is an IDL attribute for a specific event handler \({ }^{\text {p954 }}\). The name of the IDL attribute is the same as the name \({ }^{\text {p954 }}\) of the event handler \({ }^{\text {p954 }}\).

The getter of an event handler IDL attribute \({ }^{\text {p955 }}\) with name name, when called, must run these steps:
1. Let eventTarget be the result of determining the target of an event handler \({ }^{\text {p954 }}\) given this object and name.
2. If eventTarget is null, then return null.
3. Return the result of getting the current value of the event handler \({ }^{p 959}\) given eventTarget and name.

The setter of an event handler IDL attribute \({ }^{\text {p955 }}\) with name name, when called, must run these steps:
1. Let eventTarget be the result of determining the target of an event handler \({ }^{\text {p954 }}\) given this object and name.
2. If eventTarget is null, then return.
3. If the given value is null, then deactivate an event handler \({ }^{\text {p956 }}\) given eventTarget and name.
4. Otherwise:
1. Let handlerMap be eventTarget's event handler map \({ }^{\text {p955 }}\).
2. Let eventHandler be handlerMap[name].
3. Set eventHandler's value \({ }^{\text {p954 }}\) to the given value.
4. Activate an event handler \({ }^{p 956}\) given eventTarget and name.

\section*{Note}

Certain event handler IDL attributes \({ }^{p 955}\) have additional requirements, in particular the onmessage \({ }^{\text {p1024 }}\) attribute of MessagePort \({ }^{\text {p1022 }}\) objects.

An event handler content attribute is a content attribute for a specific event handler \({ }^{p 954}\). The name of the content attribute is the same as the name \({ }^{\text {p954 }}\) of the event handler \({ }^{\text {p954 }}\).

Event handler content attributes \({ }^{\text {p955 }}\), when specified, must contain valid JavaScript code which, when parsed, would match the FunctionBody production after automatic semicolon insertion.

The following attribute change steps are used to synchronize between event handler content attributes \({ }^{\text {p955 }}\) and event handlers \({ }^{\text {p954 }}\) : [DOM] \({ }^{\text {p1287 }}\)
1. If namespace is not null, or localName is not the name of an event handler content attribute \({ }^{\text {p955 }}\) on element, then return.
2. Let eventTarget be the result of determining the target of an event handler \({ }^{\text {p954 }}\) given element and localName.
3. If eventTarget is null, then return.
4. If value is null, then deactivate an event handler \({ }^{p 956}\) given eventTarget and localName.
5. Otherwise:
1. If the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "Blocked" when executed upon element, "script attribute", and value, then return. [CSP] \({ }^{\text {p1285 }}\)
2. Let handlerMap be eventTarget's event handler map \({ }^{\text {p955 }}\).
3. Let eventHandler be handlerMap[localName].
4. Let location be the script location that triggered the execution of these steps.
5. Set eventHandler's value \({ }^{\text {p954 }}\) to the internal raw uncompiled handler \({ }^{\text {p959 }}\) value/location.
6. Activate an event handler \({ }^{p 956}\) given eventTarget and localName.

\section*{Note}

Per the DOM Standard, these steps are run even if oldValue and value are identical (setting an attribute to its current value), but not if oldValue and value are both null (removing an attribute that doesn't currently exist). [DOM] \({ }^{\text {p1287 }}\)

To deactivate an event handler given an EventTarget object eventTarget and a string name that is the name \({ }^{\text {p954 }}\) of an event handler \({ }^{\text {p954 }}\), run these steps:
1. Let handlerMap be eventTarget's event handler map \({ }^{\text {p955 }}\).
2. Let eventHandler be handlerMap[name].
3. Set eventHandler's value \({ }^{\text {p954 }}\) to null.
4. Let listener be eventHandler's listener \({ }^{\text {p954 }}\).
5. If listener is not null, then remove an event listener with eventTarget and listener.
6. Set eventHandler's listener \({ }^{\text {p954 }}\) to null.

To erase all event listeners and handlers given an EventTarget object eventTarget, run these steps:
1. If eventTarget has an associated event handler map \({ }^{\text {p955 }}\), then for each name \(\rightarrow\) eventHandler of eventTarget's associated event handler map \({ }^{\text {p955 }}\), deactivate an event handler \({ }^{\text {p956 }}\) given eventTarget and name.
2. Remove all event listeners given eventTarget.

\section*{Note \\ ```
This algorithm is used to define document.open() (p969
```}

To activate an event handler given an EventTarget object eventTarget and a string name that is the name \({ }^{\text {p954 }}\) of an event handler \({ }^{\text {p954 }}\), run these steps:
1. Let handlerMap be eventTarget's event handler map \({ }^{\text {p955 }}\).
2. Let eventHandler be handlerMap[name].
3. If eventHandler's listener \({ }^{\text {p954 }}\) is not null, then return.
4. Let callback be the result of creating a Web IDL EventListener instance representing a reference to a function of one argument that executes the steps of the event handler processing algorithm \({ }^{\text {p957 }}\), given eventTarget, name, and its argument.

The EventListener's callback context can be arbitrary; it does not impact the steps of the event handler processing algorithm \({ }^{\text {p957 }}\). [DOM] \({ }^{\text {p1287 }}\)

\section*{Note}

The callback is emphatically not the event handler \({ }^{p 954}\) itself. Every event handler ends up registering the same callback, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.
5. Let listener be a new event listener whose type is the event handler event type corresponding to eventHandler and callback is callback.

Note
To be clear, an event listener is different from an EventListener.
6. Add an event listener with eventTarget and listener.
7. Set eventHandler's listener \({ }^{\text {p954 }}\) to listener.

Note
The event listener registration happens only if the event handler \({ }^{\text {p954' }}\) s value \({ }^{\text {p954 }}\) is being set to non-null, and the event handler \({ }^{\text {p954 }}\) is not already activated. Since listeners are called in the order they were registered, assuming no deactivation \({ }^{p 956}\) occurred, the order of event listeners for a particular event type will always be:
1. the event listeners registered with addEventListener() before the first time the event handler \({ }^{p 954} \mathrm{~s}\) value \({ }^{\text {p954 }}\) was set to non-null
2. then the callback to which it is currently set, if any
3. and finally the event listeners registered with addEventListener() after the first time the event handler \({ }^{p 954}\) ' \(s\) value \({ }^{\text {p954 }}\) was set to non-null.

\section*{Example}

This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.
```
<button id="test">Start Demo</button>
<script>
    var button = document.getElementById('test');
    button.addEventListener('click', function () { alert('ONE') }, false);
    button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler listener is registered
here
    button.addEventListener('click', function () { alert('THREE') }, false);
    button.onclick = function () { alert('TWO'); };
    button.addEventListener('click', function () { alert('FOUR') }, false);
</script>
```

However, in the following example, the event handler is deactivated \({ }^{\text {p956 }}\) after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with "ONE", "TWO", "THREE", "FOUR", and "FIVE" respectively, in order.
```
<button id="test">Start Demo</button>
<script>
    var button = document.getElementById('test');
    button.addEventListener('click', function () { alert('ONE') }, false);
    button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler is activated here
    button.addEventListener('click', function () { alert('TWO') }, false);
    button.onclick = null; // but deactivated here
    button.addEventListener('click', function () { alert('THREE') }, false);
    button.onclick = function () { alert('FOUR'); }; // and re-activated here
    button.addEventListener('click', function () { alert('FIVE') }, false);
</script>
```

Note
The interfaces implemented by the event object do not influence whether an event handler \({ }^{p 954}\) is triggered or not.

The event handler processing algorithm for an EventTarget object eventTarget, a string name representing the name \({ }^{\text {p954 }}\) of an event handler \({ }^{\text {p954 }}\), and an Event object event is as follows:
1. Let callback be the result of getting the current value of the event handler \({ }^{\text {p959 }}\) given eventTarget and name.
2. If callback is null, then return.
3. Let special error event handling be true if event is an ErrorEvent \({ }^{\text {p937 }}\) object, event's type is error \({ }^{p 1281}\), and event's currentTarget implements the WindowOrWorkerGlobalScope \({ }^{\text {p965 }}\) mixin. Otherwise, let special error event handling be false.
4. Process the Event object event as follows:

\section*{\(\rightarrow\) If special error event handling is true}

Invoke callback with five arguments, the first one having the value of event's message \({ }^{\text {p937 }}\) attribute, the second having the value of event's filename \({ }^{\text {p937 }}\) attribute, the third having the value of event's lineno \({ }^{\text {p937 }}\) attribute, the fourth having the value of event's colno \({ }^{\text {p938 }}\) attribute, the fifth having the value of event's error \({ }^{\text {p938 }}\) attribute, and with the callback this value set to event's currentTarget. Let return value be the callback's return value. [WEBIDL] \({ }^{\text {p1292 }}\)

\section*{\(\hookrightarrow\) Otherwise}

Invoke callback with one argument, the value of which is the Event object event, with the callback this value set to event's currentTarget. Let return value be the callback's return value. [WEBIDL] \({ }^{\text {p1292 }}\)

If an exception gets thrown by the callback, end these steps and allow the exception to propagate. (It will propagate to the DOM event dispatch logic, which will then report the exception \({ }^{\text {p937. }}\).)
5. Process return value as follows:
\(\rightarrow\) If event is a BeforeUnloadEvent \({ }^{\text {p887 }}\) object and event's type is beforeunload \({ }^{\text {p1281 }}\)

\section*{Note}

In this case, the event handler IDL attribute \({ }^{\text {p955' }}\) 's type will be OnBeforeUnloadEventHandler \({ }^{\text {p959 }}\), so return value will have been coerced into either null or a DOMString.

If return value is not null, then:
1. Set event's canceled flag.
2. If event's returnValue \({ }^{\text {p887 }}\) attribute's value is the empty string, then set event's returnValue \({ }^{\text {p887 }}\) attribute's value to return value.

\section*{\(\rightarrow\) If special error event handling is true}

If return value is true, then set event's canceled flag.
\(\hookrightarrow\) Otherwise
If return value is false, then set event's canceled flag.

\section*{Note}

If we've gotten to this "Otherwise" clause because event's type is beforeunload \({ }^{\text {p1281 }}\) but event is not a BeforeUnloadEvent \({ }^{\text {p887 }}\) object, then return value will never be false, since in such cases return value will have been coerced into either null or a DOMString.

The EventHandler \({ }^{\text {p958 }}\) callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:
IDL [LegacyTreatNonObjectAsNull]
```
callback EventHandlerNonNull = any (Event event);
typedef EventHandlerNonNull? EventHandler;
```

\section*{Note}

In JavaScript, any Function object implements this interface.

\section*{Example}

For example, the following document fragment:
```
<body onload="alert(this)" onclick="alert(this)">
```
...leads to an alert saying "[object Window]" when the document is loaded, and an alert saying "[object HTMLBodyElement]" whenever the user clicks something in the page.

\section*{Note}

The return value of the function affects whether the event is canceled or not: as described above, if the return value is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:
- The onerror \({ }^{\mathrm{p962}}\) handlers on global objects, where returning true cancels the event
- The onbeforeunload \({ }^{\text {p963 }}\) handler, where returning any non-null and non-undefined value will cancel the event.

For historical reasons, the onerror \({ }^{\text {p962 }}\) handler has different arguments:
IDL [LegacyTreatNonObjectAsNull]
callback OnErrorEventHandlerNonNull = any ((Event or DOMString) event, optional DOMString source, optional unsigned long lineno, optional unsigned long colno, optional any error); typedef OnErrorEventHandlerNonNull? OnErrorEventHandler;

Example
window.onerror = (message, source, lineno, colno, error) => \{ ... \};

Similarly, the onbeforeunload \({ }^{\text {p963 }}\) handler has a different return value:
IDL [LegacyTreatNonObjectAsNull]
callback OnBeforeUnloadEventHandlerNonNull = DOMString? (Event event);
typedef OnBeforeUnloadEventHandlerNonNull? OnBeforeUnloadEventHandler;

An internal raw uncompiled handler is a tuple with the following information:
- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to get the current value of the event hander given an EventTarget object eventTarget and a string name that is the name \({ }^{\text {p954 }}\) of an event handler \({ }^{\text {p954 }}\), it must run these steps:
1. Let handlerMap be eventTarget's event handler map \({ }^{\text {p955 }}\).
2. Let eventHandler be handlerMap[name].
3. If eventHandler's value \({ }^{\text {p954 }}\) is an internal raw uncompiled handler \({ }^{\text {p959 }}\), then:
1. If eventTarget is an element, then let element be eventTarget, and document be element's node document. Otherwise, eventTarget is a Window \({ }^{\text {p824 }}\) object, let element be null, and document be eventTarget's associated Document \({ }^{\text {p826. }}\).
2. If scripting is disabled \({ }^{\text {p924 }}\) for document, then return null.
3. Let body be the uncompiled script body in eventHandler's value \({ }^{\text {p954 }}\).
4. Let location be the location where the script body originated, as given by eventHandler's value \({ }^{\text {p954 }}\).
5. If element is not null and element has a form owner \({ }^{\mathrm{p566}}\), let form owner be that form owner \({ }^{\mathrm{p} 566}\). Otherwise, let form owner be null.
6. Let settings object be the relevant settings object \({ }^{\mathrm{p} 924}\) of document.
7. If body is not parsable as FunctionBody or if parsing detects an early error, then follow these substeps:
1. Set eventHandler's value \({ }^{\text {p954 }}\) to null.

\section*{Note}

This does not deactivate \({ }^{\text {p956 }}\) the event handler, which additionally removes the event handler's listener \({ }^{p 954}\) (if present).
2. Report the error \({ }^{\text {p936 }}\) for the appropriate script \({ }^{9925}\) and with the appropriate position (line number and column number) given by location, using settings object's global object \({ }^{\text {p918 }}\). If the error is still not \(h_{\text {handled }}{ }^{\text {p936 }}\) after this, then the error may be reported to a developer console.
3. Return null.
8. Push settings object's realm execution context \({ }^{\text {p917 }}\) onto the JavaScript execution context stack; it is now the running JavaScript execution context.

\section*{Note}

This is necessary so the subsequent invocation of OrdinaryFunctionCreate takes place in the correct JavaScript Realm.
9. Let function be the result of calling OrdinaryFunctionCreate, with arguments:

\section*{functionPrototype}
\%Function.prototype\%

\section*{sourceText}
\(\rightarrow\) If name is onerror \({ }^{\text {p962 }}\) and eventTarget is a Window \({ }^{\text {p824 }}\) object
The string formed by concatenating "function ", name, "(event, source, lineno, colno, error) \{", U+000A LF, body, U+000A LF, and "\}".
\(\rightarrow\) Otherwise
The string formed by concatenating "function ", name, "(event) \{", U+000A LF, body, U+000A LF, and "\}".

\section*{ParameterList}
\(\rightarrow\) If name is onerror \({ }^{p 962}\) and eventTarget is a Window \({ }^{\text {p824 }}\) object
Let the function have five arguments, named event, source, lineno, colno, and error.
\(\rightarrow\) Otherwise
Let the function have a single argument called event.

\section*{Body}

The result of parsing body above.

\section*{thisMode}
non-lexical-this

\section*{Scope}
1. Let realm be settings object's Realm \({ }^{\text {p918 }}\).
2. Let scope be realm.[[GlobalEnv]].
3. If eventHandler is an element's event handler \({ }^{\text {p954 }}\), then set scope to NewObjectEnvironment(document, scope).
(Otherwise, eventHandler is a Window \({ }^{\text {p824 }}\) object's event handler \({ }^{\text {p954 }}\).)
4. If form owner is not null, then set scope to NewObjectEnvironment(form owner, scope).
5. If element is not null, then set scope to NewObjectEnvironment(element, scope).
6. Return scope.
10. Remove settings object's realm execution context \({ }^{\text {p917 }}\) from the JavaScript execution context stack.
11. Set function.[[ScriptOrModule]] to null.

Note
This is done because the default behavior, of associating the created function with the nearest script \({ }^{p 925}\) on the stack, can lead to path-dependent results. For example, an event handler which is first invoked by user interaction would end up with null [[ScriptOrModule]] (since then this algorithm would be first invoked when the active script \({ }^{p 925}\) is null), whereas one that is first invoked by dispatching an event from script would have its [[ScriptOrModule]] set to that script.

Instead, we just always set [[ScriptOrModule]] to null. This is more intuitive anyway; the idea that the first script which dispatches an event is somehow responsible for the event handler code is dubious.

In practice, this only affects the resolution of relative URLs via import(), which consult the base URL \({ }^{p 925}\) of the associated script. Nulling out [[ScriptOrModule]] means that HostResolvelmportedModule \({ }^{\text {p943 }}\) and HostImportModuleDynamically \({ }^{p 942}\) will fall back to the current settings object \({ }^{p 924}\) 's API base URL \({ }^{p 917}\).
12. Set eventHandler's value \({ }^{\text {p954 }}\) to the result of creating a Web IDL EventHandler \({ }^{\text {p958 }}\) callback function object whose object reference is function and whose callback context is settings object.
4. Return eventHandler's value \({ }^{\text {p954 }}\).

\subsection*{8.1.7.2 Event handlers on elements, Document \({ }^{\text {p114 }}\) objects, and Window \({ }^{\text {p824 }}\) objects \(\S_{1}^{\text {p96 }}\)}

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported by all \(\mathrm{HTML}^{\text {( }}\) elements \({ }^{\text {p44 }}\), as both event handler content attributes \({ }^{\text {p955 }}\) and event handler IDL attributes \({ }^{\text {p955 }}\); and that must be supported by all Document \({ }^{\text {p114 }}\) and Window \({ }^{\text {p824 }}\) objects, as event handler IDL attributes \({ }^{\text {p955 }}\) :
\begin{tabular}{|c|c|}
\hline Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\

\subsection*{8.1.7.3 Event firing \(\S_{5}^{p 96}\)}

Certain operations and methods are defined as firing events on elements. For example, the click() \({ }^{\text {p769 }}\) method on the HTMLElement \({ }^{p 124}\) interface is defined as firing a click event on the element. [UIEVENTS] \({ }^{p 1292}\)

Firing a synthetic mouse event named e at target, with an optional not trusted flag, means running these steps:
1. Let event be the result of creating an event using MouseEvent.
2. Initialize event's type attribute to e.
3. Initialize event's bubbles and cancelable attributes to true.
4. Set event's composed flag.
5. If the not trusted flag is set, initialize event's isTrusted attribute to false.
6. Initialize event's ctrlKey, shiftKey, altKey, and metaKey attributes according to the current state of the key input device, if any (false for any keys that are not available).
7. Initialize event's view attribute to target's node document's Window \({ }^{\mathrm{p} 824}\) object, if any, and null otherwise.
8. event's getModifierState() method is to return values appropriately describing the current state of the key input device.
9. Return the result of dispatching event at target.

Firing a click event at target means firing a synthetic mouse event named click \({ }^{\text {p965 }}\) at target.

\subsection*{8.2 The WindowOrWorkerGlobalScope \({ }^{\text {p965 }}\) mixin \(\S_{5}^{\text {p96 }}\)}

The WindowOrWorkerGlobalScope \({ }^{\text {p965 }}\) mixin is for use of APIs that are to be exposed on Window \({ }^{\text {p824 }}\) and WorkerGlobalScope \({ }^{\text {p1044 }}\) objects.

\section*{Note}

Other standards are encouraged to further extend it using partial interface mixin Window0rWorkerGlobalScope \({ }^{\text {p965 }}\) \{ ... \}; along with an appropriate reference.

IDL
```
typedef (DOMString or Function) TimerHandler;
interface mixin WindowOrWorkerGlobalScope {
    [Replaceable] readonly attribute USVString origin;
```
```
    readonly attribute boolean isSecureContext;
    readonly attribute boolean crossOriginIsolated;
    // base64 utility methods
    DOMString btoa(DOMString data);
    ByteString atob(DOMString data);
    // timers
    long setTimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
    undefined clearTimeout(optional long handle = 0);
    long setInterval(TimerHandler handler, optional long timeout = 0, any... arguments);
    undefined clearInterval(optional long handle = 0);
    // microtask queuing
    undefined queueMicrotask(VoidFunction callback);
    // ImageBitmap
    Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options =
{});
    Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, long sw, long sh,
optional ImageBitmapOptions options = {});
};
Window includes WindowOrWorkerGlobalScope;
WorkerGlobalScope includes WindowOrWorkerGlobalScope;
```

\section*{For web developers (non-normative)}

\section*{self . isSecureContext \({ }^{\text {p966 }}\)}

Returns whether or not this global object represents a secure context \({ }^{\text {p924 }}\). [SECURE-CONTEXTS] \({ }^{\text {p1291 }}\)
self. origin \({ }^{\text {p966 }}\)
Returns the global object's origin \({ }^{\text {p837 }}\), serialized as string.
self . crossOriginIsolated \({ }^{\text {p966 }}\)
Returns whether scripts running in this global are allowed to use APIs that require cross-origin isolation. This depends on the `Cross-Origin-Opener-Policy` and `Cross-Origin-Embedder-Policy` HTTP response headers and the "cross-originisolated \({ }^{\text {p67" }}\) feature.

\section*{Example}

Developers are strongly encouraged to use self.origin over location.origin. The former returns the origin \({ }^{p 837}\) of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on https://stargate.example/:
```
var frame = document.createElement("iframe")
frame.onload = function() {
        var frameWin = frame.contentWindow
        console.log(frameWin.location.origin) // "null"
        console.log(frameWin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)
```
self.origin is a more reliable security indicator.

The isSecureContext getter steps are to return true if this's relevant settings object \({ }^{\text {p924 }}\) is a secure context \({ }^{\text {p924 }}\), or false otherwise.
The origin getter steps are to return this's relevant settings object \({ }^{\mathrm{p} 924}\) 's origin \({ }^{\mathrm{p917}}\), serialized \({ }^{\mathrm{p} 838}\).
The crossOriginIsolated getter steps are to return this's relevant settings object \({ }^{\text {p924 }}\) 's cross-origin isolated capability \({ }^{\text {p917 }}\).

\subsection*{8.3 Base64 utility methods \(\S^{p 96}\)}

The atob( ) \({ }^{\mathrm{p967}}\) and btoa( ( \()^{\mathrm{p967}}\) methods allow developers to transform content to and from the base64 encoding.

\section*{Note}

In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.

\section*{For web developers (non-normative)}
result = self . btoa \({ }^{\text {p967 }}\) ( data )
Takes the input data, in the form of a Unicode string containing only characters in the range U+0000 to U+00FF, each representing a binary byte with values \(0 \times 00\) to \(0 x F F\) respectively, and converts it to its base64 representation, which it returns.

Throws an "InvalidCharacterError" DOMException exception if the input string contains any out-of-range characters.
result \(=\) self \(\cdot\) atob \(^{\text {p967 }}\) (data )
Takes the input data, in the form of a Unicode string containing base64-encoded binary data, decodes it, and returns a string consisting of characters in the range U+0000 to U+00FF, each representing a binary byte with values \(0 \times 00\) to \(0 \times F F\) respectively, corresponding to that binary data.
Throws an "InvalidCharacterError" DOMException if the input string is not valid base64 data

The btoa(data) method must throw an "InvalidCharacterError" DOMException if data contains any character whose code point is greater than U+00FF. Otherwise, the user agent must convert data to a byte sequence whose \(n\)th byte is the eight-bit representation of the \(n\)th code point of data, and then must apply forgiving-base64 encode to that byte sequence and return the result.

The atob(data) method, when invoked, must run the following steps:
1. Let decodedData be the result of running forgiving-base64 decode on data.
2. If decodedData is failure, then throw an "InvalidCharacterError" DOMException.
3. Return decodedData.

\subsection*{8.4 Dynamic markup insertion \(\S^{p 96}\)}

\section*{Note}

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with HTML documents (and the HTML parser \({ }^{p 1079}\) ) or XML documents (and the XML parser \({ }^{p 1188}\) ).

Document \({ }^{\text {p114 }}\) objects have a throw-on-dynamic-markup-insertion counter, which is used in conjunction with the create an element for the token \({ }^{\text {p1127 }}\) algorithm to prevent custom element constructors \({ }^{\text {p703 }}\) from being able to use document. open () \({ }^{\text {p969 }}\), document.close( ) \({ }^{\text {p969 }}\), and document. write( () \({ }^{\text {p97e }}\) when they are invoked by the parser. Initially, the counter must be set to zero.

\subsection*{8.4.1 Opening the input stream \(\S^{p 96}\)}

\section*{For web developers (non-normative)}

\section*{document \(=\) document . open \({ }^{\text {p969 }}\) ( )}

Causes the Document \({ }^{\text {p114 }}\) to be replaced in-place, as if it was a new Document \({ }^{\text {p114 }}\) object, but reusing the previous object, which is then returned.

The resulting Document \({ }^{\text {p114 }}\) has an HTML parser associated with it, which can be given data to parse using
document.write() \({ }^{\text {p970 }}\).
The method has no effect if the Document \({ }^{p 114}\) is still being parsed.
Throws an "InvalidStateError" DOMException if the Document \({ }^{\text {p114 }}\) is an XML document.
Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor \({ }^{\text {p703 }}\).
```
window = document . open }\mp@subsup{}{}{\textrm{p969}}\mathrm{ ( url, name, features )
```

Works like the window. open() \({ }^{\text {p827 }}\) method.

Document \({ }^{\text {p114 }}\) objects have an ignore-opens-during-unload counter, which is used to prevent scripts from invoking the document. open () \({ }^{\text {p969 }}\) method (directly or indirectly) while the document is being unloaded \({ }^{\text {p886 }}\). Initially, the counter must be set to zero.

Document \({ }^{\text {p114 }}\) objects have an active parser was aborted boolean, which is used to prevent scripts from invoking the document.open() \({ }^{\text {p969 }}\) and document. write() ( \({ }^{\text {p970 }}\) methods (directly or indirectly) after the document's active parser \({ }^{\text {p117 }}\) has been aborted. It is initially false.

The document open steps, given a document, are as follows:
1. If document is an XML document, then throw an "InvalidStateError" DOMException exception.
2. If document's throw-on-dynamic-markup-insertion counter \({ }^{\text {p967 }}\) is greater than 0 , then throw an "InvalidStateError" DOMException.
3. Let entryDocument be the entry global object \({ }^{\text {p921 }} \mathrm{s}\) associated Document \({ }^{\mathrm{p826}}\).
4. If document's origin \({ }^{\mathrm{p} 837}\) is not same origin \({ }^{\text {p838 }}\) to entryDocument's origin \({ }^{p 837}\), then throw a "SecurityError" D0MException.
5. If document has an active parser \({ }^{p 117}\) whose script nesting level \({ }^{p 1081}\) is greater than 0 , then return document.

\section*{Note}

This basically causes document. open() \({ }^{\text {p969 }}\) to be ignored when it's called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.
6. Similarly, if document's ignore-opens-during-unload counter \({ }^{\text {p968 }}\) is greater than 0 , then return document.

\section*{Note}

This basically causes document. open ( ) \({ }^{\text {p969 }}\) to be ignored when it's called from a beforeunload \({ }^{\text {p1281 }}\), pagehide \({ }^{\text {p1282 }}\), or unload \({ }^{\text {p1282 }}\) event handler while the Document \({ }^{\text {p114 }}\) is being unloaded.
7. If document's active parser was aborted \({ }^{\text {p968 }}\) is true, then return document.

\section*{Note}

This notably causes document. open () \({ }^{\text {p969 }}\) to be ignored if it is called after a navigation \({ }^{p 866}\) has started, but only during the initial parse. See issue \#4723 for more background.
8. If document's browsing context \({ }^{\text {p811 }}\) is non-null and there is an existing attempt to navigate \({ }^{\text {p866 }}\) document's browsing context \({ }^{\text {p811 }}\), then stop document loading \({ }^{\text {p888 }}\) given document.

> Issue \#3447 looks into the distinction between an ongoing instance of the navigate \({ }^{\text {p866 }}\) algorithm versus tasks to navigate \({ }^{\text {p866 }}\) that are still queued. For the purpose of implementing this step, both an ongoing instance of the navigate \({ }^{\text {p866 }}\) algorithm and tasks queued to navigate \({ }^{\text {p866 }}\) should be counted towards "an existing attempt to \(\underline{\text { navigate }{ }^{\text {p866 }}}, "\) at least until that issue is resolved.
9. For each shadow-including inclusive descendant node of document, erase all event listeners and handlers \({ }^{\text {p956 }}\) given node.
10. If document is the associated Document \({ }^{\mathrm{p} 826}\) of document's relevant global object \({ }^{\mathrm{p} 924}\), then erase all event listeners and handlers \({ }^{\text {p956 }}\) given document's relevant global object \({ }^{\text {p924 }}\).
11. Replace all with null within document, without firing any mutation events.
12. If document is fully active \({ }^{\text {p815 }}\), then:
1. Let newURL be a copy of entryDocument's URL.
2. If entryDocument is not document, then set newURL's fragment to null.
3. Run the URL and history update steps \({ }^{8853}\) with document and newURL.
13. If document's iframe load in progress \({ }^{\mathrm{p} 364}\) flag is set, then set document's mute iframe load \({ }^{\mathrm{p} 364}\) flag.
14. Set document to no-quirks mode.
15. Create a new HTML parser \({ }^{\text {p1079 }}\) and associate it with document. This is a script-created parser (meaning that it can be closed by the document. open( ) \({ }^{\text {p969 }}\) and document. close( () \({ }^{\text {p969 }}\) methods, and that the tokenizer will wait for an explicit call to document. close( ) \({ }^{\text {p969 }}\) before emitting an end-of-file token). The encoding confidence \({ }^{\text {p1086 }}\) is irrelevant.
16. Set the current document readiness \({ }^{\mathrm{p} 117}\) of document to "loading".
17. Finally, set the insertion point \({ }^{p 1092}\) to point at just before the end of the input stream \({ }^{\text {p1091 }}\) (which at this point will be empty).
18. Return document.

\section*{Note}

The document open steps \({ }^{\text {p968 }}\) do not affect whether a Document \({ }^{\text {p114 }}\) is ready for post-load tasks \({ }^{\text {p1165 }}\) or completely loaded \({ }^{\text {p885 }}\).

The open (unused1, unused2) method must return the result of running the document open steps \({ }^{\text {p968 }}\) with this Document \({ }^{\text {p114 }}\) object.

\section*{Note}

The unused1 and unused2 arguments are ignored, but kept in the IDL to allow code that calls the function with one or two arguments to continue working. They are necessary due to Web IDL overload resolution algorithm rules, which would throw a TypeError exception for such calls had the arguments not been there. heycam/webidl issue \#581 investigates changing the algorithm to allow for their removal. [WEBIDL] \({ }^{\text {p1292 }}\)

The open(url, name, features) method must run these steps:
1. If this Document \({ }^{\text {p114 }}\) object is not an active document \({ }^{\text {p811 }}\), then throw an "InvalidAccessError" DOMException exception.
2. Return the result of running the window open steps \({ }^{\text {p826 }}\) with url, name, and features.

\subsection*{8.4.2 Closing the input stream \(\S^{p 96}\)}

\section*{For web developers (non-normative)}

\section*{document. close \({ }^{\text {p969 }}\) ()}

Closes the input stream that was opened by the document. open( ) \({ }^{\text {p969 }}\) method.
Throws an "InvalidStateError" DOMException if the Document \({ }^{\text {p114 }}\) is an XML document.
Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor \({ }^{\text {p703 }}\).

The close() method must run the following steps:
1. If the Document \({ }^{\text {p114 }}\) object is an XML document, then throw an "InvalidStateError" DOMException.
2. If the Document \({ }^{\text {p114 }}\) object's throw-on-dynamic-markup-insertion counter \({ }^{\text {p967 }}\) is greater than zero, then throw an "InvalidStateError" DOMException.
3. If there is no script-created parser \({ }^{\text {p969 }}\) associated with the document, then return.
4. Insert an explicit "EOF" character \({ }^{\text {p1092 }}\) at the end of the parser's input stream \({ }^{\text {p1091 }}\).
5. If there is a pending parsing-blocking script \({ }^{\mathrm{p} 623}\), then return.
6. Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the explicit "EOF" character \({ }^{\text {p1092 }}\) or spins the event loop \({ }^{\text {p949 }}\).

\subsection*{8.4.3 document.write() \({ }^{\text {p97e }} \S^{\text {p97 }}\)}

\section*{For web developers (non-normative)}
document . write \({ }^{\text {p979 }}\) (text...)
In general, adds the given string(s) to the Document \({ }^{\text {p114 ' }}\) 's input stream.

\section*{\(\triangle\) Warning!}

This method has very idiosyncratic behavior. In some cases, this method can affect the state of the HTML parser \({ }^{\text {p1079 }}\) while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string "<plaintext>" or "<! - -"). In other cases, the call can clear the current page first, as if document. open( ) \({ }^{\text {p969 }}\) had been called. In yet more cases, the method is simply ignored, or throws an exception. Users agents are explicitly allowed to avoid executing script elements inserted via this method \({ }^{p 1136}\). And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. For all these reasons, use of this method is strongly discouraged.

Throws an "InvalidStateError" DOMException when invoked on XML documents.
Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor \({ }^{\text {p703 }}\).

Document \({ }^{\text {p114 }}\) objects have an ignore-destructive-writes counter, which is used in conjunction with the processing of script \({ }^{\text {p614 }}\) elements to prevent external scripts from being able to use document. write() \({ }^{\text {p970 }}\) to blow away the document by implicitly calling document. open () \({ }^{\text {p969 }}\). Initially, the counter must be set to zero.

The document write steps, given a Document \({ }^{\text {p114 }}\) object document and a string input, are as follows:
1. If document is an XML document, then throw an "InvalidStateError" DOMException.
2. If document's throw-on-dynamic-markup-insertion counter \({ }^{\mathrm{p} 967}\) is greater than 0 , then throw an "InvalidStateError" DOMException.
3. If document's active parser was aborted \({ }^{\mathrm{p} 968}\) is true, then return.
4. If the insertion point \({ }^{\text {p1092 }}\) is undefined, then:
1. If document's ignore-opens-during-unload counter \({ }^{\mathrm{p968}}\) is greater than 0 or document's ignore-destructive-writes counter \({ }^{\text {p970 }}\) is greater than 0 , then return.
2. Run the document open steps \({ }^{\text {p968 }}\) with document.
5. Insert input into the input stream \({ }^{\text {p1091 }}\) just before the insertion point \({ }^{\text {p1092 }}\).
6. If there is no pending parsing-blocking script \({ }^{\text {p623 }}\), have the HTML parser \({ }^{\text {p1079 }}\) process input, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a script \({ }^{\text {p614 }}\) end tag token is emitted by the tokenizer).

\section*{Note}

If the document. write() \({ }^{\text {p970 }}\) method was called from script executing inline (i.e. executing because the parser parsed a set of script \({ }^{\text {p614 }}\) tags), then this is a reentrant invocation of the parser \({ }^{p 1080}\). If the parser pause flag \({ }^{p 1081}\) is set, the tokenizer will abort immediately and no HTML will be parsed, per the tokenizer's parser pause flag check \({ }^{\text {p1097. }}\).

The document.write(...) method, when invoked, must run the document write steps \({ }^{\text {p970 }}\) with this Document \({ }^{\text {p114 }}\) object and a string that is the concatanation of all arguments passed.

\subsection*{8.4.4 document.writeln() \()^{\text {p971 }} \S^{\text {p97 }}\)}

For web developers (non-normative)
document. writeln \({ }^{\text {p971 }}\) (text...)
Adds the given string(s) to the Document \({ }^{p 114}\) 's input stream, followed by a newline character. If necessary, calls the open() \({ }^{\text {p969 }}\) method implicitly first.

Throws an "InvalidStateError" DOMException when invoked on XML documents.
Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor \({ }^{\text {p703 }}\).

The document.writeln(...) method, when invoked, must run the document write steps \({ }^{\text {p970 }}\) with this Document \({ }^{\text {p114 }}\) object and a string that is the concatanation of all arguments passed and U+000A LINE FEED.

\subsection*{8.5 DOM parsing \(\S^{p 97}\)}

The DOMParser \({ }^{\text {p971 }}\) interface allows authors to create new Document \({ }^{\text {p114 }}\) objects by parsing strings, as either HTML or XML.

\section*{For web developers (non-normative)}
parser = new DOMParser \({ }^{\text {p971 }}\) ()
Constructs a new DOMParser \({ }^{\text {p971 }}\) object.

\section*{document \(=\) parser. parseFromString \({ }^{\text {p971 }}\) ( string, type )}

Parses string using either the HTML or XML parser, according to type, and returns the resulting Document \({ }^{\text {p114 }}\). type can be "text/ html \({ }^{\text {p1250" }}\) (which will invoke the HTML parser), or any of "text/xml \({ }^{\text {p1284" }}\), "application/xml \({ }^{\text {p1283" }}\) " "application/ xhtml \(+x\) l \(^{\text {p1252" }}\), or "image/svg+xml \({ }^{\text {p1283" }}\) (which will invoke the XML parser).

For the XML parser, if string cannot be parsed, then the returned Document \({ }^{\text {p114 }}\) will contain elements describing the resulting error.

Note that script \({ }^{\text {p614 }}\) elements are not evaluated during parsing, and the resulting document's encoding will always be UTF-8. Values other than the above for type will cause a TypeError exception to be thrown.

\section*{Note}

The design of DOMParser \({ }^{\text {p971 }}\), as a class that needs to be constructed and then have its parseFromString() \({ }^{\text {p971 }}\) method called, is an unfortunate historical artifact. If we were designing this functionality today it would be a standalone function.
```
IDL
[Exposed=Window]
interface DOMParser {
    constructor();
    [NewObject] Document parseFromString(DOMString string, DOMParserSupportedType type);
};
enum DOMParserSupportedType {
    "text/html",
    "text/xml",
    "application/xml",
    "application/xhtml+xml",
    "image/svg+xml"
};
```

The new DOMParser() constructor steps are to do nothing.

The parseFromString(string, type) method steps are:
1. Let document be a new Document \({ }^{\text {p114 }}\), whose content type is type and url is this's relevant global object \({ }^{\text {p924 }}\) 's associated Document \({ }^{\text {p826 }}\) 's URL.

\section*{Note}

The document's encoding will be left as its default, of UTF-8. In particular, any XML declarations or meta \({ }^{\text {p164 }}\) elements found while parsing string will have no effect.
2. Switch on type:
1. Set document's type to "html".
2. Create an HTML parser \({ }^{\text {p1079 }}\) parser, associated with document.
3. Place string into the input stream \({ }^{\text {p1091 }}\) for parser. The encoding confidence \({ }^{\text {p1086 }}\) is irrelevant.
4. Start parser and let it run until it has consumed all the characters just inserted into the input stream.

\section*{Note}

This might mutate the document's mode.

\section*{Note}

Since document does not have a browsing context \({ }^{p 811}\), scripting is disabled \({ }^{\text {p924 }}\).

\section*{\(\rightarrow\) Otherwise}
1. Create an XML parser \({ }^{\text {p1188 }}\) parse, associated with document, and with XML scripting support disabled \({ }^{\text {p1189 }}\).
2. Parse string using parser.
3. If the previous step resulted in an XML well-formedness or XML namespace well-formedness error, then:
1. Assert: document has no child nodes.
2. Let root be the result of creating an element given document, "parsererror", and "http://www.mozilla.org/newlayout/xml/parsererror.xml".
3. Optionally, add attributes or children to root to describe the nature of the parsing error.
4. Append root to document.
3. Return document.

\subsection*{8.6 Timers \(\S^{\text {p97 }}\)}

The setTimeout ( \()^{\text {p973 }}\) and setInterval ( ( \({ }^{\text {p973 }}\) methods allow authors to schedule timer-based callbacks.

\section*{For web developers (non-normative)}

\section*{handle \(=\) self . setTimeout \({ }^{\text {p973 }}\) ( handler [, timeout [, arguments... ] ] )}

Schedules a timeout to run handler after timeout milliseconds. Any arguments are passed straight through to the handler.

\section*{handle \(=\) self. setTimeout \({ }^{\text {p973 }}\) ( code [, timeout ] )}

Schedules a timeout to compile and run code after timeout milliseconds.
self. clearTimeout \({ }^{\text {p973 }}\) ( handle )
Cancels the timeout set with setTimeout() \({ }^{\text {p973 }}\) or setInterval() \()^{\mathrm{p973}}\) identified by handle.
handle \(=\) self.\(\underline{s e t I n t e r v a l}{ }^{\text {p973 }}\) ( handler [, timeout [, arguments... ] ] )
Schedules a timeout to run handler every timeout milliseconds. Any arguments are passed straight through to the handler.

\section*{handle \(=\) self. setInterval \({ }^{\text {p973 }}\) ( code [, timeout ] )}

Schedules a timeout to compile and run code every timeout milliseconds.
self . clearInterval \({ }^{\text {p973 }}\) ( handle )
Cancels the timeout set with setInterval( ) \({ }^{\text {p973 }}\) or setTimeout() \()^{\text {p973 }}\) identified by handle.

\section*{Note}

Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.

This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.

Objects that implement the WindowOrWorkerGlobalScope \({ }^{\text {p965 }}\) mixin have a list of active timers. Each entry in this lists is identified by a number, which must be unique within the list for the lifetime of the object that implements the Window0rWorkerGlobalScope \({ }^{\text {p965 }}\) mixin.

The setTimeout () method must return the value returned by the timer initialization steps \({ }^{\text {p973 }}\), passing them the method's arguments, the object on which the method for which the algorithm is running is implemented (a Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object) as the method context, and the repeat flag set to false.

The setInterval() method must return the value returned by the timer initialization steps \({ }^{\text {p973 }}\), passing them the method's arguments, the object on which the method for which the algorithm is running is implemented (a Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object) as the method context, and the repeat flag set to true.

The clearTimeout () and clearInterval() methods must clear the entry identified as handle from the list of active timers \({ }^{\text {p973 }}\) of the WindowOrWorkerGlobalScope \({ }^{\text {p965 }}\) object on which the method was invoked, if any, where handle is the argument passed to the method. (If handle does not identify an entry in the list of active timers \({ }^{\text {p973 }}\) of the WindowOrWorkerGlobalScope \({ }^{\text {p965 }}\) object on which the method was invoked, the method does nothing.)

\section*{Note}

Because clearTimeout( ) \({ }^{\text {p973 }}\) and clearInterval() \({ }^{\text {p973 }}\) clear entries from the same list, either method can be used to clear timers created by setTimeout() \()^{\text {p973 }}\) or setInterval() \({ }^{\text {p973 }}\).

The timer initialization steps, which are invoked with some method arguments, a method context, a repeat flag which can be true or false, and optionally (and only if the repeat flag is true) a previous handle, are as follows:
1. Let method context proxy be method context if that is a WorkerGlobalScope \({ }^{\text {p1944 }}\) object, or else the WindowProxy \({ }^{\text {p834 }}\) that corresponds to method context.
2. If previous handle was provided, let handle be previous handle; otherwise, let handle be an implementation-defined integer that is greater than zero that will identify the timeout to be set by this call in the list of active timers \({ }^{\text {p973 }}\).
3. If previous handle was not provided, add an entry to the list of active timers \({ }^{\text {p973 }}\) for handle.
4. Let callerRealm be the current Realm Record, and calleeRealm be method context's JavaScript realm.
5. Let initiating script be the active script \({ }^{\mathrm{p} 925}\).
6. Assert: initiating script is not null, since this algorithm is always called from some script.
7. Let task be a task \({ }^{\text {p944 }}\) that runs the following substeps:
1. If the entry for handle in the list of active timers \({ }^{\text {p973 }}\) has been cleared, then abort these steps.
2. Run the appropriate set of steps from the following list:
\(\rightarrow\) If the first method argument is a Function
Invoke the Function. Use the third and subsequent method arguments (if any) as the arguments for invoking the Function. Use method context proxy as the callback this value.
\(\leftrightarrow\) Otherwise
1. Perform HostEnsureCanCompileStrings \({ }^{\text {p940 }}\) (callerRealm, calleeRealm). If this throws an exception, catch it, report the exception \({ }^{\text {p937 }}\), and abort these steps.
2. Let script source be the first method argument.
3. Let settings object be method context's environment settings object \({ }^{\text {p917 }}\).
4. Let base URL be initiating script's base URL \({ }^{\mathrm{p} 925}\).
5. Let fetch options be a script fetch options \({ }^{9926}\) whose cryptographic nonce \({ }^{\text {p926 }}\) is initiating script's fetch options \({ }^{\text {p925 's }}\) cryptographic nonce \({ }^{\text {p926 }}\), integrity metadata \({ }^{\text {p926 }}\) is the empty string, parser
metadata \({ }^{\text {p926 }}\) is "not-parser-inserted", credentials mode \({ }^{\text {p926 }}\) is initiating script's fetch options \({ }^{\text {p925 's }}\) credentials mode \({ }^{\text {p926 }}\), and referrer policy \({ }^{\text {p926 }}\) is initiating script's fetch options \({ }^{\text {p925 }}\) 's referrer policy \({ }^{\text {p926 }}\).

\section*{Note}

The effect of these options ensures that the string compilation done by setTimeout() \({ }^{\text {p973 }}\) and setInterval ( ) \({ }^{\text {p973 }}\) behaves equivalently to that done by eval ( ). That is, module script \({ }^{p 925}\) fetches via import() will behave the same in both contexts.
6. Let script be the result of creating a classic script \({ }^{\text {p933 }}\) given script source, settings object, base URL, and fetch options.
7. Run the classic script \({ }^{\text {p934 }}\) script.
3. If the repeat flag is true, then call timer initialization steps \({ }^{\text {p973 }}\) again, passing them the same method arguments, the same method context, with the repeat flag still set to true, and with the previous handle set to handler.
8. Let timeout be the second method argument.
9. If the currently running task \({ }^{\text {p944 }}\) is a task that was created by this algorithm, then let nesting level be the task \({ }^{\text {p944 }} \mathrm{s}\) timer nesting level \({ }^{\text {p974 }}\). Otherwise, let nesting level be zero.

\section*{Note}

The task's timer nesting level \({ }^{p 974}\) is used both for nested calls to setTimeout () \()^{\text {p973 }}\), and for the repeating timers created by setInterval( () \({ }^{\text {p973 }}\). (Or, indeed, for any combination of the two.) In other words, it represents nested invocations of this algorithm, not of a particular method.
10. If timeout is less than 0 , then set timeout to 0 .
11. If nesting level is greater than 5 , and timeout is less than 4 , then set timeout to 4 .
12. Increment nesting level by one.
13. Let task's timer nesting level be nesting level.
14. Return handle, and then continue running this algorithm in parallel \({ }^{\mathrm{p} 42}\).
15. If method context is a Window \({ }^{p 824}\) object, wait until the Document \({ }^{\text {p114 }}\) associated with method context has been fully active \({ }^{\text {p815 }}\) for a further timeout milliseconds (not necessarily consecutively).

Otherwise, method context is a WorkerGlobalScope \({ }^{\text {p1044 }}\) object; wait until timeout milliseconds have passed with the worker not suspended (not necessarily consecutively).
16. Wait until any invocations of this algorithm that had the same method context, that started before this one, and whose timeout is equal to or less than this one's, have completed.

\section*{Note}

Argument conversion as defined by Web IDL (for example, invoking toString () methods on objects passed as the first argument) happens in the algorithms defined in Web IDL, before this algorithm is invoked.

\section*{Example}

So for example, the following rather silly code will result in the log containing "ONE TWO ":
```
var log = '';
function logger(s) { log += s + ' '; }
setTimeout({ toString: function () {
    setTimeout("logger('ONE')", 100);
    return "logger('TWO')";
} }, 100);
```
17. Optionally, wait a further implementation-defined length of time.

This is intended to allow user agents to pad timeouts as needed to optimize the power usage of the device. For example, some processors have a low-power mode where the granularity of timers is reduced; on such platforms, user agents can slow timers down to fit this schedule instead of requiring the processor to use the more accurate mode with its associated higher power usage.
18. Queue a global task \({ }^{\text {p945 }}\) on the timer task source given method context to run task.

\section*{Note}

Once the task has been processed, if the repeat flag is false, it is safe to remove the entry for handle from the list of active timers \({ }^{p 973}\) (there is no way for the entry's existence to be detected past this point, so it does not technically matter one way or the other).

\section*{Example}

To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:
```
function doExpensiveWork() {
    var done = false;
    // ...
    // this part of the function takes up to five milliseconds
    // set done to true if we're done
    // ...
    return done;
}
function rescheduleWork() {
    var handle = setTimeout(rescheduleWork, 0); // preschedule next iteration
    if (doExpensiveWork())
        clearTimeout(handle); // clear the timeout if we don't need it
}
function scheduleWork() {
    setTimeout(rescheduleWork, 0);
}
scheduleWork(); // queues a task to do lots of work
```

\subsection*{8.7 Microtask queuing \(\S_{5}^{\text {p97 }}\)}

\section*{For web developers (non-normative)}
self. queueMicrotask \({ }^{\text {p975 }}\) (callback)
Queues \({ }^{\text {p946 }}\) a microtask \({ }^{\text {p945 }}\) to run the given callback.

The queueMicrotask (callback) method must queue a microtask \({ }^{\text {p946 }}\) to invoke callback, and if callback throws an exception, report the exception \({ }^{\text {p937 }}\).

The queueMicrotask () \()^{\text {p975 }}\) method allows authors to schedule a callback on the microtask queue \({ }^{\text {p945 }}\). This allows their code to run after the currently-executing task \({ }^{\text {p944 }}\) has run to completion and the JavaScript execution context stack is empty, but without yielding control back to the event loop \({ }^{\text {p944 }}\), as would be the case when using, for example, setTimeout \((f, 0)^{\text {p973 }}\).

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering or scrolling. In many cases, requestAnimationFrame() \({ }^{\text {p996 }}\) or requestIdleCallback() is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of requestAnimationFrame() \({ }^{\text {p996 }}\).

As can be seen from the following examples, the best way of thinking about queueMicrotask() \()^{\text {p975 }}\) is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the current task's worth of non-queued JavaScript.

\section*{Example}

The most common reason for using queueMicrotask ( ) \({ }^{\text {p975 }}\) is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a load event, that also maintains an internal cache of previously-loaded data. A naïve implementation might look like:
```
MyElement.prototype.loadData = function (url) {
    if (this._cache[url]) {
        this._setData(this._cache[url]);
        this.dispatchEvent(new Event("load"));
    } else {
        fetch(url).then(res => res.arrayBuffer()).then(data => {
            this._cache[url] = data;
            this._setData(data);
            this.dispatchEvent(new Event("load"));
        });
    }
};
```

This naïve implementation is problematic, however, in that it causes its users to experience inconsistent behavior. For example, code such as
```
element.addEventListener("load", () => console.log("loaded"));
console.log("1");
element.loadData();
console.log("2");
```
will sometimes log "1, 2, loaded" (if the data needs to be fetched), and sometimes \(\log\) " 1 , loaded, 2 " (if the data is already cached). Similarly, after the call to loadData (), it will be inconsistent whether or not the data is set on the element.

To get a consistent ordering, queueMicrotask( ) \({ }^{\text {p975 }}\) can be used:
```
MyElement.prototype.loadData = function (url) {
    if (this._cache[url]) {
        queueMicrotask(() => {
            this._setData(this._cache[url]);
            this.dispatchEvent(new Event("load"));
        });
    } else {
        fetch(url).then(res => res.arrayBuffer()).then(data => {
            this._cache[url] = data;
            this._setData(data);
            this.dispatchEvent(new Event("load"));
        });
    }
};
```

By essentially rearranging the queued code to be after the currently-executing task, this ensures a consistent ordering and update of the element's state.

\section*{Example}

Another interesting use of queueMicrotask( ) \({ }^{\text {p975 }}\) is to allow uncoordinated "batching" of work by multiple callers. For example, consider a library function that wants to send data somewhere as soon as possible, but doesn't want to make multiple network requests if doing so is easily avoidable. One way to balance this would be like so:
```
const queuedToSend = [];
function sendData(data) {
    queuedToSend.push(data);
    if (queuedToSend.length === 1) {
        queueMicrotask(() => {
            const stringToSend = JSON.stringify(queuedToSend);
            queuedToSend.length = 0;
            fetch("/endpoint", stringToSend);
        });
    }
}
```

With this architecture, multiple subsequent calls to sendData () within the same turn of the event loop will be batched together into one fetch() call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used setTimeout ( \()^{\text {p973 }}\) ).

\subsection*{8.8 User prompts \(\S^{p 97}\)}

\subsection*{8.8.1 Simple dialogs \(\S_{7}^{\text {p97 }}\)}

\section*{For web developers (non-normative)}

\section*{window . alert \({ }^{\text {p977 }}\) (message)}

Displays a modal alert with the given message, and waits for the user to dismiss it.
result \(=\boldsymbol{w i n d o w}\). confirm \({ }^{\text {p978 }}\) (message)
Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks OK and false if the user clicks Cancel.
result \(=\) window \(\cdot\) prompt \(^{\text {p978 }}\) (message \([\), default \(\left.]\right)\)
Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

\section*{Note}

Logic that depends on tasks \({ }^{p 944}\) or microtasks \({ }^{p 945}\), such as media elements \({ }^{\text {p387 }}\) loading their media data \({ }^{\text {p389 }}\), are stalled when these methods are invoked.

To optionally truncate a simple dialog string \(s\), return either \(s\) itself or some string derived from \(s\) that is shorter. User agents should not provide UI for displaying the elided portion of \(s\), as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click 'Show More' for full details!".

\section*{Note}

For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "...". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.

The alert(message) method, when invoked, must run the following steps:
1. If the event loop \({ }^{\text {p944 }}\) 's termination nesting level \({ }^{\text {p885 }}\) is nonzero, optionally return.
2. If the active sandboxing flag set \({ }^{\mathrm{p} 844}\) of this Window \({ }^{\mathrm{p} 824}\) object's associated Document \({ }^{\mathrm{p} 826}\) has the sandboxed modals flag \({ }^{\mathrm{p} 843}\) set, then return.
3. Optionally, return. (For example, the user agent might give the user the option to ignore all alerts, and would thus abort at
this step whenever the method was invoked.)
4. If the method was invoked with no arguments, then let message be the empty string; otherwise, let message be the method's first argument.
5. Set message to the result of normalizing newlines given message.
6. Set message to the result of optionally truncating \({ }^{\text {p977 }}\) message.
7. Show message to the user, treating U+000A LF as a line break.
8. Optionally, pause \({ }^{p 951}\) while waiting for the user to acknowledge the message.

The confirm(message) method, when invoked, must run the following steps:
1. If the event loop \({ }^{\text {p944 }}\) 's termination nesting level \({ }^{p 885}\) is nonzero, optionally return false.
2. If the active sandboxing flag set \({ }^{\mathrm{p844}}\) of this Window \({ }^{\mathrm{p} 824}\) object's associated Document \({ }^{\mathrm{p} 826}\) has the sandboxed modals flag \({ }^{\mathrm{p} 843}\) set, then return.
3. Optionally, return false. (For example, the user agent might give the user the option to ignore all prompts, and would thus abort at this step whenever the method was invoked.)
4. Set message to the result of normalizing newlines given message.
5. Set message to the result of optionally truncating \({ }^{\text {p977 }}\) message.
6. Show message to the user, treating U+000A LF as a line break, and ask the user to respond with a positive or negative response.
7. Pause \({ }^{\text {p951 }}\) until the user responds either positively or negatively.
8. If the user responded positively, return true; otherwise, the user responded negatively: return false.

The prompt(message, default) method, when invoked, must run the following steps:
1. If the event loop \({ }^{\mathrm{p944}}\) 's termination nesting level \({ }^{\mathrm{p} 885}\) is nonzero, optionally return null.
2. If the active sandboxing flag set \({ }^{\mathrm{p} 844}\) of this Window \({ }^{\mathrm{p} 824}\) object's associated Document \({ }^{\mathrm{p} 826}\) has the sandboxed modals flag \({ }^{\mathrm{p} 843}\) set, then return.
3. Optionally, return null. (For example, the user agent might give the user the option to ignore all prompts, and would thus abort at this step whenever the method was invoked.)
4. Set message to the result of optionally truncating \({ }^{\text {p977 }}\) message.
5. Set message to the result of normalizing newlines given message.
6. Set default to the result of optionally truncating \({ }^{\text {p977 }}\) default.
7. Show message to the user, treating U+000A LF as a line break, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by default.
8. Pause \({ }^{\text {p951 }}\) while waiting for the user's response.
9. If the user aborts, then return null; otherwise, return the string that the user responded with.

\subsection*{8.8.2 Printing \({ }_{8}^{8997}\)}

For web developers (non-normative)
window. print \({ }^{\text {p978 }}\) ()
Prompts the user to print the page.

When the print () method is invoked, if the Document \({ }^{p 114}\) is ready for post-load tasks \({ }^{p 1165}\), then the user agent must run the printing steps \({ }^{\text {p979 }}\). Otherwise, the user agent must only set the print when loaded flag on the Document \({ }^{p 114}\).

User agents should also run the printing steps \({ }^{\text {p979 }}\) whenever the user asks for the opportunity to obtain a physical form \({ }^{\text {p1229 }}\) (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The printing steps are as follows:
1. The user agent may display a message to the user or return (or both).

\section*{Example}

For instance, a kiosk browser could silently ignore any invocations of the print () \()^{\text {p978 }}\) method.

\section*{Example}

For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.
2. If the active sandboxing flag set \({ }^{\mathrm{p} 844}\) of this Window \({ }^{\mathrm{p} 824}\) object's associated Document \({ }^{\mathrm{p} 826}\) has the sandboxed modals flag \({ }^{\mathrm{p} 843}\) set, then return.

\section*{Note}

If the printing dialog is blocked by a Document \({ }^{\text {p114 }}\) 's sandbox, then neither the beforeprint \({ }^{\text {p1281 }}\) nor afterprint \({ }^{\text {p1281 }}\) events will be fired.
3. The user agent must fire an event named beforeprint \({ }^{p 1281}\) at the relevant global object \({ }^{\text {p924 }}\) of the Document \({ }^{p 114}\) that is being printed, as well as any child browsing contexts \({ }^{\text {p814 }}\) in it.

\section*{Example}

The beforeprint \({ }^{\text {p1281 }}\) event can be used to annotate the printed copy, for instance adding the time at which the document was printed.
4. The user agent should offer the user the opportunity to obtain a physical form \({ }^{\text {p1229 }}\) (or the representation of a physical form) of the document. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must pause \({ }^{\text {p951 }}\) while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.
5. The user agent must fire an event named afterprint \({ }^{\text {p1281 }}\) at the relevant global object \({ }^{\text {p924 }}\) of the Document \({ }^{\text {p114 }}\) that is being printed, as well as any child browsing contexts \({ }^{\text {p814 }}\) in it.

\section*{Example}

The afterprint \({ }^{\text {p1281 }}\) event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

\subsection*{8.9 System state and capabilities \(\S^{\text {p97 }}\)}

\subsection*{8.9.1 The Navigator \({ }^{\text {p979 }}\) object \(\S^{\text {p97 }}\)}

The navigator attribute of the Window \({ }^{\mathrm{p} 824}\) interface must return an instance of the Navigator \({ }^{\text {p979 }}\) interface, which represents the identity and state of the user agent (the client), and allows web pages to register themselves as potential protocol handlers:
```
[Exposed=Window]
interface Navigator {
    // objects implementing this interface also implement the interfaces given below
};
Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
Navigator includes NavigatorOnLine;
Navigator includes NavigatorContentUtils;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrentHardware;
```

These interface mixins are defined separately so that WorkerNavigator \(r^{p 1057}\) can re-use parts of the Navigator \({ }^{\text {p979 }}\) interface.

\subsection*{8.9.1.1 Client identification \(\S^{p 98}\)}
```
interface mixin NavigatorID {
    readonly attribute DOMString appCodeName; // constant "Mozilla"
    readonly attribute DOMString appName; // constant "Netscape"
    readonly attribute DOMString appVersion;
    readonly attribute DOMString platform;
    readonly attribute DOMString product; // constant "Gecko"
    [Exposed=Window] readonly attribute DOMString productSub;
    readonly attribute DOMString userAgent;
    [Exposed=Window] readonly attribute DOMString vendor;
    [Exposed=Window] readonly attribute DOMString vendorSub; // constant ""
};
```

In certain cases, despite the best efforts of the entire industry, web browsers have bugs and limitations that web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the kind of user agent in use, in order to work around these issues.

The user agent has a navigator compatibility mode, which is either Chrome, Gecko, or WebKit.

\section*{Note \\ The navigator compatibility mode \({ }^{p 980}\) constrains the NavigatorlD \({ }^{p 980}\) interface to the combinations of attribute values and presence of taintEnabled( () \({ }^{\text {p981 }}\) and oscpu \({ }^{\text {p981 }}\) that are known to be compatible with existing web content.}

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

\section*{For web developers (non-normative)}
self . navigator \({ }^{\text {p979 }} \cdot\) appCodeName \({ }^{\text {p980 }}\)
Returns the string "Mozilla".
self . navigator \({ }^{\text {p979 }} \cdot\) appName \({ }^{\text {p981 }}\)
Returns the string "Netscape".
self . navigator \({ }^{\text {p979 }}\). appVersion \({ }^{\text {p981 }}\)
Returns the version of the browser.
self. navigator \({ }^{\text {p979 }}\). platform \({ }^{\text {p981 }}\)
Returns the name of the platform.
self . navigator \({ }^{\text {p979 }} \cdot\) product \(^{\text {p981 }}\)
Returns the string "Gecko".
window. navigator \({ }^{\text {p979 }}\). productSub \({ }^{\text {p981 }}\)
Returns either the string "20030107", or the string "20100101".
self . navigator \({ }^{\text {p979 }} \cdot\) userAgent \(^{\text {p981 }}\)
Returns the complete `User-Agent` header.
window. navigator \({ }^{\text {p979 }}\) • vendor \({ }^{\text {p981 }}\)
Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc.".
window . navigator \({ }^{\text {p979 }} \cdot\) vendorSub \(^{\text {p981 }}\)
Returns the empty string.
appCodeName
Must return the string "Mozilla".

Must return the string "Netscape".
appVersion
Must return either the string " 4.0 " or a string representing the version of the browser in detail, e.g. " 1.0 (VMS; en-US)
Mellblomenator/9000".
platform
Must return either the empty string or a string representing the platform on which the browser is executing, e.g. "MacIntel", "Win32", "FreeBSD i386", "WebTV OS".
product
Must return the string "Gecko".
productSub
Must return the appropriate string from the following list:
\(\rightarrow\) If the navigator compatibility mode \({ }^{\text {p980 }}\) is Chrome or WebKit The string "20030107".
\(\hookrightarrow\) If the navigator compatibility mode \({ }^{\text {p980 }}\) is Gecko
The string "20100101".
userAgent
Must return the default `User-Agent` value.
vendor
Must return the appropriate string from the following list:
\(\hookrightarrow\) If the navigator compatibility mode \({ }^{\text {p980 }}\) is Chrome The string "Google Inc.".
\(\rightarrow\) If the navigator compatibility mode \({ }^{\text {p980 }}\) is Gecko The empty string.
\(\rightarrow\) If the navigator compatibility mode \({ }^{\text {p980 }}\) is WebKit The string "Apple Computer, Inc.".
vendorSub
Must return the empty string.
If the navigator compatibility mode \({ }^{p 980}\) is Gecko, then the user agent must also support the following partial interface:
```
IDL partial interface mixin NavigatorID {
    [Exposed=Window] boolean taintEnabled(); // constant false
    [Exposed=Window] readonly attribute DOMString oscpu;
};
```

The taintEnabled() method must return false.

The oscpu attribute's getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. "Windows NT 10.0; Win64; x64", "Linux x86_64".

\section*{\(\triangle\) Warning!}

Any information in this API that varies from user to user can be used to profile the user: In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.

IDL interface mixin NavigatorLanguage \{
readonly attribute DOMString language;
    readonly attribute FrozenArray<DOMString> languages;
\};

For web developers (non-normative)
self. navigator \({ }^{\text {p979 }} \cdot\) language \(^{\text {p982 }}\)
Returns a language tag representing the user's preferred language.
self . navigator \({ }^{\text {p979 }} \cdot\) languages \(^{\text {p982 }}\)
Returns an array of language tags representing the user's preferred languages, with the most preferred language first. The most preferred language is the one returned by navigator. language \({ }^{\text {p982 }}\).

\section*{Note}

A languagechange \({ }^{\text {p1281 }}\) event is fired at the Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object when the user agent's understanding of what the user's preferred languages are changes.

\section*{language}

Must return a valid BCP 47 language tag representing either a plausible language \({ }^{\text {p982 }}\) or the user's most preferred language. [BCP47] \({ }^{p 1285}\)

\section*{languages}

Must return a frozen array of valid BCP 47 language tags representing either one or more plausible languages \({ }^{\text {p982 }}\), or the user's preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [BCP47] \({ }^{\text {p1285 }}\)

Whenever the user agent needs to make the navigator. languages \({ }^{\text {p982 }}\) attribute of a Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object global return a new set of language tags, the user agent must queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given global to fire an event named languagechange \({ }^{\text {p1281 }}\) at global, and wait until that task begins to be executed before actually returning a new value.

To determine a plausible language, the user agent should bear in mind the following:
- Any information in this API that varies from user to user can be used to profile or identify the user.
- If the user is not using a service that obfuscates the user's point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [TOR] \({ }^{\text {p1291 }}\)
- If the user is using an anonymizing service, then the value "en-US" is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP `Accept-Language` header.
8.9.1.3 Custom scheme handlers: the registerProtocolHandler () \({ }^{\text {p983 }}\) method \(\S^{\text {p98 }}\)

IDL interface mixin NavigatorContentUtils \{ [SecureContext] undefined registerProtocolHandler(DOMString scheme, USVString url); [SecureContext] undefined unregisterProtocolHandler(DOMString scheme, USVString url);
\};

\section*{For web developers (non-normative)}
window . navigator \({ }^{\text {p979 }}\) • registerProtocolHandler \({ }^{\text {p983 }}\) (scheme, url)
Registers a handler for scheme at url. For example, an online telephone messaging service could register itself as a handler of the sms: scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. [SMS] \({ }^{\text {p1291 }}\)

The string "\%s" in url is used as a placeholder for where to put the URL of the content to be handled.
Throws a "SecurityError" DOMException if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a "SyntaxError" DOMException if the "\%s" string is missing in url.
window . navigator \({ }^{\text {p979 }}\). unregisterProtocolHandler \({ }^{\text {p983 }}\) (scheme, url)
Unregisters the handler given by the arguments.
Throws a "SecurityError" DOMException if the user agent blocks the deregistration (this might happen if with invalid schemes, for instance).

Throws a "SyntaxError" DOMException if the "\%s" string is missing in url.

The registerProtocolHandler(scheme, url) method steps are:
1. Let (normalizedScheme, normalizedURLString) be the result of running normalize protocol handler parameters \({ }^{\text {p984 }}\) with scheme, url, and this's relevant settings object \({ }^{\text {p924 }}\).
2. In parallel \({ }^{\text {p42 }}\) : register a handler for normalizedScheme and normalizedURLString. User agents may, within the constraints described, do whatever they like. A user agent could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. User agents could also silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

When the user agent uses this handler for a URL inputURL:
1. Assert: inputURL's scheme is normalizedScheme.
2. Let inputURLString be the serialization of inputURL.
3. Let encodedURL be the result of running UTF-8 percent-encode on inputURLString using the component percentencode set.
4. Let handlerURLString be normalizedURLString.
5. Replace the first instance of "\%s" in handlerURLString with encodedURL.
6. Let resultURL be the result of parsing handlerURLString.
7. Navigate \({ }^{\mathrm{p} 866}\) an appropriate browsing context \({ }^{\mathrm{p} 811}\) to resultURL.

\section*{Example}

If the user had visited a site at https://example.com/ that made the following call:
```
navigator.registerProtocolHandler('web+soup', 'soup?url=%s', 'SoupWebm')
```
...and then, much later, while visiting https://www. example. net/, clicked on a link such as:
<a href="web+soup:chicken-kïwi">Download our Chicken Kïwi soup!</a>
...then the UA might navigate to the following URL:
```
https://example.com/soup?url=web+soup:chicken-k%C3%AFwi
```

This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).
This does not define when the handler is used. To some extent, the processing model for navigating across documents \({ }^{\text {p866 }}\) defines some cases where it is relevant, but in general user agents may use this information wherever they would otherwise consider handing schemes to native plugins or helper applications.

The unregisterProtocolHandler(scheme, url) method steps are:
1. Let (normalizedScheme, normalizedURLString) be the result of running normalize protocol handler parameters \({ }^{\text {p984 }}\) with
scheme, url, and this's relevant settings object \({ }^{\text {p924 }}\).
2. In parallel \({ }^{\mathrm{p42}}\) : unregister the handler described by normalizedScheme and normalizedURLString.

To normalize protocol handler parameters, given a string scheme, a string url, and an environment settings object \({ }^{\text {p917 }}\) environment, run these steps:
1. Set scheme to scheme, converted to ASCII lowercase.
2. If scheme is neither a safelisted scheme \({ }^{\text {p984 }}\) nor a string starting with "web+" followed by one or more ASCII lower alphas, then throw a "SecurityError" DOMException.

\section*{Note}

This means that including a colon in scheme (as in "mailto:") will throw.
The following schemes are the safelisted schemes:
```
- bitcoin
- geo
- im
- irc
- ircs
- magnet
- mailto
- mms
- news
- nntp
- openpgp4fpr
- sip
- sms
- smsto
- ssh
- tel
- urn
- webcal
- wtai
- xmpp
```

Note
This list can be changed. If there are schemes that ought to be added, please send feedback.
3. If url does not contain "\%s", then throw a "SyntaxError" DOMException.
4. Parse \({ }^{\text {p89 }}\) url relative to environment.
5. If that fails, then throw a "SyntaxError" DOMException.

\section*{Note}

This is forcibly the case if the \%s placeholder is in the host or port of the URL.
6. If the resulting URL record \({ }^{\mathrm{p89}} \mathrm{~s}\) scheme is not "https" or the resulting URL record \({ }^{\mathrm{p89}}\) 's origin is not same origin \({ }^{\mathrm{p838}}\) with environment's origin \({ }^{\text {p917 }}\), then throw a "SecurityError" DOMException.
7. Return (scheme, resulting URL string \({ }^{\mathrm{p89}}\) ).

\section*{Note}

The resulting URL string \({ }^{\text {p89 }}\) will by definition not be a valid URL string as it includes the string "\%s" which is not a valid component in a URL.

\subsection*{8.9.1.3.1 Security and privacy \({ }_{8}^{\text {p98 }}\)}

Custom scheme handlers can introduce a number of concerns, in particular privacy concerns.
Hijacking all web usage. User agents should not allow schemes that are key to its normal operation, such as an \(\mathrm{HTTP}(\mathrm{S})\) scheme, to be rerouted through third-party sites. This would allow a user's activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

Hijacking defaults. User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

Registration spamming. User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for web+spam: - analogous practices abusing other web browser features have been used by pornography web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

Hostile handler metadata. User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that overlong strings do not cause crashes or buffer overruns, and so forth.

Leaking private data. Web page authors may reference a custom scheme handler using URL data considered private. They might do so with the expectation that the user's choice of handler points to a page inside the organization, ensuring that sensitive data will not be exposed to third parties. However, a user may have registered a handler pointing to an external site, resulting in a data leak to that third party. Implementors might wish to consider allowing administrators to disable custom handlers on certain subdomains, content types, or schemes.

Leaking credentials. User agents must never send username or password information in the URLs that are escaped and included sent to the handler sites. User agents may even avoid attempting to pass to web-based handlers the URLs of resources that are known to require authentication to access, as such sites would be unable to access the resources in question without prompting the user for credentials themselves (a practice that would require the user to know whether to trust the third-party handler, a decision many users are unable to make or even understand).

Interface interference. User agents should be prepared to handle intentionally long arguments to the methods. For example, if the user interface exposed consists of an "accept" button and a "deny" button, with the "accept" binding containing the name of the handler, it's important that a long name not cause the "deny" button to be pushed off the screen.

\subsection*{8.9.1.4 Cookies \(\S^{\text {p98 }}\)}

IDL interface mixin NavigatorCookies \{ readonly attribute boolean cookieEnabled;
\};

\section*{For web developers (non-normative)}
window . navigator \({ }^{\text {p979 }} \cdot\) cookieEnabled \({ }^{\text {p985 }}\)
Returns false if setting a cookie will be ignored, and true otherwise.

The cookieEnabled attribute must return true if the user agent attempts to handle cookies according to HTTP State Management Mechanism, and false if it ignores cookie change requests. [COOKIES] \({ }^{\text {p1285 }}\)

\subsection*{8.9.1.5 Plugins \(\S^{p 98}\)}
```
interface mixin NavigatorPlugins {
    [SameObject] readonly attribute PluginArray plugins;
    [SameObject] readonly attribute MimeTypeArray mimeTypes;
    boolean javaEnabled();
};
[Exposed=Window,
    LegacyUnenumerableNamedProperties]
interface PluginArray {
    undefined refresh(optional boolean reload = false);
    readonly attribute unsigned long length;
    getter Plugin? item(unsigned long index);
    getter Plugin? namedItem(DOMString name);
};
```
```
[Exposed=Window,
LegacyUnenumerableNamedProperties]
interface MimeTypeArray {
    readonly attribute unsigned long length;
    getter MimeType? item(unsigned long index);
    getter MimeType? namedItem(DOMString name);
};
[Exposed=Window,
LegacyUnenumerableNamedProperties]
interface Plugin {
    readonly attribute DOMString name;
    readonly attribute DOMString description;
    readonly attribute DOMString filename;
    readonly attribute unsigned long length;
    getter MimeType? item(unsigned long index);
    getter MimeType? namedItem(DOMString name);
};
[Exposed=Window]
interface MimeType {
    readonly attribute DOMString type;
    readonly attribute DOMString description;
    readonly attribute DOMString suffixes; // comma-separated
    readonly attribute Plugin enabledPlugin;
};
```

\section*{For web developers (non-normative)}

\section*{window . navigator \({ }^{\text {p979 }}\) • plugins \({ }^{\text {p987 }}\) • refresh \({ }^{\text {p988 }}\) ([ refresh ])}

Updates the lists of supported plugins and MIME types for this page, and reloads the page if the lists have changed.
window . navigator \({ }^{\text {p979 }} \cdot\) plugins \(^{\text {p987 }} \cdot\) length \(^{\text {p988 }}\)
Returns the number of plugins, represented by Plugin \({ }^{\text {p986 }}\) objects, that the user agent reports.
plugin \(=\) window \(\cdot\) navigator \({ }^{\text {p979 }} \cdot\) plugins \(^{\text {p987 }} \cdot\) item \(^{\text {p988 }}\) (index)
window . navigator \({ }^{\text {p979 }}\). plugins \({ }^{\text {p987 }}\) [index]
Returns the specified Plugin \({ }^{\text {p986 }}\) object.
plugin \(=\) window \(\cdot\) navigator \(^{\text {p979 }} \cdot\) plugins \(^{\text {p987 }} \cdot\) item \(^{\text {p988 }}(\) name \()\)
window . navigator \({ }^{\text {p979 }}\). plugins \({ }^{\text {p987 }}\) [name]
Returns the Plugin \({ }^{\text {p986 }}\) object for the plugin with the given name.
window. navigator \({ }^{\text {p979 }} \cdot\) mimeTypes \(^{\text {p987 }} \cdot\) length \({ }^{\text {p988 }}\)
Returns the number of MIME types, represented by MimeType \({ }^{\text {p986 }}\) objects, supported by the plugins that the user agent reports.
mimeType \(=\) window \(\cdot\) navigator \({ }^{\text {p979 }} \cdot\) mimeTypes \(^{\text {p987 }} \cdot\) item \(^{\text {p988 }}\) (index)
window . navigator \({ }^{\text {p979 }} \cdot\) mimeTypes \({ }^{\text {p987 }}\) [index]
Returns the specified MimeType \({ }^{\text {p986 }}\) object.
mimeType \(=\) window \(\cdot\) navigator \({ }^{\text {p979 }}\). mimeTypes \({ }^{\text {p987 }} \cdot\) item \(^{\text {p988 }}\) (name)
window. navigator \({ }^{\text {p979 }}\). mimeTypes \({ }^{\text {p987 }}\) [name]
Returns the MimeType \({ }^{\text {p986 }}\) object for the given MIME type.
plugin . name \({ }^{\text {p989 }}\)
Returns the plugin's name.
plugin. description \({ }^{\text {p989 }}\)
Returns the plugin's description.
plugin.filename \({ }^{\text {p989 }}\)
Returns the plugin library's filename, if applicable on the current platform.

\section*{plugin. length \({ }^{\text {p989 }}\)}

Returns the number of MIME types, represented by MimeType \({ }^{\text {p986 }}\) objects, supported by the plugin.

\section*{mimeType \(=\) plugin. item \(^{\text {p989 }}(\) index \()\)}

\section*{plugin[index]}

Returns the specified MimeType \({ }^{\text {p986 }}\) object.
mimeType \(=\) plugin. item \({ }^{\text {p989 }}\) (name)
plugin[name]
Returns the MimeType \({ }^{\text {p986 }}\) object for the given MIME type.

\section*{mimeType. type \({ }^{\text {p989 }}\)}

Returns the MIME type.

\section*{mimeType . description \({ }^{\text {p989 }}\)}

Returns the MIME type's description.

\section*{mimeType. suffixes \({ }^{\text {p989 }}\)}

Returns the MIME type's typical file extensions, in a comma-separated list.

\section*{mimeType . enabledPlugin \({ }^{\text {p990 }}\)}

Returns the Plugin \({ }^{\text {p986 }}\) object that implements this MIME type.
window . navigator \({ }^{\text {p979 }} \cdot{\text { javaEnabled ( })^{\text {p990 }}}^{\text {jab }}\)
Returns true if there's a plugin that supports the MIME type "application/x-java-vm".

The navigator. plugins attribute must return a PluginArray \({ }^{\text {p985 }}\) object.
The navigator.mimeTypes attribute must return a MimeTypeArray \({ }^{\text {p986 }}\) object.

A PluginArray \({ }^{\text {p985 }}\) object represents none, some, or all of the plugins \({ }^{\text {p45 }}\) supported by the user agent, each of which is represented by a Plugin \({ }^{\text {p986 }}\) object. Each of these Plugin \({ }^{\text {p986 }}\) objects may be hidden plugins. A hidden plugin \({ }^{\text {p987 }}\) can't be enumerated, but can still be inspected by using its name.

\section*{Note}

The fewer plugins \({ }^{\text {p45 }}\) are represented by the PluginArray \({ }^{\text {p985 }}\) object, and of those, the more that are hidden \({ }^{\text {p987 }}\), the more the user's privacy will be protected. Each exposed plugin increases the number of bits that can be derived for fingerprinting. Hiding a plugin helps, but unless it is an extremely rare plugin, it is likely that a site attempting to derive the list of plugins can still determine whether the plugin is supported or not by probing for it by name (the names of popular plugins are widely known). Therefore not exposing a plugin at all is preferred. Unfortunately, many legacy sites use this feature to determine, for example, which plugin to use to play video. Not exposing any plugins at all might therefore not be entirely plausible.

The PluginArray \({ }^{\text {p985 }}\) objects created by a user agent must not be live \({ }^{\text {p45 }}\). The set of plugins represented by the objects must not change once an object is created, except when it is updated by the refresh () \({ }^{\text {p988 }}\) method.

Each plugin \({ }^{\text {p45 }}\) represented by a PluginArray \({ }^{\text {p985 }}\) can support a number of MIME types. For each such plugin \({ }^{\text {p45 }}\), the user agent must pick one or more of these MIME types to be those that are explicitly supported.

\section*{Note}

The explicitly supported \({ }^{p 987}\) MIME types of a plugin \({ }^{\text {p45 }}\) are those that are exposed through the Plugin \({ }^{\text {p986 }}\) and MimeTypeArray \({ }^{\text {p986 }}\) interfaces. As with plugins \({ }^{p 45}\) themselves, any variation between users regarding what is exposed allows sites to fingerprint users. User agents are therefore encouraged to expose the same MIME types for all users of a plugin \({ }^{\text {p45 }}\), regardless of the actual types supported... at least, within the constraints imposed by compatibility with legacy content.

The supported property indices of a PluginArray \({ }^{\text {p985 }}\) object are the numbers from zero to the number of non-hidden \({ }^{\text {p987 }}\) plugins \({ }^{\text {p45 }}\) represented by the object, if any.

The length attribute must return the number of non-hidden \({ }^{\text {p987 }}\) plugins \({ }^{\text {p45 }}\) represented by the object.
The item() method of a PluginArray \({ }^{\text {p985 }}\) object must return null if the argument is not one of the object's supported property indices, and otherwise must return the result of running the following steps, using the method's argument as index:
1. Let list be the Plugin \({ }^{\text {p986 }}\) objects representing the non-hidden \({ }^{\text {p987 }}\) plugins \({ }^{\text {p45 }}\) represented by the PluginArray \({ }^{\text {p985 }}\) object.
2. Sort list alphabetically by the name \({ }^{\text {p989 }}\) of each Plugin \({ }^{\text {p986 }}\).
3. Return the indexth entry in list.

\section*{Note}

It is important for privacy that the order of plugins not leak additional information, e.g., the order in which plugins were installed.

The supported property names of a PluginArray \({ }^{\text {p985 }}\) object are the values of the name \({ }^{\text {p989 }}\) attributes of all the Plugin \({ }^{\text {p986 }}\) objects represented by the PluginArray \({ }^{\text {p985 }}\) object.

The namedItem() method of a PluginArray \({ }^{\text {p985 }}\) object must return null if the argument is not one of the object's supported property names, and otherwise must return the Plugin \({ }^{\text {p986 }}\) object, of those represented by the PluginArray \({ }^{\text {p985 }}\) object, that has a name \({ }^{\text {p989 }}\) equal to the method's argument.

The refresh() method of the PluginArray \({ }^{\text {p985 }}\) object of a Navigator \({ }^{\text {p979 }}\) object, when invoked, must check to see if any plugins \({ }^{\text {p45 }}\) have been installed or reconfigured since the user agent created the PluginArray \({ }^{p 985}\) object. If so, and the method's argument is true, then the user agent must act as if the location. reload ( \()^{\text {p863 }}\) method was called instead. Otherwise, the user agent must update the PluginArray \({ }^{\text {p985 }}\) object and MimeTypeArray \({ }^{\text {p986 }}\) object created for attributes of that Navigator \({ }^{\text {p979 }}\) object, and the Plugin \({ }^{\text {p986 }}\) and MimeType \({ }^{\text {p986 }}\) objects created for those PluginArray \({ }^{\text {p985 }}\) and MimeTypeArray \({ }^{\text {p986 }}\) objects, using the same Plugin \({ }^{\text {p986 }}\) objects for cases where the name \({ }^{\text {p989 }}\) is the same, and the same MimeType \({ }^{\text {p986 }}\) objects for cases where the type \({ }^{\text {p989 }}\) is the same, and creating new objects for cases where there were no matching objects immediately prior to the refresh() \()^{\text {p988 }}\) call. Old Plugin \({ }^{\text {p986 }}\) and MimeType \({ }^{\text {p986 }}\) objects must continue to return the same values that they had prior to the update, though naturally now the data is stale and may appear inconsistent (for example, an old MimeType \({ }^{\text {p986 }}\) entry might list as its enabledPlugin \({ }^{\text {p998 }}\) a Plugin \({ }^{\text {p986 }}\) object that no longer lists that MimeType \({ }^{\text {p986 }}\) as a supported MimeType \({ }^{\text {p9866 }}\) ).

A MimeTypeArray \({ }^{\text {p986 }}\) object represents the MIME types explicitly supported \({ }^{\text {p987 }}\) by plugins \({ }^{\text {p45 }}\) supported by the user agent, each of which is represented by a MimeType \({ }^{\text {p986 }}\) object.

The MimeTypeArray \({ }^{\text {p986 }}\) objects created by a user agent must not be live \({ }^{\text {p45 }}\). The set of MIME types represented by the objects must not change once an object is created, except when it is updated by the PluginArray \({ }^{\text {p985 }}\) object's refresh() \({ }^{\text {p988 }}\) method.

The supported property indices of a MimeTypeArray \({ }^{\text {p986 }}\) object are the numbers from zero to the number of MIME types explicitly supported \({ }^{\text {p987 }}\) by non-hidden \({ }^{\text {p987 }}\) plugins \({ }^{\text {p45 }}\) represented by the corresponding PluginArray \({ }^{\text {p985 }}\) object, if any.

The length attribute must return the number of MIME types explicitly supported \({ }^{\text {p987 }}\) by non-hidden \({ }^{\text {p987 }}\) plugins \({ }^{\text {p45 }}\) represented by the corresponding PluginArray \({ }^{\text {p985 }}\) object, if any.

The item() method of a MimeTypeArray \({ }^{\text {p986 }}\) object must return null if the argument is not one of the object's supported property indices, and otherwise must return the result of running the following steps, using the method's argument as index:
1. Let list be the MimeType \({ }^{\text {p986 }}\) objects representing the MIME types explicitly supported \({ }^{\text {p987 }}\) by non-hidden \({ }^{\text {p987 }}\) plugins \(^{\text {p45 }}\) represented by the corresponding PluginArray \({ }^{\text {p985 }}\) object, if any.
2. Sort list alphabetically by the type \({ }^{\mathrm{p989}}\) of each MimeType \({ }^{\mathrm{p986}}\).
3. Return the indexth entry in list.

\section*{Note}

It is important for privacy that the order of MIME types not leak additional information, e.g., the order in which plugins were installed.

The supported property names of a MimeTypeArray \({ }^{\text {p986 }}\) object are the values of the type \({ }^{\text {p989 }}\) attributes of all the MimeType \({ }^{\text {p986 }}\) objects represented by the MimeTypeArray \({ }^{\text {p986 }}\) object.

The namedItem() method of a MimeTypeArray \({ }^{\text {p986 }}\) object must return null if the argument is not one of the object's supported property names, and otherwise must return the MimeType \({ }^{\text {p986 }}\) object that has a type \({ }^{\text {p989 }}\) equal to the method's argument.

A Plugin \({ }^{\text {p986 }}\) object represents a plugin \({ }^{\text {p45 }}\). It has several attributes to provide details about the plugin, and can be enumerated to obtain the list of MIME types that it explicitly supports \({ }^{\text {p987 }}\).

The Plugin \({ }^{\text {p986 }}\) objects created by a user agent must not be live \({ }^{\text {p45 }}\). The set of MIME types represented by the objects, and the values of the objects' attributes, must not change once an object is created, except when updated by the PluginArray \({ }^{\text {p985 }}\) object's refresh() \({ }^{\text {p988 }}\) method.

The reported MIME types for a Plugin \({ }^{\text {p986 }}\) object are the MIME types explicitly supported \({ }^{\text {p987 }}\) by the corresponding plugin \({ }^{\text {p45 }}\) when this object was last created or updated by refresh() \({ }^{\text {p988 }}\), whichever happened most recently.

The supported property indices of a Plugin \({ }^{\text {p986 }}\) object are the numbers from zero to the number of reported MIME types \({ }^{\text {p989 }}\).
The length attribute must return the number of reported MIME types \({ }^{\text {p989 }}\).
The item() method of a Plugin \({ }^{\text {p986 }}\) object must return null if the argument is not one of the object's supported property indices, and otherwise must return the result of running the following steps, using the method's argument as index:
1. Let list be the MimeType \({ }^{\text {p986 }}\) objects representing the reported MIME types \({ }^{\text {p989 }}\).
2. Sort list alphabetically by the type \({ }^{\text {p989 }}\) of each MimeType \({ }^{\text {p986 }}\).
3. Return the indexth entry in list.

\section*{Note}

It is important for privacy that the order of MIME types not leak additional information, e.g., the order in which plugins were installed.

The supported property names of a Plugin \({ }^{\text {p986 }}\) object are the values of the type \({ }^{\text {p989 }}\) attributes of the MimeType \({ }^{\text {p986 }}\) objects representing the reported MIME types \({ }^{\text {p989 }}\).

The namedItem() method of a Plugin \({ }^{\text {p986 }}\) object must return null if the argument is not one of the object's supported property names, and otherwise must return the MimeType \({ }^{\text {p986 }}\) object that has a type \({ }^{\text {p989 }}\) equal to the method's argument.

The name attribute must return the plugin \({ }^{\text {p45 }}\) 's name.
The description and filename attributes must return implementation-defined (in all likelihood, plugin \({ }^{\text {p45 }}\)-defined) strings. In each case, the same string must be returned each time, except that the strings returned may change when the refresh() \({ }^{\text {p988 }}\) method updates the object.

\section*{\(\triangle\) Warning!} If the values returned by the description \({ }^{\text {p989 }}\) or filename \({ }^{\text {p989 }}\) attributes vary between versions of a plugin \({ }^{\text {p45 }}\), they can be used both as a fingerprinting vector and, even more importantly, as a trivial way to determine what security vulnerabilities a plugin \({ }^{\text {p45 }}\) (and thus a browser) may have. It is thus highly recommended that the description \({ }^{\text {p989 }}\) attribute just return the same value as the name \({ }^{\text {p989 }}\) attribute, and that the filename \({ }^{\text {p989 }}\) attribute return the empty string.

\section*{A MimeType \({ }^{\text {p986 }}\) object represents a MIME type that is, or was, explicitly supported \({ }^{\text {p987 }}\) by a plugin \({ }^{\text {p45 }}\).}

The MimeType \({ }^{\text {p986 }}\) objects created by a user agent must not be live \({ }^{\text {p45 }}\). The values of the objects' attributes must not change once an object is created, except when updated by the PluginArray \({ }^{\text {p985 }}\) object's refresh() \({ }^{\text {p988 }}\) method.

The type attribute must return the valid MIME type string with no parameters describing the MIME type.
The description and suffixes attributes must return implementation-defined (in all likelihood, plugin \({ }^{\text {p45 }}\)-defined) strings. In each
case, the same string must be returned each time, except that the strings returned may change when the refresh() \({ }^{\text {p988 }}\) method updates the object.

\section*{\(\triangle\) Warning!}

If the values returned by the description \({ }^{\text {p989 }}\) or suffixes \({ }^{\text {p989 }}\) attributes vary between versions of a plugin \({ }^{\text {p45 }}\), they can be used both as a fingerprinting vector and, even more importantly, as a trivial way to determine what security vulnerabilities a plugin \({ }^{\text {p45 }}\) (and thus a browser) may have. It is thus highly recommended that the description \({ }^{\text {p989 }}\) attribute just return the same value as the type \({ }^{\text {p989 }}\) attribute, and that the suffixes \({ }^{\text {p989 }}\) attribute return the empty string.

\section*{Note}

Commas in the suffixes \({ }^{\text {p989 }}\) attribute are interpreted as separating subsequent filename extensions, as in "htm, html".

The enabledPlugin attribute must return the Plugin \({ }^{\text {p986 }}\) object that represents the plugin \({ }^{\text {p45 }}\) that explicitly supported \({ }^{\text {p987 }}\) the MIME type that this MimeType \({ }^{\text {p986 }}\) object represents when this object was last created or updated by refresh ( \()^{\text {p988 }}\), whichever happened most recently.

The navigator. javaEnabled() method must return true if the user agent supports a plugin \({ }^{\text {p45 }}\) that supports the MIME type "application/x-java-vm"; otherwise it must return false.

\subsection*{8.10 Images \(\S^{p 99}\)}

IDL [Exposed=(Window,Worker), Serializable, Transferable]
interface ImageBitmap \{
    readonly attribute unsigned long width;
    readonly attribute unsigned long height;
    undefined close();
\};
typedef (CanvasImageSource or
                        Blob or
                        ImageData) ImageBitmapSource;
enum ImageOrientation \{ "none", "flipY" \};
enum PremultiplyAlpha \{ "none", "premultiply", "default" \};
enum ColorSpaceConversion \{ "none", "default" \};
enum ResizeQuality \{ "pixelated", "low", "medium", "high" \};
dictionary ImageBitmapOptions \{
    ImageOrientation imageOrientation = "none";
    PremultiplyAlpha premultiplyAlpha = "default";
    ColorSpaceConversion colorSpaceConversion = "default";
    [EnforceRange] unsigned long resizeWidth;
    [EnforceRange] unsigned long resizeHeight;
    ResizeOuality resizeOuality = "low";
\};

An ImageBitmap \({ }^{p 99 \theta}\) object represents a bitmap image that can be painted to a canvas without undue latency.

\section*{Note}

The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.
```
promise = self . createImageBitmap }\mp@subsup{}{}{\mathrm{ p992 (image [, options ])}
promise = self . createImageBitmapp992(image, sx, sy, sw, sh [, options ])
```

Takes image, which can be an img \({ }^{\text {p320 }}\) element, an SVG image element, a video \({ }^{\text {p380 }}\) element, a canvas \({ }^{p 634}\) element, a Blob object, an ImageData \({ }^{\text {p642 }}\) object, or another ImageBitmap \({ }^{\text {p998 }}\) object, and returns a promise that is resolved when a new ImageBitmap \({ }^{\text {p990 }}\) is created.
If no ImageBitmap \({ }^{\text {p998 }}\) object can be constructed, for example because the provided image data is not actually an image, then the promise is rejected instead.

If \(s x, s y, s w\), and \(s h\) arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by transparent black. These coordinates are in the source image's pixel coordinate space, not in CSS pixels.

If options is provided, the ImageBitmap \({ }^{\text {p99e }}\) object's bitmap data is modified according to options. For example, if the premultiplyAlpha \({ }^{\text {p994 }}\) option is set to "premultiply \({ }^{\text {p994" }}\), the bitmap data \({ }^{\text {p9911' }}\) s color channels are premultiplied by its alpha channel.
Rejects the promise with an "InvalidStateError" DOMException if the source image is not in a valid state (e.g., an img \({ }^{\text {p320 }}\) element that hasn't loaded successfully, an ImageBitmap \({ }^{\text {p990 }}\) object whose [[Detached] \(]^{\text {p104 }}\) internal slot value is true, an ImageData \({ }^{\text {p642 }}\) object whose data \({ }^{\text {p676 }}\) attribute value's [[ViewedArrayBuffer]] internal slot is detached, or a Blob whose data cannot be interpreted as a bitmap image).

Rejects the promise with a "SecurityError" DOMException if the script is not allowed to access the image data of the source image (e.g. a video \({ }^{\text {p388 }}\) that is CORS-cross-origin \({ }^{\text {p90 }}\), or a canvas \({ }^{\text {p634 }}\) being drawn on by a script in a worker from another origin \({ }^{\text {p837 }}\) )

\section*{imageBitmap . close \({ }^{\text {p994 }}\) ()}

Releases imageBitmap's underlying bitmap data \({ }^{\text {p991 }}\).
imageBitmap . width \({ }^{\text {p994 }}\)
Returns the intrinsic width of the image, in CSS pixels.
imageBitmap . height \({ }^{\text {p994 }}\)
Returns the intrinsic height of the image, in CSS pixels.

An ImageBitmap \({ }^{\text {p99e }}\) object whose [[Detached] \(]^{\text {p104 }}\) internal slot value is false always has associated bitmap data, with a width and a height. However, it is possible for this data to be corrupted. If an ImageBitmap \({ }^{p 999}\) object's media data can be decoded without errors, it is said to be fully decodable.

An ImageBitmap \({ }^{\text {p998 }}\) object's bitmap has an origin-clean \({ }^{\text {p635 }}\) flag, which indicates whether the bitmap is tainted by content from a different origin \({ }^{\text {p837 }}\). The flag is initially set to true and may be changed to false by the steps of createImageBitmap ( ) \({ }^{\text {p992 }}\).

ImageBitmap \({ }^{\text {p990 }}\) objects are serializable objects \({ }^{\text {p102 }}\) and transferable objects \({ }^{\text {p103 }}\).
Their serialization steps \({ }^{\text {p102 }}\), given value and serialized, are:
1. If value's origin-clean \({ }^{\text {p635 }}\) flag is not set, then throw a "DataCloneError" DOMException.
2. Set serialized.[[BitmapData]] to a copy of value's bitmap data \({ }^{\text {p991 }}\).

Their deserialization steps \({ }^{\text {p103 }}\), given serialized and value, are:
1. Set value's bitmap data \({ }^{\text {p991 }}\) to serialized.[[BitmapData]].

Their transfer steps \({ }^{\text {p104 }}\), given value and dataHolder, are:
1. If value's origin-clean \({ }^{\text {p635 }}\) flag is not set, then throw a "DataCloneError" DOMException.
2. Set dataHolder.[[BitmapData]] to value's bitmap data \({ }^{\text {p991 }}\).
3. Unset value's bitmap data \({ }^{\text {p991 }}\).

Their transfer-receiving steps \({ }^{\text {p104 }}\), given dataHolder and value, are:
1. Set value's bitmap data \({ }^{\text {p9911 }}\) to dataHolder.[[BitmapData]].

The createImageBitmap(image, options) and createImageBitmap(image \(s x, s y, s w, ~ s h, o p t i o n s)\) methods, when invoked, must run these steps:
1. Let \(p\) be a new promise.
2. If either \(s w\) or \(s h\) is given and is 0 , then return \(p\) rejected with a RangeError.
3. If either options's resizeWidth or options's resizeHeight is present and is 0 , then return \(p\) rejected with an "InvalidStateError" DOMException.
4. Check the usability of the image argument \({ }^{\text {p662 }}\). If this throws an exception or returns bad, then return \(p\) rejected with an "InvalidStateError" DOMException.
5. Let imageBitmap be a new ImageBitmap \({ }^{p 99 \theta}\) object.
6. Switch on image:
\(\rightarrow\) img \(^{\text {p320 }}\)
\(\rightarrow\) SVG image
1. If image's media data has no intrinsic dimensions (e.g., it's a vector graphic with no specified content size) and either options's resizeWidth \({ }^{\text {p992 }}\) or options's resizeHeight \({ }^{\text {p992 }}\) is not present, then return \(p\) rejected with an "InvalidStateError" DOMException.
2. If image's media data has no intrinsic dimensions (e.g., it's a vector graphics with no specified content size), it should be rendered to a bitmap of the size specified by the resizeWidth \({ }^{\text {p992 }}\) and the resizeHeight \({ }^{\text {p992 }}\) options.
3. Set imageBitmap's bitmap data \({ }^{\text {p991 }}\) to a copy of image's media data, cropped to the source rectangle with formatting \({ }^{\text {p993 }}\). If this is an animated image, imageBitmap's bitmap data \({ }^{\text {p991 }}\) must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
4. If the origin \({ }^{\text {p837 }}\) of image's image is not same origin \({ }^{\text {p838 }}\) with entry settings object \({ }^{\text {p921 }}\) 's origin \({ }^{\text {p917 }}\), then set the origin-clean \({ }^{\text {p635 }}\) flag of imageBitmap's bitmap to false.
5. Run this step in parallel \({ }^{\mathrm{p} 42}\) :
1. Resolve \(p\) with imageBitmap.
\(\rightarrow\) video \(^{\text {p380 }}\)
1. If image's networkState \({ }^{\mathrm{p} 392}\) attribute is NETWORK_EMPTY \({ }^{\mathrm{p} 392}\), then return \(p\) rejected with an "InvalidStateError" DOMException.
2. Set imageBitmap's bitmap data \({ }^{\text {p991 }}\) to a copy of the frame at the current playback position \({ }^{\text {p404 }}\), at the media resource \({ }^{\mathrm{p} 389}\) 's intrinsic width \({ }^{\mathrm{p} 382}\) and intrinsic height \({ }^{\mathrm{p} 382}\) (i.e., after any aspect-ratio correction has been applied), cropped to the source rectangle with formatting \({ }^{\text {p993 }}\).
3. If the origin \({ }^{\mathrm{p} 837}\) of image's video is not same origin \({ }^{\mathrm{p} 838}\) with entry settings object \({ }^{\mathrm{p} 921}\) 's origin \({ }^{\mathrm{p} 917}\), then set the origin-clean \({ }^{\text {p635 }}\) flag of imageBitmap's bitmap to false.
4. Run this step in parallel \(\left.\right|^{p 42}\) :
1. Resolve \(p\) with imageBitmap.
\(\rightarrow\) canvas \(^{\text {p634 }}\)
1. Set imageBitmap's bitmap data \({ }^{\text {p991 }}\) to a copy of image's bitmap data \({ }^{\text {p991 }}\), cropped to the source rectangle with formatting \({ }^{\text {p993 }}\).
2. Set the origin-clean \({ }^{\text {p635 }}\) flag of the imageBitmap's bitmap to the same value as the origin-clean \({ }^{\text {p635 }}\) flag of image's bitmap.
3. Run this step in parallel \({ }^{\mathrm{p} 42}\) :
1. Resolve \(p\) with imageBitmap.
\(\rightarrow\) Blob
Run these step in parallel \({ }^{\text {p42 }}\) :
1. Let imageData be the result of reading image's data. If an error occurs during reading of the object \({ }^{\text {p57 }}\), then reject \(p\) with an "InvalidStateError" DOMException and abort these steps.
2. Apply the image sniffing rules to determine the file format of imageData, with MIME type of image (as given by image's type attribute) giving the official type.
3. If imageData is not in a supported image file format (e.g., it's not an image at all), or if imageData is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no intrinsic size), then reject \(p\) with an "InvalidStateError" DOMException and abort these steps.
4. Set imageBitmap's bitmap data \({ }^{\text {p991 }}\) to imageData, cropped to the source rectangle with formatting \({ }^{\text {p993 }}\). If this is an animated image, imageBitmap's bitmap data \({ }^{\text {p991 }}\) must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
5. Resolve \(p\) with imageBitmap.
\(\rightarrow\) ImageData \({ }^{\text {p642 }}\)
1. Let buffer be image's data \({ }^{p 676}\) attribute value's [[ViewedArrayBuffer]] internal slot.
2. If IsDetachedBuffer(buffer) is true, then return \(p\) rejected with an "InvalidStateError" DOMException.
3. Set imageBitmap's bitmap data \({ }^{\text {p991 }}\) to image's image data, cropped to the source rectangle with formatting \({ }^{\text {p9933 }}\).
4. Run this step in parallel \({ }^{\mathrm{p} 42}\) :
1. Resolve \(p\) with imageBitmap.
\(\rightarrow\) ImageBitmap \(^{\text {p990 }}\)
1. Set imageBitmap's bitmap data \({ }^{\text {p991 }}\) to a copy of image's bitmap data \({ }^{\text {p991 }}\), cropped to the source rectangle with formatting \({ }^{\text {p993 }}\).
2. Set the origin-clean \({ }^{\text {p635 }}\) flag of imageBitmap's bitmap to the same value as the origin-clean \({ }^{\text {p635 }}\) flag of image's bitmap.
3. Run this step in parallel \(l^{\mathrm{p} 42}\) :
1. Resolve \(p\) with imageBitmap.
7. Return \(p\).

When the steps above require that the user agent crop bitmap data to the source rectangle with formatting, the user agent must run the following steps:
1. Let input be the bitmap data \({ }^{\text {p991 }}\) being transformed.
2. If \(s x, s y, s w\) and \(s h\) are specified, let sourceRectangle be a rectangle whose corners are the four points ( \(s x, s y\) ), ( \(s x+s w\), \(s y),(s x+s w, s y+s h),(s x, s y+s h)\). Otherwise let sourceRectangle be a rectangle whose corners are the four points ( 0,0 ), (width of input, 0 ), (width of input, height of input), ( 0 , height of input).

Note
If either sw or sh are negative, then the top-left corner of this rectangle will be to the left or above the (sx, sy) point.
3. Clip sourceRectangle to the dimensions of input.
4. Let outputWidth be determined as follows:
\(\rightarrow\) If the resizeWidth \({ }^{\text {p992 }}\) member of options is specified the value of the resizeWidth \({ }^{\text {p992 }}\) member of options
\(\rightarrow\) If the resizeWidth \({ }^{\text {p992 }}\) member of options is not specified, but the resizeHeight \({ }^{\text {p992 }}\) member is specified the width of sourceRectangle, times the value of the resizeHeight \({ }^{\text {p992 }}\) member of options, divided by the height of sourceRectangle, rounded up to the nearest integer
\(\rightarrow\) If neither resizeWidth \({ }^{\text {p992 }}\) nor resizeHeight \({ }^{\text {p992 }}\) are specified the width of sourceRectangle
5. Let outputHeight be determined as follows:
\(\rightarrow\) If the resizeHeight \({ }^{\text {p992 }}\) member of options is specified
the value of the resizeHeight \({ }^{\text {p992 }}\) member of options
\(\rightarrow\) If the resizeHeight \({ }^{\text {p992 }}\) member of options is not specified, but the resizeWidth \({ }^{\text {p992 }}\) member is specified the height of sourceRectangle, times the value of the resizeWidth \({ }^{\text {p992 }}\) member of options, divided by the width of sourceRectangle, rounded up to the nearest integer
\(\leftrightarrow\) If neither resizeWidth \({ }^{\text {p992 }}\) nor resizeHeight \({ }^{\text {p992 }}\) are specified
the height of sourceRectangle
6. Place input on an infinite transparent black grid plane, positioned so that its top left corner is at the origin of the plane, with the \(x\)-coordinate increasing to the right, and the \(y\)-coordinate increasing down, and with each pixel in the input image data occupying a cell on the plane's grid.
7. Let output be the rectangle on the plane denoted by sourceRectangle.
8. Scale output to the size specified by outputWidth and outputHeight. The user agent should use the value of the resizeQuality option to guide the choice of scaling algorithm.
9. If the value of the imageOrientation member of options is "flipY", output must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [EXIF] \({ }^{\text {p1287 }}\)

\section*{Note}

If the value is "none", no extra step is required.
10. If image is an \(\underline{i m g}{ }^{\mathrm{p} 320}\) element or a Blob object, let val be the value of the colorSpaceConversion member of options, and then run these substeps:
1. If \(v a l\) is "default", the color space conversion behavior is implementation-specific, and should be chosen according to the color space that the implementation uses for drawing images onto the canvas.
2. If val is "none", output must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.

\section*{Note}

The native color space of canvas is currently unspecified, but this is expected to change in the future.
11. Let val be the value of premultiplyAlpha member of options, and then run these substeps:
1. If \(v a l\) is "default", the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deems optimal for drawing images onto the canvas.
2. If val is "premultiply", the output that is not premultiplied by alpha must have its color components multiplied by alpha and that is premultiplied by alpha must be left untouched.
3. If val is "none", the output that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components divided by alpha.
12. Return output.

When the close() method is called, the user agent must run these steps:
1. Set this ImageBitmap \({ }^{\text {p998 }}\) object's [[Detached] \(]^{\text {p104 }}\) internal slot value to true.
2. Unset this ImageBitmap \({ }^{\text {p996 }}\) object's bitmap data \({ }^{\text {p991 }}\).

The width attribute's getter must run these steps:
1. If this ImageBitmap \({ }^{\text {p998 }}\) object's [[Detached] \(]^{p 104}\) internal slot's value is true, then return 0 .
2. Return this ImageBitmap \({ }^{\text {p998 }}\) object's width, in CSS pixels.

The height attribute's getter must run these steps:
1. If this ImageBitmap \({ }^{\text {p998 }}\) object's [[Detached]] \(]^{p 104}\) internal slot's value is true, then return 0 .
2. Return this ImageBitmap \({ }^{\text {p998 }}\) object's height, in CSS pixels.

The ResizeOuality \({ }^{\text {p998 }}\) enumeration is used to express a preference for the interpolation quality to use when scaling images.
The "pixelated" value indicates a preference to scale the image that maximizes the appearance. Scaling algorithms that "smooth" colors are acceptable, such as bilinear interpolation.

The "low" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "medium" value indicates a preference for a medium level of image interpolation quality.
The "high" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

\section*{Note}

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-scaling algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used unless the value is "pixelated \({ }^{\text {p995" }}\).

\section*{Example}

Using this API, a sprite sheet can be precut and prepared:
```
var sprites = {};
function loadMySprites() {
    var image = new Image();
    image.src = 'mysprites.png';
    var resolver;
    var promise = new Promise(function (arg) { resolver = arg });
    image.onload = function () {
        resolver(Promise.all([
            createImageBitmap(image, 0, 0, 40, 40).then(function (image) { sprites.person = image }),
            createImageBitmap(image, 40, 0, 40, 40).then(function (image) { sprites.grass = image }),
            createImageBitmap(image, 80, 0, 40, 40).then(function (image) { sprites.tree = image }),
            createImageBitmap(image, 0, 40, 40, 40).then(function (image) { sprites.hut = image }),
            createImageBitmap(image, 40, 40, 40, 40).then(function (image) { sprites.apple = image }),
            createImageBitmap(image, 80, 40, 40, 40).then(function (image) { sprites.snake = image })
            ]));
    };
    return promise;
}
function runDemo() {
    var canvas = document.querySelector('canvas#demo');
    var context = canvas.getContext('2d');
    context.drawImage(sprites.tree, 30, 10);
    context.drawImage(sprites.snake, 70, 10);
}
loadMySprites().then(runDemo);
```

\subsection*{8.11 Animation frames \(\S^{p 99}\)}

Some objects include the AnimationFrameProvider \({ }^{\text {p995 }}\) interface mixin.
IDL callback FrameRequestCallback = undefined (DOMHighResTimeStamp time);
```
interface mixin AnimationFrameProvider {
```
```
    unsigned long requestAnimationFrame(FrameRequestCallback callback);
    undefined cancelAnimationFrame(unsigned long handle);
};
Window includes AnimationFrameProvider;
DedicatedWorkerGlobalScope includes AnimationFrameProvider;
```

Each AnimationFrameProvider \({ }^{\text {p995 }}\) object also has a target object that stores the provider's internal state. It is defined as follows:
If the AnimationFrameProvider \({ }^{p 995}\) is a Window \({ }^{\text {p824 }}\)
The Window \({ }^{\text {p824 }}\) 's associated Document \({ }^{\text {p826 }}\)
If the AnimationFrameProvider \({ }^{\text {p995 }}\) is a DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\)
The DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\)
Each target object \({ }^{\text {p996 }}\) has a map of animation frame callbacks, which is an ordered map that must be initially empty, and an animation frame callback identifier, which is a number that must initially be zero.

An AnimationFrameProvider \({ }^{\text {p995 }}\) provider is considered supported if any of the following hold:
- provider is a Window \({ }^{p 824}\).
- provider's owner set \({ }^{\text {p1045 }}\) contains a Document \({ }^{\text {p114 }}\) object.
- Any of the DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) objects in provider's owner set \({ }^{\text {p1045 }}\) are supported \({ }^{\text {p996 }}\).

The requestAnimationFrame(callback) method must run the following steps:
1. If this AnimationFrameProvider \({ }^{\text {p995 }}\) is not supported \({ }^{\text {p996 }}\), then throw a "NotSupportedError" DOMException.
2. Let target be this AnimationFrameProvider \(r^{\text {p995 }}\) 's target object \({ }^{\text {p996 }}\).
3. Increment target's animation frame callback identifier \({ }^{\text {p996 }}\) by one, and let handle be the result.
4. Let callbacks be target's map of animation frame callbacks \({ }^{\text {p996 }}\).
5. Set callbacks[handle] to callback.
6. Return handle.

The cancelAnimationFrame(handle) method must run the following steps:
1. If this AnimationFrameProvider \({ }^{\text {p995 }}\) is not supported \({ }^{\text {p996 }}\), then throw a "NotSupportedError" DOMException.
2. Let callbacks be this AnimationFrameProvider \(r^{\text {p995 }}\) 's target object \({ }^{\text {p996' }}\) 's map of animation frame callbacks \({ }^{\text {p996 }}\).
3. Remove callbacks[handle].

To run the animation frame callbacks for a target object \({ }^{\text {p996 }}\) target with a timestamp now:
1. Let callbacks be target's map of animation frame callbacks \({ }^{\text {p996 }}\).
2. Let callbackHandles be the result of getting the keys of callbacks.
3. For each handle in callbackHandles, if handle exists in callbacks:
1. Let callback be callbacks[handle].
2. Remove callbacks[handle].
3. Invoke callback, passing now as the only argument, and if an exception is thrown, report the exception \({ }^{\text {p937 }}\).

\section*{Example}

Inside workers, requestAnimationFrame() \({ }^{\text {p996 }}\) can be used together with an 0 ffscreenCanvas \({ }^{\text {p689 }}\) transferred from a canvas \({ }^{\text {p634 }}\) element. First, in the document, transfer control to the worker:
```
const offscreenCanvas = document.getElementById("c").transferControlToOffscreen();
```
worker. postMessage(offscreenCanvas, [offscreenCanvas]);

Then, in the worker, the following code will draw a rectangle moving from left to right:
```
let ctx, pos = 0;
function draw(dt)
    ctx.clearRect(0, 0, 100, 100)
    ctx.fillRect(pos, 0, 10, 10);
    pos += 10 * dt;
    requestAnimationFrame(draw);
}
self.onmessage = function(ev) {
    const transferredCanvas = ev.data;
    ctx = transferredCanvas.getContext("2d");
    draw();
};
```

\section*{9 Communication \(\S^{\text {p99 }}\)}

\subsection*{9.1 The MessageEvent \({ }^{\text {p998 }}\) interface \({ }_{8}^{\S^{\text {p99 }}}\)}

Messages in server-sent events \({ }^{\text {p999 }}\), web sockets \({ }^{\text {p1008 }}\), cross-document messaging \({ }^{\text {p1016 }}\), channel messaging \({ }^{\text {p1018 }}\), and broadcast channels \({ }^{\text {p1025 }}\) use the MessageEvent \({ }^{\text {p998 }}\) interface for their message \({ }^{\text {p1282 }}\) events:

IDL [Exposed=(Window, Worker, AudioWorklet)]
interface MessageEvent : Event \{ constructor(DOMString type, optional MessageEventInit eventInitDict = \{\});
readonly attribute any data;
readonly attribute USVString origin;
readonly attribute DOMString lastEventId;
readonly attribute MessageEventSource? source;
readonly attribute FrozenArray<MessagePort> ports;
undefined initMessageEvent(DOMString type, optional boolean bubbles = false, optional boolean
cancelable = false, optional any data = null, optional USVString origin = "", optional DOMString lastEventId = "", optional MessageEventSource? source = null, optional sequence<MessagePort> ports = []);
\};
dictionary MessageEventInit : EventInit \{
any data = null;
USVString origin = "";
DOMString lastEventId = "";
MessageEventSource? source = null;
sequence<MessagePort> ports = [];
\};
typedef (WindowProxy or MessagePort or ServiceWorker) MessageEventSource;

\section*{For web developers (non-normative)}

\section*{event . data \({ }^{\text {p998 }}\)}

Returns the data of the message.
event. origin \({ }^{\text {p998 }}\)
Returns the origin of the message, for server-sent events \({ }^{\text {p999 }}\) and cross-document messaging \({ }^{\text {p1016 }}\).
event. LastEventId \({ }^{\text {p998 }}\)
Returns the last event ID string \({ }^{\text {p1000 }}\), for server-sent events \({ }^{\text {p999 }}\).
event. source \({ }^{\text {p999 }}\)
Returns the WindowProxy \({ }^{\text {p834 }}\) of the source window, for cross-document messaging \({ }^{\text {p1016 }}\), and the MessagePort \({ }^{\text {p1022 }}\) being attached, in the connect \({ }^{\text {p1281 }}\) event fired at SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) objects.
event. ports \({ }^{\text {p999 }}\)
Returns the MessagePort \({ }^{\text {p1022 }}\) array sent with the message, for cross-document messaging \({ }^{\text {p1016 }}\) and channel messaging \({ }^{\text {p1018 }}\).

The data attribute must return the value it was initialized to. It represents the message being sent.
The origin attribute must return the value it was initialized to. It represents, in server-sent events \({ }^{\text {p999 }}\) and cross-document messaging \({ }^{\text {p1016 }}\), the origin \({ }^{\text {p837 }}\) of the document that sent the message (typically the scheme, hostname, and port of the document, but not its path or fragment).

The lastEventId attribute must return the value it was initialized to. It represents, in server-sent events \({ }^{\text {p999 }}\), the last event ID string \({ }^{\text {p1000 }}\) of the event source.

The source attribute must return the value it was initialized to. It represents, in cross-document messaging \({ }^{\text {p1016 }}\), the WindowProxy \({ }^{\text {p834 }}\) of the browsing context \({ }^{\mathrm{p} 811}\) of the Window \({ }^{\mathrm{p} 824}\) object from which the message came; and in the connect \({ }^{p 1281}\) events used by shared workers \({ }^{\text {p1047 }}\), the newly connecting MessagePort \({ }^{\text {p1022 }}\).

The ports attribute must return the value it was initialized to. It represents, in cross-document messaging \({ }^{\text {p1016 }}\) and channel messaging \({ }^{\text {p1018 }}\), the MessagePort \({ }^{\text {p1022 }}\) array being sent.

The initMessageEvent () method must initialize the event in a manner analogous to the similarly-named initEvent() method. [DOM] \({ }^{\text {p1287 }}\)

\section*{Note}

Various APIs (e.g., WebSocket \({ }^{\text {p1008 }}\), EventSource \({ }^{\text {p1000 }}\) ) use the MessageEvent \({ }^{\text {p998 }}\) interface for their message \({ }^{\text {p1282 }}\) event without using the MessagePort \({ }^{\text {p1022 }}\) API.

\subsection*{9.2 Server-sent events \(\S^{p 99}\)}

\subsection*{9.2.1 Introduction \(\S_{9}{ }^{p 99}\)}

This section is non-normative.
To enable servers to push data to web pages over HTTP or using dedicated server-push protocols, this specification introduces the EventSource \({ }^{\text {p1000 }}\) interface.

Using this API consists of creating an EventSource \({ }^{\text {p1008 }}\) object and registering an event listener.
```
var source = new EventSource('updates.cgi');
source.onmessage = function (event) {
    alert(event.data);
};
```

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the text/event-stream \({ }^{\text {p1256 }}\) MIME type:
```
data: This is the first message.
data: This is the second message, it
data: has two lines.
data: This is the third message.
```

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":
event: add
data: 73857293
event: remove
data: 2153
event: add
data: 113411

The script to handle such a stream would look like this (where addHandler and removeHandler are functions that take one argument, the event):
```
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
```

The default event type is "message".

Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using XMLHttpRequest or an iframe \({ }^{\text {p361 }}\) allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section below on connectionless push \({ }^{\text {p1006 }}\).

\subsection*{9.2.2 The EventSource \({ }^{p 1000}\) interface \(\S^{p 10}\)}
```
[Exposed=(Window,Worker)]
interface EventSource : EventTarget {
    constructor(USVString url, optional EventSourceInit eventSourceInitDict = {});
    readonly attribute USVString url;
    readonly attribute boolean withCredentials;
    // ready state
    const unsigned short CONNECTING = 0;
    const unsigned short OPEN = 1;
    const unsigned short CLOSED = 2;
    readonly attribute unsigned short readyState;
    // networking
    attribute EventHandler onopen;
    attribute EventHandler onmessage;
    attribute EventHandler onerror;
    undefined close();
};
dictionary EventSourceInit {
    boolean withCredentials = false;
};
```

Each EventSource \({ }^{\text {p1000 }}\) object has the following associated with it:
- A url (a URL record). Set during construction.
- A request. This must initially be null.
- A reconnection time, in milliseconds. This must initially be an implementation-defined value, probably in the region of a few seconds.
- A last event ID string. This must initially be the empty string.

Apart from url \({ }^{\text {p1000 }}\) these are not currently exposed on the EventSource \({ }^{\text {p1000 }}\) object.

\section*{For web developers (non-normative)}
source \(=\) new EventSource \({ }^{\text {p1001 }}\left(\right.\) url [, \{ withCredentials \({ }^{\text {p1000 }}\) : true \}])
Creates a new EventSource \({ }^{\text {p1000 }}\) object.
url is a string giving the URL that will provide the event stream.
Setting withCredentials \({ }^{p 10 \theta \theta}\) to true will set the credentials mode for connection requests to url to "include".
source. close \({ }^{\text {p1002 }}\) ()
Aborts any instances of the fetch algorithm started for this EventSource \({ }^{\text {p1000 }}\) object, and sets the readyState \({ }^{\text {p1001 }}\) attribute to CLOSED \({ }^{\text {p1001 }}\).
source. \(\underline{u r l}^{\text {p1001 }}\)
Returns the URL providing the event stream \({ }^{\text {p1000 }}\).
source . withCredentials \({ }^{\text {p1001 }}\)
Returns true if the credentials mode for connection requests to the URL providing the event stream \({ }^{\text {p1000 }}\) is set to "include", and false otherwise.
source . readyState \({ }^{\text {p1001 }}\)
Returns the state of this EventSource \({ }^{\text {p1000 }}\) object's connection. It can have the values described below.

The EventSource(url, eventSourceInitDict) constructor, when invoked, must run these steps:
1. Let ev be a new EventSource \({ }^{p 1000}\) object.
2. Let settings be ev's relevant settings object \({ }^{\text {p924 }}\).
3. Let urlRecord be the result of parsing url with settings's API base URL \({ }^{\text {p917 }}\) and settings's API URL character encoding \({ }^{\text {p917 }}\).
4. If urIRecord is failure, then throw a "SyntaxError" DOMException.
5. Set ev's uri \({ }^{p 1000}\) to urlRecord.
6. Let corsAttributeState be Anonymous \({ }^{\mathrm{p91}}\).
7. If the value of eventSourceInitDict's withCredentials \({ }^{p 10 \theta \theta}\) member is true, then set corsAttributeState to Use Credentials \({ }^{\text {p91 }}\) and set \(e v\) 's withCredentials \({ }^{p 1001}\) attribute to true.
8. Let request be the result of creating a potential-CORS request \({ }^{\text {p90 }}\) given urlRecord, the empty string, and corsAttributeState.
9. Set request's client to settings.
10. User agents may set `Accept`/'text/event-stream \({ }^{\text {p1256` }}\) in request's header list.
11. Set request's cache mode to "no-store".
12. Set ev's request \({ }^{\text {p1000 }}\) to request.
13. Run this step in parallel \({ }^{\mathrm{p} 42}\) :
1. Fetch request.
14. Return ev.

The url attribute's getter must return the serialization of this EventSource \({ }^{\text {p1000 }}\) object's url \({ }^{\text {p1000 }}\).
The withCredentials attribute must return the value to which it was last initialized. When the object is created, it must be initialized to false.

The readyState attribute represents the state of the connection. It can have the following values:

\section*{CONNECTING (numeric value 0)}

The connection has not yet been established, or it was closed and the user agent is reconnecting.
OPEN (numeric value 1)
The user agent has an open connection and is dispatching events as it receives them.

\section*{CLOSED (numeric value 2)}

The connection is not open, and the user agent is not trying to reconnect. Either there was a fatal error or the close( () \({ }^{\text {p1002 }}\) method was invoked.

When the object is created its readyState \({ }^{\text {p1001 }}\) must be set to CONNECTING \({ }^{\text {p1001 }}(0)\). The rules given below for handling the connection define when the value changes.

The close() method must abort any instances of the fetch algorithm started for this EventSource \({ }^{\text {p100日 }}\) object, and must set the readyState \({ }^{\text {p1001 }}\) attribute to CLOSED \({ }^{\text {p1001 }}\).

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by all objects implementing the EventSource \({ }^{\text {p1000 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onopen & open \(^{\text {p1282 }}\) \\
\hline onmessage & message \(^{\text {p1282 }}\) \\
\hline onerror & error \(^{\text {p1281 }}\) \\
\hline
\end{tabular}

\subsection*{9.2.3 Processing model \(\S^{p 10}\) \\ 02}

The resource indicated in the argument to the EventSource \({ }^{p 1001}\) constructor is fetched when the constructor is run.
As data is received, the tasks \({ }^{\text {p944 }}\) queued by the networking task source \({ }^{\text {p952 }}\) to handle the data must act as follows.
HTTP 200 OK responses with a `Content-Type \({ }^{\text {p90`` }}\) header specifying the type `text/event-stream \({ }^{\text {p1256` }}\), ignoring any MIME type parameters, must be processed line by line as described below \({ }^{\text {p1003 }}\).

When a successful response with a supported MIME type is received, such that the user agent begins parsing the contents of the stream, the user agent must announce the connection \({ }^{\text {p1002 }}\).

The task \({ }^{\text {p944 }}\) that the networking task source \({ }^{\text {p952 }}\) places on the task queue \({ }^{\text {p944 }}\) once fetching for such a resource (with the correct MIME type) has completed must cause the user agent to reestablish the connection \({ }^{\text {p1002 }}\) in parallel \(l^{\text {p422 }}\). This applies whether the connection is closed gracefully or unexpectedly (but does not apply when fetching is canceled by the user agent, e.g., in response to window. stop () \()^{\text {p829 }}\), since in those cases the final task \({ }^{\text {p944 }}\) is actually discarded). It doesn't apply for the error conditions listed below except where explicitly specified.

HTTP 200 OK responses that have a Content-Type \({ }^{\text {p90 }}\) specifying an unsupported type, or that have no Content-Type \({ }^{\text {p90 }}\) at all, must cause the user agent to fail the connection \({ }^{\text {p1003 }}\).

Network errors that prevents the connection from being established in the first place (e.g. DNS errors), should cause the user agent to reestablish the connection \({ }^{\text {p1002 }}\) in parallel \({ }^{\text {p42 }}\), unless the user agent knows that to be futile, in which case the user agent may fail the connection \({ }^{\text {p1003 }}\).

Any other HTTP response code not listed here, as well as the cancelation of the fetch algorithm by the user agent (e.g. in response to window. stop () \()^{\text {p829 }}\) or the user canceling the network connection manually) must cause the user agent to fail the connection \({ }^{\text {p1003 }}\).

When a user agent is to announce the connection, the user agent must queue a task \({ }^{\text {p945 }}\) which, if the readyState \({ }^{\text {p1001 }}\) attribute is set to a value other than CLOSED \({ }^{p 1001}\), sets the readyState \({ }^{p 1001}\) attribute to \(\underline{O P E N}{ }^{\text {p1001 }}\) and fires an event named open \({ }^{p 1282}\) at the EventSource \({ }^{\text {p1000 }}\) object.

When a user agent is to reestablish the connection, the user agent must run the following steps. These steps are run in parallel \({ }^{\mathrm{p} 42}\), not as part of a task \({ }^{\text {p944 }}\). (The tasks that it queues, of course, are run like normal tasks and not themselves in parallel \({ }^{\text {p42 }}\).)
1. Queue a task \({ }^{\text {p945 }}\) to run the following steps:
1. If the readyState \({ }^{\text {p1001 }}\) attribute is set to CLOSED \({ }^{\text {p1001 }}\), abort the task.
2. Set the readyState \({ }^{\text {p1001 }}\) attribute to CONNECTING \({ }^{\text {p1001 }}\).
3. Fire an event named error \({ }^{p 1281}\) at the EventSource \({ }^{\text {p1000 }}\) object.
2. Wait a delay equal to the reconnection time of the event source.
3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.
4. Wait until the aforementioned task has run, if it has not yet run.
5. Queue a task \({ }^{\text {p945 }}\) to run the following steps:
1. If the EventSource \({ }^{\text {p100日 }}\) object's readyState \({ }^{\text {p1001 }}\) attribute is not set to CONNECTING \({ }^{\text {p1001 }}\), return.
2. Let request be the EventSource \({ }^{\text {p1000 }}\) object's request \({ }^{\text {p1000 }}\).
3. If the EventSource \({ }^{\text {p1000 }}\) object's last event ID string \({ }^{\text {p1000 }}\) is not the empty string, set ` Last-Event-ID \({ }^{\text {p1259 }}\) / last event ID string \({ }^{\text {p1000 }}\), encoded as UTF-8, in request's header list.
4. Fetch request and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to fail the connection, the user agent must queue a task \({ }^{\text {p945 }}\) which, if the readyState \({ }^{\text {p1001 }}\) attribute is set to a value other than CLOSED \({ }^{\text {p1001 }}\), sets the readyState \({ }^{\text {p1001 }}\) attribute to CLOSED \({ }^{p 1001}\) and fires an event named error \(r^{p 1281}\) at the EventSource \({ }^{\text {p1000 }}\) object. Once the user agent has failed the connection \({ }^{\text {p1003 }}\), it does not attempt to reconnect!

The task source \({ }^{\text {p945 }}\) for any tasks \({ }^{\text {p944 }}\) that are queued \({ }^{\text {p945 }}\) by EventSource \({ }^{\text {p1000 }}\) objects is the remote event task source.

\subsection*{9.2.4 Parsing an event stream \(\S^{p 10}\)}

This event stream format's MIME type is text/event-stream \({ }^{p 1256}\).
The event stream format is as described by the stream production of the following ABNF, the character set for which is Unicode. [ABNF] \({ }^{\text {p1285 }}\)
```
stream = [ bom ] *event
event }=*(\mathrm{ comment / field ) end-of-line
comment = colon *any-char end-of-line
field = 1*name-char [ colon [ space ] *any-char ] end-of-line
end-of-line = ( cr lf / cr / lf )
; characters
lf = %x000A ; U+000A LINE FEED (LF)
Cr = %x000D ; U+000D CARRIAGE RETURN (CR)
space = %x0020 ; U+0020 SPACE
colon = %x003A ; U+003A COLON (:)
bom = %xFEFF ; U+FEFF BYTE ORDER MARK
name-char = %x0000-0009 / %x000B-000C / %x000E-0039 / %x003B-10FFFF
    ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), or
U+003A COLON (:)
any-char = %x0000-0009 / %x000B-000C / %x000E-10FFFF
    ; a scalar value other than U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8. [ENCODING] \({ }^{\text {p1287 }}\)
Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single \(U+000 A\) LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

\subsection*{9.2.5 Interpreting an event stream \(\underset{{ }_{3}{ }^{\text {p10 }}}{\substack{\text { I }}}\)}

Streams must be decoded using the UTF-8 decode algorithm.

The UTF-8 decode algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a data buffer, an event type buffer, and a last event ID buffer must be associated with it. They must be initialized to the empty string

Lines must be processed, in the order they are received, as follows:
\(\leftrightarrow\) If the line is empty (a blank line) Dispatch the event \({ }^{\text {p1004 }}\), as defined below.
\(\hookrightarrow\) If the line starts with a U+003A COLON character (:) Ignore the line.
\(\rightarrow\) If the line contains a U+003A COLON character (:)
Collect the characters on the line before the first U+003A COLON character (:), and let field be that string.
Collect the characters on the line after the first U+003A COLON character (:), and let value be that string. If value starts with a U+0020 SPACE character, remove it from value.

Process the field \({ }^{p 1004}\) using the steps described below, using field as the field name and value as the field value.
\(\rightarrow\) Otherwise, the string is not empty but does not contain a U+003A COLON character (:)
Process the field \({ }^{\text {p1004 }}\) using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to process the field given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.
\(\rightarrow\) If the field name is "event"
Set the event type buffer to field value.
\(\leftrightarrow\) If the field name is "data"
Append the field value to the data buffer, then append a single U+000A LINE FEED (LF) character to the data buffer.
\(\hookrightarrow\) If the field name is "id"
If the field value does not contain \(U+0000\) NULL, then set the last event ID buffer to the field value. Otherwise, ignore the field.
\(\leftrightarrow\) If the field name is "retry" If the field value consists of only ASCII digits, then interpret the field value as an integer in base ten, and set the event stream's reconnection time \({ }^{\text {p1000 }}\) to that integer. Otherwise, ignore the field.
\(\leftrightarrow\) Otherwise
The field is ignored.
When the user agent is required to dispatch the event, the user agent must process the data buffer, the event type buffer, and the last event ID buffer using steps appropriate for the user agent.

For web browsers, the appropriate steps to dispatch the event \({ }^{\text {p1004 }}\) are as follows:
1. Set the last event ID string \({ }^{\text {p1000 }}\) of the event source to the value of the last event ID buffer. The buffer does not get reset, so the last event ID string \({ }^{\mathrm{p} 1000}\) of the event source remains set to this value until the next time it is set by the server.
2. If the data buffer is an empty string, set the data buffer and the event type buffer to the empty string and return.
3. If the data buffer's last character is a U+000A LINE FEED (LF) character, then remove the last character from the data buffer.
4. Let event be the result of creating an event using MessageEvent \({ }^{\text {p998 }}\), in the relevant Realm \({ }^{\text {p924 }}\) of the EventSource \({ }^{\text {p1000 }}\) object.
5. Initialize event's type attribute to message \({ }^{p 1282}\), its data \({ }^{\text {p998 }}\) attribute to data, its origin \({ }^{\text {p998 }}\) attribute to the serialization \({ }^{\text {p838 }}\) of
the origin of the event stream's final URL (i.e., the URL after redirects), and its lastEventId \({ }^{p 998}\) attribute to the last event ID string \({ }^{\text {p1000 }}\) of the event source.
6. If the event type buffer has a value other than the empty string, change the type of the newly created event to equal the value of the event type buffer.
7. Set the data buffer and the event type buffer to the empty string.
8. Queue a task \({ }^{\text {p945 }}\) which, if the readyState \({ }^{\text {p1001 }}\) attribute is set to a value other than CLOSED \({ }^{\text {p1001 }}\), dispatches the newly created event at the EventSource \({ }^{\text {p1000 }}\) object.

\section*{Note}

If an event doesn't have an "id" field, but an earlier event did set the event source's last event ID string \({ }^{p 1000}\), then the event's
lastEventId \({ }^{\text {p998 }}\) field will be set to the value of whatever the last seen "id" field was.

For other user agents, the appropriate steps to dispatch the event \({ }^{p 1004}\) are implementation dependent, but at a minimum they must set the data and event type buffers to the empty string before returning.

\section*{Example}

The following event stream, once followed by a blank line:
```
data: YHOO
data: +2
data: 10
```
...would cause an event message \({ }^{\text {p1282 }}\) with the interface MessageEvent \({ }^{\text {p998 }}\) to be dispatched on the EventSource \({ }^{\text {p10e日 }}\) object. The event's data \({ }^{\text {p998 }}\) attribute would contain the string "YH0O\n+2\n10" (where "\n" represents a newline).

This could be used as follows:
```
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function (event) {
    var data = event.data.split('\n');
    updateStocks(data[0], data[1], data[2]);
};
```
...where updateStocks () is a function defined as:
```
function updateStocks(symbol, delta, value) { ... }
```
...or some such.

\section*{Example}

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names "data" and "id" respectively; an event will be fired for this block, with the data "first event", and will then set the last event ID to " 1 " so that if the connection died between this block and the next, the server would be sent a `Last-Event-ID \({ }^{\text {p1259 }}\), header with the value " 1 ". The third block fires an event with data "second event", and also has an "id" field, this time with no value, which resets the last event ID to the empty string (meaning no `Last-Event-ID \({ }^{\text {p1259, }}\) header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data " third event" (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.
```
: test stream
```
data: first event
id: 1
data:second event
id
data: third event

The following stream fires two events:
```
data
data
data
data:
```

The first block fires events with the data set to the empty string, as would the last block if it was followed by a blank line. The middle block fires an event with the data set to a single newline character. The last block is discarded because it is not followed by a blank line.

\section*{Example}

The following stream fires two identical events:
```
data:test
data: test
```

This is because the space after the colon is ignored if present.

\subsection*{9.2.6 Authoring notes \(\S^{p 10}\)}

Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a ':' character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn't work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP's per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an EventSource \({ }^{\text {p100日 }}\) to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names per connection, or by allowing the user to enable or disable the EventSource \({ }^{\text {p100e }}\) functionality on a per-page basis, or by sharing a single EventSource \({ }^{\text {p1000 }}\) object using a shared worker \({ }^{\text {p1047 }}\).

\subsection*{9.2.7 Connectionless push and other features \(\S^{p 10}\)}

User agents running in controlled environments, e.g. browsers on mobile handsets tied to specific carriers, may offload the management of the connection to a proxy on the network. In such a situation, the user agent for the purposes of conformance is considered to include both the handset software and the network proxy.

\section*{Example}

For example, a browser on a mobile device, after having established a connection, might detect that it is on a supporting network and request that a proxy server on the network take over the management of the connection. The timeline for such a situation might be as follows:
1. Browser connects to a remote HTTP server and requests the resource specified by the author in the EventSource \({ }^{\text {p1001 }}\) constructor.
2. The server sends occasional messages.
3. In between two messages, the browser detects that it is idle except for the network activity involved in keeping the TCP connection alive, and decides to switch to sleep mode to save power.
4. The browser disconnects from the server.
5. The browser contacts a service on the network, and requests that the service, a "push proxy", maintain the connection instead.
6. The "push proxy" service contacts the remote HTTP server and requests the resource specified by the author in the EventSource \({ }^{\text {p1001 }}\) constructor (possibly including a `Last-Event-ID \({ }^{\text {p1259` }}\) HTTP header, etc).
7. The browser allows the mobile device to go to sleep.
8. The server sends another message.
9. The "push proxy" service uses a technology such as OMA push to convey the event to the mobile device, which wakes only enough to process the event and then returns to sleep.

This can reduce the total data usage, and can therefore result in considerable power savings.
As well as implementing the existing API and text/event-stream \({ }^{p 1256}\) wire format as defined by this specification and in more distributed ways as described above, formats of event framing defined by other applicable specifications \({ }^{\mathrm{p} 65}\) may be supported. This specification does not define how they are to be parsed or processed.

\subsection*{9.2.8 Garbage collection \(\S^{p 10}\)}

While an EventSource \({ }^{\text {p1000 }}\) object's readyState \({ }^{\text {p1001 }}\) is CONNECTING \({ }^{p 1001}\), and the object has one or more event listeners registered for open \({ }^{\text {p1282 }}\), message \({ }^{\text {p1282 }}\) or error \({ }^{\text {p1281 }}\) events, there must be a strong reference from the Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object that the EventSource \({ }^{\text {p1000 }}\) object's constructor was invoked from to the EventSource \({ }^{\text {p1000 }}\) object itself.

While an EventSource \({ }^{\text {p1000 }}\) object's readyState \({ }^{\text {p1001 }}\) is OPEN \(^{\text {p1001 }}\), and the object has one or more event listeners registered for message \({ }^{\text {p1282 }}\) or error \({ }^{\text {p1281 }}\) events, there must be a strong reference from the Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object that the EventSource \({ }^{\text {p1000 }}\) object's constructor was invoked from to the EventSource \({ }^{\text {p1008 }}\) object itself.

While there is a task queued by an EventSource \({ }^{\text {p1000 }}\) object on the remote event task source \({ }^{\text {p1003 }}\), there must be a strong reference from the Window \({ }^{\text {p824 }}\) or WorkerGlobalScope \({ }^{\text {p1044 }}\) object that the EventSource \({ }^{\text {p1000 }}\) object's constructor was invoked from to that EventSource \({ }^{\text {p1000 }}\) object.

If a user agent is to forcibly close an EventSource \({ }^{\text {p1000 }}\) object (this happens when a Document \({ }^{\text {p114 }}\) object goes away permanently), the user agent must abort any instances of the fetch algorithm started for this EventSource \({ }^{\text {p1000 }}\) object, and must set the readyState \({ }^{\text {p1001 }}\) attribute to CLOSED \({ }^{\text {p1001 }}\).

If an EventSource \({ }^{\text {p10e日 }}\) object is garbage collected while its connection is still open, the user agent must abort any instance of the fetch algorithm opened by this EventSource \({ }^{\text {p190日 }}\).

\subsection*{9.2.9 Implementation advice \(\S^{\text {p10 }}\)}

This section is non-normative.
User agents are strongly urged to provide detailed diagnostic information about EventSource \({ }^{\text {p1000 }}\) objects and their related network connections in their development consoles, to aid authors in debugging code using this API.

For example, a user agent could have a panel displaying all the EventSource \({ }^{p 10 \theta \theta}\) objects a page has created, each listing the constructor's arguments, whether there was a network error, what the CORS status of the connection is and what headers were sent by the client and received from the server to lead to that status, the messages that were received and how they were parsed, and so forth.
is fired, since little to no information can be made available in the events themselves.

\subsection*{9.3 Web sockets \(\S^{p 10}\)}

\subsection*{9.3.1 Introduction \(\S^{\S^{p 10}}\)}

This section is non-normative.
To enable web applications to maintain bidirectional communications with server-side processes, this specification introduces the WebSocket \({ }^{\text {p1008 }}\) interface.

\section*{Note}

This interface does not allow for raw access to the underlying network. For example, this interface could not be used to implement an IRC client without proxying messages through a custom server.

\subsection*{9.3.2 The WebSocket \({ }^{\text {p1008 }}\) interface \(\S^{p 10}\)}

IDL enum BinaryType \{ "blob", "arraybuffer" \};
[Exposed=(Window, Worker)]
interface WebSocket : EventTarget \{
constructor(USVString url, optional (DOMString or sequence<DOMString>) protocols = []);
readonly attribute USVString url;
// ready state
const unsigned short CONNECTING \(=0\);
const unsigned short OPEN = 1;
const unsigned short CLOSING \(=2\);
const unsigned short CLOSED \(=3\);
readonly attribute unsigned short readyState;
readonly attribute unsigned long long bufferedAmount;
// networking
attribute EventHandler onopen;
attribute EventHandler onerror;
attribute EventHandler onclose;
readonly attribute DOMString extensions;
readonly attribute DOMString protocol;
undefined close(optional [Clamp] unsigned short code, optional USVString reason);
// messaging
attribute EventHandler onmessage;
attribute BinaryType binaryType;
undefined send(USVString data);
undefined send(Blob data);
undefined send(ArrayBuffer data);
undefined send(ArrayBufferView data);

Each WebSocket \({ }^{\text {p10e8 }}\) object has an associated url (a URL record).

\section*{For web developers (non-normative)}

Creates a new WebSocket \({ }^{\text {p1008 }}\) object, immediately establishing the associated WebSocket connection.
url is a string giving the URL over which the connection is established. Only "ws" or "wss" schemes are allowed; others will cause a "SyntaxError" DOMException. URLs with fragments will also cause such an exception.
protocols is either a string or an array of strings. If it is a string, it is equivalent to an array consisting of just that string; if it is omitted, it is equivalent to the empty array. Each string in the array is a subprotocol name. The connection will only be established if the server reports that it has selected one of these subprotocols. The subprotocol names have to match the requirements for elements that comprise the value of Sec-WebSocket-Protocol \({ }^{\text {p63 }}\) fields as defined by The WebSocket protocol. [WSP] \({ }^{\text {p1292 }}\)
socket . send \({ }^{\text {p1012 }}\) (data )
Transmits data using the WebSocket connection. data can be a string, a Blob, an ArrayBuffer, or an ArrayBufferView.
socket . close \({ }^{\text {p1010 }}\) ([ code ] [, reason ] )
Closes the WebSocket connection, optionally using code as the the WebSocket connection close code \({ }^{\text {p63 }}\) and reason as the the WebSocket connection close reason \({ }^{\text {p63 }}\).
socket. url \({ }^{\text {p1010 }}\)
Returns the URL that was used \({ }^{\text {p1008 }}\) to establish the WebSocket connection.

\section*{socket . readyState \({ }^{\text {p1010 }}\)}

Returns the state of the WebSocket \({ }^{\text {p1008 }}\) object's connection. It can have the values described below.

\section*{socket . bufferedAmount \({ }^{\text {p1011 }}\)}

Returns the number of bytes of application data (UTF-8 text and binary data) that have been queued using send() \({ }^{\text {p1012 }}\) but not yet been transmitted to the network.

If the WebSocket connection is closed, this attribute's value will only increase with each call to the send() \({ }^{\text {p1012 }}\) method. (The number does not reset to zero once the connection closes.)
socket . extensions \({ }^{\text {p1010 }}\)
Returns the extensions selected by the server, if any.
socket . protocol \({ }^{\text {p1010 }}\)
Returns the subprotocol selected by the server, if any. It can be used in conjunction with the array form of the constructor's second argument to perform subprotocol negotiation.
socket \(\cdot\) binaryType \({ }^{\text {p1011 }}\) [ = value ]
Returns a string that indicates how binary data from the WebSocket \({ }^{p 1008}\) object is exposed to scripts:
"blob \({ }^{\text {p1013" }}\)
Binary data is returned in Blob form.
"arraybuffer \({ }^{\text {p1013" }}\)
Binary data is returned in ArrayBuffer form.
Can be set, to change how binary data is returned. The default is "blob \({ }^{\text {p1013". }}\).

The WebSocket(url, protocols) constructor, when invoked, must run these steps:
1. Let urIRecord be the result of applying the URL parser to url.
2. If urIRecord is failure, then throw a "SyntaxError" DOMException.
3. If urlRecord's scheme is not "ws" or "wss", then throw a "SyntaxError" DOMException.
4. If urIRecord's fragment is non-null, then throw a "SyntaxError" DOMException.
5. If protocols is a string, set protocols to a sequence consisting of just that string.
6. If any of the values in protocols occur more than once or otherwise fail to match the requirements for elements that comprise the value of Sec-WebSocket-Protocol \({ }^{\text {p63 }}\) fields as defined by The WebSocket protocol, then throw a "SyntaxError" DOMException. [WSP] \({ }^{\text {p1292 }}\)
7. Run this step in parallel \({ }^{\text {p42 }}\) :
1. Establish a WebSocket connection given urlRecord, protocols, and the entry settings object \({ }^{\text {p921 }}\). \([\text { FETCH }]^{\text {p1287 }}\)

\section*{Note}

If the establish a WebSocket connection algorithm fails, it triggers the fail the WebSocket connection \({ }^{\text {p62 }}\) algorithm, which then invokes the close the WebSocket connection \({ }^{\text {p62 }}\) algorithm, which then establishes that the WebSocket connection is closed \({ }^{p 63}\), which fires the close \({ }^{p 1281}\) event as described below \({ }^{\text {p1013 }}\).
8. Return a new WebSocket \({ }^{\text {p1008 }}\) object whose url \({ }^{\text {p1008 }}\) is urlRecord.

The url attribute's getter must return this WebSocket \({ }^{p 1008}\) object's url \({ }^{p 1008}\), serialized.
The readyState attribute represents the state of the connection. It can have the following values:

\section*{CONNECTING (numeric value 0)}

The connection has not yet been established.
OPEN (numeric value 1)
The WebSocket connection is established \({ }^{p 62}\) and communication is possible.

\section*{CLOSING (numeric value 2)}

The connection is going through the closing handshake, or the close( () \({ }^{\text {p1010 }}\) method has been invoked.

\section*{CLOSED (numeric value 3)}

The connection has been closed or could not be opened.
When the object is created its readyState \({ }^{\text {p1010 }}\) must be set to CONNECTING \({ }^{\text {p1010 }}\) ( 0 ).
The extensions attribute must initially return the empty string. After the WebSocket connection is established \({ }^{p 62}\), its value might change, as defined below.

The protocol attribute must initially return the empty string. After the WebSocket connection is established \({ }^{p 62}\), its value might change, as defined below.

The close(code, reason) method, when invoked, must run these steps:
1. If code is present, but is neither an integer equal to 1000 nor an integer in the range 3000 to 4999 , inclusive, throw an "InvalidAccessError" DOMException.
2. If reason is present, then run these substeps:
1. Let reasonBytes be the result of encoding reason.
2. If reasonBytes is longer than 123 bytes, then throw a "SyntaxError" DOMException.
3. Run the first matching steps from the following list:
\(\rightarrow\) If the readyState \({ }^{\text {p1010 }}\) attribute is in the CLOSING \({ }^{p 1010}\) (2) or CLOSED \({ }^{\text {p1010 }}\) (3) state
Do nothing.

\section*{Note}

The connection is already closing or is already closed. If it has not already, a close \({ }^{\text {p1281 }}\) event will eventually fire as described below \({ }^{\text {p1013 }}\).
\(\leftrightarrow\) If the WebSocket connection is not yet established \({ }^{\text {p62 }}\) [WSP] \({ }^{\text {p1292 }}\)
Fail the WebSocket connection \({ }^{p 62}\) and set the readyState \({ }^{\text {p1010 }}\) attribute's value to CLOSING \({ }^{\text {p1010 }}\) (2). [WSP] \(]^{\text {p1292 }}\)

\section*{Note}

The fail the WebSocket connection \({ }^{\text {p62 }}\) algorithm invokes the close the WebSocket connection \({ }^{\text {p62 }}\) algorithm, which then establishes that the WebSocket connection is closed \({ }^{p 63}\), which fires the close \({ }^{p 1281}\) event as described below \({ }^{\text {p1013 }}\).
\(\leftrightarrow\) If the WebSocket closing handshake has not yet been started \({ }^{\text {p63 }}\) [WSP] \({ }^{\text {p1292 }}\)
Start the WebSocket closing handshake \({ }^{\text {p63 }}\) and set the readyState \({ }^{\text {p1010 }}\) attribute's value to CLOSING \({ }^{\text {p1010 }}\) (2). [WSP] \({ }^{\text {p1292 }}\) If neither code nor reason is present, the WebSocket Close message must not have a body.

\section*{Note}

WebSocket Protocol erroneously states that the status code is required for the start the WebSocket closing handshake \({ }^{\text {p63 }}\) algorithm.

\section*{If code is present, then the status code to use in the WebSocket Close message must be the integer given by close.} [WSP] \({ }^{\text {p1292 }}\)

If reason is also present, then reasonBytes must be provided in the Close message after the status code. [WSP] \({ }^{p 1292}\)

\section*{Note}

The start the WebSocket closing handshake \({ }^{\text {p63 }}\) algorithm eventually invokes the close the WebSocket connection \({ }^{\text {p62 }}\) algorithm, which then establishes that the WebSocket connection is closed \({ }^{\text {p63 }}\), which fires the close \({ }^{\text {p1281 }}\) event as described below \({ }^{\text {p1013 }}\).

\section*{\(\leftrightarrow\) Otherwise}

Set the readyState \({ }^{\text {p1010 }}\) attribute's value to CLOSING \({ }^{\text {p1010 }}\) (2).

\section*{Note}

The WebSocket closing handshake is started \({ }^{\text {p63 }}\), and will eventually invoke the close the WebSocket connection \({ }^{\text {p62 }}\) algorithm, which will establish that the WebSocket connection is closed \({ }^{\text {p63 }}\), and thus the close \({ }^{\text {p1281 }}\) event will fire, as described below \({ }^{\text {p1013 }}\).

\section*{Note}

The close() \()^{\text {p1010 }}\) method does not discard previously sent messages before starting the WebSocket closing handshake - even if, in practice, the user agent is still busy sending those messages, the handshake will only start after the messages are sent.

The bufferedAmount attribute must return the number of bytes of application data (UTF-8 text and binary data) that have been queued using send () \()^{\text {p1012 }}\) but that, as of the last time the event loop \({ }^{\text {p944 }}\) reached step \(1^{\text {p946 }}\), had not yet been transmitted to the network. (This thus includes any text sent during the execution of the current task, regardless of whether the user agent is able to transmit text in the background in parallel \({ }^{\text {p42 }}\) with script execution.) This does not include framing overhead incurred by the protocol, or buffering done by the operating system or network hardware.

\section*{Example}

In this simple example, the bufferedAmount \({ }^{\text {p1011 }}\) attribute is used to ensure that updates are sent either at the rate of one update every 50 ms , if the network can handle that rate, or at whatever rate the network can handle, if that is too fast.
```
var socket = new WebSocket('ws://game.example.com:12010/updates');
socket.onopen = function () {
    setInterval(function() {
        if (socket.bufferedAmount == 0)
            socket.send(getUpdateData());
    }, 50);
};
```

The bufferedAmount \({ }^{\text {p1011 }}\) attribute can also be used to saturate the network without sending the data at a higher rate than the network can handle, though this requires more careful monitoring of the value of the attribute over time.

When a WebSocket \({ }^{\text {p1008 }}\) object is created, its binaryType IDL attribute must be set to the string "blob \({ }^{\text {p1013" }}\). On getting, it must return the last value it was set to. On setting, the user agent must set the IDL attribute to the new value.

\section*{Note}

User agents can use the binaryType \({ }^{\text {p1011 }}\) attribute as a hint for how to handle incoming binary data: if the attribute is set to "blob \({ }^{\text {p1013" }}\), it is safe to spool it to disk, and if it is set to "arraybuffer \({ }^{p 1013 "}\) ", it is likely more efficient to keep the data in memory. Naturally, user agents are encouraged to use more subtle heuristics to decide whether to keep incoming data in memory or not, e.g. based on how big the data is or how common it is for a script to change the attribute at the last minute. This latter aspect is important in particular because it is quite possible for the attribute to be changed after the user agent has received the data but

The send (data) method transmits data using the connection. If the readyState \({ }^{\text {p1010 }}\) attribute is CONNECTING \({ }^{\text {p1018 }}\), it must throw an "InvalidStateError" DOMException. Otherwise, the user agent must run the appropriate set of steps from the following list:

\section*{If the argument is a string}

If the WebSocket connection is established \(d^{p 62}\) and the WebSocket closing handshake has not yet started \({ }^{p 63}\), then the user agent must send a WebSocket Message \({ }^{p 62}\) comprised of the data argument using a text frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full \({ }^{\text {p1013 }}\) and then close the WebSocket connection \({ }^{p 62}\). Any invocation of this method with a string argument that does not throw an exception must increase the bufferedAmount \({ }^{\text {p1011 }}\) attribute by the number of bytes needed to express the argument as UTF-8. [UNICODE] \({ }^{\text {p1292 }}\) [ENCODING] \({ }^{\text {p1287 }}\) [WSP] \({ }^{\text {p1292 }}\)

\section*{If the argument is a Blob object}

If the WebSocket connection is established \({ }^{p 62}\), and the WebSocket closing handshake has not yet started \({ }^{p 63}\), then the user agent must send a WebSocket Message \({ }^{\text {p62 }}\) comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full \({ }^{\text {p1013 }}\) and then close the WebSocket connection \({ }^{p 62}\). The data to be sent is the raw data represented by the Blob object. Any invocation of this method with a Blob argument that does not throw an exception must increase the bufferedAmount \({ }^{\text {p1011 }}\) attribute by the size of the Blob object's raw data, in bytes. [WSP] \({ }^{\text {p1292 }}\) [FILEAPI] \({ }^{\text {p1287 }}\)

\section*{If the argument is an ArrayBuffer object}

If the WebSocket connection is established \({ }^{p 62}\), and the WebSocket closing handshake has not yet started \({ }^{p 63}\), then the user agent must send a WebSocket Message \({ }^{p 62}\) comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full \({ }^{\text {p1013 }}\) and then close the WebSocket connection \({ }^{p 62}\). The data to be sent is the data stored in the buffer described by the ArrayBuffer object. Any invocation of this method with an ArrayBuffer argument that does not throw an exception must increase the bufferedAmount \({ }^{\text {p1011 }}\) attribute by the length of the ArrayBuffer in bytes. [WSP] \({ }^{\text {p1292 }}\)

If the argument is an object that matches the ArrayBufferView type definition
If the WebSocket connection is established \({ }^{p 62}\), and the WebSocket closing handshake has not yet started \({ }^{p 63}\), then the user agent must send a WebSocket Message \({ }^{p 62}\) comprised of data using a binary frame opcode; if the data cannot be sent, e.g. because it would need to be buffered but the buffer is full, the user agent must flag the WebSocket as full \({ }^{\text {p1013 }}\) and then close the WebSocket connection \({ }^{p 62}\). The data to be sent is the data stored in the section of the buffer described by the ArrayBuffer object that data references. Any invocation of this method with this kind of argument that does not throw an exception must increase the bufferedAmount \({ }^{\text {p1011 }}\) attribute by the length of data's buffer in bytes. [WSP] \({ }^{\text {p1292 }}\)

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by all objects implementing the WebSocket \({ }^{\text {p1008 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \(^{\text {p957 }}\) \\
\hline onopen & open \(^{\text {p1282 }}\) \\
\hline onmessage & message \(^{\text {p1282 }}\) \\
\hline onerror & error \(^{p 1281}\) \\
\hline onclose & close \(^{\text {p1281 }}\) \\
\hline
\end{tabular}

\subsection*{9.3.3 Feedback from the protocol \(\S^{p 10}\) \\ 12}

When the WebSocket connection is established \({ }^{\text {p62 }}\), the user agent must queue a task \({ }^{\text {p945 }}\) to run these steps:
1. Change the readyState \({ }^{\text {p1010 }}\) attribute's value to OPEN \(^{p 101 \theta}\) (1).
2. Change the extensions \({ }^{\text {p1010 }}\) attribute's value to the extensions in use \({ }^{p 62}\), if it is not the null value. [WSP] \({ }^{\text {p1292 }}\)
3. Change the protocol \(2^{\text {p1010 }}\) attribute's value to the subprotocol in \(u s e^{p 62}\), if it is not the null value. [WSP] \(]^{p 1292}\)
4. Fire an event named open \({ }^{p 1282}\) at the WebSocket \({ }^{\text {p1008 }}\) object.

Since the algorithm above is queued as a task \({ }^{p 945}\), there is no race condition between the WebSocket connection being established \({ }^{\text {p62 }}\) and the script setting up an event listener for the open \({ }^{\text {p1282 }}\) event.

When a WebSocket message has been received \({ }^{\text {p62 }}\) with type type and data data, the user agent must queue a task \({ }^{\text {p945 }}\) to follow these steps: [WSP] \({ }^{\text {p1292 }}\)
1. If the readyState \({ }^{\text {p1010 }}\) attribute's value is not \(\operatorname{OPEN}^{\text {p1010 }}\) (1), then return.
2. Let dataForEvent be determined by switching on type and binaryType \({ }^{\text {p1011 }}\) :

\section*{\(\rightarrow\) type indicates that the data is Text}
a new DOMString containing data
\(\rightarrow\) type indicates that the data is Binary and binaryType \({ }^{\text {p1011 }}\) is "blob"
a new Blob object, created in the relevant Realm \({ }^{\text {p924 }}\) of the WebSocket \({ }^{\text {p1008 }}\) object, that represents data as its raw data [FILEAPI] \({ }^{\text {p1287 }}\)
\(\rightarrow\) type indicates that the data is Binary and binaryType \({ }^{\text {p1011 }}\) is "arraybuffer"
a new ArrayBuffer object, created in the relevant Realm \({ }^{\text {p924 }}\) of the WebSocket \({ }^{\text {p1008 }}\) object, whose contents are data
3. Fire an event named message \({ }^{\text {p1282 }}\) at the WebSocket \({ }^{\text {p1008 }}\) object, using MessageEvent \({ }^{\text {p998 }}\), with the origin \({ }^{\text {p998 }}\) attribute initialized to the serialization \({ }^{\text {p838 }}\) of the WebSocket \({ }^{\text {p1088 }}\) object's url \({ }^{\text {p1008 }}\) 's origin, and the data \({ }^{\text {p998 }}\) attribute initialized to dataForEvent.

\section*{Note}

User agents are encouraged to check if they can perform the above steps efficiently before they run the task, picking tasks from other task queues \({ }^{\text {p944 }}\) while they prepare the buffers if not. For example, if the binaryType \({ }^{\text {p1011 }}\) attribute was set to "blob \({ }^{\text {p1013" }}\) when the data arrived, and the user agent spooled all the data to disk, but just before running the above task \({ }^{p 944}\) for this particular message the script switched binaryType \({ }^{\text {p1011 }}\) to "arraybuffer \({ }^{p 1013 ",}\), the user agent would want to page the data back to RAM before running this task \({ }^{\text {p944 }}\) so as to avoid stalling the main thread while it created the ArrayBuffer object.

\section*{Example}

Here is an example of how to define a handler for the message \({ }^{\text {p1282 }}\) event in the case of text frames:
```
mysocket.onmessage = function (event) {
    if (event.data == 'on') {
        turnLampOn();
    } else if (event.data == 'off') {
        turnLampOff();
    }
};
```

The protocol here is a trivial one, with the server just sending "on" or "off" messages.

When the WebSocket closing handshake is started \({ }^{p 63}\), the user agent must queue a task \({ }^{\text {p945 }}\) to change the readyState \({ }^{\text {p1010 }}\) attribute's value to CLOSING \({ }^{\text {p1010 }}\) (2). (If the close( () \({ }^{\text {p1010 }}\) method was called, the readyState \({ }^{\text {p1010 }}\) attribute's value will already be set to CLOSING \({ }^{\text {p1010 }}\) (2) when this task runs.) [WSP] \({ }^{\text {p1292 }}\)

When the WebSocket connection is closed \({ }^{\text {p63 }}\), possibly cleanly, the user agent must queue a task \({ }^{\text {p945 }}\) to run the following substeps:
1. Change the readyState \({ }^{\text {p1010 }}\) attribute's value to CLOSED \({ }^{\text {p1010 }}\) (3).
2. If the user agent was required to fail the WebSocket connection \({ }^{p 62}\), or if the the WebSocket connection was closed \({ }^{p 63}\) after being flagged as full, fire an event named error at the WebSocket \({ }^{\text {p1008 }}\) object. [WSP] \({ }^{\text {p1292 }}\)
3. Fire an event named \(\subseteq\) lose \({ }^{p 1281}\) at the WebSocket \({ }^{p 1008}\) object, using CloseEvent \({ }^{p 1014}\), with the wasClean \({ }^{p 1015}\) attribute initialized to true if the connection closed cleanly and false otherwise, the code \({ }^{p 1015}\) attribute initialized to the WebSocket connection close code \({ }^{\text {p63 }}\), and the reason \({ }^{\text {p1015 }}\) attribute initialized to the result of applying UTF-8 decode without BOM to the

\section*{\(\triangle\) Warning!}

User agents must not convey any failure information to scripts in a way that would allow a script to distinguish the following situations:
- A server whose host name could not be resolved.
- A server to which packets could not successfully be routed.
- A server that refused the connection on the specified port.
- A server that failed to correctly perform a TLS handshake (e.g., the server certificate can't be verified).
- A server that did not complete the opening handshake (e.g. because it was not a WebSocket server).
- A WebSocket server that sent a correct opening handshake, but that specified options that caused the client to drop the connection (e.g. the server specified a subprotocol that the client did not offer).
- A WebSocket server that abruptly closed the connection after successfully completing the opening handshake.

In all of these cases, the the WebSocket connection close code \({ }^{\text {p63 }}\) would be 1006, as required by WebSocket Protocol. [WSP] \({ }^{\text {p1292 }}\)

Allowing a script to distinguish these cases would allow a script to probe the user's local network in preparation for an attack.

\section*{Note}

In particular, this means the code 1015 is not used by the user agent (unless the server erroneously uses it in its close frame, of course).

The task source \({ }^{\text {p945 }}\) for all tasks \({ }^{\text {p944 }}\) queued \(^{\text {p945 }}\) in this section is the WebSocket task source.

\subsection*{9.3.4 Ping and Pong frames \(\S_{14}^{\text {p10 }}\)}

The WebSocket protocol defines Ping and Pong frames that can be used for keep-alive, heart-beats, network status probing, latency instrumentation, and so forth. These are not currently exposed in the API.

User agents may send ping and unsolicited pong frames as desired, for example in an attempt to maintain local network NAT mappings, to detect failed connections, or to display latency metrics to the user. User agents must not use pings or unsolicited pongs to aid the server; it is assumed that servers will solicit pongs whenever appropriate for the server's needs.

\subsection*{9.3.5 The CloseEvent \({ }^{\text {p1014 }}\) interface \(\S^{p 10}\)}
\(\underline{\text { WebSocket }}{ }^{\mathrm{p1008}}\) objects use the CloseEvent \({ }^{\mathrm{p1014}}\) interface for their close \({ }^{\text {p1281 }}\) events:
```
[Exposed=(Window,Worker)]
interface CloseEvent : Event {
    constructor(DOMString type, optional CloseEventInit eventInitDict = {});
        readonly attribute boolean wasClean;
        readonly attribute unsigned short code;
        readonly attribute USVString reason;
    };
    dictionary CloseEventInit : EventInit {
```
```
boolean wasClean = false;
unsigned short code = 0;
USVString reason = "";
};
```

\section*{For web developers (non-normative)}

\section*{event . wasClean \({ }^{\text {p1015 }}\)}

Returns true if the connection closed cleanly; false otherwise.
event . code \({ }^{\text {p1015 }}\)
Returns the WebSocket connection close code provided by the server.
event . reason \({ }^{\text {p1015 }}\)
Returns the WebSocket connection close reason provided by the server.

The wasClean attribute must return the value it was initialized to. It represents whether the connection closed cleanly or not.

The code attribute must return the value it was initialized to. It represents the WebSocket connection close code provided by the server.

The reason attribute must return the value it was initialized to. It represents the WebSocket connection close reason provided by the server.

\subsection*{9.3.6 Garbage collection \(\S^{p 10}\)}

A WebSocket \({ }^{\text {p1008 }}\) object whose readyState \({ }^{\text {p1010 }}\) attribute's value was set to CONNECTING \({ }^{\text {p1010 }}(0)\) as of the last time the event loop \({ }^{\text {p944 }}\) reached step \(1^{\text {p946 }}\) must not be garbage collected if there are any event listeners registered for open \({ }^{\text {p1282 }}\) events, message \({ }^{\text {p1282 }}\) events, error \({ }^{\text {p1281 }}\) events, or close \({ }^{\text {p1281 }}\) events.

A WebSocket \({ }^{\text {p1008 }}\) object whose readyState \({ }^{\text {p1010 }}\) attribute's value was set to OPEN \({ }^{\text {p1010 }}\) (1) as of the last time the event loop \({ }^{\text {p944 }}\) reached step \(1^{p 946}\) must not be garbage collected if there are any event listeners registered for message \({ }^{p 1282}\) events, error \({ }^{p 1281}\), or \(c l o s e^{p 1281}\) events.

A WebSocket \({ }^{\text {p1008 }}\) object whose readyState \({ }^{\text {p1010 }}\) attribute's value was set to CLOSING \({ }^{\text {p1010 }}\) (2) as of the last time the event loop \({ }^{\text {p944 }}\) reached step \(1^{\text {p946 }}\) must not be garbage collected if there are any event listeners registered for error \({ }^{\text {p1281 }}\) or close \({ }^{\text {p1281 }}\) events.

A WebSocket \({ }^{p 1008}\) object with an established connection \({ }^{p 62}\) that has data queued to be transmitted to the network must not be garbage collected. [WSP] \({ }^{\text {p1292 }}\)

If a WebSocket \({ }^{\text {p1008 }}\) object is garbage collected while its connection is still open, the user agent must start the WebSocket closing handshake \({ }^{p 63}\), with no status code for the Close message. [WSP] \({ }^{p 1292}\)

If a user agent is to make disappear a WebSocket \({ }^{\text {p1008 }}\) object (this happens when a Document \({ }^{\text {p114 }}\) object goes away), the user agent must follow the first appropriate set of steps from the following list:
\(\rightarrow\) If the WebSocket connection is not yet established \({ }^{\text {p62 }}\) [WSP] \({ }^{\text {p1292 }}\)
Fail the WebSocket connection \({ }^{p 62}\). [WSP] \({ }^{\text {p1292 }}\)
\(\hookrightarrow\) If the WebSocket closing handshake has not yet been started \({ }^{\text {p63 }}\) [WSP] \({ }^{\text {p1292 }}\)
Start the WebSocket closing handshake \({ }^{p 63}\), with the status code to use in the WebSocket Close message being 1001. [WSP] \({ }^{\text {p1292 }}\)
\(\leftrightarrow\) Otherwise
Do nothing.

\subsection*{9.4 Cross-document messaging \(\S^{p 10}\)}

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

\section*{Note}

The postMessage( \()^{\text {p1018 }}\) API can be used as a tracking vector.

\subsection*{9.4.1 Introduction \(\S^{p 10}\)}

This section is non-normative.

\section*{Example}

For example, if document A contains an iframe \({ }^{\mathrm{p} 361}\) element that contains document \(B\), and script in document \(A\) calls postMessage ( ( \({ }^{\text {p1018 }}\) on the Window \({ }^{\text {p824 }}\) object of document \(B\), then a message event will be fired on that object, marked as originating from the Window \({ }^{\text {p824 }}\) of document \(A\). The script in document A might look like:
```
var o = document.getElementsByTagName('iframe')[0];
o.contentWindow.postMessage('Hello world', 'https://b.example.org/');
```

To register an event handler for incoming events, the script would use addEventListener() (or similar mechanisms). For example, the script in document B might look like:
```
window.addEventListener('message', receiver, false);
function receiver(e) {
    if (e.origin == 'https://example.com') {
        if (e.data == 'Hello world') {
            e.source.postMessage('Hello', e.origin);
            } else {
                alert(e.data);
            }
        }
}
```

This script first checks the domain is the expected domain, and then looks at the message, which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.

\subsection*{9.4.2 Security \(\S^{\text {p10 }}\)}

\subsection*{9.4.2.1 Authors \(\S^{p 16}\)}

\section*{\(\triangle\) Warning!}

Use of this API requires extra care to protect users from hostile entities abusing a site for their own purposes.

Authors should check the origin \({ }^{\text {p998 }}\) attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author's message handling code could be exploited by hostile sites.

Furthermore, even after checking the origin \({ }^{\text {p998 }}\) attribute, authors should also check that the data in question is of the expected format. Otherwise, if the source of the event has been attacked using a cross-site scripting flaw, further unchecked processing of information sent using the postMessage( ) \({ }^{\text {p1018 }}\) method could result in the attack being propagated into the receiver.

Authors should not use the wildcard keyword (*) in the targetOrigin argument in messages that contain any confidential information, as
otherwise there is no way to guarantee that the message is only delivered to the recipient to which it was intended.

Authors who accept messages from any origin are encouraged to consider the risks of a denial-of-service attack. An attacker could send a high volume of messages; if the receiving page performs expensive computation or causes network traffic to be sent for each such message, the attacker's message could be multiplied into a denial-of-service attack. Authors are encouraged to employ rate limiting (only accepting a certain number of messages per minute) to make such attacks impractical.

\subsection*{9.4.2.2 User agents \(\S^{\text {plo }}\)}

The integrity of this API is based on the inability for scripts of one origin \({ }^{\text {p837 }}\) to post arbitrary events (using dispatchEvent () or otherwise) to objects in other origins (those that are not the same \({ }^{\text {p838 }}\) ).

\section*{Note}

Implementors are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.

User agents are also encouraged to consider rate-limiting message traffic between different origins \({ }^{\text {p837 }}\), to protect naïve sites from denial-of-service attacks.

\subsection*{9.4.3 Posting messages \(\S^{p 17}\)}

\section*{For web developers (non-normative)}
window . postMessage \({ }^{\text {p1018 }}\) (message [, options ])
Posts a message to the given window. Messages can be structured objects, e.g. nested objects and arrays, can contain JavaScript values (strings, numbers, Date objects, etc), and can contain certain data objects such as File Blob, FileList, and ArrayBuffer objects.
Objects listed in the transfer \({ }^{p 1022}\) member of options are transferred, not just cloned, meaning that they are no longer usable on the sending side.
A target origin can be specified using the target0rigin \({ }^{\text {p825 }}\) member of options. If not provided, it defaults to "/". This default restricts the message to same-origin targets only.

If the origin of the target window doesn't match the given target origin, the message is discarded, to avoid information leakage. To send the message to the target regardless of origin, set the target origin to "*".

Throws a "DataCloneError" DOMException if transfer array contains duplicate objects or if message could not be cloned.

\section*{window. postMessage \({ }^{\text {p1018 }}\) (message, targetOrigin [, transfer ])}

This is an alternate version of postMessage() () pro18 where the target origin is specified as a parameter. Calling window. postMessage(message, target, transfer) is equivalent to window.postMessage(message, \{target0rigin, transfer\}).

\section*{Note}

When posting a message to a Window \({ }^{p 824}\) of a browsing context \({ }^{p 811}\) that has just been navigated to a new Document \({ }^{\text {p114 }}\) is likely to result in the message not receiving its intended recipient: the scripts in the target browsing context \({ }^{p 811}\) have to have had time to set up listeners for the messages. Thus, for instance, in situations where a message is to be sent to the Window \({ }^{\text {p824 }}\) of newly created child iframe \({ }^{\mathrm{p} 361}\), authors are advised to have the child Document \({ }^{\text {p114 }}\) post a message to their parent announcing their readiness to receive messages, and for the parent to wait for this message before beginning posting messages.

The window post message steps, given a targetWindow, message, and options, are as follows:
1. Let targetRealm be targetWindow's Realm \({ }^{\text {p918 }}\).
2. Let incumbentSettings be the incumbent settings object \({ }^{\text {p921 }}\).
3. Let targetOrigin be options["target0rigin \({ }^{\text {p825" }}\) ].
4. If targetOrigin is a single U+002F SOLIDUS character (/), then set targetOrigin to incumbentSettings's origin \({ }^{\text {p917 }}\).
5. Otherwise, if targetOrigin is not a single U+002A ASTERISK character (*), then:
1. Let parsedURL be the result of running the URL parser on targetOrigin.
2. If parsedURL is failure, then throw a "SyntaxError" DOMException.
3. Set targetOrigin to parsedURL's origin.
6. Let transfer be options["transfer \({ }^{\text {p1022" }}\) ].
7. Let serializeWithTransferResult be StructuredSerializeWithTransfer \({ }^{\text {p111 }}\) (message, transfer). Rethrow any exceptions.
8. Queue a global task \({ }^{\text {p945 }}\) on the posted message task source given targetWindow to run the following steps:
1. If the targetOrigin argument is not a single literal U+002A ASTERISK character ( \({ }^{*}\) ) and targetWindow's associated Document \({ }^{\mathrm{p} 826}\) 's origin \({ }^{\mathrm{p} 837}\) is not same origin \({ }^{\mathrm{p} 838}\) with targetOrigin, then return.
2. Let origin be the serialization \({ }^{\mathrm{p} 838}\) of incumbentSettings's origin \({ }^{\text {p917 }}\).
3. Let source be the WindowProxy \({ }^{\text {p834 }}\) object corresponding to incumbentSettings's global object \({ }^{\text {p918 }}\) (a Window \({ }^{\text {p824 }}\) object).
4. Let deserializeRecord be StructuredDeserializeWithTransfer \({ }^{\text {p112 }}\) (serializeWithTransferResult, targetRealm). If this throws an exception, catch it, fire an event named messageerror \({ }^{p 1282}\) at targetWindow, using MessageEvent \({ }^{\text {p998 }}\), with the origin \({ }^{\text {p998 }}\) attribute initialized to origin and the source \({ }^{\text {p999 }}\) attribute initialized to source, and then return.
5. Let messageClone be deserializeRecord.[[Deserialized]].
6. Let newPorts be a new frozen array consisting of all MessagePort \({ }^{\text {p1022 }}\) objects in deserializeRecord.[[TransferredValues]], if any, maintaining their relative order.
7. Fire an event named message \({ }^{\text {p1282 }}\) at targetWindow, using MessageEvent \({ }^{\text {p998 }}\), with the origin \({ }^{\text {p998 }}\) attribute initialized to origin, the source \({ }^{\text {p999 }}\) attribute initialized to source, the data \({ }^{\text {p998 }}\) attribute initialized to messageClone, and the ports \({ }^{\text {p999 }}\) attribute initialized to newPorts.

The postMessage(message, options) method, when invoked on a Window \({ }^{p 824}\) object, must run the following steps:
1. Let targetWindow be this Window \({ }^{\text {p824 }}\) object.
2. Run the window post message steps \({ }^{\mathrm{p} 1017}\) providing targetWindow, message, and options.

The postMessage(message, targetOrigin, transfer) method, when invoked on a Window \({ }^{p 824}\) object, must run the following steps:
1. Let targetWindow be this Window \({ }^{\text {p824 }}\) object.
2. Let options be «[ "target0rigin \({ }^{\text {p825" } " ~} \rightarrow\) targetOrigin, "transfer \({ }^{\text {p1022" }} \rightarrow\) transfer \(] »\).
3. Run the window post message steps \({ }^{\mathrm{p} 1017}\) providing targetWindow, message, and options.

\subsection*{9.5 Channel messaging \({ }_{\delta_{18}^{p 10}}^{\text {p10 }}\)}

\subsection*{9.5.1 Introduction \(\S^{p 10}\)}

This section is non-normative.
To enable independent pieces of code (e.g. running in different browsing contexts \({ }^{\text {p811 }}\) ) to communicate directly, authors can use channel messaging \({ }^{\text {p1018 }}\).

Communication channels in this mechanism are implemented as two-ways pipes, with a port at each end. Messages sent in one port are delivered at the other port, and vice-versa. Messages are delivered as DOM events, without interrupting or blocking running tasks \({ }^{\text {p944 }}\).

To create a connection (two "entangled" ports), the MessageChannel ( ) constructor is called:
```
var channel = new MessageChannel();
```

One of the ports is kept as the local port, and the other port is sent to the remote code, e.g. using postMessage( () \({ }^{\text {p1018 }}\) :
```
otherWindow.postMessage('hello', 'https://example.com', [channel.port2]);
```

To send messages, the postMessage( \()^{\text {p1024 }}\) method on the port is used:
```
channel.port1.postMessage('hello');
```

To receive messages, one listens to message \({ }^{\text {p1282 }}\) events:
```
channel.port1.onmessage = handleMessage;
function handleMessage(event) {
    // message is in event.data
    // ...
}
```

Data sent on a port can be structured data; for example here an array of strings is passed on a MessagePort \({ }^{\text {p1022 }}\) :
```
port1.postMessage(['hello', 'world']);
```

\subsection*{9.5.1.1 Examples \(\mathbb{S}^{p 10}\)}

This section is non-normative.

\section*{Example}

In this example, two JavaScript libraries are connected to each other using MessagePort \({ }^{\text {p1022 }} \mathbf{s}\). This allows the libraries to later be hosted in different frames, or in Worker \({ }^{p 1053}\) objects, without any change to the APIs.
```
<script src="contacts.js"></script> <!-- exposes a contacts object -->
<script src="compose-mail.js"></script> <!-- exposes a composer object -->
<script>
    var channel = new MessageChannel();
    composer.addContactsProvider(channel.port1);
    contacts.registerConsumer(channel.port2);
</script>
```

Here's what the "addContactsProvider()" function's implementation could look like:
```
function addContactsProvider(port) {
    port.onmessage = function (event) {
            switch (event.data.messageType) {
            'search-result': handleSearchResult(event.data.results); break;
            'search-done': handleSearchDone(); break;
            'search-error': handleSearchError(event.data.message); break;
            // ...
        }
    };
};
```

Alternatively, it could be implemented as follows:
```
function addContactsProvider(port) {
    port.addEventListener('message', function (event) {
        if (event.data.messageType == 'search-result')
            handleSearchResult(event.data.results);
    });
    port.addEventListener('message', function (event) {
        if (event.data.messageType == 'search-done')
            handleSearchDone();
    });
    port.addEventListener('message', function (event) {
        if (event.data.messageType == 'search-error')
        handleSearchError(event.data.message);
    });
    // ...
    port.start();
};
```

The key difference is that when using addEventListener(), the start () \({ }^{\text {p1024 }}\) method must also be invoked. When using onmessage \({ }^{\text {p1024 }}\), the call to start() \()^{\text {p1024 }}\) is implied.

The start () \({ }^{\text {p1024 }}\) method, whether called explicitly or implicitly (by setting onmessage \({ }^{\text {p1024 }}\) ), starts the flow of messages: messages posted on message ports are initially paused, so that they don't get dropped on the floor before the script has had a chance to set up its handlers.

\subsection*{9.5.1.2 Ports as the basis of an object-capability model on the web \(\S^{p 10}\)}

This section is non-normative.
Ports can be viewed as a way to expose limited capabilities (in the object-capability model sense) to other actors in the system. This can either be a weak capability system, where the ports are merely used as a convenient model within a particular origin, or as a strong capability model, where they are provided by one origin provider as the only mechanism by which another origin consumer can effect change in or obtain information from provider.

For example, consider a situation in which a social web site embeds in one iframe \({ }^{\text {p361 }}\) the user's email contacts provider (an address book site, from a second origin), and in a second iframe \({ }^{p 361}\) a game (from a third origin). The outer social site and the game in the second iframe \({ }^{\text {p361 }}\) cannot access anything inside the first iframe \({ }^{\text {p361 }}\); together they can only:
- Navigate \({ }^{\text {p866 }}\) the iframe \({ }^{\text {p361 }}\) to a new URL, such as the same URL but with a different fragment, causing the Window \({ }^{\text {p824 }}\) in the iframe \({ }^{\text {p361 }}\) to receive a hashchange \({ }^{\text {p1281 }}\) event.
- Resize the iframe \({ }^{\mathrm{p} 361}\), causing the Window \({ }^{p 824}\) in the iframe \({ }^{\mathrm{p} 361}\) to receive a resize event.
- Send a message \({ }^{\text {p1282 }}\) event to the Window \({ }^{p 824}\) in the iframe \({ }^{\text {p361 }}\) using the window. postMessage() \({ }^{\text {p1018 }}\) API.

The contacts provider can use these methods, most particularly the third one, to provide an API that can be accessed by other origins to manipulate the user's address book. For example, it could respond to a message "add-contact Guillaume Tell
<tell@pomme. example. net>" by adding the given person and email address to the user's address book.
To avoid any site on the web being able to manipulate the user's contacts, the contacts provider might only allow certain trusted sites, such as the social site, to do this.

Now suppose the game wanted to add a contact to the user's address book, and that the social site was willing to allow it to do so on its behalf, essentially "sharing" the trust that the contacts provider had with the social site. There are several ways it could do this; most simply, it could just proxy messages between the game site and the contacts site. However, this solution has a number of difficulties: it requires the social site to either completely trust the game site not to abuse the privilege, or it requires that the social site verify each request to make sure it's not a request that it doesn't want to allow (such as adding multiple contacts, reading the contacts, or deleting them); it also requires some additional complexity if there's ever the possibility of multiple games simultaneously trying to interact with the contacts provider.

Using message channels and MessagePort \({ }^{\text {p1022 }}\) objects, however, all of these problems can go away. When the game tells the social
site that it wants to add a contact, the social site can ask the contacts provider not for it to add a contact, but for the capability to add a single contact. The contacts provider then creates a pair of MessagePort \({ }^{p 1022}\) objects, and sends one of them back to the social site, who forwards it on to the game. The game and the contacts provider then have a direct connection, and the contacts provider knows to only honor a single "add contact" request, nothing else. In other words, the game has been granted the capability to add a single contact.

\subsection*{9.5.1.3 Ports as the basis of abstracting out service implementations \(\S^{\text {p10 }}\)}

This section is non-normative.

Continuing the example from the previous section, consider the contacts provider in particular. While an initial implementation might have simply used XMLHttpRequest objects in the service's iframe \({ }^{p 361}\), an evolution of the service might instead want to use a shared \(\underline{\text { worker }}{ }^{\text {p1054 }}\) with a single WebSocket \({ }^{\text {p1008 }}\) connection.

If the initial design used MessagePort \({ }^{\text {p1022 }}\) objects to grant capabilities, or even just to allow multiple simultaneous independent sessions, the service implementation can switch from the XMLHttpRequests-in-each-iframe \({ }^{\text {p361 }}\) model to the shared-WebSocket \({ }^{\text {p1008 }}\) model without changing the API at all: the ports on the service provider side can all be forwarded to the shared worker without it affecting the users of the API in the slightest.

\subsection*{9.5.2 Message channels \(\S^{p 10}\)}

IDL [Exposed=(Window, Worker)]
interface MessageChannel \{ constructor();
readonly attribute MessagePort port1; readonly attribute MessagePort port2;
\};

\section*{For web developers (non-normative)}
channel \(=\) new MessageChannel \({ }^{\text {p1021 }}\) ()
Returns a new MessageChannel \({ }^{p 1021}\) object with two new MessagePort \({ }^{\text {p1022 }}\) objects.
channel. port1 \({ }^{\text {p1021 }}\)
Returns the first MessagePort \({ }^{\text {p1022 }}\) object.
channel. port2 \({ }^{\text {p1021 }}\)
Returns the second MessagePort \({ }^{\text {p1022 }}\) object.

A MessageChannel \({ }^{\text {p1021 }}\) object has an associated port 1 and an associated port 2, both MessagePort \({ }^{\text {p1022 }}\) objects.
The new MessageChannel() constructor steps are:
1. Set this's port \(1^{\text {p1021 }}\) to a new MessagePort \({ }^{\text {p1022 }}\) in this's relevant Realm \({ }^{\text {p924 }}\).
2. Set this's port \(2^{\text {p1021 }}\) to a new MessagePort \({ }^{\text {p1022 }}\) in this's relevant Realm \({ }^{\text {p924 }}\).
3. Entangle \({ }^{\text {p1022 }}\) this's port \(1^{\text {p1021 }}\) and this's port \(2^{\text {p1021 }}\).

The port1 getter steps are to return this's port \(1^{\text {p1021 }}\).
The port2 getter steps are to return this's port \(2^{\text {p1021 }}\).

\subsection*{9.5.3 Message ports \(\S_{21}^{\text {p10 }}\)}

Each channel has two message ports. Data sent through one port is received by the other port, and vice versa.
```
IDL [Exposed=(Window,Worker,AudioWorklet), Transferable]
interface MessagePort : EventTarget {
    undefined postMessage(any message, sequence<object> transfer);
    undefined postMessage(any message, optional PostMessageOptions options = {});
    undefined start();
    undefined close();
    // event handlers
    attribute EventHandler onmessage;
    attribute EventHandler onmessageerror;
};
dictionary PostMessageOptions {
    sequence<object> transfer = [];
};
```

\section*{For web developers (non-normative)}
port . postMessage \({ }^{\text {p1024 }}\) (message [, transfer] )
port . postMessage \({ }^{\text {p1024 }}\) (message [, \{ transfer \}])
Posts a message through the channel. Objects listed in transfer are transferred, not just cloned, meaning that they are no longer usable on the sending side.
Throws a "DataCloneError" DOMException if transfer contains duplicate objects or port, or if message could not be cloned.
port . start \({ }^{\text {p1024 }}\) ()
Begins dispatching messages received on the port.
port . close \({ }^{\text {p1024 }}\) ()
Disconnects the port, so that it is no longer active.

Each MessagePort \({ }^{\text {p1022 }}\) object can be entangled with another (a symmetric relationship). Each MessagePort \({ }^{\text {p1022 }}\) object also has a task source \({ }^{\text {p945 }}\) called the port message queue, initially empty. A port message queue \({ }^{\text {p1022 }}\) can be enabled or disabled, and is initially disabled. Once enabled, a port can never be disabled again (though messages in the queue can get moved to another queue or removed altogether, which has much the same effect). A MessagePort \({ }^{p 1022}\) also has a has been shipped flag, which must initially be false.

When a port's port message queue \({ }^{\text {p1022 }}\) is enabled, the event loop \({ }^{\text {p944 }}\) must use it as one of its task sources \({ }^{\text {p945 }}\). When a port's relevant global object \({ }^{\text {p924 }}\) is a Window \({ }^{\text {p824 }}\), all tasks \({ }^{\text {p944 }}\) queued \({ }^{\text {p945 }}\) on its port message queue \({ }^{\text {p1022 }}\) must be associated with the port's relevant global object \({ }^{\text {p924 's }}\) associated Document \({ }^{\text {p826 }}\).

\section*{Note}

If the document is fully active \({ }^{p 815}\), but the event listeners all have scripts whose settings objects \({ }^{p 925}\) specify responsible documents \({ }^{p 917}\) that are not fully active \({ }^{p 815}\), then the messages will not be recieved unless and until the documents become fully active \({ }^{\text {p815 }}\) again.

Each event loop \({ }^{\text {p944 }}\) has a task source \({ }^{\text {p945 }}\) called the unshipped port message queue. This is a virtual task source \({ }^{\text {p945 }}\) : it must act as if it contained the tasks \({ }^{\text {p944 }}\) of each port message queue \({ }^{\text {p1022 }}\) of each MessagePort \({ }^{p 1022}\) whose has been shipped \({ }^{p 1022}\) flag is false, whose port message queue \({ }^{\text {p1022 }}\) is enabled, and whose relevant agent \({ }^{\text {p914 }}\) 's event loop \({ }^{\text {p944 }}\) is that event loop \({ }^{\text {p944 }}\), in the order in which they were added to their respective task source \({ }^{\text {p945 }}\). When a task \({ }^{\text {p944 }}\) would be removed from the unshipped port message queue \({ }^{\text {p1022 }}\), it must instead be removed from its port message queue \({ }^{\text {p1022 }}\).

When a MessagePort \({ }^{\text {p1022 }}\) 's has been shipped \({ }^{\text {p1022 }}\) flag is false, its port message queue \({ }^{\text {p1022 }}\) must be ignored for the purposes of the event loop \({ }^{\text {p944 }}\). (The unshipped port message queue \({ }^{\text {p1022 }}\) is used instead.)

\section*{Note}

The has been shipped \({ }^{p 1022}\) flag is set to true when a port, its twin, or the object it was cloned from, is or has been transferred. When a MessagePort \({ }^{p 1022}\) 's has been shipped \({ }^{p 1022}\) flag is true, its port message queue \({ }^{p 1022}\) acts as a first-class task source \({ }^{p 945}\), unaffected to any unshipped port message queue \({ }^{\text {p1022 }}\).

When the user agent is to entangle two MessagePort \({ }^{\text {p1022 }}\) objects, it must run the following steps:
1. If one of the ports is already entangled, then disentangle it and the port that it was entangled with.

Note
If those two previously entangled ports were the two ports of a MessageChannel \({ }^{\text {p1021 }}\) object, then that MessageChannel \({ }^{\text {p1021 }}\) object no longer represents an actual channel: the two ports in that object are no longer entangled.
2. Associate the two ports to be entangled, so that they form the two parts of a new channel. (There is no MessageChanne \({ }^{p 1021}\) object that represents this channel.)

Two ports \(A\) and \(B\) that have gone through this step are now said to be entangled; one is entangled to the other, and vice versa.

\section*{Note}

While this specification describes this process as instantaneous, implementations are more likely to implement it via message passing. As with all algorithms, the key is "merely" that the end result be indistinguishable, in a black-box sense, from the specification.

\section*{MessagePort \({ }^{\mathrm{p} 1022}\) objects are transferable objects \({ }^{\mathrm{p} 103}\). Their transfer steps \({ }^{\text {p104 }}\), given value and dataHolder, are:}
1. Set value's has been shipped \({ }^{\text {p1022 }}\) flag to true.
2. Set dataHolder.[[PortMessageQueue]] to value's port message queue \({ }^{\text {p1022 }}\).
3. If value is entangled with another port remotePort, then:
1. Set remotePort's has been shipped \({ }^{p 1022}\) flag to true.
2. Set dataHolder.[[RemotePort]] to remotePort.
4. Otherwise, set dataHolder.[[RemotePort]] to null.

Their transfer-receiving steps \({ }^{\text {p104 }}\), given dataHolder and value, are:
1. Set value's has been shipped \({ }^{\text {p1022 }}\) flag to true.
2. Move all the tasks \({ }^{\text {p944 }}\) that are to fire message \({ }^{\text {p1282 }}\) events in dataHolder.[[PortMessageQueue]] to the port message queue \({ }^{\text {p1022 }}\) of value, if any, leaving value's port message queue \({ }^{\text {p1022 }}\) in its initial disabled state, and, if value's relevant global object \({ }^{\text {p924 }}\) is a Window \({ }^{\text {p824 }}\), associating the moved tasks \({ }^{\text {p944 }}\) with value's relevant global object \({ }^{\text {p924's }}\) associated Document \({ }^{\text {p826 }}\).
3. If dataHolder.[[RemotePort]] is not null, then entangle \({ }^{\text {p1022 }}\) dataHolder.[[RemotePort]] and value. (This will disentangle dataHolder.[[RemotePort]] from the original port that was transferred.)

The message port post message steps, given a targetPort, message and options are as follows:
1. Let transfer be options["transfer \({ }^{\text {p1022" } "] . ~}\)
2. If transfer contains this MessagePort \({ }^{\text {p1022 }}\), then throw a "DataCloneError" DOMException.
3. Let doomed be false.
4. If targetPort is not null and transfer contains targetPort, then set doomed to true and optionally report to a developer console that the target port was posted to itself, causing the communication channel to be lost.
5. Let serializeWithTransferResult be StructuredSerializeWithTransfer \({ }^{\text {p111 }}\) (message, transfer). Rethrow any exceptions.
6. If targetPort is null, or if doomed is true, then return.
7. Add a task \({ }^{\text {p944 }}\) that runs the following steps to the port message queue \({ }^{\text {p1022 }}\) of targetPort:
1. Let finalTargetPort be the MessagePort \({ }^{p 1022}\) in whose port message queue \({ }^{\text {p1022 }}\) the task now finds itself.

\section*{Note}

This can be different from targetPort, if targetPort itself was transferred and thus all its tasks moved along with it.
2. Let targetRealm be finalTargetPort's relevant Realm \({ }^{\text {p924 }}\).
3. Let deserializeRecord be StructuredDeserializeWithTransfer \({ }^{\text {p112 }}\) (serializeWithTransferResult, targetRealm).

If this throws an exception, catch it, fire an event named messageerror \({ }^{p 1282}\) at finalTargetPort, using
MessageEvent \({ }^{\text {p998 }}\), and then return.
4. Let messageClone be deserializeRecord.[[Deserialized]].
5. Let newPorts be a new frozen array consisting of all MessagePort \({ }^{\text {p1022 }}\) objects in deserializeRecord.[[TransferredValues]], if any, maintaining their relative order.
6. Fire an event named message \({ }^{\text {p1282 }}\) at finalTargetPort, using MessageEvent \({ }^{\text {p998 }}\), with the data \({ }^{\text {p998 }}\) attribute initialized to messageClone and the ports \({ }^{\text {p999 }}\) attribute initialized to newPorts.

The postMessage(message, options) method, when invoked on a MessagePort \({ }^{\text {p1022 }}\) object must run the following steps:
1. Let targetPort be the port with which this MessagePort \({ }^{\text {p1022 }}\) is entangled, if any; otherwise let it be null.
2. Run the message port post message steps \({ }^{\text {p1023 }}\) providing targetPort, message and options.

The postMessage(message, transfer) method, when invoked on a MessagePort \({ }^{1022}\) object must run the following steps:
1. Let targetPort be the port with which this MessagePort \({ }^{\text {p1022 }}\) is entangled, if any; otherwise let it be null.
2. Let options be «[ "transfer \({ }^{\text {p1022" }} \rightarrow\) transfer ]».
3. Run the message port post message steps \({ }^{\text {p1023 }}\) providing targetPort, message and options.

The start() method, when invoked, must enable this MessagePort \({ }^{\text {p1022 }}\) object's port message queue \({ }^{\text {p1022 }}\), if it is not already enabled.

The close() method, when invoked, must run these steps:
1. Set this MessagePort \({ }^{p 1022}\) object's [[Detached]] \({ }^{\text {p104 }}\) internal slot value to true.
2. If this MessagePort \({ }^{\text {p1022 }}\) object is entangled, disentangle it.

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p9577 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by all objects implementing the MessagePort \({ }^{\text {p1022 }}\) interface:

Event handler \({ }^{\text {p954 }}\) Event handler event type \({ }^{\text {p957 }}\)
\begin{tabular}{l|l}
\hline onmessage & message \(^{\text {P1282 }}\) \\
\hline onmessageerror & messageerror \(^{\text {p1282 }}\) \\
\hline
\end{tabular}

The first time a MessagePort \({ }^{\text {p1022 }}\) object's onmessage \({ }^{\text {p1024 }}\) IDL attribute is set, the port's port message queue \({ }^{\text {p1022 }}\) must be enabled, as if the start( () \({ }^{p 1024}\) method had been called.

\subsection*{9.5.4 Broadcasting to many ports \(\S^{\text {p10 }}\)}

This section is non-normative.
Broadcasting to many ports is in principle relatively simple: keep an array of MessagePort \({ }^{\text {p1022 }}\) objects to send messages to, and iterate through the array to send a message. However, this has one rather unfortunate effect: it prevents the ports from being garbage collected, even if the other side has gone away. To avoid this problem, implement a simple protocol whereby the other side acknowledges it still exists. If it doesn't do so after a certain amount of time, assume it's gone, close the MessagePort \({ }^{\text {p1022 }}\) object, and let it be garbage collected.

\subsection*{9.5.5 Ports and garbage collection \(\S^{p 10}\)}

When a MessagePort \({ }^{\text {p1022 }}\) object \(o\) is entangled, user agents must either act as if o's entangled MessagePort \({ }^{\text {p1022 }}\) object has a strong reference to \(o\), or as if \(o\) 's relevant global object \({ }^{\text {p924 }}\) has a strong reference to \(o\).

\section*{Note}

Thus, a message port can be received, given an event listener, and then forgotten, and so long as that event listener could receive a message, the channel will be maintained.

Of course, if this was to occur on both sides of the channel, then both ports could be garbage collected, since they would not be reachable from live code, despite having a strong reference to each other.

Furthermore, a MessagePort \({ }^{\text {p1022 }}\) object must not be garbage collected while there exists an event referenced by a task \({ }^{\text {p944 }}\) in a task queue \({ }^{\text {p944 }}\) that is to be dispatched on that MessagePort \({ }^{\text {p1022 }}\) object, or while the MessagePort \({ }^{p 1022}\) object's port message queue \({ }^{\text {p1022 }}\) is enabled and not empty.

\section*{Note}

Authors are strongly encouraged to explicitly close MessagePort \({ }^{\text {p1022 }}\) objects to disentangle them, so that their resources can be recollected. Creating many MessagePort \({ }^{\text {p1022 }}\) objects and discarding them without closing them can lead to high transient memory usage since garbage collection is not necessarily performed promptly, especially for MessagePort \({ }^{\text {p1022 }} s\) where garbage collection can involve cross-process coordination.

\subsection*{9.6 Broadcasting to other browsing contexts \(\S^{\text {p10 }}\)}

Pages on a single origin \({ }^{\text {p837 }}\) opened by the same user in the same user agent but in different unrelated browsing contexts \({ }^{\text {p811 }}\)
sometimes need to send notifications to each other, for example "hey, the user logged in over here, check your credentials again".
For elaborate cases, e.g. to manage locking of shared state, to manage synchronization of resources between a server and multiple local clients, to share a WebSocket \({ }^{p 1008}\) connection with a remote host, and so forth, shared workers \({ }^{\text {p1054 }}\) are the most appropriate solution.

For simple cases, though, where a shared worker would be an unreasonable overhead, authors can use the simple channel-based broadcast mechanism described in this section.

IDL [Exposed=(Window, Worker)]
interface BroadcastChannel : EventTarget \{ constructor(DOMString name);
readonly attribute DOMString name;
undefined postMessage(any message);
undefined close();
attribute EventHandler onmessage;
attribute EventHandler onmessageerror;
\};

\section*{For web developers (non-normative)}

\section*{broadcastChannel \(=\) new BroadcastChannel \({ }^{\text {p1026 }}\) (name)}

Returns a new BroadcastChannel \({ }^{\text {p1025 }}\) object via which messages for the given channel name can be sent and received.

\section*{broadcastChannel . name \({ }^{\text {p1026 }}\)}

Returns the channel name (as passed to the constructor).

\section*{broadcastChannel . postMessage \({ }^{\text {p1026 }}\) (message)}

Sends the given message to other BroadcastChannet \({ }^{p 1025}\) objects set up for this channel. Messages can be structured objects, e.g. nested objects and arrays.
broadcastChannel . close \({ }^{\text {p1026 }}\) ()
Closes the BroadcastChannel \({ }^{\text {p1025 }}\) object, opening it up to garbage collection.

The new BroadcastChannel(name) constructor steps are:
1. Set this's channel name \({ }^{\text {p1026 }}\) to name.
2. Set this's closed flag \({ }^{\text {p1026 }}\) to false.

The name getter steps are to return this's channel name \({ }^{\text {p1026 }}\).
The postMessage(message) method steps are:
1. If this's closed flag \({ }^{\text {p1026 }}\) is true, then throw an "InvalidStateError" DOMException.
2. Let serialized be StructuredSerialize \({ }^{\text {p108 }}\) (message). Rethrow any exceptions.
3. Let sourceOrigin be this's relevant settings object \({ }^{\mathrm{p} 924}\) 's origin \({ }^{\text {p917 }}\).
4. Let destinations be a list of BroadcastChannel \(l^{p 1025}\) objects that match the following criteria:
- Their relevant global object \({ }^{\text {p924 }}\) is either:
- a Window \({ }^{\text {p824 }}\) object whose associated Document \({ }^{\text {p826 }}\) is fully active \({ }^{\text {p815 }}\), or
- a WorkerGlobalScope \({ }^{\text {p1044 }}\) object whose closing \({ }^{\text {p1047 }}\) flag is false and whose worker \({ }^{\text {p1053 }}\) is not a suspendable worker \({ }^{\text {p1048 }}\).
- Their relevant settings object \({ }^{\text {p924 }}\) 's origin \({ }^{\text {p917 }}\) is same origin \({ }^{\text {p838 }}\) with sourceOrigin.
- Their channel name \({ }^{\text {p1026 }}\) is this's channel name \({ }^{\text {p1026 }}\).
5. Remove source from destinations.
6. Sort destinations such that all BroadcastChannel \({ }^{\text {p1025 }}\) objects whose relevant agents \({ }^{\text {p914 }}\) are the same are sorted in creation order, oldest first. (This does not define a complete ordering. Within this constraint, user agents may sort the list in any implementation-defined manner.)
7. For each destination in destinations, queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\mathrm{p952}}\) given destination's relevant global object \({ }^{\text {p924 }}\) to perform the following steps:
1. If destination's closed flag \({ }^{\text {p1026 }}\) is true, then abort these steps.
2. Let targetRealm be destination's relevant Realm \({ }^{\text {p924 }}\).
3. Let data be StructuredDeserialize \({ }^{\text {p108 }}\) (serialized, targetRealm).

If this throws an exception, catch it, fire an event named messageerror \({ }^{\text {p1282 }}\) at destination, using MessageEvent \({ }^{\text {p998 }}\), with the origin \({ }^{\text {p998 }}\) attribute initialized to the serialization \({ }^{\text {p838 }}\) of sourceOrigin, and then abort these steps.
4. Fire an event named message \({ }^{\text {p1282 }}\) at destination, using MessageEvent \({ }^{\text {p998 }}\), with the data \({ }^{\text {p998 }}\) attribute initialized to data and the origin \({ }^{\text {p998 }}\) attribute initialized to the serialization \({ }^{\text {p838 }}\) of sourceOrigin.

While a BroadcastChanne \(l^{\text {p1025 }}\) object whose closed flag \({ }^{\text {p1026 }}\) is false has an event listener registered for message \({ }^{\text {p1282 }}\) or messageerror \({ }^{\text {p1282 }}\) events, there must be a strong reference from the BroadcastChannel \({ }^{\text {p1025 }}\) object's relevant global object \({ }^{\text {p924 }}\) to the BroadcastChannel \({ }^{\text {p1025 }}\) object itself.

The close() method steps are to set this's closed flag \({ }^{\text {p1026 }}\) to true.

\section*{Note}

Authors are strongly encouraged to explicitly close BroadcastChannel \({ }^{p 1025}\) objects when they are no longer needed, so that they can be garbage collected. Creating many BroadcastChannel \({ }^{p 1025}\) objects and discarding them while leaving them with an event listener and without closing them can lead to an apparent memory leak, since the objects will continue to live for as long as they have an event listener (or until their page or worker is closed).

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p9577 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by all objects implementing the BroadcastChannel \({ }^{\text {p1025 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline &
\end{tabular}
\begin{tabular}{l|l}
\hline onmessage & message \(^{\mathrm{P} 1282}\) \\
\hline onmessageerror & messageerror \(^{\mathrm{p} 1282}\) \\
\hline
\end{tabular}

\section*{Example}

Suppose a page wants to know when the user logs out, even when the user does so from another tab at the same site:
```
var authChannel = new BroadcastChannel('auth');
authChannel.onmessage = function (event) {
    if (event.data == 'logout')
        showLogout();
}
function logoutRequested() {
    // called when the user asks us to log them out
        doLogout();
        showLogout();
        authChannel.postMessage('logout');
}
    function doLogout() {
        // actually log the user out (e.g. clearing cookies)
        // ...
}
    function showLogout() {
        // update the UI to indicate we're logged out
    // ...
}
```

\section*{10 Web workers \(\S^{\text {p10 }}\)}

28

\subsection*{10.1 Introduction \(\S^{p 10}\) \\ 28}

\subsection*{10.1.1 Scope \(\S^{p 10}\)}

This section is non-normative.
This specification defines an API for running scripts in the background independently of any user interface scripts.
This allows for long-running scripts that are not interrupted by scripts that respond to clicks or other user interactions, and allows long tasks to be executed without yielding to keep the page responsive.

Workers (as these background scripts are called herein) are relatively heavy-weight, and are not intended to be used in large numbers. For example, it would be inappropriate to launch one worker for each pixel of a four megapixel image. The examples below show some appropriate uses of workers.

Generally, workers are expected to be long-lived, have a high start-up performance cost, and a high per-instance memory cost.

\subsection*{10.1.2 Examples \(\S^{\text {p10 }}\)}

This section is non-normative.
There are a variety of uses that workers can be put to. The following subsections show various examples of this use.

\section*{}

This section is non-normative.

The simplest use of workers is for performing a computationally expensive task without interrupting the user interface.
In this example, the main document spawns a worker to (naïvely) compute prime numbers, and progressively displays the most recently found prime number.

The main page is as follows:
```
<!DOCTYPE HTML>
<html lang="en">
    <head>
        <meta charset="utf-8">
        <title>Worker example: One-core computation</title>
    </head>
    <body>
        <p>The highest prime number discovered so far is: <output id="result"></output></p>
        <script>
        var worker = new Worker('worker.js');
        worker.onmessage = function (event) {
            document.getElementById('result').textContent = event.data;
        };
    </script>
    </body>
</html>
```
communicate with the worker. That object's onmessage \({ }^{\text {p11054 }}\) event handler allows the code to receive messages from the worker.
The worker itself is as follows:
```

var n = 1;
search: while (true) {
n += 1;
for (var i = 2; i <= Math.sqrt(n); i += 1)
if (n % i == 0)
continue search;
// found a prime!
postMessage(n);
}

```

The bulk of this code is simply an unoptimized search for a prime number. The postMessage( ) \({ }^{\text {p1046 }}\) method is used to send a message back to the page when a prime is found.

View this example online.

\section*{}

This section is non-normative.
All of our examples so far show workers that run classic scripts \({ }^{\text {p925 }}\). Workers can instead be instantiated using module scripts \({ }^{\text {p925 }}\), which have the usual benefits: the ability to use the JavaScript import statement to import other modules; strict mode by default; and toplevel declarations not polluting the worker's global scope.

As the import statement is available, the importScripts() \({ }^{p 1056}\) method will automatically fail inside module workers.
In this example, the main document uses a worker to do off-main-thread image manipulation. It imports the filters used from another module.

The main page is as follows:
```

<!DOCTYPE html>

<html lang="en">
<meta charset="utf-8">
<title>Worker example: image decoding</title>
<p>
    <label>
        Type an image URL to decode
        <input type="url" id="image-url" list="image-list">
        <datalist id="image-list">
            <option value="https://html.spec.whatwg.org/images/drawImage.png">
            <option value="https://html.spec.whatwg.org/images/robots.jpeg">
            <option value="https://html.spec.whatwg.org/images/arcTo2.png">
        </datalist>
    </label>
</p>
<p>
    <label>
        Choose a filter to apply
        <select id="filter">
            <option value="none">none</option>
            <option value="grayscale">grayscale</option>
            <option value="brighten">brighten by 20%</option>
        </select>
    </label>
</p>
```
```
<canvas id="output"></canvas>
<script type="module">
    const worker = new Worker("worker.js", { type: "module" });
    worker.onmessage = receiveFromWorker;
    const url = document.querySelector("#image-url");
    const filter = document.querySelector("#filter");
    const output = document.querySelector("#output");
    url.oninput = updateImage;
    filter.oninput = sendToWorker;
    let imageData, context;
    function updateImage() {
        const img = new Image();
        img.src = url.value;
        img.onload = () => {
            output.innerHTML = "";
            const canvas = document.createElement("canvas");
            canvas.width = img.width
            canvas.height = img.height;
            context = canvas.getContext("2d");
            context.drawImage(img, 0, 0);
            imageData = context.getImageData(0, 0, canvas.width, canvas.height);
            sendToWorker();
            output.appendChild(canvas);
        };
    }
    function sendToWorker() {
        worker.postMessage({ imageData, filter: filter.value });
    }
    function receiveFromWorker(e) {
        context.putImageData(e.data, 0, 0);
    }
</script>
```

The worker file is then:
```
import * as filters from "./filters.js";
self.onmessage = e => {
    const { imageData, filter } = e.data;
    filters[filter](imageData);
    self.postMessage(imageData, [imageData.data.buffer]);
};
```

Which imports the file filters.js:
```
export function none() {}
export function grayscale({ data: d }) {
    for (let i = 0; i < d.length; i += 4) {
```
```
            const [r, g, b] = [d[i], d[i + 1], d[i + 2]];
            // CIE luminance for the RGB
            // The human eye is bad at seeing red and blue, so we de-emphasize them.
            d[i] = d[i + 1] = d[i + 2] = 0.2126*r + 0.7152*g + 0.0722* b;
    }
};
export function brighten({ data: d }) {
    for (let i = 0; i < d.length; ++i) {
        d[i] *= 1.2;
    }
};
```

View this example online.

\subsection*{10.1.2.3 Shared workers introduction \({ }_{31}{ }^{\mathrm{pr10}}\)}

This section is non-normative.

This section introduces shared workers using a Hello World example. Shared workers use slightly different APIs, since each worker can have multiple connections.

This first example shows how you connect to a worker and how a worker can send a message back to the page when it connects to it. Received messages are displayed in a log.

Here is the HTML page:
```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 1</title>
<pre id="log">Log:</pre>
<script>
    var worker = new SharedWorker('test.js');
    var log = document.getElementById('log');
    worker.port.onmessage = function(e) { // note: not worker.onmessage!
        log.textContent += '\n' + e.data;
    }
</script>
```

Here is the JavaScript worker:
```
onconnect = function(e) {
    var port = e.ports[0];
    port.postMessage('Hello World!');
}
```

View this example online.

This second example extends the first one by changing two things: first, messages are received using addEventListener( ) instead of an event handler IDL attribute \({ }^{\text {p955 }}\), and second, a message is sent to the worker, causing the worker to send another message in return. Received messages are again displayed in a log.

Here is the HTML page:
```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
```
```
<title>Shared workers: demo 2</title>
<pre id="log">Log:</pre>
<script>
    var worker = new SharedWorker('test.js');
    var log = document.getElementById('log');
    worker.port.addEventListener('message', function(e) {
                log.textContent += '\n' + e.data;
    }, false);
    worker.port.start(); // note: need this when using addEventListener
    worker.port.postMessage('ping');
</script>
```

Here is the JavaScript worker:
```
onconnect = function(e) {
    var port = e.ports[0];
    port.postMessage('Hello World!');
    port.onmessage = function(e) {
        port.postMessage('pong'); // not e.ports[0].postMessage!
        // e.target.postMessage('pong'); would work also
    }
}
```

View this example online.

Finally, the example is extended to show how two pages can connect to the same worker; in this case, the second page is merely in an iframe \({ }^{\text {p361 }}\) on the first page, but the same principle would apply to an entirely separate page in a separate top-level browsing context \({ }^{\text {p814 }}\).

Here is the outer HTML page:
```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
    var worker = new SharedWorker('test.js');
    var log = document.getElementById('log');
    worker.port.addEventListener('message', function(e) {
        log.textContent += '\n' + e.data;
    }, false);
    worker.port.start();
    worker.port.postMessage('ping');
</script>
<iframe src="inner.html"></iframe>
```

Here is the inner HTML page:
```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3 inner frame</title>
<pre id=log>Inner log:</pre>
<script>
    var worker = new SharedWorker('test.js');
    var log = document.getElementById('log');
    worker.port.onmessage = function(e) {
        log.textContent += '\n' + e.data;
    }
```

Here is the JavaScript worker:
```
var count = 0;
onconnect = function(e) {
    count += 1;
    var port = e.ports[0];
    port.postMessage('Hello World! You are connection #' + count);
    port.onmessage = function(e) {
        port.postMessage('pong');
    }
}
```

View this example online.

\subsection*{10.1.2.4 Shared state using a shared worker \({ }_{33}^{\S^{p 10}}\)}

This section is non-normative.
In this example, multiple windows (viewers) can be opened that are all viewing the same map. All the windows share the same map information, with a single worker coordinating all the viewers. Each viewer can move around independently, but if they set any data on the map, all the viewers are updated.

The main page isn't interesting, it merely provides a way to open the viewers:
```
<!DOCTYPE HTML>
<html lang="en">
    <head>
        <meta charset="utf-8">
        <title>Workers example: Multiviewer</title>
        <script>
        function openViewer() {
            window.open('viewer.html');
        }
        </script>
</head>
    <body>
        <p><button type=button onclick="openViewer()">Open a new
        viewer</button></p>
        <p>Each viewer opens in a new window. You can have as many viewers
        as you like, they all view the same data.</p>
    </body>
</html>
```

The viewer is more involved:
```

<!DOCTYPE HTML>

<html lang="en">
    <head>
        <meta charset="utf-8">
        <title>Workers example: Multiviewer viewer</title>
        <script>
            var worker = new SharedWorker('worker.js', 'core');
        // CONFIGURATION
        function configure(event) {
            if (event.data.substr(0, 4) != 'cfg ') return;
            var name = event.data.substr(4).split(' ', 1)[0];
```
```
    // update display to mention our name is name
    document.getElementsByTagName('h1')[0].textContent += ' ' + name;
    // no longer need this listener
    worker.port.removeEventListener('message', configure, false);
}
worker.port.addEventListener('message', configure, false);
// MAP
function paintMap(event) {
    if (event.data.substr(0, 4) != 'map ') return;
    var data = event.data.substr(4).split(',');
    // display tiles data[0] .. data[8]
    var canvas = document.getElementById('map');
    var context = canvas.getContext('2d');
    for (var y = 0; y < 3; y += 1) {
        for (var x = 0; x < 3; x += 1) {
            var tile = data[y * 3 + x];
            if (tile == '0')
                context.fillStyle = 'green';
            else
                context.fillStyle = 'maroon';
                context.fillRect(x * 50, y * 50, 50, 50);
        }
    }
}
worker.port.addEventListener('message', paintMap, false);
// PUBLIC CHAT
function updatePublicChat(event) {
    if (event.data.substr(0, 4) != 'txt ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var message = event.data.substr(4 + name.length + 1);
    // display "<name> message" in public chat
    var public = document.getElementById('public');
    var p = document.createElement('p');
    var n = document.createElement('button');
    n.textContent = '<' + name + '> ';
    n.onclick = function () { worker.port.postMessage('msg ' + name); };
    p.appendChild(n);
    var m = document.createElement('span');
    m.textContent = message;
    p.appendChild(m);
    public.appendChild(p);
}
worker.port.addEventListener('message', updatePublicChat, false);
// PRIVATE CHAT
function startPrivateChat(event) {
    if (event.data.substr(0, 4) != 'msg ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var port = event.ports[0];
    // display a private chat UI
    var ul = document.getElementById('private');
    var li = document.createElement('li');
    var h3 = document.createElement('h3');
    h3.textContent = 'Private chat with ' + name;
    li.appendChild(h3);
    var div = document.createElement('div');
    var addMessage = function(name, message) {
        var p = document.createElement('p');
        var n = document.createElement('strong');
        n.textContent = '<' + name + '> ';
```
```
            p.appendChild(n);
            var t = document.createElement('span');
            t.textContent = message;
            p.appendChild(t);
            div.appendChild(p);
        };
        port.onmessage = function (event) {
            addMessage(name, event.data);
        };
        li.appendChild(div);
        var form = document.createElement('form');
        var p = document.createElement('p');
        var input = document.createElement('input');
        input.size = 50;
        p.appendChild(input);
        p.appendChild(document.createTextNode(' '));
        var button = document.createElement('button');
        button.textContent = 'Post';
        p.appendChild(button);
        form.onsubmit = function () {
            port.postMessage(input.value);
            addMessage('me', input.value);
            input.value = '';
            return false;
        };
        form.appendChild(p);
        li.appendChild(form);
        ul.appendChild(li);
        }
        worker.port.addEventListener('message', startPrivateChat, false);
        worker.port.start();
    </script>
    </head>
    <body>
        <h1>Viewer</h1>
        <h2>Map</h2>
        <p><canvas id="map" height=150 width=150></canvas></p>
        <p>
        <button type=button onclick="worker.port.postMessage('mov left')">Left</button>
        <button type=button onclick="worker.port.postMessage('mov up')">Up</button>
        <button type=button onclick="worker.port.postMessage('mov down')">Down</button>
        <button type=button onclick="worker.port.postMessage('mov right')">Right</button>
        <button type=button onclick="worker.port.postMessage('set 0')">Set 0</button>
        <button type=button onclick="worker.port.postMessage('set 1')">Set 1</button>
    </p>
    <h2>Public Chat</h2>
    <div id="public"></div>
    <form onsubmit="worker.port.postMessage('txt ' + message.value); message.value = ''; return false;">
        <p>
            <input type="text" name="message" size="50">
            <button>Post</button>
        </p>
    </form>
    <h2>Private Chat</h2>
    <ul id="private"></ul>
    </body>
    </html>
```

There are several key things worth noting about the way the viewer is written.

Multiple listeners. Instead of a single message processing function, the code here attaches multiple event listeners, each one
performing a quick check to see if it is relevant for the message. In this example it doesn't make much difference, but if multiple authors wanted to collaborate using a single port to communicate with a worker, it would allow for independent code instead of changes having to all be made to a single event handling function.

Registering event listeners in this way also allows you to unregister specific listeners when you are done with them, as is done with the configure() method in this example.

Finally, the worker:
```

var nextName = 0;
function getNextName() {
// this could use more friendly names
// but for now just return a number
return nextName++;
}
var map = [
[0, 0, 0, 0, 0, 0, 0],
[1, 1, 0, 1, 0, 1, 1],
[0, 1, 0, 1, 0, 0, 0],
[0, 1, 0, 1, 0, 1, 1],
[0, 0, 0, 1, 0, 0, 0],
[1, 0, 0, 1, 1, 1, 1],
[1, 1, 0, 1, 1, 0, 1],
];
function wrapX(x) {
if (x < 0) return wrapX(x + map[0].length);
if (x >= map[0].length) return wrapX(x - map[0].length);
return x;
}
function wrapY(y) {
if (y < 0) return wrapY(y + map.length);
if (y >= map[0].length) return wrapY(y - map.length);
return y;
}
function wrap(val, min, max) {
if (val < min)
return val + (max-min)+1;
if (val > max)
return val - (max-min)-1;
return val;
}
function sendMapData(viewer) {
var data = '';
for (var y = viewer.y-1; y <= viewer.y+1; y += 1) {
for (var x = viewer.x-1; x <= viewer. x+1; x += 1) {
if (data != '')
data += ',';
data += map[wrap(y, 0, map[0].length-1)][wrap(x, 0, map.length-1)];
}
}
viewer.port.postMessage('map ' + data);
}

```
var viewers = \{\};
onconnect = function (event) \{
    var name \(=\) getNextName();
    event.ports[0]._data = \{ port: event.ports[0], name: name, \(\mathrm{x}: \mathrm{0}, \mathrm{y}: 0, \mathrm{f}\);
    viewers[name] = event.ports[0]._data;
```

    event.ports[0].postMessage('cfg ' + name);
    event.ports[0].onmessage = getMessage;
    sendMapData(event.ports[0]._data);
    };
function getMessage(event) {
switch (event.data.substr(0, 4)) {
case 'mov ':
var direction = event.data.substr(4);
var dx = 0;
var dy = 0;
switch (direction) {
case 'up': dy = -1; break;
case 'down': dy = 1; break;
case 'left': dx = -1; break;
case 'right': dx = 1; break;
}
event.target._data.x = wrapX(event.target._data.x + dx);
event.target._data.y = wrapY(event.target._data.y + dy);
sendMapData(event.target._data);
break;
case 'set ':
var value = event.data.substr(4);
map[event.target._data.y][event.target._data.x] = value;
for (var viewer in viewers)
sendMapData(viewers[viewer]);
break;
case 'txt ':
var name = event.target._data.name;
var message = event.data.substr(4);
for (var viewer in viewers)
viewers[viewer].port.postMessage('txt ' + name + ' ' + message);
break;
case 'msg ':
var partyl = event.target._data;
var party2 = viewers[event.data.substr(4).split(' ', 1)[0]];
if (party2) {
var channel = new MessageChannel();
partyl.port.postMessage('msg ' + party2.name, [channel.port1]);
party2.port.postMessage('msg ' + partyl.name, [channel.port2]);
}
break;
}
}

```

Connecting to multiple pages. The script uses the onconnect \({ }^{p 1047}\) event listener to listen for multiple connections.
Direct channels. When the worker receives a "msg" message from one viewer naming another viewer, it sets up a direct connection between the two, so that the two viewers can communicate directly without the worker having to proxy all the messages.

View this example online.

\subsection*{10.1.2.5 Delegation \(\S^{\text {p10 }}\)}

This section is non-normative.
With multicore CPUs becoming prevalent, one way to obtain better performance is to split computationally expensive tasks amongst multiple workers. In this example, a computationally expensive task that is to be performed for every number from 1 to \(10,000,000\) is farmed out to ten subworkers.

The main page is as follows, it just reports the result:
```

<!DOCTYPE HTML>

<html lang="en">
<head>
        <meta charset="utf-8">
        <title>Worker example: Multicore computation</title>
</head>
<body>
        <p>Result: <output id="result"></output></p>
        <script>
            var worker = new Worker('worker.js');
            worker.onmessage = function (event) {
                document.getElementById('result').textContent = event.data;
        };
        </script>
    </body>
</html>
```

The worker itself is as follows:
```

// settings
var num_workers = 10;
var items_per_worker = 1000000;
// start the workers
var result = 0;
var pending workers = num workers;
for (var i = 0; i < num_workers; i += 1) {
var worker = new Worker('core.js');
worker.postMessage(i * items_per_worker);
worker.postMessage((i+1) * items_per_worker);
worker.onmessage = storeResult;
}
// handle the results
function storeResult(event) {
result += 1*event.data;
pending_workers -= 1;
if (pending_workers <= 0)
postMessage(result); // finished!
}

```

It consists of a loop to start the subworkers, and then a handler that waits for all the subworkers to respond.
The subworkers are implemented as follows:
```

var start;
onmessage = getStart;
function getStart(event) {
start = 1*event.data;
onmessage = getEnd;
}
var end;
function getEnd(event) {
end = 1*event.data;
onmessage = null;
work();
}
function work() {
var result = 0
for (var i = start; i < end; i += 1) {

```
```

        // perform some complex calculation here
        result += 1;
    }
    postMessage(result);
    close();
    ```
\}

They receive two numbers in two events, perform the computation for the range of numbers thus specified, and then report the result back to the parent.

View this example online.

\subsection*{10.1.2.6 Providing libraries \(\S_{39}^{\S^{p 10}}\)}

This section is non-normative.

Suppose that a cryptography library is made available that provides three tasks:

\section*{Generate a public/private key pair}

Takes a port, on which it will send two messages, first the public key and then the private key.

\section*{Given a plaintext and a public key, return the corresponding ciphertext}

Takes a port, to which any number of messages can be sent, the first giving the public key, and the remainder giving the plaintext, each of which is encrypted and then sent on that same channel as the ciphertext. The user can close the port when it is done encrypting content.

\section*{Given a ciphertext and a private key, return the corresponding plaintext}

Takes a port, to which any number of messages can be sent, the first giving the private key, and the remainder giving the ciphertext, each of which is decrypted and then sent on that same channel as the plaintext. The user can close the port when it is done decrypting content.

The library itself is as follows:
```

function handleMessage(e) {
if (e.data == "genkeys")
genkeys(e.ports[0]);
else if (e.data == "encrypt")
encrypt(e.ports[0]);
else if (e.data == "decrypt")
decrypt(e.ports[0]);
}
function genkeys(p) {
var keys = _generateKeyPair();
p.postMessage(keys[0]);
p.postMessage(keys[1]);
}
function encrypt(p) {
var key, state = 0
p.onmessage = function (e) {
if (state == 0) {
key = e.data;
state = 1;
} else {
p.postMessage( encrypt(key, e.data));
}
};
}
function decrypt(p) {

```
```

    var key, state = 0;
    p.onmessage = function (e) {
        if (state == 0) {
                key = e.data;
                state = 1;
        } else {
                p.postMessage(_decrypt(key, e.data));
        }
    };
    }
// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
onmessage = handleMessage;
else // shared worker
onconnect = function (e) { e.port.onmessage = handleMessage; }
// the "crypto" functions:
function _generateKeyPair() {
return [Math.random(), Math.random()];
}
function _encrypt(k, s) {
return 'encrypted-' + k + ' ' + s;
}
function _decrypt(k, s) {
return s.substr(s.index0f(' ')+1);
}

```

\section*{Note that the crypto functions here are just stubs and don't do real cryptography.}

This library could be used as follows:
```

<!DOCTYPE HTML>

<html lang="en">
    <head>
    <meta charset="utf-8">
    <title>Worker example: Crypto library</title>
    <script>
        const cryptoLib = new Worker('libcrypto-v1.js'); // or could use 'libcrypto-v2.js'
        function startConversation(source, message) {
            const messageChannel = new MessageChannel();
            source.postMessage(message, [messageChannel.port2]);
            return messageChannel.port1;
    }
    function getKeys() {
            let state = 0;
            startConversation(cryptoLib, "genkeys").onmessage = function (e) {
                if (state === 0)
                    document.getElementById('public').value = e.data;
            else if (state === 1)
                    document.getElementById('private').value = e.data;
            state += 1;
            };
        }
        function enc() {
            const port = startConversation(cryptoLib, "encrypt");
            port.postMessage(document.getElementById('public').value);
            port.postMessage(document.getElementById('input').value);
```
```
            port.onmessage = function (e) {
                document.getElementById('input').value = e.data;
                port.close();
            };
        }
        function dec() {
            const port = startConversation(cryptoLib, "decrypt");
            port.postMessage(document.getElementById('private').value);
            port.postMessage(document.getElementById('input').value);
            port.onmessage = function (e) {
                document.getElementById('input').value = e.data;
                port.close();
            };
        }
        </script>
        <style>
            textarea { display: block; }
    </style>
    </head>
    <body onload="getKeys()">
        <fieldset>
            <legend>Keys</legend>
            <p><label>Public Key: <textarea id="public"></textarea></label></p>
            <p><label>Private Key: <textarea id="private"></textarea></label></p>
            </fieldset>
    <p><label>Input: <textarea id="input"></textarea></label></p>
    <p><button onclick="enc()">Encrypt</button> <button onclick="dec()">Decrypt</button></p>
    </body>
</html>
```

A later version of the API, though, might want to offload all the crypto work onto subworkers. This could be done as follows:
```

function handleMessage(e) {
if (e.data == "genkeys")
genkeys(e.ports[0]);
else if (e.data == "encrypt")
encrypt(e.ports[0]);
else if (e.data == "decrypt")
decrypt(e.ports[0]);
}
function genkeys(p) {
var generator = new Worker('libcrypto-v2-generator.js');
generator.postMessage('', [p]);
}
function encrypt(p) {
p.onmessage = function (e) {
var key = e.data;
var encryptor = new Worker('libcrypto-v2-encryptor.js');
encryptor.postMessage(key, [p]);
};
}
function encrypt(p) {
p.onmessage = function (e) {
var key = e.data;
var decryptor = new Worker('libcrypto-v2-decryptor.js');
decryptor.postMessage(key, [p]);
};
}

```
```

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
onmessage = handleMessage;
else // shared worker
onconnect = function (e) { e.ports[0].onmessage = handleMessage };

```

The little subworkers would then be as follows.
For generating key pairs:
```

onmessage = function (e) {
var k = _generateKeyPair();
e.ports[0].postMessage(k[0]);
e.ports[0].postMessage(k[1]);
close();
}
function generateKeyPair() {
return [Math.random(), Math.random()];
}

```

For encrypting:
```

onmessage = function (e) {
var key = e.data;
e.ports[0].onmessage = function (e) {
var s = e.data;
postMessage( encrypt(key, s));
}
}
function _encrypt(k, s) {
return 'encrypted-' + k + ' ' + s;
}

```

For decrypting:
```

onmessage = function (e) {
var key = e.data;
e.ports[0].onmessage = function (e) {
var s = e.data;
postMessage(_decrypt(key, s));
}
}
function _decrypt(k, s) {
return s.substr(s.indexOf(' ')+1);
}

```

Notice how the users of the API don't have to even know that this is happening - the API hasn't changed; the library can delegate to subworkers without changing its API, even though it is accepting data using message channels.

View this example online.
10.1.3 Tutorials \({ }_{42}^{\S^{p 10}}\)
10.1.3.1 Creating a dedicated worker \(\S^{p 12}\)

This section is non-normative.

Creating a worker requires a URL to a JavaScript file. The Worker( () \({ }^{\text {p1054 }}\) constructor is invoked with the URL to that file as its only argument; a worker is then created and returned:
```

var worker = new Worker('helper.js');

```

If you want your worker script to be interpreted as a module script \({ }^{\text {p925 }}\) instead of the default classic script \({ }^{\text {p925 }}\), you need to use a slightly different signature:
```

var worker = new Worker('helper.mjs', { type: "module" });

```

\section*{}

This section is non-normative.
Dedicated workers use MessagePort \({ }^{\text {p1022 }}\) objects behind the scenes, and thus support all the same features, such as sending structured data, transferring binary data, and transferring other ports.

To receive messages from a dedicated worker, use the onmessage \({ }^{\text {p1054 }}\) event handler IDL attribute \({ }^{\text {p955 }}\) on the Worker \({ }^{p 1053}\) object:
```

worker.onmessage = function (event) { ... };

```

You can also use the addEventListener() method.

\section*{Note}

The implicit MessagePort \({ }^{\text {p1022 }}\) used by dedicated workers has its port message queue \({ }^{\text {p1022 }}\) implicitly enabled when it is created, so there is no equivalent to the MessagePort \({ }^{p 1022}\) interface's start( ) \({ }^{p 1024}\) method on the Worker \({ }^{p 1953}\) interface.

To send data to a worker, use the postMessage( () pro53 method. Structured data can be sent over this communication channel. To send ArrayBuffer objects efficiently (by transferring them rather than cloning them), list them in an array in the second argument.
```

worker.postMessage({
operation: 'find-edges',
input: buffer, // an ArrayBuffer object
threshold: 0.6,
}, [buffer]);

```

To receive a message inside the worker, the onmessage \({ }^{\text {p1047 }}\) event handler IDL attribute \({ }^{\text {p955 }}\) is used.
```

onmessage = function (event) { ... };

```

You can again also use the addEventListener() method.
In either case, the data is provided in the event object's data \({ }^{\text {p998 }}\) attribute.
To send messages back, you again use postMessage( () \({ }^{\text {p1046 }}\). It supports the structured data in the same manner.
postMessage(event.data.input, [event.data.input]); // transfer the buffer back

\subsection*{10.1.3.3 Shared workers \({ }_{43}^{\text {p10 }}\)}

This section is non-normative.
Shared workers are identified by the URL of the script used to create it, optionally with an explicit name. The name allows multiple instances of a particular shared worker to be started.

Shared workers are scoped by origin \({ }^{\text {p837 }}\). Two different sites using the same names will not collide. However, if a page tries to use the
same shared worker name as another page on the same site, but with a different script URL, it will fail.
Creating shared workers is done using the SharedWorker () \({ }^{\text {p1055 }}\) constructor. This constructor takes the URL to the script to use for its first argument, and the name of the worker, if any, as the second argument.
```

var worker = new SharedWorker('service.js');

```

Communicating with shared workers is done with explicit MessagePort \({ }^{\text {p1022 }}\) objects. The object returned by the SharedWorker( \()^{\text {p1055 }}\) constructor holds a reference to the port on its port \({ }^{\text {p1055 }}\) attribute.
```

worker.port.onmessage = function (event) { ... };
worker.port.postMessage('some message');
worker.port.postMessage({ foo: 'structured', bar: ['data', 'also', 'possible']});

```

Inside the shared worker, new clients of the worker are announced using the connect \({ }^{\text {p1281 }}\) event. The port for the new client is given by the event object's source \({ }^{\text {p999 }}\) attribute.
```

onconnect = function (event) {
var newPort = event.source;
// set up a listener
newPort.onmessage = function (event) { ... };
// send a message back to the port
newPort.postMessage('ready!'); // can also send structured data, of course
};

```

\subsection*{10.2 Infrastructure \(\S_{44}^{\text {p10 }}\)}

This standard defines two kinds of workers: dedicated workers, and shared workers. Dedicated workers, once created, are linked to their creator, but message ports can be used to communicate from a dedicated worker to multiple other browsing contexts or workers. Shared workers, on the other hand, are named, and once created any script running in the same origin \({ }^{\text {p837 }}\) can obtain a reference to that worker and communicate with it. Service Workers defines a third kind. [SW] \({ }^{\text {p1291 }}\)

\subsection*{10.2.1 The global scope \(\S^{\text {p10 }}\)}

The global scope is the "inside" of a worker.
10.2.1.1 The WorkerGlobalScope \({ }^{\text {p1044 }}\) common interface \(\$^{\text {p10 }}\) 44
```

IDL [Exposed=Worker]
interface WorkerGlobalScope : EventTarget {
readonly attribute WorkerGlobalScope self;
readonly attribute WorkerLocation location;
readonly attribute WorkerNavigator navigator;
undefined importScripts(USVString... urls);
attribute OnErrorEventHandler onerror;
attribute EventHandler onlanguagechange;
attribute EventHandler onoffline;
attribute EventHandler ononline;
attribute EventHandler onrejectionhandled;
attribute EventHandler onunhandledrejection;
};

```

A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated owner set (a set of Document \({ }^{\text {p114 }}\) and WorkerGlobalScope \({ }^{\text {p1044 }}\) objects). It is initially empty and populated when the worker is created or obtained.

Note
It is a set, instead of a single owner, to accomodate SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) objects.

A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated worker set (a set of WorkerGlobalScope \({ }^{\text {p1044 }}\) objects). It is initially empty and populated when the worker creates or obtains further workers.

A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated type ("classic" or "module"). It is set during creation.
A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated url (null or a URL). It is initially null.
A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated name (a string). It is set during creation.

\section*{Note}

The name \({ }^{\text {p1045 }}\) can have different semantics for each subclass of WorkerGlobalScope \({ }^{\text {p1044. }}\). For DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) instances, it is simply a developer-supplied name, useful mostly for debugging purposes. For SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) instances, it allows obtaining a reference to a common shared worker via the SharedWorker() \({ }^{\text {p1055 }}\) constructor. For ServiceWorkerGlobalScope objects, it doesn't make sense (and as such isn't exposed through the JavaScript API at all).

A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated referrer policy (a referrer policy). It is initially the empty string.
A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated embedder policy (an embedder policy \({ }^{\text {p847 }}\) ).
A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated CSP list, which is a CSP list containing all of the Content Security Policy objects active for the worker. It is initially an empty list.

A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated module map. It is a module map \({ }^{\text {p941 }}\), initially empty.
A WorkerGlobalScope \({ }^{\text {p1044 }}\) object has an associated cross-origin isolated capability boolean. It is initially false.

\section*{For web developers (non-normative)}

\section*{workerGlobal . self \({ }^{\text {p1045 }}\)}

Returns workerGlobal.
workerGlobal . Location \({ }^{\text {p1045 }}\)
Returns workerGlobal's WorkerLocation \({ }^{\text {p1057 }}\) object.
workerGlobal . navigator \({ }^{\text {p1057 }}\)
Returns workerGlobal's WorkerNavigator \({ }^{\text {p1057 }}\) object.
workerGlobal . importScripts \({ }^{\text {p1056 }}\) (urls...)
Fetches each URL in urls, executes them one-by-one in the order they are passed, and then returns (or throws if something went amiss).

The self attribute must return the WorkerGlobalScope \({ }^{\text {p1044 }}\) object itself.
The location attribute must return the WorkerLocation \({ }^{\text {p1057 }}\) object whose associated WorkerGlobalScope object \({ }^{\text {p1057 }}\) is the WorkerGlobalScope \({ }^{\text {p1044 }}\) object.

\section*{Note}

While the WorkerLocation \({ }^{\text {p1057 }}\) object is created after the WorkerGlobalScope \({ }^{\text {p1044 }}\) object, this is not problematic as it cannot be observed from script.

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by objects implementing the WorkerGlobalScope \({ }^{\text {p1044 }}\) interface:
\begin{tabular}{l|l}
\multicolumn{1}{c|}{ Event handler \({ }^{\text {p954 }}\)} & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onerror & error \(^{\text {p1281 }}\) \\
\hline onlanguagechange & languagechange \(^{\text {p1281 }}\) \\
\hline onoffline & offline \({ }^{\text {p1282 }}\) \\
\hline ononline & online \({ }^{\text {p1282 }}\) \\
\hline onrejectionhandled & rejectionhandled \({ }^{\text {p1282 }}\) \\
\hline onunhandledrejection & unhandledrejection \({ }^{\text {p1282 }}\) \\
\hline
\end{tabular}
10.2.1.2 Dedicated workers and the DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) interface \(\S_{46}^{\text {p10 }}\)

IDL
```

[Global=(Worker,DedicatedWorker), Exposed=DedicatedWorker]
interface DedicatedWorkerGlobalScope : WorkerGlobalScope {
[Replaceable] readonly attribute DOMString name;
undefined postMessage(any message, sequence<object> transfer);
undefined postMessage(any message, optional PostMessageOptions options = {});
undefined close();
attribute EventHandler onmessage;
attribute EventHandler onmessageerror;
};

```

DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) objects act as if they had an implicit MessagePort \({ }^{\text {p1022 }}\) associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object.

All messages received by that port must immediately be retargeted at the DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object.

\section*{For web developers (non-normative)}
dedicatedWorkerGlobal . name \({ }^{\text {p1046 }}\)
Returns dedicatedWorkerGlobal's name \({ }^{\text {p1045 }}\), i.e. the value given to the Worker \({ }^{\text {p1053 }}\) constructor. Primarily useful for debugging.
dedicatedWorkerGlobal . postMessage \({ }^{\text {p1046 }}\) (message [, transfer ])
dedicatedWorkerGlobal . postMessage \({ }^{\text {p1046 }}\left(\right.\) message \(\left[,\left\{\right.\right.\) transfer \(\left.\left.^{\text {p1022 }}\right\}\right\}\) ])
Clones message and transmits it to the Worker \({ }^{\text {p1053 }}\) object associated with dedicatedWorkerGlobal. transfer can be passed as a list of objects that are to be transferred rather than cloned.
dedicatedWorkerGlobal . close \({ }^{\text {p1046 }}\) ()
Aborts dedicatedWorkerGlobal.

The name attribute must return the DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object's name \({ }^{\text {p1045 }}\). Its value represents the name given to the worker using the Worker \({ }^{\text {p1053 }}\) constructor, used primarily for debugging purposes.

The postMessage(message, transfer) and postMessage(message, options) methods on DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) objects act as if, when invoked, it immediately invoked the respective postMessage(message, transfer) \({ }^{\text {p1024 }}\) and postMessage(message, options) \({ }^{\text {p1024 }}\) on the port, with the same arguments, and returned the same return value.

To close a worker, given a workerGlobal, run these steps:
1. Discard any tasks \({ }^{\text {p944 }}\) that have been added to workerGlobal's relevant agent \({ }^{\text {p914' }}\) 's event loop \({ }^{\text {p944 ' }} \mathrm{s}\) task queues \({ }^{\text {p944 }}\).
2. Set workerGlobal's closing \({ }^{\text {p1047 }}\) flag to true. (This prevents any further tasks from being queued.)

The close() method, when invoked, must close a worker \({ }^{\text {p1046 }}\) with this DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object.

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by objects implementing the DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onmessage & message \({ }^{\text {p1282 }}\) \\
\hline onmessageerror & messageerror \(r^{p 1282}\) \\
\hline
\end{tabular}

For the purposes of the application cache \({ }^{p 892}\) networking model, a dedicated worker is an extension of the cache host \({ }^{\text {p894 }}\) from which it was created.
10.2.1.3 Shared workers and the SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) interface \(\S_{47}^{\text {p10 }}\)

IDL [Global=(Worker, SharedWorker), Exposed=SharedWorker]
interface SharedWorkerGlobalScope : WorkerGlobalScope \{ [Replaceable] readonly attribute DOMString name;
undefined close();
attribute EventHandler onconnect;
\};

A SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object has an associated constructor origin, constructor url, and credentials. They are initialized when the SharedWorkerGlobalScope \({ }^{p 1047}\) object is created, in the run a worker \({ }^{\text {p1048 }}\) algorithm.

Shared workers receive message ports through connect \({ }^{p 1281}\) events on their SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object for each connection.

\section*{For web developers (non-normative)}
sharedWorkerGlobal . name \({ }^{\text {p1047 }}\)
Returns sharedWorkerGlobal's name \({ }^{\text {p1045 }}\), i.e. the value given to the SharedWorker \({ }^{p 1054}\) constructor. Multiple SharedWorker \({ }^{\text {p1054 }}\) objects can correspond to the same shared worker (and SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) ), by reusing the same name.
sharedWorkerGIobal . close \({ }^{\text {p1047 }}\) ()
Aborts sharedWorkerGlobal.

The name attribute must return the SharedWorkerGlobalScope \({ }^{p 1047}\) object's name \({ }^{p 1045}\). Its value represents the name that can be used to obtain a reference to the worker using the SharedWorker \({ }^{p 1054}\) constructor.

The close() method, when invoked, must close a worker \({ }^{\text {p1046 }}\) with this SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object.

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by objects implementing the SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) interface:
\begin{tabular}{l|l} 
Event handler \(^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onconnect & connect \({ }^{\text {p1281 }}\) \\
\hline
\end{tabular}

\subsection*{10.2.2 The event loop \(\S_{47}^{\text {p10 }}\)}

A worker event loop \({ }^{\text {p944 }}\) 's task queues \({ }^{\text {p944 }}\) only have events, callbacks, and networking activity as tasks \({ }^{\text {p944 }}\). These worker event loops \({ }^{\text {p944 }}\) are created by the run a worker \({ }^{\text {p1048 }}\) algorithm.

Each WorkerGlobalScope \({ }^{\text {p1044 }}\) object has a closing flag, which must be initially false, but which can get set to true by the algorithms in the processing model section below.

Once the WorkerGlobalScope \({ }^{\text {p1044 ' }}\) s closing \({ }^{\text {p1047 }}\) flag is set to true, the event loop \({ }^{\text {p944' }}\) s task queues \({ }^{\text {p944 }}\) must discard any further \(\underline{\text { tasks }}{ }^{\text {p944 }}\) that would be added to them (tasks already on the queue are unaffected except where otherwise specified). Effectively, once the closing \({ }^{\text {p1047 }}\) flag is true, timers stop firing, notifications for all pending background operations are dropped, etc.

\subsection*{10.2.3 The worker's lifetime \(\S^{p 10}\) \\ 48}

Workers communicate with other workers and with browsing contexts \({ }^{\text {p811 }}\) through message channels \({ }^{\text {p1018 }}\) and their MessagePort \({ }^{\text {p1022 }}\) objects.

Each WorkerGlobalScope \({ }^{\text {p1044 }}\) object worker global scope has a list of the worker's ports, which consists of all the MessagePort \({ }^{\text {p1022 }}\) objects that are entangled with another port and that have one (but only one) port owned by worker global scope. This list includes the implicit MessagePort \({ }^{\text {p1022 }}\) in the case of dedicated workers \({ }^{\text {p1046 }}\).

Given an environment settings object \({ }^{\text {p917 }}\) o when creating or obtaining a worker, the relevant owner to add depends on the type of global object \({ }^{\text {p918 }}\) specified by \(o\). If o specifies a global object \({ }^{\text {p918 }}\) that is a WorkerGlobalScope \({ }^{\text {p1044 }}\) object (i.e., if we are creating a nested dedicated worker), then the relevant owner is that global object. Otherwise, o specifies a global object \({ }^{\text {p918 }}\) that is a Window \({ }^{\text {p824 }}\) object, and the relevant owner is the responsible document \({ }^{\mathrm{p} 917}\) specified by \(o\).

A worker is said to be a permissible worker if its WorkerGlobalScope \({ }^{\text {p1044 }}\) 's owner set \({ }^{p 1045}\) is not empty or:
- its owner set \({ }^{p 1045}\) has been empty for no more than a short implementation-defined timeout value,
- its WorkerGlobalScope \({ }^{\text {p1044 }}\) object is a SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object (i.e., the worker is a shared worker), and
- the user agent has a browsing context \({ }^{\text {p811 }}\) whose Document \({ }^{\text {p114 }}\) object is not completely loaded \({ }^{\text {p885 }}\).

\section*{Note}

The second part of this definition allows a shared worker to survive for a short time while a page is loading, in case that page is going to contact the shared worker again. This can be used by user agents as a way to avoid the cost of restarting a shared worker used by a site when the user is navigating from page to page within that site.

A worker is said to be an active needed worker if any its owners \({ }^{\text {p1045 }}\) are either Document \({ }^{\text {p114 }}\) objects that are fully active \({ }^{\text {p815 }}\) or active needed workers \({ }^{\text {p1048 }}\).

A worker is said to be a protected worker if it is an active needed worker \({ }^{p 1048}\) and either it has outstanding timers, database transactions, or network connections, or its list of the worker's ports \({ }^{\text {p1048 }}\) is not empty, or its WorkerGlobalScope \({ }^{\text {p1044 }}\) is actually a SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object (i.e., the worker is a shared worker).

A worker is said to be a suspendable worker if it is not an active needed worker \({ }^{\text {p1048 }}\) but it is a permissible worker \({ }^{\text {p1048 }}\).

\subsection*{10.2.4 Processing model \(\S^{p 10}\)}

When a user agent is to run a worker for a script with Worker \({ }^{p 1053}\) or SharedWorker \({ }^{p 1054}\) object worker, URL url, environment settings object \({ }^{\text {p917 }}\) outside settings, MessagePort \({ }^{\text {p1022 }}\) outside port, and a WorkerOptions \({ }^{p 1053}\) dictionary options, it must run the following steps.
1. Let is shared be true if worker is a SharedWorker \({ }^{\text {p1054 }}\) object, and false otherwise.
2. Let owner be the relevant owner to add \({ }^{\text {p1048 }}\) given outside settings.
3. Let parent worker global scope be null.
4. If owner is a WorkerGlobalScope \({ }^{\text {p1044 }}\) object (i.e., we are creating a nested dedicated worker), then set parent worker global scope to owner.
5. Let agent be the result of obtaining a dedicated/shared worker agent \({ }^{p 915}\) given outside settings and is shared. Run the rest of these steps in that agent.

For the purposes of timing APIs, this is the official moment of creation of the worker.
6. Let realm execution context be the result of creating a new JavaScript realm \({ }^{\text {p918 }}\) given agent and the following customizations:
- For the global object, if is shared is true, create a new SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object. Otherwise, create a new DedicatedWorkerGlobalScope \({ }^{\text {p1946 }}\) object.
7. Let worker global scope be the global object \({ }^{\text {p918 }}\) of realm execution context's Realm component.
8. Set up a worker environment settings object \({ }^{\text {p1052 }}\) with realm execution context and outside settings, and let inside settings be the result.
9. Set worker global scope's name \({ }^{\text {p1045 }}\) to the value of options's name member.
10. Append owner to worker global scope's owner set \({ }^{\text {p1045 }}\).
11. If parent worker global scope is not null, then append worker global scope to parent worker global scope's worker set \({ }^{\text {p1045 }}\).
12. If is shared is true, then:
1. Set worker global scope's constructor origin \({ }^{\text {p1047 }}\) to outside settings's origin \({ }^{\text {p917 }}\).
2. Set worker global scope's constructor ur| \({ }^{\text {p1047 }}\) to url.
3. Set worker global scope's type \({ }^{\text {p1045 }}\) to the value of options's type member.
4. Set worker global scope's credentials \({ }^{p 1047}\) to the value of options's credentials member.
13. Let destination be "sharedworker" if is shared is true, and "worker" otherwise.
14. Obtain script by switching on the value of options's type member:
\(\rightarrow\) "classic"
Fetch a classic worker script \({ }^{\text {p927 }}\) given url, outside settings, destination, and inside settings.
\(\rightarrow\) "module"
Fetch a module worker script graph \({ }^{\text {p930 }}\) given url, outside settings, destination, the value of the credentials member of options, and inside settings.

In both cases, to perform the fetch \({ }^{\text {p926 }}\) given request, perform the following steps if the is top-level \({ }^{p 926}\) flag is set:
1. Set request's reserved client to inside settings.
2. Fetch request, and asynchronously wait to run the remaining steps as part of fetch's process response for the response response.
3. Set worker global scope's url \({ }^{\text {p1045 }}\) to response's url.
4. Set worker global scope's referrer policy \({ }^{\text {p1045 }}\) to the result of parsing the `Referrer-Policy` header of response.
5. If response's url's scheme is a local scheme, then set worker global scope's embedder policy \({ }^{\text {p1045 }}\) to owner's embedder policy \({ }^{\text {p917 }}\).
6. Otherwise, set worker global scope's embedder policy \({ }^{\text {p1045 }}\) to the result of obtaining an embedder policy \({ }^{\text {p847 }}\) from response.
7. If worker global scope's embedder policy \({ }^{\text {p1045 }}\) is "require-corp \({ }^{\text {p847" }}\) " and is shared is true, then set agent's agent cluster's cross-origin isolated \({ }^{\text {p914 }}\) to true.

This really ought to be set when the agent cluster is created, which requires a redesign of this section.
8. If the result of checking a global object's embedder policy \({ }^{\text {p848 }}\) with worker global scope, owner, and response is false, then set response to a network error.
9. Set worker global scope's cross-origin isolated capability \({ }^{\text {p1045 }}\) to agent's agent cluster's cross-origin isolated \({ }^{\text {p914 }}\).
10. If is shared is false and owner's cross-origin isolated capability \({ }^{\text {p917 }}\) is false, then set worker global scope's crossorigin isolated capability \({ }^{\text {p1045 }}\) to false.
11. If is shared is false and response's url's scheme is "data", then set worker global scope's cross-origin isolated capability \({ }^{\text {p1045 }}\) to false.

\section*{Note}

This is a conservative default for now, while we figure out how workers in general, and data: URL workers in w3c/webappsec-permissions-policy issue \#207 for more details.
12. Execute the Initialize a global object's CSP list algorithm on worker global scope and response. [CSP] \({ }^{\text {p1285 }}\)
13. Asynchronously complete the perform the fetch \({ }^{\text {p926 }}\) steps with response.

If the algorithm asynchronously completes with null or with a script whose error to rethrow \({ }^{\text {p925 }}\) is non-null, then:
1. Queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given worker's relevant global object \({ }^{\text {p924 }}\) to fire an event named error \({ }^{p 1281}\) at worker.
2. Run the environment discarding steps \({ }^{\text {p917 }}\) for inside settings.
3. Return.

Otherwise, continue the rest of these steps after the algorithm's asynchronous completion, with script being the asynchronous completion value.
15. Associate worker with worker global scope.
16. Let inside port be a new MessagePort \({ }^{p 1022}\) object in inside settings's Realm \({ }^{\text {p918 }}\).
17. Associate inside port with worker global scope.
18. Entangle \({ }^{\text {p1022 }}\) outside port and inside port.
19. Create a new WorkerLocation \({ }^{\text {p1057 }}\) object and associate it with worker global scope.
20. Closing orphan workers: Start monitoring the worker such that no sooner than it stops being a protected worker \({ }^{\text {p1048 }}\), and no later than it stops being a permissible worker \({ }^{\text {p1048 }}\), worker global scope's closing \({ }^{\text {p1047 }}\) flag is set to true.
21. Suspending workers: Start monitoring the worker, such that whenever worker global scope's closing \({ }^{\text {p1047 }}\) flag is false and the worker is a suspendable worker \({ }^{p 1048}\), the user agent suspends execution of script in that worker until such time as either the closing \({ }^{\text {p1047 }}\) flag switches to true or the worker stops being a suspendable worker \({ }^{\text {p1048 }}\).
22. Set inside settings's execution ready flag \({ }^{\text {p917 }}\).
23. If script is a classic script \({ }^{\mathrm{p} 925}\), then run the classic script \({ }^{\mathrm{p} 934}\) script. Otherwise, it is a module script \({ }^{\text {p925 }}\); run the module script \({ }^{\text {p935 }}\) script.

\section*{Note}

In addition to the usual possibilities of returning a value or failing due to an exception, this could be prematurely aborted \({ }^{\text {p936 }}\) by the terminate a worker \({ }^{p 1051}\) algorithm defined below.
24. Enable outside port's port message queue \({ }^{\text {p1022 }}\).
25. If is shared is false, enable the port message queue \({ }^{p 1022}\) of the worker's implicit port.
26. If is shared is true, then queue a global task \({ }^{\text {p945 }}\) on DOM manipulation task source \({ }^{\text {p952 }}\) given worker global scope to fire an event named connect \({ }^{\text {p1281 }}\) at worker global scope, using MessageEvent \({ }^{\text {p998 }}\), with the data \({ }^{\text {p998 }}\) attribute initialized to the empty string, the ports \({ }^{\text {p999 }}\) attribute initialized to a new frozen array containing inside port, and the source \({ }^{\text {p999 }}\) attribute initialized to inside port.
27. Enable the client message queue of the ServiceWorkerContainer object whose associated service worker client is worker global scope's relevant settings object \({ }^{\text {p924 }}\).
28. Event loop: Run the responsible event loop \({ }^{\text {p918 }}\) specified by inside settings until it is destroyed.

\section*{Note}

The handling of events or the execution of callbacks by tasks \({ }^{p 944}\) run by the event loop \({ }^{\text {p944 }}\) might get prematurely aborted \({ }^{p 936}\) by the terminate a worker \({ }^{p 1051}\) algorithm defined below.

\section*{Note}

The worker processing model remains on this step until the event loop is destroyed, which happens after the closing \({ }^{\text {p1047 }}\) flag is set to true, as described in the event loop \({ }^{p 944}\) processing model.
29. Empty the worker global scope's list of active timers \({ }^{\text {p973 }}\).
30. Disentangle all the ports in the list of the worker's ports \({ }^{\text {p1048 }}\).
31. Empty worker global scope's owner set \({ }^{\text {p1045 }}\).

When a user agent is to terminate a worker it must run the following steps in parallel \({ }^{\text {p42 }}\) with the worker's main loop (the "run a worker \({ }^{\text {p1048 " }}\) processing model defined above):
1. Set the worker's WorkerGlobalScope \({ }^{\text {p1044 }}\) object's closing \({ }^{\text {p1047 }}\) flag to true.
2. If there are any tasks \({ }^{\text {p944 }}\) queued in the WorkerGlobalScope \({ }^{\text {p1044 }}\) object's relevant agent \({ }^{\text {p914' }}\) 's event loop \({ }^{\text {p944' }}\) 's task queues \({ }^{\text {p944 }}\), discard them without processing them.
3. Abort the script \({ }^{\text {p936 }}\) currently running in the worker.
4. If the worker's WorkerGlobalScope \({ }^{p 1044}\) object is actually a DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object (i.e. the worker is a dedicated worker), then empty the port message queue \({ }^{\text {p1022 }}\) of the port that the worker's implicit port is entangled with.

User agents may invoke the terminate a worker \({ }^{p 1051}\) algorithm when a worker stops being an active needed worker \({ }^{\text {p1048 }}\) and the worker continues executing even after its closing \({ }^{\text {p1047 }}\) flag was set to true.

\subsection*{10.2.5 Runtime script errors \(\S_{51}^{\text {p10 }}\)}

Whenever an uncaught runtime script error occurs in one of the worker's scripts, if the error did not occur while handling a previous script error, the user agent must report the error \({ }^{\mathrm{p936}}\) for that script \({ }^{\mathrm{p925}}\), with the position (line number and column number) where the error occurred, using the WorkerGlobalScope \({ }^{\text {p1044 }}\) object as the target.

For shared workers, if the error is still not handled \({ }^{p 936}\) afterwards, the error may be reported to a developer console.
For dedicated workers, if the error is still not handled \({ }^{p 936}\) afterwards, the user agent must queue a task \({ }^{\text {p945 }}\) to run these steps:
1. Let notHandled be the result of firing an event named error \({ }^{p 1281}\) at the Worker \(r^{p 1053}\) object associated with the worker, using ErrorEvent \({ }^{\text {p937 }}\), with the cancelable attribute initialized to true, the message \({ }^{\text {p937 }}\), filename \({ }^{\text {p937 }}\), lineno \({ }^{\text {p937 }}\), and colno \({ }^{\text {p938 }}\) attributes initialized appropriately, and the error \({ }^{p 938}\) attribute initialized to null.
2. If notHandled is true, then the user agent must act as if the uncaught runtime script error had occurred in the global scope that the Worker \({ }^{p 1053}\) object is in, thus repeating the entire runtime script error reporting process one level up.

If the implicit port connecting the worker to its Worker \({ }^{\text {p1053 }}\) object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the Worker \({ }^{\text {p1053 }}\) object had no error \({ }^{\text {p1281 }}\) event handler and as if that worker's onerror \({ }^{\text {p1046 }}\) attribute was null, but must otherwise act as described above.

\section*{Note}

Thus, error reports propagate up to the chain of dedicated workers up to the original Document \({ }^{p 114}\), even if some of the workers along this chain have been terminated and garbage collected.

The task source \({ }^{\text {p945 }}\) for the task mentioned above is the DOM manipulation task source \({ }^{\text {p952 }}\).

\subsection*{10.2.6 Creating workers \({ }_{51}^{\S_{510}^{p 10}}\)}
10.2.6.1 The AbstractWorker \({ }^{\text {p1051 }}\) mixin \({ }_{51}^{\text {p10 }}\)
```

IDL interface mixin AbstractWorker {
attribute EventHandler onerror;
};

```

The following are the event handlers \({ }^{\mathrm{p954}}\) (and their corresponding event handler event types \({ }^{\mathrm{p957}}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by objects implementing the AbstractWorker \({ }^{\text {p1051 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onerror & error \({ }^{\text {p1281 }}\) \\
\hline
\end{tabular}

\subsection*{10.2.6.2 Script settings for workers \(\S_{52}^{\text {p10 }}\)}

When the user agent is required to set up a worker environment settings object, given a JavaScript execution context execution context and environment settings object \({ }^{\text {p917 }}\) outside settings, it must run the following steps:
1. Let inherited origin be outside settings's origin \({ }^{\text {p917 }}\).
2. Let realm be the value of execution context's Realm component.
3. Let worker global scope be realm's global object \({ }^{\text {p918 }}\).
4. Let settings object be a new environment settings object \({ }^{\mathrm{p} 917}\) whose algorithms are defined as follows:

\section*{The realm execution context \({ }^{\text {p917 }}\)}

Return execution context.

\section*{The module map \({ }^{\text {p917 }}\)}

Return worker global scope's module map \({ }^{\text {p1045 }}\).

\section*{The responsible document \({ }^{\text {p917 }}\)}

Not applicable (the responsible event loop \({ }^{\text {p918 }}\) is not a window event loop \({ }^{\text {p944 }}\) ).

\section*{The API URL character encoding \({ }^{\text {p917 }}\)}

Return UTF-8.
The API base URL \({ }^{\text {p917 }}\)
Return worker global scope's url \({ }^{\text {p1045 }}\).

\section*{The origin \({ }^{\text {p917 }}\)}

Return a unique opaque origin \({ }^{p 837}\) if worker global scope's url \({ }^{p 1045}\) 's scheme is "data", and inherited origin otherwise.
The referrer policy \({ }^{\text {p917 }}\)
Return worker global scope's referrer policy \({ }^{\text {p1045 }}\).

\section*{The embedder policy \({ }^{\text {p917 }}\)}

Return worker global scope's embedder policy \({ }^{\text {p1045 }}\).

\section*{The cross-origin isolated capability \({ }^{\text {p917 }}\)}

Return worker global scope's cross-origin isolated capability \({ }^{\text {p1045 }}\).
5. Set settings object's id \({ }^{\text {p916 }}\) to a new unique opaque string, settings object's creation URL \({ }^{\text {p916 }}\) to worker global scope's url, settings object's top-level creation URL \({ }^{\text {p916 }}\) to null, settings object's target browsing context \({ }^{\text {p917 }}\) to null, and settings object's active service worker \({ }^{\text {p917 }}\) to null.
6. If worker global scope is a DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\) object, then set settings object's top-level origin \({ }^{\text {p916 }}\) to outside settings's top-level origin \({ }^{\text {p916 }}\).
7. Otherwise, set settings object's top-level origin \({ }^{\text {p916 }}\) to an implementation-defined value.

See Client-Side Storage Partitioning for the latest on properly defining this.
8. Set realm's [[HostDefined]] field to settings object.
9. Return settings object.

IDL [Exposed=(Window, DedicatedWorker, SharedWorker)]
```

interface Worker : EventTarget {
constructor(USVString scriptURL, optional WorkerOptions options = {});

```
    undefined terminate();
    undefined postMessage(any message, sequence<object> transfer);
    undefined postMessage(any message, optional PostMessage0ptions options = \{\});
    attribute EventHandler onmessage;
    attribute EventHandler onmessageerror;
\};
dictionary WorkerOptions \{
    WorkerType type = "classic";
    RequestCredentials credentials = "same-origin"; // credentials is only used if type is "module"
    DOMString name = "";
\};
enum WorkerType \{ "classic", "module" \};
Worker includes AbstractWorker;

\section*{For web developers (non-normative)}

\section*{worker \(=\) new Worker \({ }^{\text {p1054 }}\) (scriptURL [, options ])}

Returns a new Worker \({ }^{p 1053}\) object. scriptURL will be fetched and executed in the background, creating a new global environment for which worker represents the communication channel. options can be used to define the name \({ }^{\text {p1045 }}\) of that global environment via the name option, primarily for debugging purposes. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how scriptURL is fetched through the credentials option.
worker. terminate \({ }^{\text {p1053 }}\) ()
Aborts worker's associated global environment.
worker . postMessage \({ }^{\text {p1053 }}\) (message [, transfer])
worker . postMessage \({ }^{\text {p1053 }}\) (message [, \{ transfer \(\left.\left.{ }^{\text {p1022 }}\right\} \mathbf{]}\right)\)
Clones message and transmits it to worker's global environment. transfer can be passed as a list of objects that are to be transferred rather than cloned.

The terminate() method, when invoked, must cause the terminate a worker \({ }^{p 1051}\) algorithm to be run on the worker with which the object is associated.

Worker \({ }^{\text {p1053 }}\) objects act as if they had an implicit MessagePort \({ }^{p 1022}\) associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the Worker \({ }^{p 1953}\) object.

All messages received by that port must immediately be retargeted at the Worker \({ }^{\text {p1053 }}\) object.
The postMessage(message, transfer) and postMessage(message, options) methods on Worker \({ }^{\text {p1053 }}\) objects act as if, when invoked, they immediately invoked the respective postMessage(message, transfer) \({ }^{\text {p1024 }}\) and postMessage(message, options) \({ }^{\text {p1024 }}\) on the port, with the same arguments, and returned the same return value.

\section*{Example}

The postMessage( () \({ }^{\text {p1053 }}\) method's first argument can be structured data:
```

worker.postMessage({opcode: 'activate', device: 1938, parameters: [23, 102]});

```

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler IDL attributes \({ }^{\text {p955 }}\), by objects implementing the Worker \({ }^{\text {p1053 }}\) interface:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onmessage & message \(^{\text {p1282 }}\) \\
\hline onmessageerror & messageerror \(^{\mathrm{P} 1282}\) \\
\hline
\end{tabular}

When the Worker(scriptURL, options) constructor is invoked, the user agent must run the following steps:
1. The user agent may throw a "SecurityError" DOMException if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start dedicated workers).
2. Let outside settings be the current settings object \({ }^{\text {p924 }}\).
3. Parse \({ }^{\mathrm{p} 89}\) the scriptURL argument relative to outside settings.
4. If this fails, throw a "SyntaxError" DOMException.
5. Let worker URL be the resulting URL record \({ }^{\mathrm{p} 89}\).

\section*{Note}

Any same-origin \({ }^{p 838}\) URL (including blob: URLs) can be used. data: URLs can also be used, but they create a worker with an opaque origin \({ }^{\text {p837 }}\).
6. Let worker be a new Worker \({ }^{\text {p1253 }}\) object.
7. Let outside port be a new MessagePort \({ }^{\mathrm{p} 1022}\) in outside settings's Realm \({ }^{\text {p918 }}\).
8. Associate the outside port with worker.
9. Run this step in parallel \({ }^{\text {p42 }}\) :
1. Run a worker \({ }^{\text {p1048 }}\) given worker, worker URL, outside settings, outside port, and options.
10. Return worker.
10.2.6.4 Shared workers and the SharedWorker \({ }^{\text {p1054 }}\) interface \({\underset{54}{\text { p10 }}}_{5}\)

IDL
```

[Exposed=Window]
interface SharedWorker : EventTarget {
constructor(USVString scriptURL, optional (DOMString or WorkerOptions) options = {});
readonly attribute MessagePort port;
};
SharedWorker includes AbstractWorker;

```

\section*{For web developers (non-normative)}

\section*{sharedWorker = new SharedWorker \({ }^{\text {p1055 }}\) (scriptURL [, name ])}

Returns a new SharedWorker \({ }^{\text {p1054 }}\) object. scriptURL will be fetched and executed in the background, creating a new global environment for which sharedWorker represents the communication channel. name can be used to define the name \({ }^{\text {p1045 }}\) of that global environment.

\section*{sharedWorker \(=\) new SharedWorker \({ }^{\text {p1055 }}\) (scriptURL [, options ])}

Returns a new SharedWorker \({ }^{\text {p1054 }}\) object. scriptURL will be fetched and executed in the background, creating a new global environment for which sharedWorker represents the communication channel. options can be used to define the name \({ }^{\text {p1045 }}\) of that global environment via the name option. It can also ensure this new global environment supports JavaScript modules (specify type: "module"), and if that is specified, can also be used to specify how scriptURL is fetched through the credentials option. Note that attempting to construct a shared worker with options whose type or credentials values mismatch an existing shared worker will cause the returned sharedWorker to fire an error event and not connect to the existing shared worker.
sharedWorker. port \({ }^{\text {p1055 }}\)
Returns sharedWorker's MessagePort \({ }^{\text {p1022 }}\) object which can be used to communicate with the global environment.

The port attribute must return the value it was assigned by the object's constructor. It represents the MessagePort \({ }^{p 1022}\) for communicating with the shared worker.

A user agent has an associated shared worker manager which is the result of starting a new parallel queue \({ }^{\text {p42 }}\).

\section*{Note}

Each user agent has a single shared worker manager \({ }^{p 1055}\) for simplicity. Implementations could use one per origin \({ }^{p 837}\); that would not be observably different and enables more concurrency.

When the SharedWorker(scriptURL, options) constructor is invoked:
1. Optionally, throw a "SecurityError" DOMException if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start shared workers).
2. If options is a DOMString, set options to a new WorkerOptions \({ }^{p 1053}\) dictionary whose name member is set to the value of options and whose other members are set to their default values.
3. Let outside settings be the current settings object \({ }^{\text {p924 }}\).
4. Parse \({ }^{\mathrm{p89}}\) scriptURL relative to outside settings.
5. If this fails, throw a "SyntaxError" DOMException.
6. Otherwise, let urIRecord be the resulting URL record \({ }^{\mathrm{p89}}\).

Note
Any same-origin \({ }^{p 838}\) URL (including blob: URLs) can be used. data: URLs can also be used, but they create a worker with an opaque origin \({ }^{p 837}\).
7. Let worker be a new SharedWorker \({ }^{p 1054}\) object.
8. Let outside port be a new MessagePort \({ }^{\text {p1022 }}\) in outside settings's Realm \({ }^{\text {p918 }}\).
9. Assign outside port to the port \({ }^{\text {p1055 }}\) attribute of worker.
10. Let callerlsSecureContext be true if outside settings is a secure context \({ }^{\text {p924 }}\); otherwise, false.
11. Enqueue the following steps \({ }^{\text {p42 }}\) to the shared worker manager \({ }^{p 1055}\) :
1. Let worker global scope be null.
2. If there exists a SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object whose closing \({ }^{\text {p1047 }}\) flag is false, constructor origin \({ }^{\text {p1047 }}\) is same origin \({ }^{\text {p838 }}\) with outside settings's origin \({ }^{\text {p917 }}\), constructor url \({ }^{\text {p1047 }}\) equals urlRecord, and name \({ }^{\text {p1045 }}\) equals the value of options's name member, then set worker global scope to that SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object.

\section*{Note}
data: URLs create a worker with an opaque origin \({ }^{p 837}\). Both the constructor origin \({ }^{p 1047}\) and constructor url \({ }^{p 1047}\) are compared so the same data: URL can be used within an origin \({ }^{p 837}\) to get to the same SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) object, but cannot be used to bypass the same origin \({ }^{p 838}\) restriction.
3. If worker global scope is not null, but the user agent has been configured to disallow communication between the worker represented by the worker global scope and the scripts \({ }^{\mathrm{p} 925}\) whose settings object \({ }^{\mathrm{p} 925}\) is outside settings, then set worker global scope to null.

\section*{Note}

For example, a user agent could have a development mode that isolates a particular top-level browsing context \({ }^{p 814}\) from all other pages, and scripts in that development mode could be blocked from connecting to shared workers running in the normal browser mode.
4. If worker global scope is not null, then check if worker global scope's type \({ }^{p 1045}\) and credentials \({ }^{p 1047}\) match the options values. If not, queue a task \({ }^{\text {p945 }}\) to fire an event named error \({ }^{p 1281}\) and abort these steps.
5. If worker global scope is not null, then run these subsubsteps:
1. Let settings object be the relevant settings object \({ }^{\text {p924 }}\) for worker global scope.
2. Let workerlsSecureContext be true if settings object is a secure context \({ }^{\text {p924 }}\); otherwise, false.
3. If workerlsSecureContext is not callerlsSecureContext, then queue a task \({ }^{\text {p945 }}\) to fire an event named error \({ }^{\text {p1281 }}\) at worker and abort these steps. [SECURE-CONTEXTS] \({ }^{\text {p1291 }}\)
4. Associate worker with worker global scope.
5. Let inside port be a new MessagePort \({ }^{\text {p1022 }}\) in settings object's Realm \({ }^{\text {p918 }}\).
6. Entangle \({ }^{\text {p1022 }}\) outside port and inside port.
7. Queue a task \({ }^{\text {p945 }}\), using the DOM manipulation task source \({ }^{\text {p952 }}\), to fire an event named connect \({ }^{\text {p1281 }}\) at worker global scope, using MessageEvent \({ }^{\text {p998 }}\), with the data \({ }^{\text {p998 }}\) attribute initialized to the empty string, the ports \({ }^{\text {p999 }}\) attribute initialized to a new frozen array containing only inside port, and the source \({ }^{\text {p999 }}\) attribute initialized to inside port.
8. Append the relevant owner to add \({ }^{\text {p1048 }}\) given outside settings to worker global scope's owner set \({ }^{\text {p1045 }}\).
6. Otherwise, in parallel \({ }^{\mathrm{p} 42}\), run a worker \({ }^{\mathrm{p1048}}\) given worker, urlRecord, outside settings, outside port, and options.
12. Return worker.

\subsection*{10.2.7 Concurrent hardware capabilities \(\S^{p 10}\)}

56
IDL interface mixin NavigatorConcurrentHardware \{
```

    readonly attribute unsigned long long hardwareConcurrency;
    ```
\};

\section*{For web developers (non-normative)}
self . navigator \({ }^{\text {p979 }} \cdot\) hardwareConcurrency \({ }^{\text {p1056 }}\)
Returns the number of logical processors potentially available to the user agent.

The navigator . hardwareConcurrency attribute's getter must return a number between 1 and the number of logical processors potentially available to the user agent. If this cannot be determined, the getter must return 1 .

User agents should err toward exposing the number of logical processors available, using lower values only in cases where there are user-agent specific limits in place (such as a limitation on the number of workers \({ }^{\text {p1053 }}\) that can be created) or when the user agent desires to limit fingerprinting possibilities.

\subsection*{10.3 APIs available to workers \(\S^{p 10}\) \\ 56}

\subsection*{10.3.1 Importing scripts and libraries \(\S_{56}^{\text {p10 }}\)}

When a script invokes the importScripts (urls) method on a WorkerGlobalScope \({ }^{\text {p1044 }}\) object, the user agent must import scripts into worker global scope \({ }^{\text {p1056 }}\) given this WorkerGlobalScope \({ }^{\text {p1044 }}\) object and urls.

To import scripts into worker global scope, given a WorkerGlobalScope \({ }^{\text {p1044 }}\) object worker global scope and a sequence<DOMString> urls, run these steps. The algorithm may optionally be customized by supplying custom perform the fetch \({ }^{\text {p926 }}\) hooks, which if provided will be used when invoking fetch a classic worker-imported script \({ }^{\mathrm{p} 928}\).
1. If worker global scope's type \({ }^{\text {p1045 }}\) is "module", throw a TypeError exception.
2. Let settings object be the current settings object \({ }^{\text {p924 }}\).
3. If urls is empty, return.
4. Parse \({ }^{\text {p89 }}\) each value in urls relative to settings object. If any fail, throw a "SyntaxError" DOMException.
5. For each url in the resulting URL records \({ }^{\mathrm{p89}}\), run these substeps:
1. Fetch a classic worker-imported script \({ }^{\text {p928 }}\) given url and settings object, passing along any custom perform the fetch \({ }^{\text {p926 }}\) steps provided. If this succeeds, let script be the result. Otherwise, rethrow the exception.
2. Run the classic script \({ }^{\text {p934 }}\) script, with the rethrow errors argument set to true.

\section*{Note}
script will run until it either returns, fails to parse, fails to catch an exception, or gets prematurely aborted \({ }^{p 936}\) by the terminate a worker \({ }^{\text {p1051 }}\) algorithm defined above.

If an exception was thrown or if the script was prematurely aborted \({ }^{\text {p936 }}\), then abort all these steps, letting the exception or aborting continue to be processed by the calling script \({ }^{\mathrm{p} 925}\).

Note
Service Workers is an example of a specification that runs this algorithm with its own options for the perform the fetch \({ }^{\text {p926 }}\) hook. [SW] \({ }^{\text {p1291 }}\)

\subsection*{10.3.2 The WorkerNavigator \({ }^{p 1057}\) interface \({ }_{57}^{\S_{57}^{p 10}}\)}

The navigator attribute of the WorkerGlobalScope \({ }^{\text {p1044 }}\) interface must return an instance of the WorkerNavigator \({ }^{\text {p1057 }}\) interface, which represents the identity and state of the user agent (the client):

IDL
```

[Exposed=Worker]
interface WorkerNavigator {};
WorkerNavigator includes NavigatorID;
WorkerNavigator includes NavigatorLanguage;
WorkerNavigator includes NavigatorOnLine;
WorkerNavigator includes NavigatorConcurrentHardware;

```
10.3.3 The WorkerLocation \({ }^{\text {p1057 }}\) interface \(\S_{57}^{\text {p10 }}\)

IDL [Exposed=Worker]
interface WorkerLocation \{
stringifier readonly attribute USVString href;
readonly attribute USVString origin;
readonly attribute USVString protocol;
readonly attribute USVString host;
readonly attribute USVString hostname;
readonly attribute USVString port;
readonly attribute USVString pathname;
readonly attribute USVString search;
readonly attribute USVString hash;
\};

A WorkerLocation \({ }^{\text {p1057 }}\) object has an associated WorkerGlobalScope object (a WorkerGlobalScope \({ }^{\text {p1044 }}\) object).
The href attribute's getter must return the associated WorkerGlobalScope object \({ }^{\text {p1057' }} \mathrm{s}\) url \({ }^{\mathrm{p1045}}\), serialized.
The origin attribute's getter must return the serialization \({ }^{\mathrm{p} 838}\) of the associated WorkerGlobalScope object \({ }^{p 1057}\) 's url \({ }^{\text {p1045 }}\) 's origin.
The protocol attribute's getter must return the associated WorkerGlobalScope object \({ }^{\text {p1057' }} \mathrm{s}\) url \({ }^{\text {p1045's }}\) scheme, followed by ": ".
The host attribute's getter must run these steps:
1. Let \(u r l\) be the associated WorkerGlobalScope object \({ }^{\text {p1057' }} \mathrm{S}\) url \({ }^{\mathrm{p1045}}\).
2. If \(u r l\) 's host is null, return the empty string.
3. If url's port is null, return url's host, serialized.
4. Return url's host, serialized, followed by " : " and url's port, serialized.

The hostname attribute's getter must run these steps:
1. Let host be the associated WorkerGlobalScope object \({ }^{p 1057}\) 's url \({ }^{p 1045}\) 's host.
2. If host is null, return the empty string.
3. Return host, serialized.

The port attribute's getter must run these steps:
1. Let port be the associated WorkerGlobalScope object \({ }^{\text {p1057 }}\) 's url \({ }^{p 1045}\) 's port.
2. If port is null, return the empty string.
3. Return port, serialized.

The pathname attribute's getter must run these steps:
1. Let url be the associated WorkerGlobalScope object \({ }^{\text {p1057 }}\) 's url \({ }^{p 1045}\).
2. If url's cannot-be-a-base-URL flag is set, return the first string in url's path.
3. Return "/", followed by the strings in url's path (including empty strings), separated from each other by "/".

The search attribute's getter must run these steps:
1. Let query be the associated WorkerGlobalScope object \({ }^{p 1057}\) 's url \({ }^{p 1045}\) 's query.
2. If query is either null or the empty string, return the empty string.
3. Return "?", followed by query.

The hash attribute's getter must run these steps:
1. Let fragment be the associated WorkerGlobalScope object \({ }^{p 1057}\) 's url \({ }^{p 1045}\) 's fragment.
2. If fragment is either null or the empty string, return the empty string.
3. Return "\#", followed by fragment.

\section*{11 Web storage \(§^{p 10}\) \\ 59}

\subsection*{11.1 Introduction \(\S^{p 10}\)}

This section is non-normative.
This specification introduces two related mechanisms, similar to HTTP session cookies, for storing name-value pairs on the client side. [COOKIES] \({ }^{\text {p1285 }}\)

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don't really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being purchased would "leak" from one window to the other, potentially causing the user to buy two tickets for the same flight without really noticing.

To address this, this specification introduces the sessionStorage \({ }^{p 1062}\) getter. Sites can add data to the session storage, and it will be accessible to any page from the same site opened in that window.

\section*{Example}

For example, a page could have a checkbox that the user ticks to indicate that they want insurance:
```

<label>
    <input type="checkbox" onchange="sessionStorage.insurance = checked ? 'true' : ''">
        I want insurance on this trip.
    </label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:
```

if (sessionStorage.insurance) { ... }

```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session. In particular, web applications might wish to store megabytes of user data, such as entire user-authored documents or a user's mailbox, on the client side for performance reasons.

Again, cookies do not handle this case well, because they are transmitted with every request.
The localStorage \({ }^{\text {p1063 }}\) getter is used to access a page's local storage area.

\section*{Example}

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:
```

<p>
    You have viewed this page
    <span id="count">an untold number of</span>
    time(s).
</p>
<script>
    if (!localStorage.pageLoadCount)
        localStorage.pageLoadCount = 0;
```
```
    localStorage.pageLoadCount = parseInt(localStorage.pageLoadCount) + 1
    document.getElementById('count').textContent = localStorage.pageLoadCount;
</script>
```

Each site has its own separate storage area.

\section*{\(\triangle\) Warning!}

The localStorage \({ }^{p 1063}\) getter provides access to shared state. This specification does not define the interaction with other browsing contexts in a multiprocess user agent, and authors are encouraged to assume that there is no locking mechanism. A site could, for instance, try to read the value of a key, increment its value, then write it back out, using the new value as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

\subsection*{11.2 The API \(\S^{p 10}\) \\ 60}
11.2.1 The Storage \({ }^{\text {p1060 }}\) interface \({ }_{60}^{\S_{610}^{p 10}}\)

IDL
```

[Exposed=Window]
interface Storage {
readonly attribute unsigned long length;
DOMString? key(unsigned long index);
getter DOMString? getItem(DOMString key);
setter undefined setItem(DOMString key, DOMString value);
deleter undefined removeItem(DOMString key);
undefined clear();
};

```

For web developers (non-normative)

\section*{storage . length \({ }^{\text {p1061 }}\)}

Returns the number of key/value pairs.

\section*{storage. key \({ }^{\text {p1061 }}\) ( \(n\) )}

Returns the name of the \(n\)th key, or null if \(n\) is greater than or equal to the number of key/value pairs.
```

value $=$ storage $\cdot$ getItem ${ }^{\text {p1061 }}($ key $)$
value = storage[key]

```

Returns the current value associated with the given key, or null if the given key does not exist.
storage . setItem \({ }^{\text {p1061 }}\) (key, value)
storage[key] = value
Sets the value of the pair identified by key to value, creating a new key/value pair if none existed for key previously.
Throws a "QuotaExceededError" DOMException exception if the new value couldn't be set. (Setting could fail if, e.g., the user has disabled storage for the site, or if the quota has been exceeded.)

Dispatches a storage \({ }^{\text {p1282 }}\) event on Window \({ }^{p 824}\) objects holding an equivalent Storage \({ }^{\text {p1060 }}\) object.
storage . removeItem \({ }^{\text {p1062 }}\) (key )
delete storage[key]
Removes the key/value pair with the given key, if a key/value pair with the given key exists.
Dispatches a storage \({ }^{\text {p1282 }}\) event on Window \({ }^{\text {p824 }}\) objects holding an equivalent Storage \({ }^{\text {p1068 }}\) object.
storage . clear \({ }^{\text {p1062 }}\) ()
Removes all key/value pairs, if there are any.
Dispatches a storage \({ }^{\text {p1282 }}\) event on Window \({ }^{\text {p824 }}\) objects holding an equivalent Storage \({ }^{\text {p1060 }}\) object.

A Storage \({ }^{\text {p1060 }}\) object has an associated:

\section*{map}

A storage proxy map.

\section*{type}
"local" or "session".
To reorder a Storage \({ }^{\text {p1060 }}\) object storage, reorder storage's map \({ }^{\text {p1061 }}\) 's entries in an implementation-defined manner.

\section*{Note}

Unfortunate as it is, iteration order is not defined and can change upon most mutations.

To broadcast a Storage \({ }^{p 1060}\) object storage, given a key, oldValue, and newValue, run these steps:
1. Let url be storage's relevant global object \({ }^{\text {p924 }}\) 's associated Document \({ }^{p 826}\) 's URL.
2. Let remoteStorages be all Storage \({ }^{\text {p1060 }}\) objects excluding storage whose:
- type \({ }^{\text {p1061 }}\) is storage's type \({ }^{\text {p1061 }}\)
- relevant settings object \({ }^{\text {p924' }}\) s origin \({ }^{\text {p837 }}\) is same origin \({ }^{\text {p838 }}\) with storage's relevant settings object \({ }^{\text {p924' }}\) s origin \({ }^{\text {p837 }}\).
and, if type \({ }^{\text {p1061 }}\) is "session", whose relevant settings object \({ }^{\text {p924' }} \mathrm{s}\) browsing session \({ }^{\text {p849 }}\) is storage's relevant settings object \({ }^{\text {p924's }}\) s browsing session \({ }^{\text {p849 }}\).
3. For each remoteStorage of remoteStorages: queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given remoteStorage's relevant global object \({ }^{\text {p924 }}\) to fire an event named storage \({ }^{\text {p1282 }}\) at remoteStorage's relevant global object \({ }^{p 924}\), using StorageEvent \({ }^{p 1063}\), with key \({ }^{\text {p1064 }}\) initialized to \(k e y, ~ o l d V a l u e^{p 1064}\) initialized to oldValue, newValue \({ }^{\text {p1064 }}\) initialized to newValue, url \({ }^{\text {p1064 }}\) initialized to url, and storageArea \({ }^{\text {p1064 }}\) initialized to remoteStorage.

\section*{Note}

The Document \({ }^{\text {p114 }}\) object associated with the resulting task \({ }^{p 944}\) is not necessarily fully active \({ }^{p 815}\), but events fired on such objects are ignored by the event loop \({ }^{\text {p944 }}\) until the Document \({ }^{\text {p114 }}\) becomes fully active \({ }^{\text {p815 }}\) again.

The length getter steps are to return this's map \({ }^{p 1061}\) 's size.
The key ( \(n\) ) method steps are:
1. If \(n\) is greather than or equal to this's map \({ }^{\text {p1061' }} \mathrm{s}\) size, then return null.
2. Let keys be the result of running get the keys on this's map \({ }^{\text {p1061 }}\).
3. Return keys[n].

The supported property names on a Storage \({ }^{\text {p1060 }}\) object storage are the result of running get the keys on storage's map \({ }^{\text {p1061 }}\).
The getItem(key) method steps are:
1. If this's map \({ }^{p 1061}[k e y]\) does not exist, then return null.
2. Return this's map \({ }^{p 1061}[k e y]\).

The setItem(key, value) method are:
1. Let oldValue be null.
2. Let reorder be true.
3. If this's map \({ }^{p 1061}[k e y]\) exists:
1. Set oldValue to this's \(\underline{\text { map }}^{\text {p1061 }}[k e y]\).
2. If oldValue is value, then return.
3. Set reorder to false.
4. If value cannot be stored, then throw a "QuotaExceededError" DOMException exception.
5. Set this's map \({ }^{\text {p1061 }}[k e y]\) to value.
6. If reorder is true, then reorder \({ }^{\text {p1061 }}\) this.
7. Broadcast \({ }^{p 1061}\) this with key, oldValue, and value.

The removeItem(key) method steps are:
1. If this's map \({ }^{\text {p1061 }}\) [key] does not exist, then return null.
2. Set oldValue to this's map \({ }^{\text {p1061 }}[k e y]\).
3. Remove this's map \({ }^{\text {p1061 }}\) [key].
4. Reorder \({ }^{\text {p1061 }}\) this.
5. Broadcast \({ }^{\text {p1061 }}\) this with key, oldValue, and null.

The clear() method steps are:
1. Clear this's map \({ }^{\text {p1061 }}\).
2. Broadcast \({ }^{\text {p1061 }}\) this with null, null, and null.

\subsection*{11.2.2 The sessionStorage \({ }^{\text {p1062 }}\) getter \({ }_{62}^{\S^{p 10}}\)}

IDL interface mixin WindowSessionStorage \{
readonly attribute Storage sessionStorage;
\};
Window includes WindowSessionStorage;

\section*{For web developers (non-normative)}

\section*{window. sessionStorage \({ }^{\text {p1062 }}\)}

Returns the Storage \({ }^{\text {p1060 }}\) object associated with that window's origin's session storage area.
Throws a "SecurityError" DOMEXception if the Document \({ }^{p 114}\) 's origin \({ }^{p 837}\) is an opaque origin \({ }^{\text {p837 }}\) or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A Document \({ }^{p 114}\) object has an associated session storage holder, which is null or a Storage \({ }^{\text {p106日 }}\) object. It is initially null.
The sessionStorage getter steps are:
1. If this's associated Document \({ }^{p 826}\) ' \(s\) session storage holder \(r^{p 1062}\) is non-null, then return this's associated Document \({ }^{p 826}\) 's \(s\) session storage holder \({ }^{\text {p1062 }}\).
2. Let map be the result of running obtain a session storage bottle map with this's relevant settings object \({ }^{\text {p924 }}\) and "sessionStorage".
3. If map is failure, then throw a "SecurityError" DOMException.
4. Let storage be a new Storage \({ }^{\text {p1060 }}\) object whose map \({ }^{\text {p1061 }}\) is map.
5. Set this's associated Document \({ }^{\text {p826 }}\) 's session storage holder \({ }^{\text {p1062 }}\) to storage.
6. Return storage.

While creating a new auxiliary browsing context \({ }^{p 813}\), the session storage is copied \({ }^{p 813}\) over.

\subsection*{11.2.3 The localStorage \({ }^{\text {p1063 }}\) getter \(\S^{\text {p10 }}\)}

IDL interface mixin WindowLocalStorage \{ readonly attribute Storage localStorage;
\};
Window includes WindowLocalStorage;

\section*{For web developers (non-normative)}

\section*{window . localStorage \({ }^{\text {p1063 }}\)}

Returns the Storage \({ }^{\text {p1060 }}\) object associated with window's origin's local storage area.
Throws a "SecurityError" DOMException if the Document \({ }^{p 114}\) 's origin \({ }^{\text {p837 }}\) is an opaque origin \({ }^{\text {p837 }}\) or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A Document \({ }^{\text {p114 }}\) object has an associated local storage holder, which is null or a Storage \({ }^{\text {p106e }}\) object. It is initially null.
The localStorage getter steps are:
1. If this's associated Document \({ }^{p 826}\) 's local storage holder \({ }^{\text {p1063 }}\) is non-null, then return this's associated Document \({ }^{p 826}\) ' \(s\) local storage holder \({ }^{p 1063}\).
2. Let map be the result of running obtain a local storage bottle map with this's relevant settings object \({ }^{\text {p924 }}\) and "localStorage".
3. If map is failure, then throw a "SecurityError" DOMException.
4. Let storage be a new Storage \({ }^{\text {p1060 }}\) object whose map \({ }^{p 1061}\) is map.
5. Set this's associated Document \({ }^{\mathrm{p} 826}\) 's local storage holder \({ }^{p 1063}\) to storage.
6. Return storage.
11.2.4 The StorageEvent \({ }^{\text {p1063 }}\) interface \(\S_{63}^{\S^{p 10}}\)
```

[Exposed=Window]
interface StorageEvent : Event {
constructor(DOMString type, optional StorageEventInit eventInitDict = {});
readonly attribute DOMString? key;
readonly attribute DOMString? oldValue;
readonly attribute DOMString? newValue;
readonly attribute USVString url;
readonly attribute Storage? storageArea;
undefined initStorageEvent(DOMString type, optional boolean bubbles = false, optional boolean
cancelable = false, optional DOMString? key = null, optional DOMString? oldValue = null, optional
DOMString? newValue = null, optional USVString url = "", optional Storage? storageArea = null);
};
dictionary StorageEventInit : EventInit {
DOMString? key = null;
DOMString? oldValue = null;
DOMString? newValue = null;
USVString url = "";
Storage? storageArea = null;

```

For web developers (non-normative)
event . key \({ }^{\text {p1064 }}\)
Returns the key of the storage item being changed.
event. oldValue \({ }^{\text {p1064 }}\)
Returns the old value of the key of the storage item whose value is being changed.
event. newValue \({ }^{\text {p1064 }}\)
Returns the new value of the key of the storage item whose value is being changed.
event. url \({ }^{\text {p1064 }}\)
Returns the URL of the document whose storage item changed.
event. storageArea \({ }^{\text {p1064 }}\)
Returns the Storage \({ }^{\text {p1060 }}\) object that was affected.

The key, oldValue, newValue, url, and storageArea attributes must return the values they were initialized to.
The initStorageEvent() method must initialize the event in a manner analogous to the similarly-named initEvent() method. [DOM] \({ }^{\text {p1287 }}\)

\subsection*{11.3 Privacy \(\S_{64}^{\text {p10 }}\)}

\subsection*{11.3.1 User tracking \(\S_{64}^{\text {p10 }}\)}

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its local storage area to track a user across multiple sessions, building a profile of the user's interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user's real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous web usage.

There are a number of techniques that can be used to mitigate the risk of user tracking:

\section*{Blocking third-party storage}

User agents may restrict access to the localStorage \({ }^{\text {p1063 }}\) objects to scripts originating at the domain of the active document \({ }^{\text {p811 }}\) of the top-level browsing context \({ }^{\text {p814 }}\), for instance denying access to the API for pages from other domains running in iframe \({ }^{\text {p3611 }} \mathbf{s}\).

\section*{Expiring stored data}

User agents may, possibly in a manner configured by the user, automatically delete stored data after a period of time.
For example, a user agent could be configured to treat third-party local storage areas as session-only storage, deleting the data once the user had closed all the browsing contexts \({ }^{p 811}\) that could access it.

This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when they authenticate with the site itself (e.g. by making a purchase or logging in to a service).

However, this also reduces the usefulness of the API as a long-term storage mechanism. It can also put the user's data at risk, if the user does not fully understand the implications of data expiration.

\section*{Treating persistent storage as cookies}

If users attempt to protect their privacy by clearing cookies without also clearing data stored in the local storage area, sites can defeat those attempts by using the two features as redundant backup for each other. User agents should present the interfaces for clearing these in a way that helps users to understand this possibility and enables them to delete data in all persistent storage features simultaneously. [COOKIES] \({ }^{\text {p1285 }}\)

\section*{Site-specific safelisting of access to local storage areas}

User agents may allow sites to access session storage areas in an unrestricted manner, but require the user to authorize access to local storage areas.

\section*{Origin-tracking of stored data}

User agents may record the origins \({ }^{\text {p837 }}\) of sites that contained content from third-party origins that caused data to be stored.
If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blocklist ("delete this data and prevent this domain from ever storing data again"), the user can restrict the use of persistent storage to sites that they trust.

\section*{Shared blocklists}

User agents may allow users to share their persistent storage domain blocklists.
This would allow communities to act together to protect their privacy.
While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user during a session, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.

However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors' IP addresses and other user-specific data (e.g. useragent headers and configuration settings) to combine separate sessions into coherent user profiles.

\subsection*{11.3.2 Sensitivity of data \(\S^{p 10}\)}

User agents should treat persistently stored data as potentially sensitive; it's quite possible for emails, calendar appointments, health records, or other confidential documents to be stored in this mechanism.

To this end, user agents should ensure that when deleting data, it is promptly deleted from the underlying storage.

\subsection*{11.4 Security \({ }^{\S_{65}^{p 10}}\)}

\subsection*{11.4.1 DNS spoofing attacks \(\S^{\text {p10 }}\)}

Because of the potential for DNS spoofing attacks, one cannot guarantee that a host claiming to be in a certain domain really is from that domain. To mitigate this, pages can use TLS. Pages using TLS can be sure that only the user, software working on behalf of the user, and other pages using TLS that have certificates identifying them as being from the same domain, can access their storage areas.

\subsection*{11.4.2 Cross-directory attacks \(\S^{p 10}\)}

Different authors sharing one host name, for example users hosting content on the now defunct geocities. com, all share one local storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore urged to avoid using these features, as it would be trivial for other authors to read the data and overwrite it.

\section*{Note}

Even if a path-restriction feature was made available, the usual DOM scripting security model would make it trivial to bypass this protection and access the data from any path.

\subsection*{11.4.3 Implementation risks \(\S^{p 10}\) \\ 65}

The two primary risks when implementing these persistent storage features are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes information leakage, For example, a user's
shopping wishlist on one domain could be used by another domain for targeted advertising; or a user's work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.

Letting third-party sites write data to the persistent storage of other domains can result in information spoofing, which is equally dangerous. For example, a hostile site could add items to a user's wishlist; or a hostile site could set a user's session identifier to a known ID that the hostile site can then use to track the user's actions on the victim site.

Thus, strictly following the origin \({ }^{\text {p837 }}\) model described in this specification is important for user security.

\section*{12 The HTML syntax \(\S^{\text {p10 }}\)}

\section*{Note}

This section only describes the rules for resources labeled with an HTML MIME type. Rules for XML resources are discussed in the section below entitled "The XML syntax \({ }^{\text {p1188". }}\)

\subsection*{12.1 Writing HTML documents \(\S^{187}\)}

This section only applies to documents, authoring tools, and markup generators. In particular, it does not apply to conformance checkers; conformance checkers must use the requirements given in the next section ("parsing HTML documents").

Documents must consist of the following parts, in the given order:
1. Optionally, a single U+FEFF BYTE ORDER MARK (BOM) character.
2. Any number of comments \({ }^{p 1078}\) and ASCII whitespace.
3. A DOCTYPE \({ }^{\text {p1067 }}\).
4. Any number of comments \({ }^{p 1078}\) and ASCII whitespace.
5. The document element, in the form of an html \({ }^{\text {p152 }}\) element \({ }^{p 1068}\).
6. Any number of comments \({ }^{p 1078}\) and ASCII whitespace.

The various types of content mentioned above are described in the next few sections.
In addition, there are some restrictions on how character encoding declarations \({ }^{p 173}\) are to be serialized, as discussed in the section on that topic.

\section*{Note}

ASCII whitespace before the html \({ }^{p 152}\) element, at the start of the html \({ }^{p 152}\) element and before the head \({ }^{p 153}\) element, will be dropped when the document is parsed; ASCII whitespace after the html \({ }^{\text {p152 }}\) element will be parsed as if it were at the end of the body \({ }^{\text {p178 }}\) element. Thus, ASCII whitespace around the document element does not round-trip.

It is suggested that newlines be inserted after the DOCTYPE, after any comments that are before the document element, after the html \({ }^{\text {p152 }}\) element's start tag (if it is not omitted \({ }^{\text {p1071 }}\) ), and after any comments that are inside the htm \({ }^{\text {p152 }}\) element but before the head \({ }^{p 153}\) element.

Many strings in the HTML syntax (e.g. the names of elements and their attributes) are case-insensitive, but only for ASCII upper alphas and ASCII lower alphas. For convenience, in this section this is just referred to as "case-insensitive".

\subsection*{12.1.1 The DOCTYPE \(\S_{67}^{\text {p1o }}\)}

A DOCTYPE is a required preamble.

\section*{Note}

DOCTYPEs are required for legacy reasons. When omitted, browsers tend to use a different rendering mode that is incompatible with some specifications. Including the DOCTYPE in a document ensures that the browser makes a best-effort attempt at following the relevant specifications.

A DOCTYPE must consist of the following components, in this order:
1. A string that is an ASCII case-insensitive match for the string "<! DOCTYPE".
2. One or more ASCll whitespace.
3. A string that is an ASCII case-insensitive match for the string "html".
4. Optionally, a DOCTYPE legacy string \({ }^{\text {p1068 }}\).
5. Zero or more ASCII whitespace.
6. A \(U+003 E\) GREATER-THAN SIGN character ( \(>\) ).

\section*{Note}

In other words, <!DOCTYPE html>, case-insensitively.

For the purposes of HTML generators that cannot output HTML markup with the short DOCTYPE "<! DOCTYPE html>", a DOCTYPE legacy string may be inserted into the DOCTYPE (in the position defined above). This string must consist of:
1. One or more ASCII whitespace.
2. A string that is an ASCII case-insensitive match for the string "SYSTEM".
3. One or more ASCII whitespace.
4. A \(U+0022\) QUOTATION MARK or \(U+0027\) APOSTROPHE character (the quote mark).
5. The literal string "about:legacy-compat \(t^{\text {p88" }}\).
6. A matching U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (i.e. the same character as in the earlier step labeled quote mark).

\section*{Note}

In other words, <!DOCTYPE html SYSTEM "about:legacy-compat">or <!DOCTYPE html SYSTEM 'about:legacy-compat'>, caseinsensitively except for the part in single or double quotes.

The DOCTYPE legacy string \({ }^{\text {p1068 }}\) should not be used unless the document is generated from a system that cannot output the shorter string.

\subsection*{12.1.2 Elements \(\S^{p 10}\)}

There are six different kinds of elements: void elements \({ }^{\text {p1068 }}\), the template element \({ }^{\text {p1068 }}\), raw text elements \({ }^{\text {p1068 }}\), escapable raw text elements \({ }^{\text {p1068 }}\), foreign elements \({ }^{\text {p1068 }}\), and normal elements \({ }^{\text {p1068 }}\).

\section*{Void elements}

\section*{The template element}
template \({ }^{\text {p629 }}\)

\section*{Raw text elements}
script \({ }^{\text {p614 }}\), style \(^{\text {p174 }}\)

\section*{Escapable raw text elements}
textarea \({ }^{\text {p548 }}\), title \({ }^{p 154}\)

\section*{Foreign elements}

Elements from the MathML namespace and the SVG namespace.

\section*{Normal elements}

All other allowed HTML elements \({ }^{\text {p44 }}\) are normal elements.
Tags are used to delimit the start and end of elements in the markup. Raw text \({ }^{\text {p1068 }}\), escapable raw text \({ }^{\text {p1068 }}\), and normal \({ }^{\text {p1068 }}\) elements have a start tag \({ }^{\text {p1069 }}\) to indicate where they begin, and an end tag \({ }^{\text {p1070 }}\) to indicate where they end. The start and end tags of certain normal elements \({ }^{\text {p1068 }}\) can be omitted \({ }^{\text {p1071 }}\), as described below in the section on optional tags \({ }^{\text {p1071 }}\). Those that cannot be omitted must not be omitted. Void elements \({ }^{\text {p1068 }}\) only have a start tag; end tags must not be specified for void elements \({ }^{\text {p1068 }}\). Foreign elements \({ }^{\text {p1068 }}\) must either have a start tag and an end tag, or a start tag that is marked as self-closing, in which case they must not have an end tag.

The contents \({ }^{\text {p129 }}\) of the element must be placed between just after the start tag (which might be implied, in certain cases \({ }^{\text {p1071 }}\) ) and just before the end tag (which again, might be implied in certain cases \({ }^{\text {p1071 }}\) ). The exact allowed contents of each individual element depend on the content model \({ }^{\text {p129 }}\) of that element, as described earlier in this specification. Elements must not contain content that their content model disallows. In addition to the restrictions placed on the contents by those content models, however, the five types of elements have additional syntactic requirements.

Void elements \({ }^{\text {p1068 }}\) can't have any contents (since there's no end tag, no content can be put between the start tag and the end tag).

The template element \({ }^{p 1068}\) can have template contents \({ }^{\text {p631 }}\), but such template contents \({ }^{\text {p631 }}\) are not children of the template \({ }^{\text {p629 }}\) element itself. Instead, they are stored in a DocumentFragment associated with a different Document \({ }^{\text {p114 }}\) - without a browsing context \({ }^{p 811}\) - so as to avoid the template \({ }^{\text {p629 }}\) contents interfering with the main Document \({ }^{\text {p114. }}\). The markup for the template contents \({ }^{\text {p631 }}\) of a template \({ }^{p 629}\) element is placed just after the template \({ }^{\text {p629 }}\) element's start tag and just before template \({ }^{\text {p629 }}\) element's end tag (as with other elements), and may consist of any text \({ }^{\text {p1077 }}\), character references \({ }^{\text {p1077 }}\), elements \({ }^{\text {p1068 }}\), and comments \({ }^{\text {p1078 }}\), but the text must not contain the character U+003C LESS-THAN SIGN ( \(<\) ) or an ambiguous ampersand \({ }^{\text {p1078 }}\).

Raw text elements \({ }^{p 1068}\) can have text \({ }^{\text {p1077 }}\), though it has restrictions \({ }^{\text {p1077 }}\) described below.
Escapable raw text elements \({ }^{\text {p1068 }}\) can have text \({ }^{\text {p1077 }}\) and character references \({ }^{\text {p1077 }}\), but the text must not contain an ambiguous ampersand \({ }^{\text {p1078 }}\). There are also further restrictions \({ }^{\text {p1077 }}\) described below.

Foreign elements \({ }^{\text {p1068 }}\) whose start tag is marked as self-closing can't have any contents (since, again, as there's no end tag, no content can be put between the start tag and the end tag). Foreign elements \({ }^{\text {p1068 }}\) whose start tag is not marked as self-closing can have text \(^{\text {p1077 }}\), character references \({ }^{\text {p1077 }}\), CDATA sections \({ }^{\text {p1078 }}\), other elements \({ }^{\text {p1068 }}\), and comments \({ }^{\text {p1078 }}\), but the text must not contain the character U+003C LESS-THAN SIGN ( \(<\) ) or an ambiguous ampersand \({ }^{\text {p1078 }}\).

\section*{Note}

The HTML syntax does not support namespace declarations, even in foreign elements \({ }^{\text {p1068 }}\).
For instance, consider the following HTML fragment:
```

<p>
    <svg>
        <metadata>
        <!-- this is invalid -->
        <cdr:license xmlns:cdr="https://www.example.com/cdr/metadata" name="MIT"/>
        </metadata>
        </svg>
</p>
```

The innermost element, cdr:license, is actually in the SVG namespace, as the "xmlns:cdr" attribute has no effect (unlike in XML). In fact, as the comment in the fragment above says, the fragment is actually non-conforming. This is because SVG 2 does not define any elements called "cdr: license" in the SVG namespace.

Normal elements \({ }^{\text {p1068 }}\) can have text \({ }^{\text {p1077 }}\), character references \({ }^{\text {p1077 }}\), other elements \({ }^{\text {p1068 }}\), and comments \({ }^{\text {p1078 }}\), but the text must not contain the character U+003C LESS-THAN SIGN (<) or an ambiguous ampersand \({ }^{\text {p1078 }}\). Some normal elements \({ }^{\text {p1068 }}\) also have yet more restrictions \({ }^{\text {p1077 }}\) on what content they are allowed to hold, beyond the restrictions imposed by the content model and those described in this paragraph. Those restrictions are described below.

Tags contain a tag name, giving the element's name. HTML elements all have names that only use ASCII alphanumerics. In the HTML syntax, tag names, even those for foreign elements \({ }^{\text {p1068 }}\), may be written with any mix of lower- and uppercase letters that, when converted to all-lowercase, matches the element's tag name; tag names are case-insensitive.

\subsection*{12.1.2.1 Start tags \({ }_{69}{ }_{6}^{p 10}\)}

Start tags must have the following format:
1. The first character of a start tag must be a U+003C LESS-THAN SIGN character (<).
2. The next few characters of a start tag must be the element's tag name \({ }^{\text {p1069 }}\).
3. If there are to be any attributes in the next step, there must first be one or more ASCII whitespace.
4. Then, the start tag may have a number of attributes, the syntax for which \({ }^{\text {p1070 }}\) is described below. Attributes must be separated from each other by one or more ASCII whitespace.
5. After the attributes, or after the tag name \({ }^{\text {p1069 }}\) if there are no attributes, there may be one or more ASCII whitespace. (Some attributes are required to be followed by a space. See the attributes section \({ }^{\text {p1070 }}\) below.)
6. Then, if the element is one of the void elements \({ }^{\text {p1068 }}\), or if the element is a foreign element \({ }^{\text {p1068 }}\), then there may be a single U+002F SOLIDUS character (/). This character has no effect on void elements \({ }^{\text {p1068 }}\), but on foreign elements \({ }^{\text {p1068 }}\) it marks the
start tag as self-closing.
7. Finally, start tags must be closed by a U+003E GREATER-THAN SIGN character ( \(>\) ).

\subsection*{12.1.2.2 End tags \({ }_{{ }_{70}}^{\mathrm{p}_{0} 10}\)}

End tags must have the following format:
1. The first character of an end tag must be a U+003C LESS-THAN SIGN character (<).
2. The second character of an end tag must be a U+002F SOLIDUS character (/).
3. The next few characters of an end tag must be the element's tag name \({ }^{\text {p1069 }}\).
4. After the tag name, there may be one or more ASCII whitespace.
5. Finally, end tags must be closed by a U+003E GREATER-THAN SIGN character ( \(>\) ).

\subsection*{12.1.2.3 Attributes \(\S_{70}^{\delta_{710}^{p 10}}\)}

Attributes for an element are expressed inside the element's start tag.
Attributes have a name and a value. Attribute names must consist of one or more characters other than controls, U+0020 SPACE, U+0022 ("), U+0027 ('), U+003E (>), U+002F (/), U+003D (=), and noncharacters. In the HTML syntax, attribute names, even those for foreign elements \({ }^{\text {p1068 }}\), may be written with any mix of ASCII lower and ASCII upper alphas.

Attribute values are a mixture of text \({ }^{p 1077}\) and character references \({ }^{p 1077}\), except with the additional restriction that the text cannot contain an ambiguous ampersand \({ }^{p 1078}\).

Attributes can be specified in four different ways:

\section*{Empty attribute syntax}

Just the attribute name \({ }^{\text {p1070 }}\). The value is implicitly the empty string.

\section*{Example}

In the following example, the disabled \({ }^{\text {p570 }}\) attribute is given with the empty attribute syntax:
```

<input disabled>
```

If an attribute using the empty attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

\section*{Unquoted attribute value syntax}

The attribute name \({ }^{\text {p1070 }}\), followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by the attribute value \({ }^{\text {p1070 }}\), which, in addition to the requirements given above for attribute values, must not contain any literal ASCII whitespace, any U+0022 QUOTATION MARK characters ("), U+0027 APOSTROPHE characters ('), U+003D EQUALS SIGN characters ( \(=\) ), U+003C LESS-THAN SIGN characters ( \(<\) ), U+003E GREATERTHAN SIGN characters ( \(>\) ), or U+0060 GRAVE ACCENT characters ( \(`\) ), and must not be the empty string.

Example
In the following example, the value \({ }^{\text {p497 }}\) attribute is given with the unquoted attribute value syntax:
<input value=yes>

If an attribute using the unquoted attribute syntax is to be followed by another attribute or by the optional U+002F SOLIDUS character (/) allowed in step 6 of the start tag \({ }^{\text {p1069 }}\) syntax above, then there must be ASCII whitespace separating the two.

\section*{Single-quoted attribute value syntax}

The attribute name \({ }^{\text {p1070 }}\), followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0027 APOSTROPHE character ('), followed by the attribute value \({ }^{\text {p1070 }}\), which, in addition to the requirements given above for attribute values, must not contain any literal U+0027 APOSTROPHE characters ('), and finally followed by a second single U+0027 APOSTROPHE character (').

\section*{Example}

In the following example, the type \({ }^{\text {p495 }}\) attribute is given with the single-quoted attribute value syntax:
```

<input type='checkbox'>
```

If an attribute using the single-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

\section*{Double-quoted attribute value syntax}

The attribute name \({ }^{\text {p1070 }}\), followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0022 QUOTATION MARK character ("), followed by the attribute value \({ }^{\text {p1070 }}\), which, in addition to the requirements given above for attribute values, must not contain any literal U+0022 QUOTATION MARK characters ("), and finally followed by a second single U+0022 QUOTATION MARK character (").

\section*{Example}

In the following example, the name \({ }^{\text {p568 }}\) attribute is given with the double-quoted attribute value syntax:
```

<input name="be evil">
```

If an attribute using the double-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

There must never be two or more attributes on the same start tag whose names are an ASCII case-insensitive match for each other.

When a foreign element \({ }^{p 1068}\) has one of the namespaced attributes given by the local name and namespace of the first and second cells of a row from the following table, it must be written using the name given by the third cell from the same row.
\begin{tabular}{l|l|l} 
Local name & \multicolumn{1}{c|}{ Namespace } & Attribute name \\
\hline actuate & XLink namespace & xlink:actuate \\
\hline arcrole & XLink namespace & xlink:arcrole \\
\hline href & XLink namespace & xlink:href \\
\hline role & XLink namespace & xlink:role \\
\hline show & XLink namespace & xlink:show \\
\hline title & XLink namespace & xlink:title \\
\hline type & XLink namespace & xlink: type \\
\hline lang & XML namespace & xml:lang \\
\hline space & XML namespace & xml:space \\
\hline xmlns & XMLNS namespace & xmlns \\
\hline\(x l i n k ~\) & XMLNS namespace & xmlns:xlink \\
\hline
\end{tabular}

No other namespaced attribute can be expressed in the HTML syntax \({ }^{\text {p1067 }}\).

\section*{Note}

Whether the attributes in the table above are conforming or not is defined by other specifications (e.g. SVG 2 and MathML); this section only describes the syntax rules if the attributes are serialized using the HTML syntax.

\subsection*{12.1.2.4 Optional tags \(\S^{\text {p10 }}\)}

Certain tags can be omitted.

Omitting an element's start tag \({ }^{p 1069}\) in the situations described below does not mean the element is not present; it is implied, but it is still there. For example, an HTML document always has a root html \({ }^{\text {p152 }}\) element, even if the string <html> doesn't appear anywhere in the markup.

An html \({ }^{p 152}\) element's start tag \({ }^{\text {p1069 }}\) may be omitted if the first thing inside the html \({ }^{\text {p152 }}\) element is not a comment \({ }^{\text {p1078 }}\).

\section*{Example}

For example, in the following case it's ok to remove the "<html>" tag:
```

<!DOCTYPE HTML>

<html>
    <head>
        <title>Hello</title>
        </head>
        <body>
            <p>Welcome to this example.</p>
        </body>
</html>
```

Doing so would make the document look like this:
```

<!DOCTYPE HTML>
<head>
<title>Hello</title>
</head>
<body>
<p>Welcome to this example.</p>
</body>
</html>

```

This has the exact same DOM. In particular, note that whitespace around the document element is ignored by the parser. The following example would also have the exact same DOM:
```

<!DOCTYPE HTML><head>
<title>Hello</title>
</head>
<body>
<p>Welcome to this example.</p>
</body>
</html>

```

However, in the following example, removing the start tag moves the comment to before the html \({ }^{\mathrm{p} 152}\) element:
```

<!DOCTYPE HTML>

<html>
    <!-- where is this comment in the DOM? -->
    <head>
        <title>Hello</title>
    </head>
    <body>
        <p>Welcome to this example.</p>
    </body>
</html>
```

With the tag removed, the document actually turns into the same as this:
```

<!DOCTYPE HTML>

```
```

<!-- where is this comment in the DOM? -->

<html>
    <head>
        <title>Hello</title>
    </head>
    <body>
        <p>Welcome to this example.</p>
    </body>
</html>
```

This is why the tag can only be removed if it is not followed by a comment: removing the tag when there is a comment there changes the document's resulting parse tree. Of course, if the position of the comment does not matter, then the tag can be omitted, as if the comment had been moved to before the start tag in the first place.

An html \({ }^{p 152}\) element's end tag \({ }^{\mathrm{p} 1070}\) may be omitted if the \(h t m 2^{p 152}\) element is not immediately followed by a comment \({ }^{p 1078}\).
A head \({ }^{p 153}\) element's start tag \({ }^{\text {p1069 }}\) may be omitted if the element is empty, or if the first thing inside the head \({ }^{p 153}\) element is an element.

A head \({ }^{\text {p153 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the head \({ }^{\text {p153 }}\) element is not immediately followed by ASCII whitespace or a comment \({ }^{\text {p1078 }}\).

A body \({ }^{\text {p178 }}\) element's start tag \({ }^{\text {p1069 }}\) may be omitted if the element is empty, or if the first thing inside the body \({ }^{\text {p178 }}\) element is not ASCII whitespace or a comment \({ }^{\text {p1078 }}\), except if the first thing inside the body \({ }^{\text {p178 }}\) element is a meta \({ }^{\text {p164 }}\), link \({ }^{p 157}\), script \({ }^{\text {p614 }}\), style \({ }^{\text {p174 }}\), or template \({ }^{\text {p629 }}\) element.

A body \({ }^{\text {p178 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the body \({ }^{\text {p178 }}\) element is not immediately followed by a comment \({ }^{\text {p1078 }}\).

\section*{Example}

Note that in the example above, the head \({ }^{p 153}\) element start and end tags, and the body \({ }^{\text {p178 }}\) element start tag, can't be omitted, because they are surrounded by whitespace:
```

<!DOCTYPE HTML>

<html>
    <head>
        <title>Hello</title>
    </head>
    <body>
        <p>Welcome to this example.</p>
    </body>
</html>
```
(The body \({ }^{\text {p178 }}\) and html \({ }^{p 152}\) element end tags could be omitted without trouble; any spaces after those get parsed into the body \({ }^{\text {p178 }}\) element anyway.)

Usually, however, whitespace isn't an issue. If we first remove the whitespace we don't care about:
```

<!DOCTYPE HTML><html><head><title>Hello</title></head><body><p>Welcome to this
example.</p></body></html>

```

Then we can omit a number of tags without affecting the DOM:
```

<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.</p>

```

At that point, we can also add some whitespace back:
```

<!DOCTYPE HTML>
<title>Hello</title>

```
```

<p>Welcome to this example.</p>

```

This would be equivalent to this document, with the omitted tags shown in their parser-implied positions; the only whitespace text node that results from this is the newline at the end of the head \({ }^{\text {p153 }}\) element:
```

<!DOCTYPE HTML>
<html><head><title>Hello</title>
</head><body><p>Welcome to this example.</p></body></html>

```

An \(\underline{i}^{\text {p224 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the \(\underline{l i}^{p 224}\) element is immediately followed by another \(\underline{i}^{p 224}\) element or if there is no more content in the parent element.

A \(\underline{d t^{p 23 \theta}}\) element's end tag \({ }^{p 1070}\) may be omitted if the \(\underline{d t^{p 23 \theta}}\) element is immediately followed by another \(\underline{d t^{p 23 \theta}}\) element or a \(\underline{d d^{p 231}}\) element.

A dd \({ }^{p 231}\) element's end tag \({ }^{p 1070}\) may be omitted if the \(d^{p 231}\) element is immediately followed by another \(d^{p 231}\) element or a \(\mathrm{dt}^{\text {p230 }}\) element, or if there is no more content in the parent element.

A \(p^{p 211}\) element's end tag \({ }^{p 1070}\) may be omitted if the \(p^{p 211}\) element is immediately followed by an address \({ }^{p 197}\), article \({ }^{\text {p188 }}\), aside \({ }^{\text {p187 }}\),

 if there is no more content in the parent element and the parent element is an HTML element \({ }^{\text {p44 }}\) that is not an \(\underline{a}^{\text {p238 }}\), audio \({ }^{\text {p384 }}\), del \(l^{\text {p312 }}\), ins \(^{\text {p311 }}\), map \({ }^{\text {p442 }}\), noscript \({ }^{\text {p627 }}\), or video \({ }^{\text {p380 }}\) element, or an autonomous custom element \({ }^{\text {p703 }}\).

\section*{Example}

We can thus simplify the earlier example further:
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.

An \(r t^{p 258}\) element's end tag \({ }^{p 1070}\) may be omitted if the \(\underline{r t}^{p 258}\) element is immediately followed by an \(r t^{p 258}\) or \(r^{p 258}\) element, or if there is no more content in the parent element.

An rp \(\underline{p}^{p 258}\) element's end tag \({ }^{p 1070}\) may be omitted if the \(r p^{p 258}\) element is immediately followed by an \(\underline{r t}^{p 258}\) or \(\underline{r p}^{p 258}\) element, or if there is no more content in the parent element.

An optgroup \({ }^{\text {p544 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the optgroup \({ }^{\text {p544 }}\) element is immediately followed by another optgroup \({ }^{\text {p544 }}\) element, or if there is no more content in the parent element.

An option \({ }^{p 545}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the option \({ }^{\mathrm{p} 545}\) element is immediately followed by another option \({ }^{\mathrm{p} 545}\) element, or if it is immediately followed by an optgroup \({ }^{p 544}\) element, or if there is no more content in the parent element.

A colgroup \({ }^{\text {p459 }}\) element's start tag \({ }^{\text {p1069 }}\) may be omitted if the first thing inside the colgroup \({ }^{\text {p459 }}\) element is a col \({ }^{\text {p460 }}\) element, and if the element is not immediately preceded by another colgroup \({ }^{\text {p459 }}\) element whose end tag \({ }^{\text {p1070 }}\) has been omitted. (It can't be omitted if the element is empty.)

A colgroup \({ }^{\text {p459 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the colgroup \({ }^{\text {p459 }}\) element is not immediately followed by ASCII whitespace or a comment \({ }^{107078}\).

A caption \({ }^{\text {p458 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the caption \({ }^{\text {p458 }}\) element is not immediately followed by ASCII whitespace or a comment \({ }^{\text {p1078 }}\).

A thead \({ }^{\text {p462 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the thead \({ }^{\text {p462 }}\) element is immediately followed by a tbody \({ }^{\text {p461 }}\) or \(t\) foot \(t^{\text {p463 }}\) element.

A tbody \({ }^{p 461}\) element's start tag \({ }^{\text {p1069 }}\) may be omitted if the first thing inside the tbody \({ }^{\text {p461 }}\) element is a \(\underline{t r}^{p 464}\) element, and if the element
 if the element is empty.)

A tbody \({ }^{\text {p461 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the tbody \({ }^{\text {p461 }}\) element is immediately followed by a tbody \({ }^{\text {p461 }}\) or tfoot \({ }^{\text {p463 }}\) element, or if there is no more content in the parent element.

A tfoot \({ }^{\text {p463 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if there is no more content in the parent element.
A \(t r^{\text {p464 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the \(t^{p 464}\) element is immediately followed by another \(\underline{t r^{p 464}}\) element, or if there is no more content in the parent element.

A \(t d^{p 465}\) element's end tag \({ }^{p 1070}\) may be omitted if the \(t d^{p 465}\) element is immediately followed by a \(t^{p 465}\) or \(\underline{h}^{p 467}\) element, or if there is no more content in the parent element.

A \(t h^{\text {p467 }}\) element's end tag \({ }^{\text {p1070 }}\) may be omitted if the \(t h^{\text {p467 }}\) element is immediately followed by a \(t^{\text {p465 }}\) or \(\underline{t h}^{\text {p467 }}\) element, or if there is no more content in the parent element.

\section*{Example}

The ability to omit all these table-related tags makes table markup much terser.
Take this example:
```

<table>
    <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
    <colgroup><col><col><col></colgroup>
    <thead>
    <tr>
        <th>Function</th>
        <th>Control Unit</th>
        <th>Central Station</th>
    </tr>
    </thead>
    <tbody>
    <tr>
        <td>Headlights</td>
        <td>v</td>
        <td>v</td>
        </tr>
        <tr>
        <td>Interior Lights</td>
        <td>v</td>
        <td>r</td>
    </tr>
    <tr>
        <td>Electric locomotive operating sounds</td>
        <td>v</td>
        <td>v</td>
    </tr>
    <tr>
        <td>Engineer's cab lighting</td>
        <td></td>
        <td>v</td>
        </tr>
        <tr>
        <td>Station Announcements - Swiss</td>
        <td></td>
        <td>v</td>
    </tr>
    </tbody>
</table>
```

The exact same table, modulo some whitespace differences, could be marked up as follows:
```

<table>
    <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
    <colgroup><col><col><col>
    <thead>
```
```
    <tr>
    <th>Function
    <th>Control Unit
    <th>Central Station
<tbody>
    <tr>
        <td>Headlights
        <td>v
        <td>\checkmark
    <tr>
        <td>Interior Lights
        <td>v
        <td>v
    <tr>
        <td>Electric locomotive operating sounds
        <td>v
        <td>v
    <tr>
    <td>Engineer's cab lighting
    <td>
    <td>v
    <tr>
    <td>Station Announcements - Swiss
    <td>
    <td>>
</table>
```

Since the cells take up much less room this way, this can be made even terser by having each row on one line:
```

<table>
    <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
    <colgroup><col><col><col>
    <thead>
        <tr> <th>Function <th>Control Unit <th>Central Station
<tbody>
    <tr> <td>Headlights <td>\sigma <td>d
    <tr> <td>Interior Lights <td>\checkmark <td>\checkmark
    <tr> <td>Electric locomotive operating sounds <td>& <td>\checkmark
    <tr> <td>Engineer's cab lighting <td> <td>
    <tr> <td>Station Announcements - Swiss <td> <td>
</table>
```

The only differences between these tables, at the DOM level, is with the precise position of the (in any case semantically-neutral) whitespace.

However, a start tag \({ }^{\text {p1069 }}\) must never be omitted if it has any attributes.

\section*{Example}

Returning to the earlier example with all the whitespace removed and then all the optional tags removed:
```

<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.

```

If the body \({ }^{p 178}\) element in this example had to have a class \({ }^{p 137}\) attribute and the html \({ }^{p 152}\) element had to have a lang \({ }^{p 148}\) attribute, the markup would have to become:
<!DOCTYPE HTML><html lang="en"><title>Hello</title><body class="demo"><p>Welcome to this example.

This section assumes that the document is conforming, in particular, that there are no content model \({ }^{\text {p129 }}\) violations. Omitting tags in the fashion described in this section in a document that does not conform to the content models \({ }^{p 129}\) described in this specification is likely to result in unexpected DOM differences (this is, in part, what the content models are designed to avoid).

\subsection*{12.1.2.5 Restrictions on content models \(\S^{\mathrm{prp}}\)}

For historical reasons, certain elements have extra restrictions beyond even the restrictions given by their content model.
A table \({ }^{\text {p450 }}\) element must not contain \(t r^{\text {p464 }}\) elements, even though these elements are technically allowed inside table \({ }^{\text {p450 }}\) elements according to the content models described in this specification. (If a \(\underline{t r}{ }^{p 464}\) element is put inside a table \({ }^{p 45 \theta}\) in the markup, it will in fact imply a tbody \({ }^{\text {p461 }}\) start tag before it.)

A single newline \({ }^{\text {p1077 }}\) may be placed immediately after the start tag \({ }^{\text {p1069 }}\) of pre \(^{\text {p216 }}\) and textarea \({ }^{p 548}\) elements. This does not affect the processing of the element. The otherwise optional newline \({ }^{\text {p1077 }}\) must be included if the element's contents themselves start with a newline \({ }^{\text {p1077 }}\) (because otherwise the leading newline in the contents would be treated like the optional newline, and ignored).

\section*{Example}

The following two pre \({ }^{\text {p216 }}\) blocks are equivalent:
```

<pre>Hello</pre>

<pre>
Hello</pre>
```

\subsection*{12.1.2.6 Restrictions on the contents of raw text and escapable raw text elements \(\int_{77}^{\text {p10 }}\)}

The text in raw text \({ }^{\text {p1068 }}\) and escapable raw text elements \({ }^{\text {p1068 }}\) must not contain any occurrences of the string "</" (U+003C LESS-THAN SIGN, U+002F SOLIDUS) followed by characters that case-insensitively match the tag name of the element followed by one of U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, U+003E GREATER-THAN SIGN (>), or U+002F SOLIDUS (/).

\subsection*{12.1.3 Text \(\S^{\text {p10 }}\)}

Text is allowed inside elements, attribute values, and comments. Extra constraints are placed on what is and what is not allowed in text based on where the text is to be put, as described in the other sections.

\subsection*{12.1.3.1 Newlines \({ }_{77}^{\S_{710}^{p 10}}\)}

Newlines in HTML may be represented either as U+000D CARRIAGE RETURN (CR) characters, U+000A LINE FEED (LF) characters, or pairs of U+000D CARRIAGE RETURN (CR), U+000A LINE FEED (LF) characters in that order.

Where character references \({ }^{\text {p1077 }}\) are allowed, a character reference of a U+000A LINE FEED (LF) character (but not a U+000D CARRIAGE RETURN (CR) character) also represents a newline \({ }^{\text {p1077 }}\).

\subsection*{12.1.4 Character references \(\S^{p 10}\)}

In certain cases described in other sections, text \({ }^{\text {p1077 }}\) may be mixed with character references. These can be used to escape characters that couldn't otherwise legally be included in text \({ }^{\text {p1077 }}\).

Character references must start with a U+0026 AMPERSAND character (\&). Following this, there are three possible kinds of character references:

\section*{Named character references}

The ampersand must be followed by one of the names given in the named character references \({ }^{p 1178}\) section, using the same case. The name must be one that is terminated by a U+003B SEMICOLON character (;).

\section*{Decimal numeric character reference}

The ampersand must be followed by a U+0023 NUMBER SIGN character (\#), followed by one or more ASCII digits, representing a base-ten integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

\section*{Hexadecimal numeric character reference}

The ampersand must be followed by a U+0023 NUMBER SIGN character (\#), which must be followed by either a U+0078 LATIN SMALL LETTER \(X\) character \((x)\) or a U+0058 LATIN CAPITAL LETTER \(X\) character ( X ), which must then be followed by one or more ASCII hex digits, representing a hexadecimal integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

The numeric character reference forms described above are allowed to reference any code point excluding U+000D CR, noncharacters, and controls other than ASCII whitespace.

An ambiguous ampersand is a U+0026 AMPERSAND character ( \(\&\) ) that is followed by one or more ASCII alphanumerics, followed by a U+003B SEMICOLON character (;), where these characters do not match any of the names given in the named character references \({ }^{\text {p1178 }}\) section.

\subsection*{12.1.5 CDATA sections \(\S^{p 10}\)}

CDATA sections must consist of the following components, in this order:
1. The string " \(<\) ! [CDATA[".
2. Optionally, text \({ }^{\text {p1077 }}\), with the additional restriction that the text must not contain the string " ] ]>".
3. The string "] ]>".

\section*{Example}

CDATA sections can only be used in foreign content (MathML or SVG). In this example, a CDATA section is used to escape the contents of a MathML ms element:
```

<p>You can add a string to a number, but this stringifies the number:</p>

<math>
    <ms><![CDATA[x<y]]></ms>
    <mo>+</mo>
    <mn>3</mn>
    <mo>=</mo>
    <ms><! [CDATA[x<y3]]></ms>
</math>

```

\subsection*{12.1.6 Comments \(\S^{p 10}\)}

Comments must have the following format:
1. The string " \(<\) ! - -".
2. Optionally, text \({ }^{\text {p1077 }}\), with the additional restriction that the text must not start with the string ">", nor start with the string " - >", nor contain the strings "<! - - ", " - ->", or " - - ! >", nor end with the string "<! - ".
3. The string " -->".
```

Note
The text p1077 is allowed to end with the string "<!", as in <!--My favorite operators are > and <!-->.

```

\subsection*{12.2 Parsing HTML documents \(\S^{\text {p10 }}\)}

This section only applies to user agents, data mining tools, and conformance checkers.

\section*{Note}

The rules for parsing XML documents into DOM trees are covered by the next section, entitled "The XML syntax \({ }^{\text {p1188" }}\).

User agents must use the parsing rules described in this section to generate the DOM trees from text/html \({ }^{p 1250}\) resources. Together, these rules define what is referred to as the HTML parser.

\section*{Note}

While the HTML syntax described in this specification bears a close resemblance to SGML and XML, it is a separate language with its own parsing rules.

Some earlier versions of HTML (in particular from HTML2 to HTML4) were based on SGML and used SGML parsing rules. However, few (if any) web browsers ever implemented true SGML parsing for HTML documents; the only user agents to strictly handle HTML as an SGML application have historically been validators. The resulting confusion - with validators claiming documents to have one representation while widely deployed web browsers interoperably implemented a different representation - has wasted decades of productivity. This version of HTML thus returns to a non-SGML basis.

Authors interested in using SGML tools in their authoring pipeline are encouraged to use XML tools and the XML serialization of HTML.

For the purposes of conformance checkers, if a resource is determined to be in the HTML syntax \({ }^{\text {p1067 }}\), then it is an HTML document.

\section*{Note}

As stated in the terminology section \({ }^{p 44}\), references to element types \({ }^{p 44}\) that do not explicitly specify a namespace always refer to elements in the HTML namespace. For example, if the spec talks about "a menu \({ }^{p 223}\) element", then that is an element with the local name "menu", the namespace "http://www.w3.org/1999/xhtml", and the interface HTMLMenuElement \({ }^{\text {p223 }}\). Where possible, references to such elements are hyperlinked to their definition.
12.2.1 Overview of the parsing model

The input to the HTML parsing process consists of a stream of code points, which is passed through a tokenization \({ }^{\text {p1097 }}\) stage followed by a tree construction \({ }^{\text {p1125 }}\) stage. The output is a Document \({ }^{\text {p114 }}\) object.

\section*{Note}

Implementations that do not support scripting \({ }^{\text {p47 }}\) do not have to actually create a DOM Document \({ }^{\text {p114 }}\) object, but the DOM tree in such cases is still used as the model for the rest of the specification.

In the common case, the data handled by the tokenization stage comes from the network, but it can also come from script \({ }^{\text {p967 }}\) running in the user agent, e.g. using the document.write() \({ }^{\text {p976 }}\) API.

There is only one set of states for the tokenizer stage and the tree construction stage, but the tree construction stage is reentrant, meaning that while the tree construction stage is handling one token, the tokenizer might be resumed, causing further tokens to be emitted and processed before the first token's processing is complete.

\section*{Example}

In the following example, the tree construction stage will be called upon to handle a "p" start tag token while handling the "script" end tag token:
```

<script>
    document.write('<p>');
</script>
```

To handle these cases, parsers have a script nesting level, which must be initially set to zero, and a parser pause flag, which must be initially set to false.

\subsection*{12.2.2 Parse errors \(\S^{\text {p10 }}\)}

This specification defines the parsing rules for HTML documents, whether they are syntactically correct or not. Certain points in the parsing algorithm are said to be parse errors \({ }^{\text {p1081 }}\). The error handling for parse errors is well-defined (that's the processing rules described throughout this specification), but user agents, while parsing an HTML document, may abort the parser \({ }^{p 1165}\) at the first parse error \({ }^{p 1081}\) that they encounter for which they do not wish to apply the rules described in this specification.

Conformance checkers must report at least one parse error condition to the user if one or more parse error conditions exist in the document and must not report parse error conditions if none exist in the document. Conformance checkers may report more than one parse error condition if more than one parse error condition exists in the document.

Note
Parse errors are only errors with the syntax of HTML. In addition to checking for parse errors, conformance checkers will also verify that the document obeys all the other conformance requirements described in this specification.

Some parse errors have dedicated codes outlined in the table below that should be used by conformance checkers in reports.
Error descriptions in the table below are non-normative.
\begin{tabular}{|c|c|}
\hline Code & Description \\
\hline abrupt-closing-of-empty-comment & This error occurs if the parser encounters an empty comment \({ }^{\text {p1078 }}\) that is abruptly closed by a U+003E (>) code point (i.e., <! - -> or <! - - >). The parser behaves as if the comment is closed correctly. \\
\hline abrupt-doctype-public-identifier & This error occurs if the parser encounters a U+003E (>) code point in the DOCTYPE \({ }^{\text {p1067 }}\) public identifier (e.g., <! DOCTYPE html PUBLIC "foo>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document \({ }^{\text {p114 }}\) to quirks mode. \\
\hline abrupt-doctype-system-identifier & This error occurs if the parser encounters a U+003E (>) code point in the DOCTYPE \({ }^{\text {p1067 }}\) system identifier (e.g., <! DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01//EN" "foo>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document \({ }^{\text {p14 }}\) to quirks mode. \\
\hline absence-of-digits-in-numeric-characterreference & This error occurs if the parser encounters a numeric character reference \({ }^{\text {p1077 }}\) that doesn't contain any digits (e.g., \&\#qux; ). In this case the parser doesn't resolve the character reference. \\
\hline cdata-in-htmlcontent & This error occurs if the parser encounters a CDATA section \({ }^{\text {p1078 }}\) outside of foreign content (SVG or MathML). The parser treats such CDATA sections (including leading "[CDATA[" and trailing "]]" strings) as comments. \\
\hline \begin{tabular}{l}
character- \\
reference- \\
outside-unicode- \\
range
\end{tabular} & This error occurs if the parser encounters a numeric character reference \({ }^{\text {p1077 }}\) that references a code point that is greater than the valid Unicode range. The parser resolves such a character reference to a U+FFFD REPLACEMENT CHARACTER. \\
\hline control-character-in-input-stream & This error occurs if the input stream \({ }^{\text {p1091 }}\) contains a control code point that is not ASCII whitespace or U+0000 NULL. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM. \\
\hline control-characterreference & This error occurs if the parser encounters a numeric character reference \({ }^{\text {p1077 }}\) that references a control code point that is not ASCII whitespace or is a U+000D CARRIAGE RETURN. The parser resolves such character references as-is except C1 control references that are replaced according to the numeric character reference end state \({ }^{\text {p1124 }}\). \\
\hline end-tag-withattributes & This error occurs if the parser encounters an end tag \({ }^{\text {p1070 }}\) with attributes \({ }^{\text {p1070 }}\). Attributes in end tags are completely ignored and do not make their way into the DOM. \\
\hline duplicateattribute & This error occurs if the parser encounters an attribute \({ }^{p 1070}\) in a tag that already has an attribute with the same name. The parser ignores all such duplicate occurrences of the attribute. \\
\hline end-tag-with-trailing-solidus & This error occurs if the parser encounters an end tag \({ }^{\text {p1070 }}\) that has a U+002F (/) code point right before the closing U+003E ( \(>\) ) code point (e.g., </div/>). Such a tag is treated as a regular end tag. \\
\hline eof-before-tagname & This error occurs if the parser encounters the end of the input stream \({ }^{\text {p1091 }}\) where a tag name is expected. In this case the parser treats the beginning of a start tag \({ }^{\text {p1069 }}\) (i.e., <) or an end tag \({ }^{\text {p1070 }}\) (i.e., </) as text content. \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Code & Description \\
\hline eof-in-cdata & This error occurs if the parser encounters the end of the input stream \({ }^{\text {p1091 }}\) in a CDATA section \({ }^{\text {p1078 }}\). The parser treats such CDATA sections as if they are closed immediately before the end of the input stream. \\
\hline eof-in-comment & This error occurs if the parser encounters the end of the input stream \({ }^{\text {p1091 }}\) in a comment \({ }^{\text {p1078 }}\). The parser treats such comments as if they are closed immediately before the end of the input stream. \\
\hline eof-in-doctype & This error occurs if the parser encounters the end of the input stream in a DOCTYPE \({ }^{\text {p1067 }}\). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document \({ }^{p 114}\) to quirks mode. \\
\hline \multirow[t]{3}{*}{eof-in-script-htmI-comment-like-text} & This error occurs if the parser encounters the end of the input stream \({ }^{\text {p1091 }}\) in text that resembles an \(\underline{\text { HTML comment }}{ }^{\text {p1078 }}\) inside script \(^{\text {p614 }}\) element content (e.g., <script><! - foo). \\
\hline & Note \\
\hline & Syntactic structures that resemble HTML comments in script \({ }^{\text {p614 }}\) elements are parsed as text content. They can be a part of a scripting language-specific syntactic structure or be treated as an HTML-like comment, if the scripting language supports them (e.g., parsing rules for HTML-like comments can be found in Annex B of the JavaScript specification). The common reason for this error is a violation of the restrictions for contents of script elements \({ }^{\text {p624 }}\). [JAVASCRIPT] \({ }^{\text {p1288 }}\) \\
\hline eof-in-tag & This error occurs if the parser encounters the end of the input stream \({ }^{\text {p1091 }}\) in a start tag \({ }^{\text {p1069 }}\) or an end tag \({ }^{\text {p1070 }}\) (e.g., <div id=). Such a tag is completely ignored. \\
\hline incorrectly-closed-comment & This error occurs if the parser encounters a comment \({ }^{\text {p1078 }}\) that is closed by the " - -!>" code point sequence. The parser treats such comments as if they are correctly closed by the " - ->" code point sequence. \\
\hline \multirow[t]{3}{*}{incorrectly-opened-comment} & This error occurs if the parser encounters the " <! " code point sequence that is not immidiately followed by two U+002D (-) code points and that is not the start of a DOCTYPE \({ }^{\text {p1067 }}\) or a CDATA section \({ }^{\text {p1078 }}\). All content that follows the " \(<\) !" code point sequence up to a U+003E ( \(>\) ) code point (if present) or to the end of the input stream \({ }^{\text {p1091 }}\) is treated as a comment. \\
\hline & Note \\
\hline & One possible cause of this error is using an XML markup declaration (e.g., <! ELEMENT br EMPTY>) in HTML. \\
\hline invalid-character-sequence-after-doctype-name & This error occurs if the parser encounters any code point sequence other than "PUBLIC" and "SYSTEM" keywords after a DOCTYPE \({ }^{\text {p1067 }}\) name. In such a case, the parser ignores any following public or system identifiers, and if the DOCTYPE is correctly placed as a document preamble, sets the Document \({ }^{\text {p114 }}\) to quirks mode. \\
\hline \multirow[t]{6}{*}{invalid-first-character-of-tagname} & This error occurs if the parser encounters a code point that is not an ASCII alpha where first code point of a start tag p1069 name or an end tag \({ }^{\text {p1070 }}\) name is expected. If a start tag was expected such code point and a preceding \(U+003 C(<)\) is treated as text content, and all content that follows is treated as markup. Whereas, if an end tag was expected, such code point and all content that follows up to a \(U+003 \mathrm{E}\left(>\right.\) ) code point (if present) or to the end of the input stream \({ }^{\text {p1091 }}\) is treated as a comment. \\
\hline & Example \\
\hline & For example, consider the following markup:
<42></42> \\
\hline & This will be parsed into: \\
\hline & Note \\
\hline & While the first code point of a tag name is limited to an ASCII alpha, a wide range of code points (including ASCII digits) is allowed in subsequent positions. \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline missing-attributevalue &  treats the attribute as having an empty value. \\
\hline missing-doctypename & This error occurs if the parser encounters a DOCTYPE \({ }^{\text {p1067 }}\) that is missing a name (e.g., <! DOCTYPE>). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document \({ }^{\text {p114 }}\) to quirks mode. \\
\hline missing-doctype-public-identifier & This error occurs if the parser encounters a U+003E ( \(>\) ) code point where start of the DOCTYPE \({ }^{\text {p1067 }}\) public identifier is expected (e.g., \(<!\) DOCTYPE html PUBLIC >). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document \({ }^{p 114}\) to quirks mode. \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Code & Description \\
\hline missing-doctype-system-identifier & This error occurs if the parser encounters a U+003E (>) code point where start of the DOCTYPE \({ }^{\text {p1067 }}\) system identifier is expected (e.g., <!DOCTYPE html SYSTEM >). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the Document \({ }^{\text {p114 }}\) to quirks mode. \\
\hline missing-end-tagname & This error occurs if the parser encounters a U+003E ( \(>\) ) code point where an end tag \({ }^{\text {p1070 }}\) name is expected, i.e., </>. The parser completely ignores whole "</>" code point sequence. \\
\hline missing-quote-before-doctype-public-identifier & This error occurs if the parser encounters the DOCTYPE \({ }^{\text {p1067 }}\) public identifier that is not preceded by a quote (e.g., <!DOCTYPE html PUBLIC -//W3C//DTD HTML 4.01//EN">). In such a case, the parser ignores the public identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the Document \({ }^{\text {p114 }}\) to quirks mode. \\
\hline missing-quote-before-doctype-system-identifier & This error occurs if the parser encounters the DOCTYPE \({ }^{\text {p1067 }}\) system identifier that is not preceded by a quote (e.g., <!DOCTYPE html SYSTEM http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">). In such a case, the parser ignores the system identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the Document \({ }^{\text {p114 }}\) to quirks mode. \\
\hline \multirow[t]{3}{*}{missing-semicolon-after-characterreference} & This error occurs if the parser encounters a character reference \({ }^{\text {p1077 }}\) that is not terminated by a U+003B (;) code point. Usually the parser behaves as if character reference is terminated by the \(U+003 \mathrm{~B}(;)\) code point; however, there are some ambiguous cases in which the parser includes subsequent code points in the character reference. \\
\hline & Example \\
\hline & For example, \&not; in will be parsed as "ᄀin" whereas \&notin will be parsed as "\#". \\
\hline \begin{tabular}{l}
missing- \\
whitespace-after- \\
doctype-public- \\
keyword
\end{tabular} & This error occurs if the parser encounters a DOCTYPE \({ }^{\text {p1067 }}\) whose "PUBLIC" keyword and public identifier are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present. \\
\hline \begin{tabular}{l}
missing- \\
whitespace-after- \\
doctype-systemkeyword
\end{tabular} & This error occurs if the parser encounters a DOCTYPE \({ }^{\text {p1067 }}\) whose "SYSTEM" keyword and system identifier are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present. \\
\hline \begin{tabular}{l}
missing- \\
whitespace-before-doctypename
\end{tabular} & This error occurs if the parser encounters a DOCTYPE \({ }^{\text {p1067 }}\) whose "DOCTYPE" keyword and name are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present. \\
\hline missing-whitespace-betweenattributes & This error occurs if the parser encounters attributes \({ }^{\text {p1070 }}\) that are not separated by ASCII whitespace (e.g., <div id="foo"class="bar">). In this case the parser behaves as if ASCII whitespace is present. \\
\hline \begin{tabular}{l}
missing- \\
whitespace- \\
between-doctype- \\
public-and- \\
system-identifiers
\end{tabular} & This error occurs if the parser encounters a DOCTYPE \({ }^{\text {p1067 }}\) whose public and system identifiers are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present. \\
\hline nested-comment & This error occurs if the parser encounters a nested comment \({ }^{\text {p1078 }}\) (e.g., <! -- <! -- nested --> -->). Such a comment will be closed by the first occuring " - ->" code point sequence and everything that follows will be treated as markup. \\
\hline noncharacter-characterreference & This error occurs if the parser encounters a numeric character reference \({ }^{\text {p1077 }}\) that references a noncharacter. The parser resolves such character references as-is. \\
\hline noncharacter-in-input-stream & This error occurs if the input stream \({ }^{\text {p1091 }}\) contains a noncharacter. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM. \\
\hline \multirow[t]{3}{*}{non-void-html-element-start-tag-with-trailingsolidus} & This error occurs if the parser encounters a start tag \({ }^{\text {p1069 }}\) for an element that is not in the list of void elements \({ }^{\text {p1068 }}\) or is not a part of foreign content (i.e., not an SVG or MathML element) that has a U+002F (/) code point right before the closing U+003E ( \(>\) ) code point. The parser behaves as if the U+002F (/) is not present. \\
\hline & Example \\
\hline & \begin{tabular}{l}
For example, consider the following markup: \\
<div/><span></span><span></span> \\
This will be parsed into:
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Code & Description \\
\hline &  \\
\hline & Note \\
\hline & The trailing U+002F (/) in a start tag name can be used only in foreign content to specify self-closing tags. (Self-closing tags don't exist in HTML.) It is also allowed for void elements, but doesn't have any effect in this case. \\
\hline null-characterreference & This error occurs if the parser encounters a numeric character reference \({ }^{\text {p1077 }}\) that references a U+0000 NULL code point. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER. \\
\hline surrogate-characterreference & This error occurs if the parser encounters a numeric character reference \({ }^{\text {p1077 }}\) that references a surrogate. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER. \\
\hline surrogate-in-input-stream & This error occurs if the input stream \({ }^{\text {p1091 }}\) contains a surrogate. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM. \\
\hline & Note \\
\hline & Surrogates can only find their way into the input stream via script APIs such as document.write() \({ }^{\text {p970 }}\). \\
\hline unexpected-character-after-doctype-systemidentifier & This error occurs if the parser encounters any code points other than ASCII whitespace or closing U+003E ( \(>\) ) after the DOCTYPE \({ }^{\text {p1067 }}\) system identifier. The parser ignores these code points. \\
\hline unexpected-character-in- & This error occurs if the parser encounters a \(U+0022\) ("), \(U+0027\) ('), or \(U+003 C\) ( \(<\) ) code point in an attribute name \({ }^{\text {p1070 }}\). The parser includes such code points in the attribute name. \\
\hline & \begin{tabular}{l}
Note \\
Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute name.
\end{tabular} \\
\hline & Example \\
\hline & \begin{tabular}{l}
For example, consider the following markup: \\
<div foo<div> \\
Due to a forgotten \(U+003 E(>)\) code point after foo the parser treats this markup as a single div \({ }^{p 237}\) element with a "foo<div" attribute. \\
As another example of this error, consider the following markup: \\
<div id'bar'> \\
Due to a forgotten \(\mathrm{U}+003 \mathrm{D}(=)\) code point between an attribute name and value the parser treats this markup as a div \({ }^{\text {p237 }}\) element with the attribute "id'bar'" that has an empty value.
\end{tabular} \\
\hline \multirow[t]{5}{*}{unexpected-character-in-unquoted-attribute-value} & This error occurs if the parser encounters a U+0022 ("), U+0027 ('), U+003C (<), U+003D (=), or U+0060 (') code point in an unquoted attribute value \({ }^{\text {p1070 }}\). The parser includes such code points in the attribute value. \\
\hline & \begin{tabular}{l}
Note \\
Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute value.
\end{tabular} \\
\hline & \begin{tabular}{l}
Note \\
\(U+0060\) (') is in the list of code points that trigger this error because certain legacy user agents treat it as a quote.
\end{tabular} \\
\hline & Example \\
\hline & \begin{tabular}{l}
For example, consider the following markup: \\
<div foo=b'ar'> \\
Due to a misplaced U+0027 (') code point the parser sets the value of the "foo" attribute to "b 'ar'".
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Code & Description \\
\hline \multirow[t]{5}{*}{unexpected-equals-sign-before-attributename} & This error occurs if the parser encounters a U+003D (=) code point before an attribute name. In this case the parser treats U+003D (=) as the first code point of the attribute name. \\
\hline & \\
\hline & The common reason for this error is a forgotten attribute name. \\
\hline & Example \\
\hline & \begin{tabular}{l}
For example, consider the following markup: \\
<div foo="bar" ="baz"> \\
Due to a forgotten attribute name the parser treats this markup as a div \({ }^{p 237}\) element with two attributes: a "foo" attribute with a "bar" value and a "="baz"" attribute with an empty value.
\end{tabular} \\
\hline unexpected-nullcharacter & This error occurs if the parser encounters a U+0000 NULL code point in the input stream \({ }^{\text {p1091 }}\) in certain positions. In general, such code points are either completely ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER. \\
\hline \multirow[t]{5}{*}{unexpected-question-mark-instead-of-tagname} & This error occurs if the parser encounters a U+003F (?) code point where first code point of a start tag p1069 name is expected. The \(U+003 F\) (?) and all content that follows up to a \(U+003 E(>)\) code point (if present) or to the end of the input stream \({ }^{\text {p1091 }}\) is treated as a comment. \\
\hline & Example \\
\hline & \begin{tabular}{l}
For example, consider the following markup: \\
<?xml-stylesheet type="text/css" href="style.css"?> \\
This will be parsed into: \\
-\#comment: ?xml-stylesheet type="text/css" href="style.css"? \\
html \({ }^{p 152}\) \\
\(\underbrace{}_{\text {hody }^{\text {head }}}{ }^{\text {p153 }}\)
\end{tabular} \\
\hline & Note \\
\hline & The common reason for this error is an XML processing instruction (e.g., <?xml-stylesheet type="text/css" href="style.css"?>) or an XML declaration (e.g., <?xml version="1.0" encoding="UTF-8"?>) being used in HTML. \\
\hline unexpected-solidus-in-tag & This error occurs if the parser encounters a U+002F (/) code point that is not a part of a quoted attribute \({ }^{\text {p1070 }}\) value and not immediately followed by a U+003E (>) code point in a tag (e.g., <div / id="foo">). In this case the parser behaves as if it encountered ASCII whitespace. \\
\hline \begin{tabular}{l}
unknown-named- \\
character- \\
reference
\end{tabular} & This error occurs if the parser encounters an ambiguous ampersand \({ }^{\text {p1078 }}\). In this case the parser doesn't resolve the character reference \({ }^{\text {p1077. }}\). \\
\hline
\end{tabular}

\subsection*{12.2.3 The input byte stream \(\S_{85}^{\text {p10 }}\)}

The stream of code points that comprises the input to the tokenization stage will be initially seen by the user agent as a stream of bytes (typically coming over the network or from the local file system). The bytes encode the actual characters according to a particular character encoding, which the user agent uses to decode the bytes into characters.

\section*{Note}

For XML documents, the algorithm user agents are required to use to determine the character encoding is given by XML. This section does not apply to XML documents. \([X M L]^{p 1293}\)

Usually, the encoding sniffing algorithm \({ }^{\text {p1086 }}\) defined below is used to determine the character encoding.
Given a character encoding, the bytes in the input byte stream \({ }^{\text {p1085 }}\) must be converted to characters for the tokenizer's input stream \({ }^{\text {p1091 }}\), by passing the input byte stream \({ }^{\text {p1085 }}\) and character encoding to decode.

\section*{Note}

Bytes or sequences of bytes in the original byte stream that did not conform to the Encoding standard (e.g. invalid UTF-8 byte sequences in a UTF-8 input byte stream) are errors that conformance checkers are expected to report. [ENCODING] \({ }^{\text {p1287 }}\)

\section*{\(\triangle\) Warning!}

The decoder algorithms describe how to handle invalid input; for security reasons, it is imperative that those rules be followed precisely. Differences in how invalid byte sequences are handled can result in, amongst other problems, script injection vulnerabilities ("XSS").

When the HTML parser is decoding an input byte stream, it uses a character encoding and a confidence. The confidence is either tentative, certain, or irrelevant. The encoding used, and whether the confidence in that encoding is tentative or certain, is used during the parsing \({ }^{\text {p1135 }}\) to determine whether to change the encoding \({ }^{\text {p1091 }}\). If no encoding is necessary, e.g. because the parser is operating on a Unicode stream and doesn't have to use a character encoding at all, then the confidence \({ }^{\text {p1086 }}\) is irrelevant.

\section*{Note}

Some algorithms feed the parser by directly adding characters to the input stream \({ }^{\text {p1091 }}\) rather than adding bytes to the input byte stream \({ }^{\text {p1085 }}\).

\subsection*{12.2.3.1 Parsing with a known character encoding \(\S^{p 10}\)}

When the HTML parser is to operate on an input byte stream that has a known definite encoding, then the character encoding is that encoding and the confidence \({ }^{\text {p1086 }}\) is certain.

\subsection*{12.2.3.2 Determining the character encoding \(\S_{86}^{\text {p10 }}\)}

In some cases, it might be impractical to unambiguously determine the encoding before parsing the document. Because of this, this specification provides for a two-pass mechanism with an optional pre-scan. Implementations are allowed, as described below, to apply a simplified parsing algorithm to whatever bytes they have available before beginning to parse the document. Then, the real parser is started, using a tentative encoding derived from this pre-parse and other out-of-band metadata. If, while the document is being loaded, the user agent discovers a character encoding declaration that conflicts with this information, then the parser can get reinvoked to perform a parse of the document with the real encoding.

User agents must use the following algorithm, called the encoding sniffing algorithm, to determine the character encoding to use when decoding a document in the first pass. This algorithm takes as input any out-of-band metadata available to the user agent (e.g. the Content-Type metadata \({ }^{\text {p90 }}\) of the document) and all the bytes available so far, and returns a character encoding and a confidence \({ }^{\text {p1086 }}\) that is either tentative or certain.
1. If the result of BOM sniffing is an encoding, return that encoding with confidence \({ }^{\text {p1086 }}\) certain.

\section*{Note}

Although the decode algorithm will itself change the encoding to use based on the presence of a byte order mark, this algorithm sniffs the BOM as well in order to set the correct document's character encoding and confidence \({ }^{\text {p1086. }}\).
2. If the user has explicitly instructed the user agent to override the document's character encoding with a specific encoding, optionally return that encoding with the confidence \({ }^{\text {p1086 }}\) certain.

\section*{Note}

Typically, user agents remember such user requests across sessions, and in some cases apply them to documents in iframe \({ }^{\text {p361 }}\) s as well.
3. The user agent may wait for more bytes of the resource to be available, either in this step or at any later step in this algorithm. For instance, a user agent might wait 500 ms or 1024 bytes, whichever came first. In general preparsing the source to find the encoding improves performance, as it reduces the need to throw away the data structures used when parsing upon finding the encoding information. However, if the user agent delays too long to obtain data to determine the encoding, then the cost of the delay could outweigh any performance improvements from the preparse.

The authoring conformance requirements for character encoding declarations limit them to only appearing in the first 1024 bytes \(^{\text {p174 }}\). User agents are therefore encouraged to use the prescan algorithm below (as invoked by these steps) on the first 1024 bytes, but not to stall beyond that.
4. If the transport layer specifies a character encoding, and it is supported, return that encoding with the confidence \({ }^{\text {p1086 }}\) certain.
5. Optionally prescan the byte stream to determine its encoding \({ }^{\text {p1088 }}\). The end condition is that the user agent decides that scanning further bytes would not be efficient. User agents are encouraged to only prescan the first 1024 bytes. User agents may decide that scanning any bytes is not efficient, in which case these substeps are entirely skipped.

The aforementioned algorithm either aborts unsuccessfully or returns a character encoding. If it returns a character encoding, then return the same encoding, with confidence \({ }^{\text {p1086 }}\) tentative.
6. If the HTML parser \({ }^{\text {p1079 }}\) for which this algorithm is being run is associated with a Document \({ }^{\text {p114 }} d\) whose browsing context \({ }^{\text {p811 }}\) is non-null and a child browsing context \({ }^{\text {p814 }}\), then:
1. Let parentDocument be \(d\) 's browsing context \({ }^{\text {p811 }}\) 's container document \({ }^{\mathrm{p} 814}\).
2. If parentDocument's origin \({ }^{p 837}\) is same origin \({ }^{p 838}\) with \(d^{\prime} s{ }^{\text {origin }}{ }^{p 837}\) and parentDocument's character encoding is an ASCII-compatible encoding \({ }^{\text {p46 }}\), then return parentDocument's character encoding, with the confidence \({ }^{\text {p1086 }}\) tentative.
7. Otherwise, if the user agent has information on the likely encoding for this page, e.g. based on the encoding of the page when it was last visited, then return that encoding, with the confidence \({ }^{\text {p1086 }}\) tentative.
8. The user agent may attempt to autodetect the character encoding from applying frequency analysis or other algorithms to the data stream. Such algorithms may use information about the resource other than the resource's contents, including the address of the resource. If autodetection succeeds in determining a character encoding, and that encoding is a supported encoding, then return that encoding, with the confidence \({ }^{\text {p1086 }}\) tentative. [UNIVCHARDET] \({ }^{\text {p1292 }}\)

\section*{Note}

User agents are generally discouraged from attempting to autodetect encodings for resources obtained over the network, since doing so involves inherently non-interoperable heuristics. Attempting to detect encodings based on an HTML document's preamble is especially tricky since HTML markup typically uses only ASCII characters, and HTML documents tend to begin with a lot of markup rather than with text content.

\section*{Note}

The UTF-8 encoding has a highly detectable bit pattern. Files from the local file system that contain bytes with values greater than 0x7F which match the UTF-8 pattern are very likely to be UTF-8, while documents with byte sequences that do not match it are very likely not. When a user agent can examine the whole file, rather than just the preamble, detecting for UTF-8 specifically can be especially effective. [PPUTF8] \({ }^{p 1290}\) [UTF8DET] \({ }^{\text {p1292 }}\)
9. Otherwise, return an implementation-defined or user-specified default character encoding, with the confidence \({ }^{\text {p1086 }}\) tentative.

In controlled environments or in environments where the encoding of documents can be prescribed (for example, for user agents intended for dedicated use in new networks), the comprehensive UTF-8 encoding is suggested.

In other environments, the default encoding is typically dependent on the user's locale (an approximation of the languages, and thus often encodings, of the pages that the user is likely to frequent). The following table gives suggested defaults based on the user's locale, for compatibility with legacy content. Locales are identified by BCP 47 language tags. [BCP47] p1285 [ENCODING] \({ }^{\text {p1287 }}\)
\begin{tabular}{l|l|l}

\end{tabular}

The contents of this table are derived from the intersection of Windows, Chrome, and Firefox defaults.
The document's character encoding must immediately be set to the value returned from this algorithm, at the same time as the user agent uses the returned value to select the decoder to use for the input byte stream.

When an algorithm requires a user agent to prescan a byte stream to determine its encoding, given some defined end condition, then it must run the following steps. These steps either abort unsuccessfully or return a character encoding. If at any point during these steps (including during instances of the get an attribute \({ }^{\text {p1089 }}\) algorithm invoked by this one) the user agent either runs out of bytes (meaning the position pointer created in the first step below goes beyond the end of the byte stream obtained so far) or reaches its end condition, then abort the prescan a byte stream to determine its encoding \({ }^{\text {p1088 }}\) algorithm unsuccessfully.
1. Let position be a pointer to a byte in the input byte stream, initially pointing at the first byte.
2. Loop: If position points to:
\(\rightarrow\) A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D (`<!--`)
Advance the position pointer so that it points at the first \(0 \times 3 \mathrm{E}\) byte which is preceded by two \(0 \times 2 \mathrm{D}\) bytes (i.e. at the end of an ASCII '-->' sequence) and comes after the 0x3C byte that was found. (The two 0x2D bytes can be the same as those in the '<!--' sequence.)
\(\rightarrow\) A sequence of bytes starting with: \(0 \times 3 C, 0 \times 4 D\) or \(0 \times 6 \mathrm{D}, 0 \times 45\) or \(0 \times 65,0 \times 54\) or \(0 \times 74,0 \times 41\) or \(0 \times 61\), and one of \(0 \times 09,0 \times 0 A, 0 \times 0 C, 0 \times 0 D, 0 \times 20,0 \times 2 F\) (case-insensitive ASCII '<meta' followed by a space or slash)
1. Advance the position pointer so that it points at the next \(0 \times 09,0 \times 0 \mathrm{~A}, 0 \times 0 \mathrm{C}, 0 \times 0 \mathrm{D}, 0 \times 20\), or \(0 \times 2 \mathrm{~F}\) byte (the one in sequence of characters matched above).
2. Let attribute list be an empty list of strings.
3. Let got pragma be false.
4. Let need pragma be null.
5. Let charset be the null value (which, for the purposes of this algorithm, is distinct from an unrecognized encoding or the empty string).
6. Attributes: Get an attribute \({ }^{\text {p1089 }}\) and its value. If no attribute was sniffed, then jump to the processing step below.
7. If the attribute's name is already in attribute list, then return to the step labeled attributes.
8. Add the attribute's name to attribute list.
9. Run the appropriate step from the following list, if one applies:
\(\rightarrow\) If the attribute's name is "http-equiv"
If the attribute's value is "content-type", then set got pragma to true.
\(\leftrightarrow\) If the attribute's name is "content"
Apply the algorithm for extracting a character encoding from a meta element \({ }^{\mathrm{p90}}\), giving the attribute's value as the string to parse. If a character encoding is returned, and if charset is still set to null, let charset be the encoding returned, and set need pragma to true.
\(\hookrightarrow\) If the attribute's name is "charset" Let charset be the result of getting an encoding from the attribute's value, and set need pragma to false.
10. Return to the step labeled attributes.
11. Processing: If need pragma is null, then jump to the step below labeled next byte.
12. If need pragma is true but got pragma is false, then jump to the step below labeled next byte.
13. If charset is failure, then jump to the step below labeled next byte.
14. If charset is a UTF-16 encoding \({ }^{\mathrm{p} 46}\), then set charset to UTF-8.
15. If charset is x -user-defined, then set charset to windows-1252.
16. Abort the prescan a byte stream to determine its encoding \({ }^{\text {p1088 }}\) algorithm, returning the encoding given by charset.

\section*{\(\rightarrow\) A sequence of bytes starting with a \(0 \times 3 C\) byte (<), optionally a \(0 \times 2 F\) byte (/), and finally a byte in the range \(0 \times 41-0 \times 5 A\) or \(0 \times 61-0 \times 7 A\) (A-Z or \(a-z\) )}
1. Advance the position pointer so that it points at the next \(0 \times 09\) (HT), \(0 \times 0 \mathrm{~A}(\mathrm{LF}), 0 \times 0 \mathrm{C}(\mathrm{FF}), 0 \times 0 \mathrm{D}(\mathrm{CR}), 0 \times 20\) (SP), or \(0 \times 3 \mathrm{E}(>)\) byte.
2. Repeatedly get an attribute \({ }^{\text {p1089 }}\) until no further attributes can be found, then jump to the step below labeled next byte.
\(\rightarrow\) A sequence of bytes starting with: \(0 \times 3 C 0 \times 21\) ( \(<!`)\)
\(\rightarrow\) A sequence of bytes starting with: \(0 \times 3 \mathrm{C} 0 \times 2 \mathrm{~F}\) ( \(\left.</{ }^{`}\right)\)
\(\rightarrow\) A sequence of bytes starting with: \(0 \times 3 \mathrm{C} 0 \times 3 \mathrm{~F}\) (`<? )
Advance the position pointer so that it points at the first \(0 \times 3 \mathrm{E}\) byte ( \(>\) ) that comes after the \(0 \times 3 \mathrm{C}\) byte that was found.

\section*{\(\rightarrow\) Any other byte}

Do nothing with that byte.
3. Next byte: Move position so it points at the next byte in the input byte stream, and return to the step above labeled loop.

When the prescan a byte stream to determine its encoding \({ }^{\text {p1088 }}\) algorithm says to get an attribute, it means doing this:
1. If the byte at position is one of \(0 \times 09(\mathrm{HT}), 0 \times 0 \mathrm{~A}(\mathrm{LF}), 0 \times 0 \mathrm{C}(\mathrm{FF}), 0 \times 0 \mathrm{D}(\mathrm{CR}), 0 \times 20(\mathrm{SP})\), or \(0 \times 2 \mathrm{~F}(/)\) then advance position to the next byte and redo this step.
2. If the byte at position is \(0 \times 3 \mathrm{E}(>)\), then abort the get an attribute \({ }^{\text {p1089 }}\) algorithm. There isn't one.
3. Otherwise, the byte at position is the start of the attribute name. Let attribute name and attribute value be the empty string.
4. Process the byte at position as follows:
\(\rightarrow\) If it is \(\mathbf{0 \times 3 D}(=)\), and the attribute name is longer than the empty string
Advance position to the next byte and jump to the step below labeled value.
\(\rightarrow\) If it is \(0 \times 09\) (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) Jump to the step below labeled spaces.
\(\rightarrow\) If it is \(0 \times 2 \mathrm{~F}(/)\) or \(0 \times 3 \mathrm{E}(>)\)
Abort the get an attribute \({ }^{\text {p1089 }}\) algorithm. The attribute's name is the value of attribute name, its value is the empty string.
\(\rightarrow\) If it is in the range \(0 \times 41(A)\) to \(0 \times 5 A(Z)\)
Append the code point \(b+0 \times 20\) to attribute name (where \(b\) is the value of the byte at position). (This converts the input to lowercase.)
\(\hookrightarrow\) Anything else
Append the code point with the same value as the byte at position to attribute name. (It doesn't actually matter how bytes outside the ASCII range are handled here, since only ASCII bytes can contribute to the detection of a character encoding.)
5. Advance position to the next byte and return to the previous step.
6. Spaces: If the byte at position is one of \(0 \times 09(\mathrm{HT}), 0 \times 0 \mathrm{~A}(\mathrm{LF}), 0 \times 0 \mathrm{C}(\mathrm{FF}), 0 \times 0 \mathrm{D}(\mathrm{CR})\), or \(0 \times 20(\mathrm{SP})\) then advance position to the next byte, then, repeat this step.
7. If the byte at position is not \(0 \times 3 \mathrm{D}(=)\), abort the get an attribute \({ }^{\text {p1089 }}\) algorithm. The attribute's name is the value of attribute name, its value is the empty string.
8. Advance position past the 0x3D (=) byte.
9. Value: If the byte at position is one of \(0 \times 09\) (HT), \(0 \times 0 \mathrm{~A}(\mathrm{LF}), 0 \times 0 \mathrm{C}(\mathrm{FF}), 0 \times 0 \mathrm{D}(\mathrm{CR})\), or \(0 \times 20(\mathrm{SP})\) then advance position to the next byte, then, repeat this step.
10. Process the byte at position as follows:
\(\rightarrow\) If it is \(0 \times 22\) (") or \(0 \times 27\) (')
1. Let \(b\) be the value of the byte at position.
2. Quote loop: Advance position to the next byte.
3. If the value of the byte at position is the value of \(b\), then advance position to the next byte and abort the "get an attribute" algorithm. The attribute's name is the value of attribute name, and its value is the value of attribute value.
4. Otherwise, if the value of the byte at position is in the range \(0 \times 41(A)\) to \(0 \times 5 A(Z)\), then append a code point to attribute value whose value is \(0 \times 20\) more than the value of the byte at position.
5. Otherwise, append a code point to attribute value whose value is the same as the value of the byte at position.
6. Return to the step above labeled quote loop.

\section*{\(\rightarrow\) If it is \(0 \times 3 \mathrm{E}(>)\)}

Abort the get an attribute \({ }^{\text {p1089 }}\) algorithm. The attribute's name is the value of attribute name, its value is the empty string.

\section*{\(\rightarrow\) If it is in the range \(0 \times 41\) ( \(A\) ) to \(0 \times 5 A(Z)\)}

Append a code point \(b+0 \times 20\) to attribute value (where \(b\) is the value of the byte at position). Advance position to the next byte.

\section*{\(\leftrightarrow\) Anything else}

Append a code point with the same value as the byte at position to attribute value. Advance position to the next byte.
11. Process the byte at position as follows:
\(\rightarrow\) If it is \(0 \times 09\) (HT), 0x0A (LF), \(0 \times 0 \mathrm{C}\) (FF), 0x0D (CR), \(0 \times 20\) (SP), or \(0 \times 3 E\) ( \(>\) )
Abort the get an attribute \({ }^{\text {p1089 }}\) algorithm. The attribute's name is the value of attribute name and its value is the value of attribute value.
\(\rightarrow\) If it is in the range \(0 \times 41(A)\) to \(0 \times 5 A(Z)\)
Append a code point \(b+0 \times 20\) to attribute value (where \(b\) is the value of the byte at position).

\section*{\(\hookrightarrow\) Anything else}

Append a code point with the same value as the byte at position to attribute value.
12. Advance position to the next byte and return to the previous step.

For the sake of interoperability, user agents should not use a pre-scan algorithm that returns different results than the one described above. (But, if you do, please at least let us know, so that we can improve this algorithm and benefit everyone...)

\subsection*{12.2.3.3 Character encodings \(\S^{\text {p10 }}\)}

User agents must support the encodings defined in Encoding, including, but not limited to, UTF-8, ISO-8859-2, ISO-8859-7, ISO-8859-8, windows-874, windows-1250, windows-1251, windows-1252, windows-1254, windows-1255, windows-1256, windows-1257, windows-1258, gb18030, Big5, ISO-2022-JP, Shift JIS, EUC-KR, UTF-16BE, UTF-16LE, and X-user-defined. User agents must not support other encodings.

\section*{Note}

The above prohibits supporting, for example, CESU-8, UTF-7, BOCU-1, SCSU, EBCDIC, and UTF-32. This specification does not make any attempt to support prohibited encodings in its algorithms; support and use of prohibited encodings would thus lead to unexpected behavior. [CESU8] p1285 [UTF7]p1292 [BOCU1] \({ }^{p 1285}\) [SCSU] \({ }^{p 1291}\)

\subsection*{12.2.3.4 Changing the encoding while parsing \(\S^{p 10}\)}

When the parser requires the user agent to change the encoding, it must run the following steps. This might happen if the encoding sniffing algorithm \({ }^{\text {p1086 }}\) described above failed to find a character encoding, or if it found a character encoding that was not the actual encoding of the file.
1. If the encoding that is already being used to interpret the input stream is a UTF-16 encoding \({ }^{\text {p46 }}\), then set the confidence \({ }^{\text {p1086 }}\) to certain and return. The new encoding is ignored; if it was anything but the same encoding, then it would be clearly incorrect.
2. If the new encoding is a UTF-16 encoding \({ }^{\text {p46 }}\), then change it to UTF-8.
3. If the new encoding is \(x\)-user-defined, then change it to windows-1252.
4. If the new encoding is identical or equivalent to the encoding that is already being used to interpret the input stream, then set the confidence \({ }^{\text {p1086 }}\) to certain and return. This happens when the encoding information found in the file matches what the encoding sniffing algorithm \({ }^{\text {p1086 }}\) determined to be the encoding, and in the second pass through the parser if the first pass found that the encoding sniffing algorithm described in the earlier section failed to find the right encoding.
5. If all the bytes up to the last byte converted by the current decoder have the same Unicode interpretations in both the current encoding and the new encoding, and if the user agent supports changing the converter on the fly, then the user agent may change to the new converter for the encoding on the fly. Set the document's character encoding and the encoding used to convert the input stream to the new encoding, set the confidence \({ }^{\text {p1086 }}\) to certain, and return.
6. Otherwise, navigate \({ }^{\text {p866 }}\) to the document again, with historyHandling \({ }^{p 866}\) set to "replace \({ }^{\text {p866" }}\), and using the same source browsing context \({ }^{\text {p866 }}\), but this time skip the encoding sniffing algorithm \({ }^{\text {p1086 }}\) and instead just set the encoding to the new encoding and the confidence \({ }^{\text {p1086 }}\) to certain. Whenever possible, this should be done without actually contacting the network layer (the bytes should be re-parsed from memory), even if, e.g., the document is marked as not being cacheable. If this is not possible and contacting the network layer would involve repeating a request that uses a method other than `GET`, then instead set the confidence \({ }^{\text {p1086 }}\) to certain and ignore the new encoding. The resource will be misinterpreted. User agents may notify the user of the situation, to aid in application development.

\section*{Note}

This algorithm is only invoked when a new encoding is found declared on a meta \({ }^{\text {p164 }}\) element.

\subsection*{12.2.3.5 Preprocessing the input stream \(\S_{91}^{\text {p10 }}\)}

The input stream consists of the characters pushed into it as the input byte stream \({ }^{\text {p1085 }}\) is decoded or from the various APIs that
directly manipulate the input stream.
Any occurrences of surrogates are surrogate-in-input-stream \({ }^{\text {p1084 }}\) parse errors \({ }^{\text {p1081 }}\). Any occurrences of noncharacters are noncharacter-in-input-stream \({ }^{\text {p1083 }}\) parse errors \({ }^{\text {p1081 }}\) and any occurrences of controls other than ASCII whitespace and U+0000 NULL characters are control-character-in-input-stream \({ }^{\text {p1081 }}\) parse errors \({ }^{\text {p1081 }}\).

\section*{Note}

The handling of U+0000 NULL characters varies based on where the characters are found and happens at the later stages of the parsing. They are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER. This handling is, by necessity, spread across both the tokenization stage and the tree construction stage.

Before the tokenization \({ }^{\text {p1097 }}\) stage, the input stream must be preprocessed by normalizing newlines. Thus, newlines in HTML DOMs are represented by U +000 A LF characters, and there are never any U+000D CR characters in the input to the tokenization \({ }^{\text {p1097 }}\) stage.

The next input character is the first character in the input stream \({ }^{\text {p1091 }}\) that has not yet been consumed or explicitly ignored by the requirements in this section. Initially, the next input character \({ }^{p 1092}\) is the first character in the input. The current input character is the last character to have been consumed.

The insertion point is the position (just before a character or just before the end of the input stream) where content inserted using document. write() \({ }^{\text {p970 }}\) is actually inserted. The insertion point is relative to the position of the character immediately after it, it is not an absolute offset into the input stream. Initially, the insertion point is undefined.

The "EOF" character in the tables below is a conceptual character representing the end of the input stream \({ }^{\text {p1091 }}\). If the parser is a script-created parser \({ }^{\mathrm{p} 969}\), then the end of the input stream \({ }^{\text {p1091 }}\) is reached when an explicit "EOF" character (inserted by the document.close( () \({ }^{\text {p969 }}\) method) is consumed. Otherwise, the "EOF" character is not a real character in the stream, but rather the lack of any further characters.

\subsection*{12.2.4 Parse state \({ }_{92}^{\S^{p 10}}\)}

\subsection*{12.2.4.1 The insertion mode \({ }_{92}^{\delta^{p 10}}\)}

The insertion mode is a state variable that controls the primary operation of the tree construction stage.
Initially, the insertion mode \({ }^{\text {p1092 }}\) is "initial \({ }^{\text {p1132" }}\). It can change to "before html \({ }^{\text {p1133" }}\), "before head \({ }^{\text {p1134" } ", ~ " i n ~ h e a d ~}{ }^{\text {p1135 ", "in head }}\)

 frameset \({ }^{\text {p1160" }}\) ", "after frameset \({ }^{\text {p1161 " }}\), "after after body \({ }^{\text {p1161" } ", ~ a n d ~ " a f t e r ~ a f t e r ~ f r a m e s e t ~}{ }^{\text {p1162" }}\) during the course of the parsing, as described in the tree construction \({ }^{\text {p1125 }}\) stage. The insertion mode affects how tokens are processed and whether CDATA sections are supported.

Several of these modes, namely "in head \({ }^{\text {p1135" }}\), "in body \({ }^{\text {p1138" }}\), "in table \({ }^{\text {p1150" } ", ~ a n d ~ " i n ~ s e l e c t ~}{ }^{\text {p1156" }}\), are special, in that the other modes defer to them at various times. When the algorithm below says that the user agent is to do something "using the rules for the \(m\) insertion mode", where \(m\) is one of these modes, the user agent must use the rules described under the \(m\) insertion mode \({ }^{\text {p1092 's }}\) section, but must leave the insertion mode \({ }^{\text {p1092 }}\) unchanged unless the rules in \(m\) themselves switch the insertion mode \({ }^{\text {p1092 }}\) to a new value.

When the insertion mode is switched to "text \({ }^{\text {p1148" }}\) or "in table text \({ }^{\text {p1152" }}\) ", the original insertion mode is also set. This is the insertion mode to which the tree construction stage will return.

Similarly, to parse nested template \({ }^{\text {p629 }}\) elements, a stack of template insertion modes is used. It is initially empty. The current template insertion mode is the insertion mode that was most recently added to the stack of template insertion modes \({ }^{\text {p1092 }}\). The algorithms in the sections below will push insertion modes onto this stack, meaning that the specified insertion mode is to be added to the stack, and pop insertion modes from the stack, which means that the most recently added insertion mode must be removed from the stack.

When the steps below require the UA to reset the insertion mode appropriately, it means the UA must follow these steps:
1. Let last be false.
2. Let node be the last node in the stack of open elements \({ }^{\text {p1093 }}\).
3. Loop: If node is the first node in the stack of open elements, then set last to true, and, if the parser was created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\) (fragment case \({ }^{\text {p1177 }}\) ), set node to the context \({ }^{p 1177}\) element passed to that algorithm.
4. If node is a select \({ }^{\text {p537 }}\) element, run these substeps:
1. If last is true, jump to the step below labeled done.
2. Let ancestor be node.
3. Loop: If ancestor is the first node in the stack of open elements \({ }^{\text {p1093 }}\), jump to the step below labeled done.
4. Let ancestor be the node before ancestor in the stack of open elements \({ }^{\text {p1093 }}\).
5. If ancestor is a template \({ }^{p 629}\) node, jump to the step below labeled done.
6. If ancestor is a table \({ }^{\text {p450 }}\) node, switch the insertion mode \({ }^{\text {p1092 }}\) to "in select in table \({ }^{\text {p1158" }}\) and return.
7. Jump back to the step labeled loop.
8. Done: Switch the insertion mode \({ }^{\text {p1092 }}\) to "in select \({ }^{\text {p1156" }}\) and return.
5. If node is a \(\underline{t d^{\mathrm{p} 465}}\) or \(\underline{\mathrm{th}^{\mathrm{p} 467}}\) element and last is false, then switch the insertion mode \({ }^{\mathrm{p} 1092}\) to "in cell \({ }^{\text {p1156" }}\) and return.
6. If node is a \(\underline{\underline{r^{p 464}}}\) element, then switch the insertion mode \({ }^{\mathrm{p} 1092}\) to "in row \({ }^{\mathrm{p} 1155 \text { " }}\) and return.
7. If node is a tbody \({ }^{\text {p461 }}\), thead \(^{\text {p462 }}\), or \(\underline{\text { tfoot }}{ }^{\text {p463 }}\) element, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in table body \({ }^{\text {p1154" }}\) and return.
8. If node is a caption \({ }^{\text {p458 }}\) element, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in caption \({ }^{\text {p1152" }}\) and return.
9. If node is a colgroup \({ }^{\text {p459 }}\) element, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in column group \({ }^{\text {p1153" }}\) and return.
10. If node is a table \({ }^{\text {p450 }}\) element, then switch the insertion mode \({ }^{p 1092}\) to "in table \({ }^{\text {p1150" }}\) and return.
11. If node is a template \({ }^{\text {p629 }}\) element, then switch the insertion mode \({ }^{\text {p1092 }}\) to the current template insertion mode \({ }^{\text {p1092 }}\) and return.
12. If node is a head \({ }^{\text {p153 }}\) element and last is false, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in head \({ }^{\text {p1135" }}\) and return.
13. If node is a body \({ }^{\text {p178 }}\) element, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in body \({ }^{\text {p1138" }}\) and return.
14. If node is a frameset \({ }^{\text {p1239 }}\) element, then switch the insertion mode \({ }^{p 1092}\) to "in frameset \({ }^{\mathrm{p} 1160}\) " and return. (fragment case \({ }^{\text {p1177 }}\) )
15. If node is an \(h t m l^{p 152}\) element, run these substeps:
1. If the head element pointer \({ }^{\text {p1096 }}\) is null, switch the insertion mode \({ }^{\text {p1092 }}\) to "before head \({ }^{p 1134 "}\) and return. (fragment case \({ }^{\text {p1177 }}\) )
2. Otherwise, the head element pointer \({ }^{\text {p1096 }}\) is not null, switch the insertion mode \({ }^{\text {p1092 }}\) to "after head \({ }^{\text {p1137" }}\) and return.
16. If last is true, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in body \({ }^{\text {p1138" }}\) and return. (fragment case \({ }^{\text {p1177 }}\) )
17. Let node now be the node before node in the stack of open elements \({ }^{p 1093}\).
18. Return to the step labeled loop.

\section*{}

Initially, the stack of open elements is empty. The stack grows downwards; the topmost node on the stack is the first one added to the stack, and the bottommost node of the stack is the most recently added node in the stack (notwithstanding when the stack is manipulated in a random access fashion as part of the handling for misnested tags \({ }^{\text {p1147 }}\) ).

\section*{Note}

The "before htm \({ }^{p 1133 "}\) insertion mode \({ }^{p 1092}\) creates the html \({ }^{p 152}\) document element, which is then added to the stack.

\section*{Note}

In the fragment case \({ }^{p 1177}\), the stack of open elements \({ }^{p 1093}\) is initialized to contain an html \({ }^{p 152}\) element that is created as part of that algorithm \({ }^{p 1177}\). (The fragment case \({ }^{\text {p1177 }}\) skips the "before html \({ }^{p 1133 "}\) insertion mode \({ }^{p 1092}\).)

The html \({ }^{p 152}\) node, however it is created, is the topmost node of the stack. It only gets popped off the stack when the parser finishes \({ }^{\text {p1165 }}\).

The current node is the bottommost node in this stack of open elements \({ }^{\text {p1093 }}\).
The adjusted current node is the context \({ }^{p 1177}\) element if the parser was created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\) and the stack of open elements \({ }^{\text {p1093 }}\) has only one element in it (fragment case \({ }^{\text {p1177 }}\) ); otherwise, the adjusted current node \({ }^{\text {p1094 }}\) is the current node \({ }^{\text {p1094 }}\).

Elements in the stack of open elements \({ }^{\text {p1093 }}\) fall into the following categories:

\section*{Special}

The following elements have varying levels of special parsing rules: HTML's \(\underline{\text { address }{ }^{\text {p197 }}}\), \(\underline{a p p l e t}{ }^{\mathrm{p} 1232}\), \(\underline{a r e a}{ }^{\text {p443 }}, \underline{\operatorname{article}}{ }^{\text {p188 }}\), aside \({ }^{\text {p187 }}\), base \({ }^{\text {p155 }}\), basefont \({ }^{\text {p1233 }}, \underline{\text { bgsound }}{ }^{\text {p1232 }}\), blockquote \({ }^{\text {p217 }}\), body \({ }^{\text {p178 }}\), br \(^{\text {p288 }}\), button \(n^{\text {p535 }}\), caption \({ }^{\text {p458 }}\), center \({ }^{\text {p1233 }}\), col \(^{\text {p460 }}\),

 noembed \({ }^{p 1232}\), noframes \({ }^{\text {p1232 }}\), noscript \({ }^{\text {p627 }}\), object \({ }^{\text {p373 }}\), ol \(^{\text {p228 }}\), p \(^{\text {p211 }}\), param \({ }^{\text {p378 }}\), plaintext \({ }^{\text {p1232 }}\), pre \({ }^{\text {p216 }}\), script \({ }^{\text {p614 }}\), section \({ }^{\text {p182 }}\),
 \(t i t l e^{p 154}, ~ t r^{p 464}, ~ t r a c k^{p 385}, ~ u l^{p 222}, ~ w b r^{p 281}, ~ x m p^{p 1233}\); MathML mi, MathML mo, MathML mn, MathML ms, MathML mtext, and MathML annotation-xml; and SVG foreign0bject, SVG desc, and SVG title.

\section*{Note}

An image start tag token is handled by the tree builder, but it is not in this list because it is not an element; it gets turned into an img \({ }^{\text {p320 }}\) element.

\section*{Formatting}

The following HTML elements are those that end up in the list of active formatting elements \({ }^{p 1095}: \underline{a}^{p 238}, \underline{b}^{p 273}, \underline{b i g}^{p 1233}, c^{p o d e}{ }^{p 267}\),

\section*{Ordinary}

All other elements found while parsing an HTML document.

\section*{Note}

Typically, the special \({ }^{\text {p1094 }}\) elements have the start and end tag tokens handled specifically, while ordinary \({ }^{\text {p1094 }}\) elements' tokens fall into "any other start tag" and "any other end tag" clauses, and some parts of the tree builder check if a particular element in the stack of open elements \({ }^{p 1093}\) is in the special \({ }^{p 1094}\) category. However, some elements (e.g., the option \({ }^{p 545}\) element) have their start or end tag tokens handled specifically, but are still not in the special \({ }^{p 1094}\) category, so that they get the ordinary \({ }^{\text {p1094 }}\) handling elsewhere.

The stack of open elements \({ }^{\text {p1093 }}\) is said to have an element target node in a specific scope consisting of a list of element types list when the following algorithm terminates in a match state:
1. Initialize node to be the current node \({ }^{\text {p1094 }}\) (the bottommost node of the stack).
2. If node is the target node, terminate in a match state.
3. Otherwise, if node is one of the element types in list, terminate in a failure state.
4. Otherwise, set node to the previous entry in the stack of open elements \({ }^{\text {p1093 }}\) and return to step 2. (This will never fail, since the loop will always terminate in the previous step if the top of the stack - an html \({ }^{\text {p152 }}\) element - is reached.)

The stack of open elements \({ }^{\text {p1093 }}\) is said to have a particular element in scope when it has that element in the specific scope \({ }^{\text {p1094 }}\) consisting of the following element types:
- applet \({ }^{p 1232}\)
- caption \({ }^{\text {p458 }}\)
- html \({ }^{p 152}\)
- table \({ }^{\mathrm{p} 450}\)
- \(t d^{\text {p465 }}\)
- \(t h^{\text {p467 }}\)
- marquee \({ }^{\text {p1237 }}\)
- object \({ }^{\text {P373 }}\)
- template \({ }^{\text {p629 }}\)
- MathML mi
- MathML mo
- MathML mn
- MathML ms
- MathML mtext
- MathML annotation-xml
- SVG foreign0bject
- SVG desc
- SVGtitle

The stack of open elements \({ }^{\text {p1093 }}\) is said to have a particular element in list item scope when it has that element in the specific scope \({ }^{\text {p1094 }}\) consisting of the following element types:
- All the element types listed above for the has an element in scope \({ }^{\text {p1094 }}\) algorithm.
- \(\mathrm{ol}^{\mathrm{p} 220}\) in the HTML namespace
- \(u^{p 222}\) in the HTML namespace

The stack of open elements \({ }^{\text {p1093 }}\) is said to have a particular element in button scope when it has that element in the specific scope \({ }^{\text {p1094 }}\) consisting of the following element types:
- All the element types listed above for the has an element in scope \({ }^{p 1094}\) algorithm.
- button \({ }^{p 535}\) in the HTML namespace

The stack of open elements \({ }^{\text {p1093 }}\) is said to have a particular element in table scope when it has that element in the specific scope \({ }^{\text {p1094 }}\) consisting of the following element types:
- \(h t m 2^{p 152}\) in the HTML namespace
- table \({ }^{\text {p450 }}\) in the HTML namespace
- template \({ }^{\text {p629 }}\) in the HTML namespace

The stack of open elements \({ }^{p 1093}\) is said to have a particular element in select scope when it has that element in the specific scope \({ }^{\text {p1094 }}\) consisting of all element types except the following:
- optgroup \({ }^{p 544}\) in the HTML namespace
- option \({ }^{\text {p545 }}\) in the HTML namespace

Nothing happens if at any time any of the elements in the stack of open elements \({ }^{\text {p1093 }}\) are moved to a new location in, or removed from, the Document \({ }^{p 114}\) tree. In particular, the stack is not changed in this situation. This can cause, amongst other strange effects, content to be appended to nodes that are no longer in the DOM.

\section*{Note}

In some cases (namely, when closing misnested formatting elements \({ }^{p 1147}\) ), the stack is manipulated in a random-access fashion.

\subsection*{12.2.4.3 The list of active formatting elements \(\S^{p 10}\) \\ 95}

Initially, the list of active formatting elements is empty. It is used to handle mis-nested formatting element tags \({ }^{\text {p1094 }}\).
The list contains elements in the formatting \({ }^{\text {p1094 }}\) category, and markers \({ }^{\text {p1095 }}\). The markers are inserted when entering applet \({ }^{\text {p1232 }}\),
 applet \({ }^{\text {p1232 }}\), object \({ }^{\text {p373 }}\), marquee \({ }^{\text {p1237 }}\), template \({ }^{\text {p629 }}\), td \(^{\mathrm{p} 465}\), \(\mathrm{th}^{\mathrm{p} 467}\), and caption \({ }^{\mathrm{p} 458}\) elements.

In addition, each element in the list of active formatting elements \({ }^{\text {p1095 }}\) is associated with the token for which it was created, so that further elements can be created for that token if necessary.

When the steps below require the UA to push onto the list of active formatting elements an element element, the UA must perform the following steps:
1. If there are already three elements in the list of active formatting elements \({ }^{p 1095}\) after the last marker \({ }^{\text {p1095 }}\), if any, or anywhere in the list if there are no markers \({ }^{\text {p1095 }}\), that have the same tag name, namespace, and attributes as element, then remove the earliest such element from the list of active formatting elements \({ }^{\text {p1095 }}\). For these purposes, the attributes must be compared as they were when the elements were created by the parser; two elements have the same attributes if all their parsed attributes can be paired such that the two attributes in each pair have identical names, namespaces, and values (the order of the attributes does not matter).

This is the Noah's Ark clause. But with three per family instead of two.
2. Add element to the list of active formatting elements \({ }^{\text {p1095 }}\).

When the steps below require the UA to reconstruct the active formatting elements, the UA must perform the following steps:
1. If there are no entries in the list of active formatting elements \({ }^{\text {p1095 }}\), then there is nothing to reconstruct; stop this algorithm.
2. If the last (most recently added) entry in the list of active formatting elements \({ }^{\text {p1095 }}\) is a marker \({ }^{\text {p1095 }}\), or if it is an element that is in the stack of open elements \({ }^{\text {p1093 }}\), then there is nothing to reconstruct; stop this algorithm.
3. Let entry be the last (most recently added) element in the list of active formatting elements \({ }^{\text {p1095 }}\).
4. Rewind: If there are no entries before entry in the list of active formatting elements \({ }^{\text {p1095 }}\), then jump to the step labeled create.
5. Let entry be the entry one earlier than entry in the list of active formatting elements \({ }^{\text {p1095 }}\).
6. If entry is neither a marker \({ }^{\mathrm{p1095}}\) nor an element that is also in the stack of open elements \({ }^{\text {p1093 }}\), go to the step labeled rewind.
7. Advance: Let entry be the element one later than entry in the list of active formatting elements \({ }^{\text {p1095 }}\).
8. Create: Insert an HTML element \({ }^{\text {p1129 }}\) for the token for which the element entry was created, to obtain new element.
9. Replace the entry for entry in the list with an entry for new element.
10. If the entry for new element in the list of active formatting elements \({ }^{\text {p1095 }}\) is not the last entry in the list, return to the step labeled advance.

This has the effect of reopening all the formatting elements that were opened in the current body, cell, or caption (whichever is youngest) that haven't been explicitly closed.

\section*{Note}

The way this specification is written, the list of active formatting elements \({ }^{p 1095}\) always consists of elements in chronological order with the least recently added element first and the most recently added element last (except for while steps 7 to 10 of the above algorithm are being executed, of course).

When the steps below require the UA to clear the list of active formatting elements up to the last marker, the UA must perform the following steps:
1. Let entry be the last (most recently added) entry in the list of active formatting elements \({ }^{\text {p1095 }}\).
2. Remove entry from the list of active formatting elements \({ }^{\mathrm{p} 1095}\).
3. If entry was a marker \({ }^{\text {p1095 }}\), then stop the algorithm at this point. The list has been cleared up to the last marker \({ }^{\text {p1095 }}\).
4. Go to step 1.

\subsection*{12.2.4.4 The element pointers \(\S^{p 10}\)}

Initially, the head element pointer and the form element pointer are both null.
Once a head \({ }^{\text {p153 }}\) element has been parsed (whether implicitly or explicitly) the head element pointer \({ }^{\text {p1096 }}\) gets set to point to this node.

The form element pointer \({ }^{p 1096}\) points to the last form \({ }^{p 486}\) element that was opened and whose end tag has not yet been seen. It is used to make form controls associate with forms in the face of dramatically bad markup, for historical reasons. It is ignored inside template \({ }^{\text {p629 }}\) elements.

\subsection*{12.2.4.5 Other parsing state flags \(\S^{p 10}\)}

The scripting flag is set to "enabled" if scripting was enabled \({ }^{\text {p924 }}\) for the Document \({ }^{\text {p114 }}\) with which the parser is associated when the parser was created, and "disabled" otherwise.

The scripting flag \({ }^{\text {p1096 }}\) can be enabled even when the parser was created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), even though script \({ }^{p 614}\) elements don't execute in that case.

The frameset-ok flag is set to "ok" when the parser is created. It is set to "not ok" after certain tokens are seen.

\subsection*{12.2.5 Tokenization \(\S^{\text {p10 }}\)}

Implementations must act as if they used the following state machine to tokenize HTML. The state machine must start in the data state \({ }^{\text {p1098 }}\). Most states consume a single character, which may have various side-effects, and either switches the state machine to a new state to reconsume \({ }^{\text {p1097 }}\) the current input character \({ }^{\text {p1092 }}\), or switches it to a new state to consume the next character \({ }^{\text {p1092 }}\), or stays in the same state to consume the next character. Some states have more complicated behavior and can consume several characters before switching to another state. In some cases, the tokenizer state is also changed by the tree construction stage.

When a state says to reconsume a matched character in a specified state, that means to switch to that state, but when it attempts to consume the next input character \({ }^{\text {p1092 }}\), provide it with the current input character \({ }^{\text {p1092 }}\) instead.

The exact behavior of certain states depends on the insertion mode \({ }^{\text {p1092 }}\) and the stack of open elements \({ }^{p 1093}\). Certain states also use a temporary buffer to track progress, and the character reference state \({ }^{\text {p1122 }}\) uses a return state to return to the state it was invoked from.

The output of the tokenization step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, end-of-file. DOCTYPE tokens have a name, a public identifier, a system identifier, and a force-quirks flag. When a DOCTYPE token is created, its name, public identifier, and system identifier must be marked as missing (which is a distinct state from the empty string), and the force-quirks flag \({ }^{\text {p1097 }}\) must be set to off (its other state is on). Start and end tag tokens have a tag name, a self-closing flag, and a list of attributes, each of which has a name and a value. When a start or end tag token is created, its selfclosing flag \({ }^{\text {p1097 }}\) must be unset (its other state is that it be set), and its attributes list must be empty. Comment and character tokens have data.

When a token is emitted, it must immediately be handled by the tree construction \({ }^{\text {p1125 }}\) stage. The tree construction stage can affect the state of the tokenization stage, and can insert additional characters into the stream. (For example, the script \({ }^{\text {p614 }}\) element can result in scripts executing and using the dynamic markup insertion \({ }^{\text {p967 }}\) APIs to insert characters into the stream being tokenized.)

\section*{Note}

Creating a token and emitting it are distinct actions. It is possible for a token to be created but implicitly abandoned (never emitted), e.g. if the file ends unexpectedly while processing the characters that are being parsed into a start tag token.

When a start tag token is emitted with its self-closing flag \({ }^{p 1097}\) set, if the flag is not acknowledged when it is processed by the tree construction stage, that is a non-void-html-element-start-tag-with-trailing-solidus \({ }^{\text {p1083 }}\) parse error \({ }^{p 1081}\).

When an end tag token is emitted with attributes, that is an end-tag-with-attributes \({ }^{\text {p1081 }}\) parse error \({ }^{\text {p1081 }}\).
When an end tag token is emitted with its self-closing flag \({ }^{p 1097}\) set, that is an end-tag-with-trailing-solidus \({ }^{p 1081}\) parse error \({ }^{\text {p1081 }}\).
An appropriate end tag token is an end tag token whose tag name matches the tag name of the last start tag to have been emitted from this tokenizer, if any. If no start tag has been emitted from this tokenizer, then no end tag token is appropriate.

A character reference \({ }^{\text {p1077 }}\) is said to be consumed as part of an attribute if the return state \({ }^{p 1097}\) is either attribute value (doublequoted) state \({ }^{\text {p1109 }}\), attribute value (single-quoted) state \({ }^{\text {p1110 }}\) or attribute value (unquoted) state \({ }^{\text {p1110 }}\).

When a state says to flush code points consumed as a character reference, it means that for each code point in the temporary buffer \({ }^{\text {p1097 }}\) (in the order they were added to the buffer) user agent must append the code point from the buffer to the current attribute's value if the character reference was consumed as part of an attribute \({ }^{\text {p1097 }}\), or emit the code point as a character token otherwise.

Before each step of the tokenizer, the user agent must first check the parser pause flag \({ }^{\text {p1081 }}\). If it is true, then the tokenizer must abort the processing of any nested invocations of the tokenizer, yielding control back to the caller.

The tokenizer state machine consists of the states defined in the following subsections.

\subsection*{12.2.5.1 Data state \(\S^{\delta^{p 10}}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+0026 AMPERSAND (\&)
Set the return state \({ }^{\text {p1097 }}\) to the data state \({ }^{\text {p1098 }}\). Switch to the character reference state \({ }^{\text {p1122 }}\).
\(\hookrightarrow\) U+003C LESS-THAN SIGN (<)
Switch to the tag open state \({ }^{\text {p1099 }}\).
\(\rightarrow \mathbf{U + 0 0 0 0}\) NULL
This is an unexpected-null-character \({ }^{\text {p1085 }}\) parse error \({ }^{\text {p1081 }}\). Emit the current input character \({ }^{\text {p1092 }}\) as a character token.
\(\rightarrow\) EOF
Emit an end-of-file token.
\(\rightarrow\) Anything else
Emit the current input character \({ }^{p 1092}\) as a character token.

\subsection*{12.2.5.2 RCDATA state \(\underset{{ }_{9}{ }^{\text {p10 }}}{\substack{ \\\hline}}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+0026 AMPERSAND (\&)
Set the return state \({ }^{\text {p1097 }}\) to the RCDATA state \({ }^{\text {p1098 }}\). Switch to the character reference state \({ }^{\text {p1122 }}\).
\(\rightarrow\) U+003C LESS-THAN SIGN (<)
Switch to the RCDATA less-than sign state \({ }^{\text {p1100 }}\).
\(\rightarrow \mathbf{U + 0 0 0 0}\) NULL
This is an unexpected-null-character \({ }^{p 1085}\) parse error \({ }^{p 1081}\). Emit a U+FFFD REPLACEMENT CHARACTER character token.
\(\rightarrow\) EOF
Emit an end-of-file token.
\(\rightarrow\) Anything else
Emit the current input character \({ }^{p 1092}\) as a character token.

\subsection*{12.2.5.3 RAWTEXT state \({ }^{8810}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+003C LESS-THAN SIGN (<)
Switch to the RAWTEXT less-than sign state \({ }^{\text {p1101 }}\).
\(\rightarrow \mathbf{U + 0 0 0 0}\) NULL
This is an unexpected-null-character \({ }^{p 1085}\) parse error \({ }^{p 1081}\). Emit a U+FFFD REPLACEMENT CHARACTER character token.
\(\rightarrow\) EOF
Emit an end-of-file token.
\(\rightarrow\) Anything else
Emit the current input character \({ }^{\text {p1092 }}\) as a character token.

\subsection*{12.2.5.4 Script data state \({ }_{98}^{\text {p10 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+003C LESS-THAN SIGN (<)
Switch to the script data less-than sign state \({ }^{\text {p1102 }}\).

This is an unexpected-null-character \({ }^{\text {p1085 }}\) parse error \({ }^{\text {p1081 }}\). Emit a U+FFFD REPLACEMENT CHARACTER character token.
\(\rightarrow\) EOF
Emit an end-of-file token.
\(\rightarrow\) Anything else
Emit the current input character \({ }^{\text {p1092 }}\) as a character token.

\subsection*{12.2.5.5 PLAINTEXT state \(\S^{p 10}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow \mathbf{U + 0 0 0 0}\) NULL
This is an unexpected-null-character \({ }^{p 1085}\) parse error \({ }^{p 1081}\). Emit a U+FFFD REPLACEMENT CHARACTER character token.
\(\rightarrow\) EOF
Emit an end-of-file token.

\section*{\(\rightarrow\) Anything else}

Emit the current input character \({ }^{\text {p1092 }}\) as a character token.

\subsection*{12.2.5.6 Tag open state \({ }_{9}{ }_{9}^{110}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+0021 EXCLAMATION MARK (!)
Switch to the markup declaration open state \({ }^{p 1112}\).
\(\rightarrow \mathbf{U + 0 0 2 F}\) SOLIDUS (/)
Switch to the end tag open state \({ }^{\text {p1099 }}\).
\(\rightarrow\) ASCII alpha
Create a new start tag token, set its tag name to the empty string. Reconsume \({ }^{\text {p1097 }}\) in the tag name state \({ }^{\text {p1100 }}\).
\(\rightarrow\) U+003F QUESTION MARK (?)
This is an unexpected-question-mark-instead-of-tag-name \({ }^{\text {p1085 }}\) parse error \({ }^{\text {p1081 }}\). Create a comment token whose data is the empty string. Reconsume \({ }^{\text {p1097 }}\) in the bogus comment state \({ }^{\text {p1111 }}\).
\(\rightarrow\) EOF
This is an eof-before-tag-name \({ }^{\text {p1081 }}\) parse error \({ }^{\text {p1081 }}\). Emit a U+003C LESS-THAN SIGN character token and an end-of-file token.
\(\rightarrow\) Anything else
This is an invalid-first-character-of-tag-name \({ }^{\text {p1082 }}\) parse error \({ }^{\text {p1081 }}\). Emit a U+003C LESS-THAN SIGN character token.
Reconsume \({ }^{\text {p1097 }}\) in the data state \({ }^{\text {p1098 }}\).

\subsection*{12.2.5.7 End tag open state \(\S^{\text {p1o }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :

\section*{\(\rightarrow\) ASCII alpha}

Create a new end tag token, set its tag name to the empty string. Reconsume \({ }^{\text {p1097 }}\) in the tag name state \({ }^{\text {p1100 }}\).
\(\rightarrow\) U+003E GREATER-THAN SIGN ( \(>\) )
This is a missing-end-tag-name \({ }^{\text {p1083 }}\) parse error \({ }^{\text {p1081 }}\). Switch to the data state \({ }^{\text {p1098 }}\).
\(\rightarrow\) EOF
This is an eof-before-tag-name \({ }^{\text {p1081 }}\) parse error \({ }^{\text {p1081 }}\). Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token and an end-of-file token.

This is an invalid-first-character-of-tag-name \({ }^{\text {p1082 }}\) parse error \({ }^{\text {p1081 }}\). Create a comment token whose data is the empty string. Reconsume \({ }^{\text {p1097 }}\) in the bogus comment state \({ }^{\text {p1111 }}\).

\subsection*{12.2.5.8 Tag name state \({ }_{{ }_{0}{ }^{p 11}}^{\text {p1 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\hookrightarrow\) U+0009 CHARACTER TABULATION (tab)
\(\rightarrow\) U+000A LINE FEED (LF)
\(\rightarrow\) U+000C FORM FEED (FF)
\(\rightarrow \mathbf{U + 0 0 2 0}\) SPACE
Switch to the before attribute name state \({ }^{p 1108}\).
\(\rightarrow \mathbf{U + 0 0 2 F}\) SOLIDUS (/)
Switch to the self-closing start tag state \({ }^{\text {p1111 }}\).
\(\rightarrow\) U+003E GREATER-THAN SIGN (>)
Switch to the data state \({ }^{\text {p1098 }}\). Emit the current tag token.
\(\rightarrow\) ASCII upper alpha
Append the lowercase version of the current input character \({ }^{\text {p1092 }}\) (add \(0 \times 0020\) to the character's code point) to the current tag token's tag name.
\(\rightarrow\) U+0000 NULL
This is an unexpected-null-character \({ }^{\text {p1085 }}\) parse error \({ }^{\text {p1081 }}\). Append a U+FFFD REPLACEMENT CHARACTER character to the current tag token's tag name.
\(\rightarrow\) EOF
This is an eof-in-tag \({ }^{\text {p1082 }}\) parse error \({ }^{p 1081}\). Emit an end-of-file token.
\(\hookrightarrow\) Anything else
Append the current input character \({ }^{\text {p1092 }}\) to the current tag token's tag name.

\subsection*{12.2.5.9 RCDATA less-than sign state \(\S_{\substack{p 11}}^{\substack{\text { plo }}}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\leftrightarrow\) U+002F SOLIDUS (/)
Set the temporary buffer \({ }^{\text {p1097 }}\) to the empty string. Switch to the RCDATA end tag open state \({ }^{\text {p1100 }}\).
\(\rightarrow\) Anything else
Emit a U+003C LESS-THAN SIGN character token. Reconsume \({ }^{\text {p1097 }}\) in the RCDATA state \({ }^{\text {p1098 }}\).

\subsection*{12.2.5.10 RCDATA end tag open state \(\S_{00}^{\S_{011}^{p 1}}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) ASCII alpha
Create a new end tag token, set its tag name to the empty string. Reconsume \({ }^{\text {p1097 }}\) in the RCDATA end tag name state \({ }^{\text {p1101 }}\).
\(\rightarrow\) Anything else
Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume \({ }^{\text {p1097 }}\) in the RCDATA state \({ }^{\text {p1098 }}\).

\subsection*{12.2.5.11 RCDATA end tag name state \(\S^{\text {p11 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\hookrightarrow\) U+0009 CHARACTER TABULATION (tab)
\(\rightarrow\) U+000A LINE FEED (LF)
\(\rightarrow\) U+000C FORM FEED (FF)
\(\rightarrow\) U+0020 SPACE
If the current end tag token is an appropriate end tag token \({ }^{\text {p1097 }}\), then switch to the before attribute name state \({ }^{\text {p1108 }}\). Otherwise, treat it as per the "anything else" entry below.
\(\rightarrow \mathbf{U + 0 0 2 F}\) SOLIDUS (/)
If the current end tag token is an appropriate end tag token \({ }^{\text {p1097 }}\), then switch to the self-closing start tag state \({ }^{\text {p1111 }}\). Otherwise, treat it as per the "anything else" entry below.
\(\rightarrow\) U+003E GREATER-THAN SIGN (>)
If the current end tag token is an appropriate end tag token \({ }^{\text {p1097 }}\), then switch to the data state \({ }^{\text {p1098 }}\) and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.
\(\rightarrow\) ASCII upper alpha
Append the lowercase version of the current input character \({ }^{p 1092}\) (add \(0 \times 0020\) to the character's code point) to the current tag token's tag name. Append the current input character \({ }^{\text {p1092 }}\) to the temporary buffer \({ }^{\text {p1097 }}\).
\(\rightarrow\) ASCII lower alpha
Append the current input character \({ }^{\text {p1092 }}\) to the current tag token's tag name. Append the current input character \({ }^{\text {p1092 }}\) to the temporary buffer \({ }^{p 1097}\).
\(\rightarrow\) Anything else
Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the temporary buffer \({ }^{p 1097}\) (in the order they were added to the buffer). Reconsume \({ }^{\text {p1097 }}\) in the RCDATA state \({ }^{\text {p1098 }}\).

\subsection*{12.2.5.12 RAWTEXT less-than sign state \(\S_{01}^{\S^{p 11}}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow \mathbf{U + 0 0 2 F}\) SOLIDUS (/)
Set the temporary buffer \({ }^{p 1097}\) to the empty string. Switch to the RAWTEXT end tag open state \({ }^{\text {p1101 }}\).
\(\rightarrow\) Anything else
Emit a U+003C LESS-THAN SIGN character token. Reconsume \({ }^{\text {p1097 }}\) in the RAWTEXT state \({ }^{\text {p1098 }}\).

\subsection*{12.2.5.13 RAWTEXT end tag open state \(\S^{p 11}\)}

Consume the next input character \({ }^{p 1092}\) :

\section*{\(\hookrightarrow\) ASCII alpha}

Create a new end tag token, set its tag name to the empty string. Reconsume \({ }^{\text {p1097 }}\) in the RAWTEXT end tag name state \({ }^{\text {p1101 }}\).

\section*{\(\rightarrow\) Anything else}

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume \({ }^{\text {p1097 }}\) in the RAWTEXT state \({ }^{\text {p1098 }}\)

\subsection*{12.2.5.14 RAWTEXT end tag name state \(\S^{\text {p }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+0009 CHARACTER TABULATION (tab)
\(\rightarrow\) U+000A LINE FEED (LF)
\(\hookrightarrow\) U+000C FORM FEED (FF)
\(\rightarrow\) U+0020 SPACE
If the current end tag token is an appropriate end tag token \({ }^{\text {p1097 }}\), then switch to the before attribute name state \({ }^{\text {p1108 }}\). Otherwise, treat it as per the "anything else" entry below.

This is an unexpected-character-in-attribute-name \({ }^{\text {p1084 }}\) parse error \({ }^{p 1081}\). Treat it as per the "anything else" entry below.

\section*{\(\rightarrow\) Anything else}

Append the current input character \({ }^{\text {p1092 }}\) to the current attribute's name.
When the user agent leaves the attribute name state (and before emitting the tag token, if appropriate), the complete attribute's name must be compared to the other attributes on the same token; if there is already an attribute on the token with the exact same name, then this is a duplicate-attribute \({ }^{p 1081}\) parse error \({ }^{p 1081}\) and the new attribute must be removed from the token.

If an attribute is so removed from a token, it, and the value that gets associated with it, if any, are never subsequently used by the parser, and are therefore effectively discarded. Removing the attribute in this way does not change its status as the "current attribute" for the purposes of the tokenizer, however.

\(\hookrightarrow\) EOF
This is an eof-in-doctype \({ }^{p 1082}\) parse error \({ }^{p 1081}\). Set the DOCTYPE token's force-quirks flag \({ }^{p 1097}\) to on. Emit that DOCTYPE token. Emit an end-of-file token.
\(\rightarrow\) Anything else
This is an unexpected-character-after-doctype-system-identifier \({ }^{\text {p1084 }}\) parse error \({ }^{\text {p1081 }}\). Reconsume \({ }^{\text {p1097 }}\) in the bogus DOCTYPE state \({ }^{\text {p1121 }}\). (This does not set the DOCTYPE token's force-quirks flag \({ }^{\text {p1097 }}\) to on.)

\subsection*{12.2.5.68 Bogus DOCTYPE state \(\S_{21}^{\text {p11 }}\)}

Consume the next input character \({ }^{p 1092}\) :
\(\rightarrow\) U+003E GREATER-THAN SIGN (>)
Switch to the data state \({ }^{\text {p1098 }}\). Emit the DOCTYPE token.
\(\rightarrow \mathbf{U + 0 0 0 0}\) NULL
This is an unexpected-null-character \({ }^{\text {p1085 }}\) parse error \({ }^{\text {p1081 }}\). Ignore the character.
\(\rightarrow\) EOF
Emit the DOCTYPE token. Emit an end-of-file token.
\(\rightarrow\) Anything else
Ignore the character.

\subsection*{12.2.5.69 CDATA section state \(\delta^{\text {p11 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) U+005D RIGHT SQUARE BRACKET (])
Switch to the CDATA section bracket state \({ }^{\text {p1122 }}\).
\(\rightarrow\) EOF
This is an eof-in-cdata \({ }^{\text {p1082 }}\) parse error \({ }^{\text {p1081 }}\). Emit an end-of-file token.
\(\rightarrow\) Anything else
Emit the current input character \({ }^{\text {p1092 }}\) as a character token.

U+0000 NULL characters are handled in the tree construction stage, as part of the in foreign content \({ }^{p 162}\) insertion mode, which is the only place where CDATA sections can appear.

\subsection*{12.2.5.70 CDATA section bracket state \(\S^{\text {p11 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :

\section*{\(\hookrightarrow\) U+005D RIGHT SQUARE BRACKET (J)}

Switch to the CDATA section end state \({ }^{\text {p1122 }}\).
\(\rightarrow\) Anything else
Emit a U+005D RIGHT SQUARE BRACKET character token. Reconsume \({ }^{\text {p1097 }}\) in the CDATA section state \({ }^{\text {p1121 }}\).

\subsection*{12.2.5.71 CDATA section end state \(\S_{22}^{\text {p11 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\hookrightarrow\) U+005D RIGHT SQUARE BRACKET (])
Emit a U+005D RIGHT SQUARE BRACKET character token.
\(\hookrightarrow\) U+003E GREATER-THAN SIGN character
Switch to the data state \({ }^{\text {p1098 }}\).
\(\rightarrow\) Anything else
Emit two U+005D RIGHT SQUARE BRACKET character tokens. Reconsume \({ }^{\text {p1097 }}\) in the CDATA section state \({ }^{\text {p1121 }}\).

\subsection*{12.2.5.72 Character reference state \(\S^{\text {p11 }}\)}

Set the temporary buffer \({ }^{p 1097}\) to the empty string. Append a U+0026 AMPERSAND (\&) character to the temporary buffer \({ }^{\text {p1097 }}\). Consume the next input character \({ }^{\text {p1092 }}\) :

\section*{\(\rightarrow\) ASCII alphanumeric}

Reconsume \({ }^{\text {p1097 }}\) in the named character reference state \({ }^{\text {p1122 }}\).

\section*{\(\rightarrow\) U+0023 NUMBER SIGN (\#)}

Append the current input character \({ }^{p 1092}\) to the temporary buffer \({ }^{p 1097}\). Switch to the numeric character reference state \({ }^{\text {p1123 }}\).
\(\rightarrow\) Anything else
Flush code points consumed as a character reference \({ }^{\text {p1097 }}\). Reconsume \({ }^{\text {p1097 }}\) in the return state \({ }^{\text {p1097 }}\).

\subsection*{12.2.5.73 Named character reference state \(\S_{22}^{\text {p11 }}\)}

Consume the maximum number of characters possible, where the consumed characters are identical to one of the identifiers in the first column of the named character references \({ }^{\text {p1178 }}\) table. Append each character to the temporary buffer \({ }^{p 1097}\) when it's consumed.

\section*{\(\rightarrow\) If there is a match}

If the character reference was consumed as part of an attribute \({ }^{\text {p1097 }}\), and the last character matched is not a U+003B SEMICOLON character (;), and the next input character \({ }^{\text {p1092 }}\) is either a U+003D EQUALS SIGN character (=) or an ASCII alphanumeric, then, for historical reasons, flush code points consumed as a character reference \({ }^{\text {p1097 }}\) and switch to the return state \({ }^{\text {p1097 }}\).

Otherwise:
1. If the last character matched is not a U+003B SEMICOLON character (;), then this is a missing-semicolon-after-character-reference \({ }^{\text {p1083 }}\) parse error \({ }^{\text {p1081 }}\).
2. Set the temporary buffer \({ }^{p 1097}\) to the empty string. Append one or two characters corresponding to the character reference name (as given by the second column of the named character references \({ }^{\text {p1178 }}\) table) to the temporary buffer \({ }^{\text {p1097. }}\).
3. Flush code points consumed as a character reference \({ }^{\text {p1097 }}\). Switch to the return state \({ }^{\text {p1097 }}\).

\section*{\(\rightarrow\) Otherwise}

Flush code points consumed as a character reference \({ }^{\text {p1097 }}\). Switch to the ambiguous ampersand state \({ }^{\text {p1123 }}\).

\section*{Example}

If the markup contains (not in an attribute) the string I'm \&notit; I tell you, the character reference is parsed as "not", as in, I'm ᄀit; I tell you (and this is a parse error). But if the markup was I'm \&notin; I tell you, the character reference would be parsed as "notin;", resulting in I'm \(\notin\) I tell you (and no parse error).

However, if the markup contains the string I'm \&notit; I tell you in an attribute, no character reference is parsed and string remains intact (and there is no parse error).

\subsection*{12.2.5.74 Ambiguous ampersand state \(\S^{\text {p11 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :

\section*{\(\rightarrow\) ASCII alphanumeric}

If the character reference was consumed as part of an attribute \({ }^{\text {p1097 }}\), then append the current input character \({ }^{\text {p1092 }}\) to the current attribute's value. Otherwise, emit the current input character \({ }^{p 1092}\) as a character token.
\(\rightarrow \mathbf{U + 0 0 3 B}\) SEMICOLON (;)
This is an unknown-named-character-reference \({ }^{\text {p1085 }}\) parse error \({ }^{\text {p1081 }}\). Reconsume \({ }^{\text {p1097 }}\) in the return state \({ }^{\text {p1097 }}\).

\section*{\(\hookrightarrow\) Anything else}

Reconsume \({ }^{\text {p1097 }}\) in the return state \({ }^{\text {p1097 }}\).

\subsection*{12.2.5.75 Numeric character reference state \(\S_{23}^{\text {p11 }}\)}

Set the character reference code to zero (0).
Consume the next input character \({ }^{\text {p1092 }}\) :

\section*{\(\rightarrow\) U+0078 LATIN SMALL LETTER \(X\)}

\section*{\(\rightarrow \mathbf{U + 0 0 5 8}\) LATIN CAPITAL LETTER X}

Append the current input character \({ }^{p 1092}\) to the temporary buffer \({ }^{p 1097}\). Switch to the hexadecimal character reference start state \({ }^{\text {p1123 }}\).
\(\hookrightarrow\) Anything else
Reconsume \({ }^{\text {p1097 }}\) in the decimal character reference start state \({ }^{\text {p1124 }}\).

\subsection*{12.2.5.76 Hexadecimal character reference start state \(\S_{23}^{p 11}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) ASCII hex digit
Reconsume \({ }^{\text {p1097 }}\) in the hexadecimal character reference state \({ }^{\text {p1124 }}\).

\section*{\(\hookrightarrow\) Anything else}

This is an absence-of-digits-in-numeric-character-reference \({ }^{\text {p1081 }}\) parse error \({ }^{p 1081}\). Flush code points consumed as a character reference \({ }^{\text {p1097 }}\). Reconsume \({ }^{\text {p1097 }}\) in the return state \({ }^{\text {p1097 }}\).

\subsection*{12.2.5.77 Decimal character reference start state \(\S^{\text {pl1 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :

\section*{\(\rightarrow\) ASCII digit}

Reconsume \({ }^{\text {p1097 }}\) in the decimal character reference state \({ }^{\text {p1124 }}\).

\section*{\(\rightarrow\) Anything else}

This is an absence-of-digits-in-numeric-character-reference \({ }^{\text {p1081 }}\) parse error \({ }^{\text {p1081 }}\). Flush code points consumed as a character reference \({ }^{\text {p1097 }}\). Reconsume \({ }^{\text {p1097 }}\) in the return state \({ }^{\text {p1097 }}\).

\subsection*{12.2.5.78 Hexadecimal character reference state \(\S^{\text {p11 }}\)}

Consume the next input character \({ }^{\text {p1092 }}\) :
ASCII digit
Multiply the character reference code \({ }^{\text {p1123 }}\) by 16 . Add a numeric version of the current input character \({ }^{\text {p1092 }}\) (subtract \(0 \times 0030\) from the character's code point) to the character reference code \({ }^{p 1123}\).
\(\rightarrow\) ASCII upper hex digit
Multiply the character reference code \({ }^{p 1123}\) by 16 . Add a numeric version of the current input character \({ }^{p 1092}\) as a hexadecimal digit (subtract \(0 \times 0037\) from the character's code point) to the character reference code \({ }^{p 1123}\).
\(\rightarrow\) ASCII lower hex digit
Multiply the character reference code \({ }^{p 1123}\) by 16 . Add a numeric version of the current input character \({ }^{p 1092}\) as a hexadecimal digit (subtract \(0 \times 0057\) from the character's code point) to the character reference code \({ }^{\text {p1123 }}\).
\(\rightarrow\) U+003B SEMICOLON
Switch to the numeric character reference end state \({ }^{\text {p1124 }}\).
\(\rightarrow\) Anything else
This is a missing-semicolon-after-character-reference \({ }^{\text {p1083 }}\) parse error \({ }^{\text {p1081 }}\). Reconsume \({ }^{\text {p1097 }}\) in the numeric character reference end state \({ }^{\text {p1124 }}\).

\section*{}

Consume the next input character \({ }^{\text {p1092 }}\) :
\(\rightarrow\) ASCII digit
Multiply the character reference code \({ }^{p 1123}\) by 10 . Add a numeric version of the current input character \({ }^{p 1092}\) (subtract \(0 \times 0030\) from the character's code point) to the character reference code \({ }^{p 1123}\).
\(\rightarrow\) U+003B SEMICOLON
Switch to the numeric character reference end state \({ }^{\text {p1124 }}\).
\(\rightarrow\) Anything else
This is a missing-semicolon-after-character-reference \({ }^{\text {p1083 }}\) parse error \({ }^{p 1081}\). Reconsume \({ }^{\text {p1097 }}\) in the numeric character reference end state \({ }^{\text {p1124 }}\).

\subsection*{12.2.5.80 Numeric character reference end state \(\S_{24}^{\text {p11 }}\)}

Check the character reference code \({ }^{\text {p1123 }}\) :
- If the number is \(0 \times 00\), then this is a null-character-reference \({ }^{\text {p1084 }}\) parse error \({ }^{\text {p1081 }}\). Set the character reference code \({ }^{p 1123}\) to \(0 x F F F D\).
- If the number is greater than \(0 \times 10 F F F F\), then this is a character-reference-outside-unicode-range \({ }^{\text {p1081 }}\) parse error \({ }^{\text {p1081 }}\). Set the character reference code \({ }^{\text {p1123 }}\) to 0xFFFD.
- If the number is a surrogate, then this is a surrogate-character-reference \({ }^{\text {p1084 }}\) parse error \({ }^{\text {p1081 }}\). Set the character reference
code \({ }^{p 1123}\) to 0xFFFD.
- If the number is a noncharacter, then this is a noncharacter-character-reference \({ }^{\text {p1083 }}\) parse error \({ }^{\text {p1081 }}\).
- If the number is \(0 \times 0 D\), or a control that's not ASCII whitespace, then this is a control-character-reference \({ }^{\text {p1081 }}\) parse error \({ }^{\text {p1081 }}\). If the number is one of the numbers in the first column of the following table, then find the row with that number in the first column, and set the character reference code \({ }^{p 1123}\) to the number in the second column of that row.
\begin{tabular}{|c|c|c|}
\hline Number & \multicolumn{2}{|r|}{Code point} \\
\hline \(0 \times 80\) & 0x20AC & EURO SIGN ( \(€\) ) \\

\hline
\end{tabular}

Set the temporary buffer \({ }^{p 1097}\) to the empty string. Append a code point equal to the character reference code \({ }^{p 1123}\) to the temporary

\subsection*{12.2.6 Tree construction \(\S^{\text {p11 }}\)}

The input to the tree construction stage is a sequence of tokens from the tokenization \({ }^{\text {p1097 }}\) stage. The tree construction stage is associated with a DOM Document \({ }^{\text {p114 }}\) object when a parser is created. The "output" of this stage consists of dynamically modifying or extending that document's DOM tree.

This specification does not define when an interactive user agent has to render the Document \({ }^{\text {p114 }}\) so that it is available to the user, or when it has to begin accepting user input.

As each token is emitted from the tokenizer, the user agent must follow the appropriate steps from the following list, known as the tree construction dispatcher:
\(\rightarrow\) If the stack of open elements \({ }^{\text {p1093 }}\) is empty
\(\rightarrow\) If the adjusted current node \({ }^{\text {p1094 }}\) is an element in the HTML namespace
\(\leftrightarrow\) If the adjusted current node \({ }^{\text {p1094 }}\) is a MathML text integration point \({ }^{\text {p1126 }}\) and the token is a start tag whose tag name is neither "mglyph" nor "malignmark"
\(\leftrightarrow\) If the adjusted current node \({ }^{\text {p1094 }}\) is a MathML text integration point \({ }^{\text {p1126 }}\) and the token is a character token
\(\rightarrow\) If the adjusted current node \({ }^{\text {p1094 }}\) is a MathML annotation-xml element and the token is a start tag whose tag name is "svg"
\(\rightarrow\) If the adjusted current node \({ }^{\text {p1094 }}\) is an HTML integration point \({ }^{\text {p1126 }}\) and the token is a start tag
\(\rightarrow\) If the adjusted current node \({ }^{\text {p1094 }}\) is an HTML integration point \({ }^{\text {p1126 }}\) and the token is a character token
\(\rightarrow\) If the token is an end-of-file token
Process the token according to the rules given in the section corresponding to the current insertion mode \({ }^{\text {p1092 }}\) in HTML content.
\(\rightarrow\) Otherwise
Process the token according to the rules given in the section for parsing tokens in foreign content \({ }^{\text {p1162 }}\).
The next token is the token that is about to be processed by the tree construction dispatcher \({ }^{\text {p1125 }}\) (even if the token is subsequently just ignored).

A node is a MathML text integration point if it is one of the following elements:
- A MathML mi element
- A MathML mo element
- A MathML mn element
- A MathML ms element
- A MathML mtext element

A node is an HTML integration point if it is one of the following elements:
- A MathML annotation-xml element whose start tag token had an attribute with the name "encoding" whose value was an ASCII case-insensitive match for the string "text/html"
- A MathML annotation-xml element whose start tag token had an attribute with the name "encoding" whose value was an ASCII case-insensitive match for the string "application/xhtml+xml"
- An SVG foreign0bject element
- An SVG desc element
- An SVG title element

\section*{Note}
\[
\text { If the node in question is the context }{ }^{p 1177} \text { element passed to the HTML fragment parsing algorithm }{ }^{p 1177} \text {, then the start tag token for }
\] that element is the "fake" token created during by that HTML fragment parsing algorithm \({ }^{p 1177}\).

\section*{Note}

Not all of the tag names mentioned below are conformant tag names in this specification; many are included to handle legacy content. They still form part of the algorithm that implementations are required to implement to claim conformance.

\section*{Note}

The algorithm described below places no limit on the depth of the DOM tree generated, or on the length of tag names, attribute names, attribute values, Text nodes, etc. While implementers are encouraged to avoid arbitrary limits, it is recognized that practical concerns \({ }^{p 48}\) will likely force user agents to impose nesting depth constraints.

\section*{}

While the parser is processing a token, it can enable or disable foster parenting. This affects the following algorithm.
The appropriate place for inserting a node, optionally using a particular override target, is the position in an element returned by running the following steps:
1. If there was an override target specified, then let target be the override target.

Otherwise, let target be the current node \({ }^{\text {p1094 }}\).
2. Determine the adjusted insertion location using the first matching steps from the following list:

\section*{Note}

Foster parenting happens when content is misnested in tables.

Run these substeps:
1. Let last template be the last template \({ }^{\text {p629 }}\) element in the stack of open elements \({ }^{\text {p1093 }}\), if any.
2. Let last table be the last table \({ }^{\text {p450 }}\) element in the stack of open elements \({ }^{\text {p1093 }}\), if any.
3. If there is a last template and either there is no last table, or there is one, but last template is lower (more recently added) than last table in the stack of open elements \({ }^{\text {p1093 }}\), then: let adjusted insertion location be inside last template's template contents \({ }^{\text {p631 }}\), after its last child (if any), and abort these steps.
4. If there is no last table, then let adjusted insertion location be inside the first element in the stack of open elements \({ }^{\text {p1093 }}\) (the html \({ }^{\text {p152 }}\) element), after its last child (if any), and abort these steps. (fragment case \({ }^{\text {p1177 }}\) )
5. If last table has a parent node, then let adjusted insertion location be inside last table's parent node, immediately before last table, and abort these steps.
6. Let previous element be the element immediately above last table in the stack of open elements \({ }^{\text {p1093 }}\).
7. Let adjusted insertion location be inside previous element, after its last child (if any).

\section*{Note}

These steps are involved in part because it's possible for elements, the table \({ }^{\text {p450 }}\) element in this case in particular, to have been moved by a script around in the DOM, or indeed removed from the DOM entirely, after the element was inserted by the parser.

\section*{\(\rightarrow\) Otherwise}

Let adjusted insertion location be inside target, after its last child (if any).
3. If the adjusted insertion location is inside a template \({ }^{p 629}\) element, let it instead be inside the template \({ }^{\text {p629 }}\) element's template contents \({ }^{\text {p631 }}\), after its last child (if any).
4. Return the adjusted insertion location.

When the steps below require the UA to create an element for a token in a particular given namespace and with a particular intended parent, the UA must run the following steps:
1. Let document be intended parent's node document.
2. Let local name be the tag name of the token.
3. Let is be the value of the "is \({ }^{\mathrm{p} 703 \mathrm{u}}\) " attribute in the given token, if such an attribute exists, or null otherwise.
4. Let definition be the result of looking up a custom element definition \({ }^{\mathrm{p} 705}\) given document, given namespace, local name, and is.
5. If definition is non-null and the parser was not created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), then let will execute script be true. Otherwise, let it be false.
6. If will execute script is true, then:
1. Increment document's throw-on-dynamic-markup-insertion counter \({ }^{\text {p967 }}\).
2. If the JavaScript execution context stack is empty, then perform a microtask checkpoint \({ }^{\text {p949 }}\).
3. Push a new element queue \({ }^{\mathrm{p} 712}\) onto document's relevant agent \({ }^{\text {p914 ' }} \mathrm{s}\) custom element reactions stack \({ }^{\mathrm{p} 712}\).
7. Let element be the result of creating an element given document, localName, given namespace, null, and is. If will execute script is true, set the synchronous custom elements flag; otherwise, leave it unset.

This will cause custom element constructors \({ }^{\text {p703 }}\) to run, if will execute script is true. However, since we incremented the throw-on-dynamic-markup-insertion counter \({ }^{p 967}\), this cannot cause new characters to be inserted into the tokenizer \({ }^{\text {p970 }}\), or the document to be blown away \({ }^{\text {p969 }}\).
8. Append each attribute in the given token to element.

\section*{Note}

This can enqueue a custom element callback reaction \({ }^{p 713}\) for the attributeChangedCallback, which might run immediately (in the next step).

\section*{Note}

Even though the is \({ }^{\text {p703 }}\) attribute governs the creation of a customized built-in element \({ }^{\text {p703 }}\), it is not present during the execution of the relevant custom element constructor \({ }^{\text {p703 }}\); it is appended in this step, along with all other attributes.
9. If will execute script is true, then:
1. Let queue be the result of popping from document's relevant agent \({ }^{\text {p914 }}\) 's custom element reactions stack \({ }^{\text {p712 }}\). (This will be the same element queue \({ }^{\mathrm{p} 712}\) as was pushed above.)
2. Invoke custom element reactions \({ }^{\mathrm{p} 713}\) in queue.
3. Decrement document's throw-on-dynamic-markup-insertion counter \({ }^{\text {p967 }}\).
10. If element has an \(x m l n s\) attribute in the XMLNS namespace whose value is not exactly the same as the element's namespace, that is a parse error \({ }^{\text {p1081 }}\). Similarly, if element has an xmlns : xlink attribute in the XMLNS namespace whose value is not the XLink Namespace, that is a parse error \({ }^{p 1081}\).
11. If element is a resettable element \({ }^{\text {p486 }}\), invoke its reset algorithm \({ }^{\text {p604 }}\). (This initializes the element's value \({ }^{\text {p566 }}\) and checkedness \({ }^{\text {p566 }}\) based on the element's attributes.)
12. If element is a form-associated element \({ }^{\text {p486 }}\) and not a form-associated custom element \({ }^{\text {p704 }}\), the form element pointer \({ }^{\text {p1096 }}\) is not null, there is no template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), element is either not listed \({ }^{\text {p486 }}\) or doesn't have a form \({ }^{\mathrm{p566}}\) attribute, and the intended parent is in the same tree as the element pointed to by the form element pointer \({ }^{\text {p1096 }}\), then associate \({ }^{\text {p567 }}\) element with the form \({ }^{\text {p486 }}\) element pointed to by the form element pointer \({ }^{\text {p1096 }}\) and set element's parser inserted flag \({ }^{\mathrm{p} 566}\).
13. Return element.

When the steps below require the user agent to insert a foreign element for a token in a given namespace, the user agent must run these steps:
1. Let the adjusted insertion location be the appropriate place for inserting a node \({ }^{\text {p1126 }}\).
2. Let element be the result of creating an element for the token \({ }^{\text {p1127 }}\) in the given namespace, with the intended parent being the element in which the adjusted insertion location finds itself.
3. If it is possible to insert element at the adjusted insertion location, then:
1. If the parser was not created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), then push a new element queue \({ }^{\text {p712 }}\) onto element's relevant agent \({ }^{\text {p914' }}\) 's custom element reactions stack \({ }^{\text {p712 }}\).
2. Insert element at the adjusted insertion location.
3. If the parser was not created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), then pop the element queue \({ }^{\text {p712 }}\) from element's relevant agent \({ }^{\text {p914 ' }} \mathrm{s}\) custom element reactions stack \({ }^{\text {p712 }}\), and invoke custom element reactions \({ }^{\text {p713 }}\) in that queue.

\section*{Note}

If the adjusted insertion location cannot accept more elements, e.g. because it's a Document \({ }^{\text {p114 }}\) that already has an element child, then element is dropped on the floor.
4. Push element onto the stack of open elements \({ }^{\text {p1093 }}\) so that it is the new current node \({ }^{\text {p1094 }}\).
5. Return element.

When the steps below require the user agent to insert an HTML element for a token, the user agent must insert a foreign element \({ }^{\text {p1128 }}\) for the token, in the HTML namespace.

When the steps below require the user agent to adjust MathML attributes for a token, then, if the token has an attribute named definitionurl, change its name to definitionURL (note the case difference).

When the steps below require the user agent to adjust SVG attributes for a token, then, for each attribute on the token whose attribute name is one of the ones in the first column of the following table, change the attribute's name to the name given in the corresponding cell in the second column. (This fixes the case of SVG attributes that are not all lowercase.)
\begin{tabular}{|c|c|}
\hline Attribute name on token & Attribute name on element \\
\hline attributename & attributeName \\
\hline attributetype & attributeType \\
\hline basefrequency & baseFrequency \\

\hline
\end{tabular}

When the steps below require the user agent to adjust foreign attributes for a token, then, if any of the attributes on the token match the strings given in the first column of the following table, let the attribute be a namespaced attribute, with the prefix being the string given in the corresponding cell in the second column, the local name being the string given in the corresponding cell in the third column, and the namespace being the namespace given in the corresponding cell in the fourth column. (This fixes the use of namespaced attributes, in particular lang attributes in the XML namespace \({ }^{\text {p140 }}\).)
\begin{tabular}{|c|c|c|c|}
\hline Attribute name & Prefix & Local name & Namespace \\
\hline xlink:actuate & xlink & actuate & XLink namespace \\
\hline xlink:arcrole & xlink & arcrole & XLink namespace \\
\hline xlink:href & xlink & href & XLink namespace \\
\hline xlink:role & xlink & role & XLink namespace \\
\hline xlink:show & xlink & show & XLink namespace \\
\hline xlink:title & xlink & title & XLink namespace \\
\hline xlink:type & xlink & type & XLink namespace \\
\hline xml:lang & xml & lang & XML namespace \\
\hline xml:space & xml & space & XML namespace \\
\hline xmlns & (none) & xmlns & XMLNS namespace \\
\hline xmlns:xlink & xmlns & xlink & XMLNS namespace \\
\hline
\end{tabular}

When the steps below require the user agent to insert a character while processing a token, the user agent must run the following steps:
1. Let data be the characters passed to the algorithm, or, if no characters were explicitly specified, the character of the character token being processed.
2. Let the adjusted insertion location be the appropriate place for inserting a node \({ }^{\text {p1126 }}\).
3. If the adjusted insertion location is in a Document \({ }^{\text {p114 }}\) node, then return.

\section*{Note}

The DOM will not let Document \({ }^{\text {p114 }}\) nodes have Text node children, so they are dropped on the floor.
4. If there is a Text node immediately before the adjusted insertion location, then append data to that Text node's data.

Otherwise, create a new Text node whose data is data and whose node document is the same as that of the element in which the adjusted insertion location finds itself, and insert the newly created node at the adjusted insertion location.

\section*{Example}

Here are some sample inputs to the parser and the corresponding number of Text nodes that they result in, assuming a user agent that executes scripts.
Input \(\quad\) Number of Text nodes
```

A<script>

```
One Text node in the document, containing "AB".
document. body. removeChild(script);
</script>B

A<script>
var text \(=\) document. createTextNode('B');
document. body. appendChild(text);
</script>C

Three Text nodes; "A" before the script, the script's contents, and "BC" after the script (the parser appends to the Text node created by the script).

> Two adjacent Text nodes in the document, containing "A" and "BC".
```

A<script>

```
var text = document. getElementsByTagName('script')[0].firstChild;
text.data = 'B';
document. body. appendChild(text);
</script>C
\begin{tabular}{|c|c|}
\hline A<table>B<tr>C</tr>D</table> & One Text node before the table, containing "ABCD". (This is caused by foster parenting \({ }^{\text {p1126 }}\).) \\
\hline A<table><tr> B</tr> C</table> & One Text node before the table, containing "A B C" (A-space-B-space-C). (This is caused by foster parenting \({ }^{\text {p1126 }}\).) \\
\hline A<table><tr> B</tr> </em>C</table> & One Text node before the table, containing "A BC" (A-space-B-C), and one Text node inside the table (as a child of a tbody \({ }^{\text {p461 }}\) ) with a single space character. (Space characters separated from nonspace characters by non-character tokens are not affected by foster parenting \({ }^{\text {p1126 }}\), even if those other tokens then get ignored.) \\
\hline
\end{tabular}

When the steps below require the user agent to insert a comment while processing a comment token, optionally with an explicitly insertion position position, the user agent must run the following steps:
1. Let data be the data given in the comment token being processed.
2. If position was specified, then let the adjusted insertion location be position. Otherwise, let adjusted insertion location be the appropriate place for inserting a node \({ }^{\text {p1126 }}\).
3. Create a Comment node whose data attribute is set to data and whose node document is the same as that of the node in which the adjusted insertion location finds itself.
4. Insert the newly created node at the adjusted insertion location.

DOM mutation events must not fire for changes caused by the UA parsing the document. This includes the parsing of any content inserted using document.write( \()^{\text {p976 }}\) and document.writeln( ( \({ }^{\text {p971 }}\) calls. [UIEVENTS] \({ }^{\text {p1292 }}\)

However, mutation observers do fire, as required by \(D O M\).

\subsection*{12.2.6.2 Parsing elements that contain only text \(\S^{\text {p11 }}\)}

The generic raw text element parsing algorithm and the generic RCDATA element parsing algorithm consist of the following steps. These algorithms are always invoked in response to a start tag token.
1. Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
2. If the algorithm that was invoked is the generic raw text element parsing algorithm \({ }^{\text {p1131 }}\), switch the tokenizer to the RAWTEXT state \({ }^{\text {p1098 }}\); otherwise the algorithm invoked was the generic RCDATA element parsing algorithm \({ }^{\text {p1131 }}\), switch the tokenizer to the RCDATA state \({ }^{\text {p1098 }}\).
3. Let the original insertion mode \({ }^{\text {p1092 }}\) be the current insertion mode \({ }^{\text {p1092 }}\).
4. Then, switch the insertion mode \({ }^{\text {p1092 }}\) to "text \({ }^{\text {p1148" }}\).

\subsection*{12.2.6.3 Closing elements that have implied end tags \(\S^{p 11}\)}

32
When the steps below require the UA to generate implied end tags, then, while the current node \({ }^{p 1094}\) is a \(\underline{d d^{p 231}}\) element, a \(\underline{d t} t^{p 230}\) element, an \(\underline{l i} i^{p 224}\) element, an optgroup \({ }^{p 544}\) element, an option \({ }^{p 545}\) element, a p \({ }^{p 211}\) element, an \(\underline{r b}{ }^{p 1232}\) element, an rp \(p^{p 258}\) element, an \(r^{p 258}\) element, or an \(r t c^{p 1232}\) element, the UA must pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).

If a step requires the UA to generate implied end tags but lists an element to exclude from the process, then the UA must perform the above steps as if that element was not in the above list.

When the steps below require the UA to generate all implied end tags thoroughly, then, while the current node \({ }^{\text {p1094 }}\) is a caption \({ }^{\text {p458 }}\) element, a colgroup \({ }^{p 459}\) element, a dd \({ }^{p 231}\) element, a dt \(t^{p 236}\) element, an \(\underline{i^{p 224}}\) element, an optgroup \({ }^{p 544}\) element, an option \({ }^{p 545}\) element, a \(p^{p 211}\) element, an \(r b^{p 1232}\) element, an \(r p^{p 258}\) element, an \(r t^{p 258}\) element, an \(r t c^{p 1232}\) element, a tbody \({ }^{p 461}\) element, \(a t d^{p 465}\) element, \(a t f o o t^{p 463}\) element, \(a t h^{p 467}\) element, a thead \({ }^{\text {p462 }}\) element, or a \(t r^{p 464}\) element, the UA must pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).

\subsection*{12.2.6.4 The rules for parsing tokens in HTML content \(\S^{p 11}\)}

\subsection*{12.2.6.4.1 The "initial" insertion mode \(\S^{p 211}\)}

When the user agent is to apply the rules for the "initial \({ }^{\text {p1132" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\hookrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE}

Ignore the token.
\(\rightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\) as the last child of the Document \({ }^{\text {p114 }}\) object.

\section*{\(\rightarrow\) A DOCTYPE token}

If the DOCTYPE token's name is not identical to "html", or the token's public identifier is not missing, or the token's system identifier is neither missing nor identical to "about:legacy-compat \({ }^{\mathrm{p88}}\) ", then there is a parse error \({ }^{\text {p1081 }}\).

Append a DocumentType node to the Document \({ }^{p 114}\) node, with the name attribute set to the name given in the DOCTYPE token, or the empty string if the name was missing; the publicId attribute set to the public identifier given in the DOCTYPE token, or the empty string if the public identifier was missing; the systemId attribute set to the system identifier given in the DOCTYPE token, or the empty string if the system identifier was missing; and the other attributes specific to DocumentType objects set to null and empty lists as appropriate. Associate the DocumentType node with the Document \({ }^{p 114}\) object so that it is returned as the value of the doctype attribute of the Document \({ }^{\text {p114 }}\) object.

Then, if the document is not an iframe srcdoc document \({ }^{\text {p362 }}\), and the DOCTYPE token matches one of the conditions in the following list, then set the Document \({ }^{\text {p114 }}\) to quirks mode:
- The force-quirks flag \({ }^{\text {p1097 }}\) is set to on.
- The name is set to anything other than "html" (compared identically).
- The public identifier is set to: " - //W30//DTD W3 HTML Strict 3.0//EN//"
- The public identifier is set to: " - /W3C/DTD HTML 4.0 Transitional/EN"
- The public identifier is set to: "HTML"
- The system identifier is set to: "http://www.ibm.com/data/dtd/v11/ibmxhtml1-transitional.dtd"
- The public identifier starts with: "+//Silmaril//dtd html Pro v0r11 19970101//"

- The public identifier starts with: " -//W3C//DTD HTML 4.0 Frameset//"
- The public identifier starts with: " -//W3C//DTD HTML 4.0 Transitional//"
- The public identifier starts with: " - //W3C//DTD HTML Experimental 19960712//"
- The public identifier starts with: "-//W3C//DTD HTML Experimental 970421//"
- The public identifier starts with: " - //W3C//DTD W3 HTML//"
- The public identifier starts with: " -//W30//DTD W3 HTML 3.0//"
- The public identifier starts with: "-//WebTechs//DTD Mozilla HTML 2.0//"
- The public identifier starts with: " -//WebTechs//DTD Mozilla HTML//"
- The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

Otherwise, if the document is not an iframe srcdoc document \({ }^{\text {p362 }}\), and the DOCTYPE token matches one of the conditions in the following list, then set the Document \({ }^{\text {p114 }}\) to limited-quirks mode:
- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Frameset//"
- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Transitional//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is not missing and the public identifier starts with: " -//W3C//DTD HTML 4.01 Transitional//"

The system identifier and public identifier strings must be compared to the values given in the lists above in an ASCII caseinsensitive manner. A system identifier whose value is the empty string is not considered missing for the purposes of the conditions above.

Then, switch the insertion mode \({ }^{\text {p1092 }}\) to "before html \({ }^{\text {p1133" }}\).

\section*{\(\rightarrow\) Anything else}

If the document is not an iframe srcdoc document \({ }^{\mathrm{p} 362}\), then this is a parse error \({ }^{\mathrm{p} 1081}\); set the Document \({ }^{\text {p114 }}\) to quirks mode. In any case, switch the insertion mode \({ }^{p 1092}\) to "before html \({ }^{\text {p1133" }}\), then reprocess the token.

\subsection*{12.2.6.4.2 The "before htmI" insertion mode \({ }_{33}^{\S^{p 11}}\)}

When the user agent is to apply the rules for the "before html \({ }^{\text {p1133" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\hookrightarrow\) A comment token}

Insert a comment \({ }^{\text {p1131 }}\) as the last child of the Document \({ }^{\text {p114 }}\) object.
\(\hookrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Ignore the token.

Create an element for the token \({ }^{\text {p1127 }}\) in the HTML namespace, with the Document \({ }^{\text {p114 }}\) as the intended parent. Append it to the Document \({ }^{\text {p114 }}\) object. Put this element in the stack of open elements \({ }^{\text {p1093 }}\).

If the Document \({ }^{\text {p114 }}\) is being loaded as part of navigation \({ }^{\text {p866 }}\) of a browsing context \({ }^{\text {p811 }}\) and Document \({ }^{\text {p114 }}\) s relevant settings object \({ }^{\text {p924 }}\) is a secure context \({ }^{\text {p924 }}\), then:
1. If the result of running match service worker registration for the document's URL is non-null, run the application cache selection algorithm \({ }^{\text {p907 }}\) passing the Document \({ }^{\text {p114 }}\) object with no manifest.
2. Otherwise, run these substeps:
1. If the newly created element has a manifest \({ }^{p 152}\) attribute whose value is not the empty string, then parse \({ }^{\text {p89 }}\) the value of that attribute, relative to the newly created element's node document, and if that is successful, run the application cache selection algorithm \({ }^{\text {p907 }}\) passing the Document \({ }^{p 114}\) object with the result of applying the URL serializer algorithm to the resulting URL record \({ }^{\text {p89 }}\) with the exclude fragment flag set.
2. Otherwise, run the application cache selection algorithm \({ }^{\text {p907 }}\) passing the Document \({ }^{\text {p114 }}\) object with no manifest.

Switch the insertion mode \({ }^{\text {p1092 }}\) to "before head \({ }^{\text {p1134" }}\).
\(\leftrightarrow\) An end tag whose tag name is one of: "head", "body", "html", "br"
Act as described in the "anything else" entry below.

\section*{\(\rightarrow\) Any other end tag}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\rightarrow\) Anything else}

Create an html \({ }^{\text {p152 }}\) element whose node document is the Document \({ }^{\text {p114 }}\) object. Append it to the Document \({ }^{\text {p114 }}\) object. Put this element in the stack of open elements \({ }^{\text {p1093 }}\).

If the Document \({ }^{\text {p114 }}\) is being loaded as part of navigation \({ }^{p 866}\) of a browsing context \({ }^{p 811}\), then: run the application cache selection algorithm \({ }^{\text {p907 }}\) with no manifest, passing it the Document \({ }^{\text {p114 }}\) object.

Switch the insertion mode \({ }^{\text {p1092 }}\) to "before head \({ }^{\text {p1134" }}\), then reprocess the token.
The document element can end up being removed from the Document \({ }^{\text {p114 }}\) object, e.g. by scripts; nothing in particular happens in such cases, content continues being appended to the nodes as described in the next section.

\subsection*{12.2.6.4.3 The "before head" insertion mode \(\S^{\text {p1. }}\)}

When the user agent is to apply the rules for the "before head \({ }^{\text {p1134" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\rightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE}

Ignore the token.
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\).

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\rightarrow\) A start tag whose tag name is "html"}

Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\rightarrow\) A start tag whose tag name is "head"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Set the head element pointer \({ }^{\text {p1096 }}\) to the newly created head \({ }^{p 153}\) element.

Switch the insertion mode \({ }^{\text {p1092 }}\) to "in head \({ }^{\text {p1135 " }}\).
\(\rightarrow\) An end tag whose tag name is one of: "head", "body", "html", "br"
Act as described in the "anything else" entry below.
\(\leftrightarrow\) Any other end tag
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) Anything else
Insert an HTML element \({ }^{\text {p1129 }}\) for a "head" start tag token with no attributes.
Set the head element pointer \({ }^{\text {p1096 }}\) to the newly created head \({ }^{p 153}\) element.
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in head \({ }^{\text {p1135 " }}\).
Reprocess the current token.

\subsection*{12.2.6.4.4 The "in head" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "in head \({ }^{\text {p1135" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\hookrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE}

Insert the character \({ }^{\text {p1130 }}\).
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\mathrm{p} 1131}\).
\(\hookrightarrow\) A DOCTYPE token
Parse error \({ }^{p 1081}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\rightarrow\) A start tag whose tag name is one of: "base", "basefont", "bgsound", "link"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
\(\rightarrow\) A start tag whose tag name is "meta"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
If the element has a charset \({ }^{p 165}\) attribute, and getting an encoding from its value results in an encoding, and the confidence \({ }^{\text {p1086 }}\) is currently tentative, then change the encoding \({ }^{\text {p1091 }}\) to the resulting encoding.

Otherwise, if the element has an http-equiv \({ }^{p 169}\) attribute whose value is an ASCII case-insensitive match for the string "Content-Type", and the element has a content \({ }^{\text {p165 }}\) attribute, and applying the algorithm for extracting a character encoding from a meta element \({ }^{p 90}\) to that attribute's value returns an encoding, and the confidence \({ }^{p 1086}\) is currently tentative, then change the encoding \({ }^{\text {p1091 }}\) to the extracted encoding.
\(\hookrightarrow\) A start tag whose tag name is "title"
Follow the generic RCDATA element parsing algorithm \({ }^{\text {p1131 }}\).
\(\hookrightarrow\) A start tag whose tag name is "noscript", if the scripting flag \({ }^{\text {p1096 }}\) is enabled
\(\leftrightarrow\) A start tag whose tag name is one of: "noframes", "style"
Follow the generic raw text element parsing algorithm \({ }^{\text {p1131 }}\).
\(\rightarrow\) A start tag whose tag name is "noscript", if the scripting flag \({ }^{\text {p1096 }}\) is disabled
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.

Switch the insertion mode \({ }^{\text {p1092 }}\) to "in head noscript \({ }^{\text {p1137 " }}\).

\section*{\(\hookrightarrow\) A start tag whose tag name is "script"}

Run these steps:
1. Let the adjusted insertion location be the appropriate place for inserting a node \({ }^{\text {p1126 }}\).
2. Create an element for the token \({ }^{\mathrm{p} 1127}\) in the HTML namespace, with the intended parent being the element in which the adjusted insertion location finds itself.
3. Set the element's parser document \({ }^{\text {p619 }}\) to the Document \({ }^{\text {p114 }}\), and unset the element's "non-blocking"p619 flag.

\section*{Note}

This ensures that, if the script is external, any document. write() \({ }^{\text {p976 }}\) calls in the script will execute in-line, instead of blowing the document away, as would happen in most other cases. It also prevents the script from executing until the end tag is seen.
4. If the parser was created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), then mark the script \({ }^{\text {p614 }}\) element as "already started" \({ }^{\text {p619 }}\). (fragment case \({ }^{\text {p1177 }}\) )
5. If the parser was invoked via the document. write() \()^{\text {p970 }}\) or document. writeln() \({ }^{\text {p971 }}\) methods, then optionally mark the script \({ }^{\text {p614 }}\) element as "already started" \({ }^{p 619}\). (For example, the user agent might use this clause to prevent execution of cross-origin \({ }^{\text {p837 }}\) scripts inserted via document. write( \()^{\text {p976 }}\) under slow network conditions, or when the page has already taken a long time to load.)
6. Insert the newly created element at the adjusted insertion location.
7. Push the element onto the stack of open elements \({ }^{\text {p1093 }}\) so that it is the new current node \({ }^{\text {p1094 }}\).
8. Switch the tokenizer to the script data state \({ }^{\text {p1098 }}\).
9. Let the original insertion mode \({ }^{\mathrm{p} 1092}\) be the current insertion mode \({ }^{\mathrm{p} 1092}\).
10. Switch the insertion mode \({ }^{\text {p1092 }}\) to "text \({ }^{\text {p1148" }}\).
\(\hookrightarrow\) An end tag whose tag name is "head"
Pop the current node \({ }^{\text {p1094 }}\) (which will be the head \({ }^{\text {p153 }}\) element) off the stack of open elements \({ }^{\text {p1093 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "after head \({ }^{\text {p1137" }}\).
\(\hookrightarrow\) An end tag whose tag name is one of: "body", "html", "br"
Act as described in the "anything else" entry below.
\(\leftrightarrow\) A start tag whose tag name is "template"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Insert a marker \({ }^{\text {p1095 }}\) at the end of the list of active formatting elements \({ }^{\text {p1095 }}\).
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
Switch the insertion mode \({ }^{\mathrm{p} 1092}\) to "in template \({ }^{\mathrm{p} 1158 \mathrm{n}}\) ".
Push "in template \({ }^{\mathrm{p} 1158 \text { " }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).
\(\leftrightarrow\) An end tag whose tag name is "template"
If there is no template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.
Otherwise, run these steps:
1. Generate all implied end tags thoroughly \({ }^{\mathrm{p} 1132}\).
2. If the current node \({ }^{\text {p1094 }}\) is not a template \({ }^{p 629}\) element, then this is a parse error \({ }^{p 1081}\).
3. Pop elements from the stack of open elements \({ }^{p 1093}\) until a template \({ }^{\text {p629 }}\) element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).
5. Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
6. Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) A start tag whose tag name is "head"
\(\leftrightarrow\) Any other end tag
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\leftrightarrow\) Anything else
Pop the current node \({ }^{\text {p1094 }}\) (which will be the head \({ }^{\text {p153 }}\) element) off the stack of open elements \({ }^{\text {p1093 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "after head \({ }^{\text {p1137". }}\).
Reprocess the token.

\subsection*{12.2.6.4.5 The "in head noscript" insertion mode \(\S_{37}^{p 11}\)}

When the user agent is to apply the rules for the "in head noscript \({ }^{\text {p1137" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end tag whose tag name is "noscript"
Pop the current node \({ }^{\text {p1094 }}\) (which will be a noscript \({ }^{\text {p627 }}\) element) from the stack of open elements \({ }^{\text {p1093 }}\); the new current node \({ }^{\text {p1094 }}\) will be a head \({ }^{\text {p153 }}\) element.

Switch the insertion mode \({ }^{\text {p1092 }}\) to "in head \({ }^{\text {p1135" }}\).
\(\rightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

\section*{\(\rightarrow\) A comment token}
\(\rightarrow\) A start tag whose tag name is one of: "basefont", "bgsound", "link", "meta", "noframes", "style"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end tag whose tag name is "br"
Act as described in the "anything else" entry below.
\(\leftrightarrow\) A start tag whose tag name is one of: "head", "noscript"
\(\rightarrow\) Any other end tag
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) Anything else
Parse error \({ }^{\text {p1081 }}\).
Pop the current node \({ }^{\text {p1094 }}\) (which will be a noscript \({ }^{\text {p627 }}\) element) from the stack of open elements \({ }^{\text {p1093 }}\); the new current node \({ }^{\text {p1094 }}\) will be a head \({ }^{\text {p153 }}\) element.

Switch the insertion mode \({ }^{\text {p1092 }}\) to "in head \({ }^{\text {p1135". }}\).
Reprocess the token.

\subsection*{12.2.6.4.6 The "after head" insertion mode \(\S_{37}^{\text {p11 }}\)}

When the user agent is to apply the rules for the "after head \({ }^{\text {p1137" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\leftrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character \({ }^{\text {p1130 }}\).
\(\rightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\).
\(\rightarrow\) A DOCTYPE token
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138 }}\) " insertion mode \({ }^{\text {p1092 }}\).
\(\rightarrow\) A start tag whose tag name is "body"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in body \({ }^{\text {p1138 " }}\).
\(\leftrightarrow\) A start tag whose tag name is "frameset"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in frameset \({ }^{\text {p1160" }}\).
\(\leftrightarrow\) A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"

Parse error \({ }^{\text {p1081 }}\).
Push the node pointed to by the head element pointer \({ }^{\text {p1096 }}\) onto the stack of open elements \({ }^{\text {p1093 }}\).
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135 } " ~ i n s e r t i o n ~ m o d e ~}{ }^{\text {p1092 }}\).
Remove the node pointed to by the head element pointer \({ }^{\text {p1096 }}\) from the stack of open elements \({ }^{\text {p1093 }}\). (It might not be the current node \({ }^{\text {p1094 }}\) at this point.)

\section*{Note}

The head element pointer \({ }^{\text {p1096 }}\) cannot be null at this point.
\(\hookrightarrow\) An end tag whose tag name is "template"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135 " }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end tag whose tag name is one of: "body", "html", "br"
Act as described in the "anything else" entry below.
\(\rightarrow\) A start tag whose tag name is "head"
\(\leftrightarrow\) Any other end tag
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\rightarrow\) Anything else
Insert an HTML element \({ }^{\text {p1129 }}\) for a "body" start tag token with no attributes.
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in body \({ }^{\text {p1138" }}\).
Reprocess the current token.

\subsection*{12.2.6.4.7 The "in body" insertion mode \({ }_{38}^{\S^{p 11}}\)}

When the user agent is to apply the rules for the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert the token's character \({ }^{\mathrm{pl1130}}\).
\(\rightarrow\) Any other character token
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert the token's character \({ }^{\text {p1130 }}\).
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\).
\(\rightarrow\) A DOCTYPE token
Parse error \({ }^{p 1081}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is "html"
Parse error \({ }^{\text {p1081 }}\).
If there is a template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), then ignore the token.
Otherwise, for each attribute on the token, check to see if the attribute is already present on the top element of the stack of open elements \({ }^{\text {p1093 }}\). If it is not, add the attribute and its corresponding value to that element.
\(\rightarrow\) A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"
\(\leftrightarrow\) An end tag whose tag name is "template"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135 " }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) A start tag whose tag name is "body"
Parse error \({ }^{p 1081}\).
If the second element on the stack of open elements \({ }^{\text {p1093 }}\) is not a body \({ }^{\text {p178 }}\) element, if the stack of open elements \({ }^{\text {p1093 }}\) has only one node on it, or if there is a template \({ }^{p 629}\) element on the stack of open elements \({ }^{p 1093}\), then ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise, set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok"; then, for each attribute on the token, check to see if the attribute is already present on the body \({ }^{\text {p178 }}\) element (the second element) on the stack of open elements \({ }^{\text {p1093 }}\), and if it is not, add the attribute and its corresponding value to that element.
\(\leftrightarrow\) A start tag whose tag name is "frameset"
Parse error \({ }^{\text {p1081 }}\).
If the stack of open elements \({ }^{\text {p1093 }}\) has only one node on it, or if the second element on the stack of open elements \({ }^{\text {p1093 }}\) is not a body \({ }^{\text {p178 }}\) element, then ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

If the frameset-ok flag \({ }^{\text {p1097 }}\) is set to "not ok", ignore the token.
Otherwise, run the following steps:
1. Remove the second element on the stack of open elements \({ }^{\text {p1093 }}\) from its parent node, if it has one.
2. Pop all the nodes from the bottom of the stack of open elements \({ }^{\text {p1093 }}\), from the current node \({ }^{\text {p1094 }}\) up to, but not including, the root html \({ }^{\text {p152 }}\) element.
3. Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
4. Switch the insertion mode \({ }^{\text {p1092 }}\) to "in frameset \({ }^{p 1160 "}\).

If the stack of template insertion modes \({ }^{\text {p1092 }}\) is not empty, then process the token using the rules for \({ }^{p 1092}\) the "in template \({ }^{\text {p1158 " }}\) insertion mode \({ }^{\text {p1092 }}\).

Otherwise, follow these steps:
1. If there is a node in the stack of open elements \({ }^{p 1093}\) that is not either a \({ }^{d d^{p 231}}\) element, a \(d t^{p 23 \theta}\) element, an \(l^{p 224}\) element, an optgroup \({ }^{p 544}\) element, an option \({ }^{p 545}\) element, a p \(p^{p 211}\) element, an \(r^{p 1232}\) element, an \(r^{p 258}\) element, an \(r t^{p 258}\) element, an \(\underline{r t c^{p 1232}}\) element, a tbody \({ }^{\text {p461 }}\) element, \(a \underline{t d^{p 465}}\) element, a \(\underline{t f o o t^{p 463}}\) element, \(a \underline{t h^{p 467}}\) element, \(a\) thead \({ }^{\text {p462 }}\) element, a \(t r^{p 464}\) element, the body \({ }^{p 178}\) element, or the \(h t m l^{p 152}\) element, then this is a parse error \({ }^{p 1081}\).
2. Stop parsing \({ }^{\text {p1165 }}\).
\(\rightarrow\) An end tag whose tag name is "body"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a body element in scope \({ }^{\text {p1094 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token.
Otherwise, if there is a node in the stack of open elements \({ }^{p 1093}\) that is not either a \(d^{p 231}\) element, a \(d^{p 23 \theta}\) element, an \(\underline{l i}^{p 224}\) element, an optgroup \({ }^{p 544}\) element, an option \({ }^{p 545}\) element, a p \({ }^{p 211}\) element, an \(r b^{p 1232}\) element, an \(r p^{p 258}\) element, an \(r t^{p 258}\) element, an \(\underline{r t c^{p 1232}}\) element, a \(\underline{t b o d y}{ }^{\text {p461 }}\) element, \(a t d^{p 465}\) element, a \(t f o t^{p 463}\) element, \(a t h^{p 467}\) element, \(a t h e a d^{p 462}\) element, \(a t r^{p 464}\) element, the body \({ }^{p 178}\) element, or the \(h t m l^{p 152}\) element, then this is a parse error \({ }^{p 1081}\).

Switch the insertion mode \({ }^{\text {p1092 }}\) to "after body \({ }^{\text {p1160" }}\).

\section*{\(\hookrightarrow\) An end tag whose tag name is "html"}

If the stack of open elements \({ }^{p 1093}\) does not have a body element in scope \({ }^{\text {p1094 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token.
Otherwise, if there is a node in the stack of open elements \({ }^{p 1093}\) that is not either a \({ }^{d d^{p 231}}\) element, a \(\underline{d t}^{p 23 \theta}\) element, an \(\underline{i^{p 224}}\) element, an optgroup \({ }^{p 544}\) element, an option \({ }^{p 545}\) element, a \(p^{p 211}\) element, an \(r b^{p 1232}\) element, an rp \({ }^{p 258}\) element, an \(r t^{p 258}\) element, an \(\underline{r t c^{p 1232}}\) element, a \(\underline{t b o d y}{ }^{p 461}\) element, a \(t d^{p 465}\) element, a \(\underline{t f o o t^{p 463}}\) element, \(a \underline{t h^{p 467}}\) element, \(a \underline{t h e a d}{ }^{p 462}\) element, \(a \underline{t^{p 464}}\) element, the body \(y^{p 178}\) element, or the \(\underline{h t m l^{p 152}}\) element, then this is a parse error \({ }^{p 1081}\).

Switch the insertion mode \({ }^{\text {p1092 }}\) to "after body \({ }^{\text {p1160" }}\).
Reprocess the token.
\(\leftrightarrow\) A start tag whose tag name is one of: "address", "article", "aside", "blockquote", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "main", "menu", "nav", "ol", "p", "section", "summary", "ul"

If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\rightarrow\) A start tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"
If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
If the current node \({ }^{\text {p1094 }}\) is an HTML element \({ }^{\text {p44 }}\) whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error \({ }^{\text {p1081 }}\); pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\hookrightarrow\) A start tag whose tag name is one of: "pre", "listing"
If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
If the next token \({ }^{\text {p1126 }}\) is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of pre \({ }^{\mathrm{p} 216}\) blocks are ignored as an authoring convenience.)

Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".

\section*{\(\rightarrow\) A start tag whose tag name is "form"}

If the form element pointer \({ }^{\text {p1096 }}\) is not null, and there is no template \({ }^{p 629}\) element on the stack of open elements \({ }^{\text {p1093 }}\), then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise:

If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
Insert an HTML element \({ }^{\text {p1129 }}\) for the token, and, if there is no template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), set the form element pointer \({ }^{\text {p1096 }}\) to point to the element created.

\section*{\(\rightarrow\) A start tag whose tag name is "li"}

Run these steps:
1. Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
2. Initialize node to be the current node \({ }^{\text {p1094 }}\) (the bottommost node of the stack).
3. Loop: If node is an \(\underline{i^{p 224}}\) element, then run these substeps:
1. Generate implied end tags \({ }^{\mathrm{p} 1132}\), except for \(\underline{i^{p 224}}\) elements.
2. If the current node \({ }^{\text {p1094 }}\) is not an \(l i^{p 224}\) element, then this is a parse error \({ }^{\text {p1081 }}\).
3. Pop elements from the stack of open elements \({ }^{p 1093}\) until an \(\underline{i^{p 224}}\) element has been popped from the stack.
4. Jump to the step labeled done below.
4. If node is in the special \({ }^{p 1094}\) category, but is not an address \({ }^{p 197}\), \(\underline{d i v}^{p 237}\), or \(p^{p 211}\) element, then jump to the step labeled done below.
5. Otherwise, set node to the previous entry in the stack of open elements \({ }^{\text {p1093 }}\) and return to the step labeled loop.
6. Done: If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
7. Finally, insert an HTML element \({ }^{\text {p1129 }}\) for the token.

\section*{\(\rightarrow\) A start tag whose tag name is one of: "dd", "dt"}

Run these steps:
1. Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
2. Initialize node to be the current node \({ }^{\text {p1094 }}\) (the bottommost node of the stack).
3. Loop: If node is a \(\mathrm{dd}^{\mathrm{p} 231}\) element, then run these substeps:
1. Generate implied end tags \({ }^{\mathrm{p} 1132}\), except for \({ }^{d d^{p 231}}\) elements.
2. If the current node \({ }^{p 1094}\) is not a \({d d^{p 231}}^{p}\) element, then this is a parse error \({ }^{p 1081}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a dd \({ }^{p 231}\) element has been popped from the stack.
4. Jump to the step labeled done below.
4. If node is a \({ }^{d t}{ }^{p 23 \theta}\) element, then run these substeps:
1. Generate implied end tags \({ }^{\text {p1132 }}\), except for \(\mathrm{dt}^{\mathrm{p} 230}\) elements.
2. If the current node \({ }^{p 1094}\) is not a \(d t^{p 230}\) element, then this is a parse error \({ }^{p 1081}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a dt \({ }^{\text {p236 }}\) element has been popped from the stack.
4. Jump to the step labeled done below.
5. If node is in the special \({ }^{p 1094}\) category, but is not an address \({ }^{p 197}\), \(\underline{\text { div }^{p 237}}\), or \(\underline{p}^{p 211}\) element, then jump to the step labeled done below.
6. Otherwise, set node to the previous entry in the stack of open elements \({ }^{\text {p1093 }}\) and return to the step labeled loop.
7. Done: If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
8. Finally, insert an HTML element \({ }^{\text {p1129 }}\) for the token.

\section*{\(\rightarrow\) A start tag whose tag name is "plaintext"}

If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Switch the tokenizer to the PLAINTEXT state \({ }^{\text {p1099 }}\).

\section*{Note}

Once a start tag with the tag name "plaintext" has been seen, that will be the last token ever seen other than character tokens (and the end-of-file token), because there is no way to switch out of the PLAINTEXT state \({ }^{\text {p1099 }}\).

\section*{\(\hookrightarrow\) A start tag whose tag name is "button"}
1. If the stack of open elements \({ }^{\text {p1093 }}\) has a button element in scope \({ }^{\text {p1094 }}\), then run these substeps:
1. Parse error \({ }^{\mathrm{p} 1081}\).
2. Generate implied end tags \({ }^{\text {p1132 }}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a button \({ }^{\text {p535 }}\) element has been popped from the stack.
2. Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
3. Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
4. Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
\(\hookrightarrow\) An end tag whose tag name is one of: "address", "article", "aside", "blockquote", "button", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "listing", "main", "menu", "nav", "ol", "pre", "section", "summary", "ul"

If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in scope \({ }^{\text {p1094 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then this is a parse error \({ }^{\mathrm{p} 1081}\); ignore the token.

Otherwise, run these steps:
1. Generate implied end tags \({ }^{\mathrm{p} 1132}\).
2. If the current node \({ }^{p 1094}\) is not an HTML element \({ }^{p 44}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token has been popped from the stack.

\section*{\(\leftrightarrow\) An end tag whose tag name is "form"}

If there is no template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), then run these substeps:
1. Let node be the element that the form element pointer \({ }^{\text {p1096 }}\) is set to, or null if it is not set to an element.
2. Set the form element pointer \({ }^{\text {p1096 }}\) to null.
3. If node is null or if the stack of open elements \({ }^{\text {p1093 }}\) does not have node in scope \({ }^{\text {p1094 }}\), then this is a parse error \({ }^{\text {p1081 }}\); return and ignore the token.
4. Generate implied end tags \({ }^{\text {p1132 }}\).
5. If the current node \({ }^{\text {p1094 }}\) is not node, then this is a parse error \({ }^{\text {p1081 }}\).
6. Remove node from the stack of open elements \({ }^{\text {p1093 }}\).

If there is a template \({ }^{p 629}\) element on the stack of open elements \({ }^{\text {p1093 }}\), then run these substeps instead:
1. If the stack of open elements \({ }^{\text {p1093 }}\) does not have a form element in scope \({ }^{\text {p1094 }}\), then this is a parse error \({ }^{\text {p1081 }}\); return and ignore the token.
2. Generate implied end tags \({ }^{\mathrm{p1132}}\).
3. If the current node \({ }^{\text {p1094 }}\) is not a form \({ }^{\text {p486 }}\) element, then this is a parse error \({ }^{\text {p1081 }}\).
4. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a form \({ }^{\text {p486 }}\) element has been popped from the stack.

If the stack of open elements \({ }^{\text {p1093 }}\) does not have a p element in button scope \({ }^{\text {p1095 }}\), then this is a parse error \({ }^{\text {p1081 }}\); insert an HTML element \({ }^{p 1129}\) for a " p " start tag token with no attributes.

Close a p element \({ }^{\text {p1147 }}\).

\section*{\(\rightarrow\) An end tag whose tag name is "li"}

If the stack of open elements \({ }^{\text {p1093 }}\) does not have an li element in list item scope \({ }^{\text {p1095 }}\), then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise, run these steps:
1. Generate implied end tags \({ }^{p 1132}\), except for \(\underline{i^{p 224}}\) elements.
2. If the current node \({ }^{\text {p1094 }}\) is not an \(\underline{i^{p 224}}\) element, then this is a parse error \({ }^{p 1081}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until an \(\underline{i^{p 224}}\) element has been popped from the stack.
\(\hookrightarrow\) An end tag whose tag name is one of: "dd", "dt"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in scope \({ }^{\text {p1094 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise, run these steps:
1. Generate implied end tags \({ }^{\text {p1132 }}\), except for HTML elements \({ }^{\text {p44 }}\) with the same tag name as the token.
2. If the current node \({ }^{\text {p1094 }}\) is not an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\).
3. Pop elements from the stack of open elements \({ }^{p 1093}\) until an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token has been popped from the stack.
\(\rightarrow\) An end tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in scope \({ }^{\text {p1094 }}\) that is an HTML element \({ }^{\text {p44 }}\) and whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise, run these steps:
1. Generate implied end tags \({ }^{\text {p1132 }}\).
2. If the current node \({ }^{\mathrm{p} 1094}\) is not an HTML element \({ }^{\mathrm{p} 44}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until an HTML element \({ }^{\text {p44 }}\) whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6" has been popped from the stack.
\(\hookrightarrow\) An end tag whose tag name is "sarcasm"
Take a deep breath, then act as described in the "any other end tag" entry below.

\section*{\(\rightarrow\) A start tag whose tag name is "a"}

If the list of active formatting elements \({ }^{p 1095}\) contains an \(a^{p 238}\) element between the end of the list and the last marker \({ }^{p 1095}\) on the list (or the start of the list if there is no marker \({ }^{p 1095}\) on the list), then this is a parse error \({ }^{p 1081}\); run the adoption agency algorithm \({ }^{\text {p1147 }}\) for the token, then remove that element from the list of active formatting elements \({ }^{\text {p1095 }}\) and the stack of open elements \({ }^{\text {p1093 }}\) if the adoption agency algorithm \({ }^{\text {p1147 }}\) didn't already remove it (it might not have if the element is not in table scope \(^{\text {p1095 }}\) ).

\section*{Example}

In the non-conforming stream <a href="a">a<table><a href="b">b</table>x, the first \(a^{p 238}\) element would be closed upon seeing the second one, and the "x" character would be inside a link to "b", not to "a". This is despite the fact that the outer a \({ }^{\text {p238 }}\) element is not in table scope (meaning that a regular </a> end tag at the start of the table wouldn't close the outer \(a^{p 238}\) element). The result is that the two \(a^{p 238}\) elements are indirectly nested inside each other - non-conforming markup will often result in non-conforming DOMs when parsed.

Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Push onto the list of active formatting elements \({ }^{\text {p1095 }}\) that element.
\(\leftrightarrow\) A start tag whose tag name is one of: "b", "big", "code", "em", "font", "i", "s", "small", "strike", "strong", "tt", "u" Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.

Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Push onto the list of active formatting elements \({ }^{\text {p1095 }}\) that element.
\(\leftrightarrow\) A start tag whose tag name is "nobr"
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
If the stack of open elements \({ }^{\text {p1093 }}\) has a nobr element in scope \({ }^{\text {p1094 }}\), then this is a parse error \({ }^{\text {p1081 }}\); run the adoption agency algorithm \({ }^{\text {p1147 }}\) for the token, then once again reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.

Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Push onto the list of active formatting elements \({ }^{\text {p1095 }}\) that element.
\(\rightarrow\) An end tag whose tag name is one of: "a", "b", "big", "code", "em", "font", "i", "nobr", "s", "small", "strike", "strong", "tt", "u"

Run the adoption agency algorithm \({ }^{\text {p1147 }}\) for the token.
\(\hookrightarrow\) A start tag whose tag name is one of: "applet", "marquee", "object"
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Insert a marker \({ }^{\text {p1095 }}\) at the end of the list of active formatting elements \({ }^{\text {p1095 }}\).
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
\(\rightarrow\) An end tag token whose tag name is one of: "applet", "marquee", "object"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in scope \({ }^{\text {p1094 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then this is a parse error \({ }^{\mathrm{p1081}}\); ignore the token.

Otherwise, run these steps:
1. Generate implied end tags \({ }^{\mathrm{p1132}}\).
2. If the current node \({ }^{p 1094}\) is not an HTML element \({ }^{p 44}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until an HTML element \({ }^{p 44}\) with the same tag name as the token has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).
\(\rightarrow\) A start tag whose tag name is "table"
If the Document \({ }^{\text {p114 }}\) is not set to quirks mode, and the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150" }}\).
\(\hookrightarrow\) An end tag whose tag name is "br"
Parse error \({ }^{\text {p1081 }}\). Drop the attributes from the token, and act as described in the next entry; i.e. act as if this was a "br" start tag token with no attributes, rather than the end tag token that it actually is.
\(\rightarrow\) A start tag whose tag name is one of: "area", "br", "embed", "img", "keygen", "wbr"
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.

Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".

\section*{\(\hookrightarrow\) A start tag whose tag name is "input"}

Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASClI caseinsensitive match for the string "hidden", then: set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
\(\hookrightarrow\) A start tag whose tag name is one of: "param", "source", "track"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
\(\leftrightarrow\) A start tag whose tag name is "hr"
If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
\(\rightarrow\) A start tag whose tag name is "image"
Parse error \({ }^{p 1081}\). Change the token's tag name to "img" and reprocess it. (Don't ask.)
\(\rightarrow\) A start tag whose tag name is "textarea"
Run these steps:
1. Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
2. If the next token \({ }^{p 1126}\) is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of textarea \({ }^{\text {p548 }}\) elements are ignored as an authoring convenience.)
3. Switch the tokenizer to the RCDATA state \({ }^{\text {p1098 }}\).
4. Let the original insertion mode \({ }^{\text {p1092 }}\) be the current insertion mode \({ }^{\text {p1092 }}\).
5. Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
6. Switch the insertion mode \({ }^{\text {p1092 }}\) to "text \({ }^{\text {p1148" }}\).
\(\leftrightarrow\) A start tag whose tag name is "xmp"
If the stack of open elements \({ }^{\text {p1093 }}\) has a p element in button scope \({ }^{\text {p1095 }}\), then close a p element \({ }^{\text {p1147 }}\).
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
Follow the generic raw text element parsing algorithm \({ }^{\text {p1131 }}\).
\(\rightarrow\) A start tag whose tag name is "iframe"
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
Follow the generic raw text element parsing algorithm \({ }^{\text {p1131 }}\).

\section*{\(\rightarrow\) A start tag whose tag name is "noembed"}
\(\hookrightarrow\) A start tag whose tag name is "noscript", if the scripting flag \({ }^{\text {p1096 }}\) is enabled
Follow the generic raw text element parsing algorithm \({ }^{\text {p1131 }}\).
\(\rightarrow\) A start tag whose tag name is "select"
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
If the insertion mode \({ }^{\text {p1092 }}\) is one of "in table \({ }^{\text {p1150" ", "in caption }}{ }^{\text {p1152" ", "in table body }}{ }^{\text {p1154" } ", ~ " i n ~ r o w ~}{ }^{\text {p1155" ", or "in cell }}{ }^{\text {p1156" } ", ~ t h e n ~ s w i t c h ~}\) the insertion mode \({ }^{\mathrm{p} 1092}\) to "in select in table \({ }^{\mathrm{p} 1158}\) ". Otherwise, switch the insertion mode \({ }^{\text {p1092 }}\) to "in select \({ }^{\mathrm{p} 1156 "}\).
\(\rightarrow\) A start tag whose tag name is one of: "optgroup", "option"
If the current node \({ }^{\text {p1094 }}\) is an option \({ }^{\text {p545 }}\) element, then pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\rightarrow\) A start tag whose tag name is one of: "rb", "rtc"
If the stack of open elements \({ }^{\text {p1093 }}\) has a ruby element in scope \({ }^{\text {p1094 }}\), then generate implied end tags \({ }^{\text {p1132 }}\). If the current node \({ }^{\text {p1094 }}\) is not now a ruby \({ }^{p 252}\) element, this is a parse error \({ }^{\text {p1081 }}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\leftrightarrow\) A start tag whose tag name is one of: "rp", "rt"
If the stack of open elements \({ }^{\text {p1093 }}\) has a ruby element in scope \({ }^{\text {p1094 }}\), then generate implied end tags \({ }^{\text {p1132 }}\), except for rtc \({ }^{\text {p1232 }}\) elements. If the current node \({ }^{\mathrm{p} 1094}\) is not now a rtc \({ }^{\mathrm{p} 1232}\) element or a ruby \({ }^{\mathrm{p} 252}\) element, this is a parse error \({ }^{\mathrm{p} 1081}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\leftrightarrow\) A start tag whose tag name is "math"
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Adjust MathML attributes \({ }^{\text {p1129 }}\) for the token. (This fixes the case of MathML attributes that are not all lowercase.)
Adjust foreign attributes \({ }^{\text {p1130 }}\) for the token. (This fixes the use of namespaced attributes, in particular XLink.)
Insert a foreign element \({ }^{\text {p1128 }}\) for the token, in the MathML namespace.
If the token has its self-closing flag \({ }^{\text {p1097 }}\) set, pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{p 1093}\) and acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\).
\(\hookrightarrow\) A start tag whose tag name is "svg"
Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Adjust SVG attributes \({ }^{\text {p1129 }}\) for the token. (This fixes the case of SVG attributes that are not all lowercase.)
Adjust foreign attributes \({ }^{\text {p1130 }}\) for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)
Insert a foreign element \({ }^{\text {p1128 }}\) for the token, in the SVG namespace.
If the token has its self-closing flag \({ }^{\text {p1097 }}\) set, pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\) and acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\).
\(\rightarrow\) A start tag whose tag name is one of: "caption", "col", "colgroup", "frame", "head", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error \({ }^{p 1081}\). Ignore the token.

\section*{\(\rightarrow\) Any other start tag}

Reconstruct the active formatting elements \({ }^{\text {p1096 }}\), if any.
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.

Note
This element will be an ordinary \({ }^{\text {p1094 }}\) element.

\section*{Any other end tag}

Run these steps:
1. Initialize node to be the current node \({ }^{\text {p1094 }}\) (the bottommost node of the stack).
2. Loop: If node is an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token, then:
1. Generate implied end tags \({ }^{\text {p1132 }}\), except for HTML elements \({ }^{\text {p44 }}\) with the same tag name as the token.
2. If node is not the current node \({ }^{p 1094}\), then this is a parse error \({ }^{p 1081}\).
3. Pop all the nodes from the current node \({ }^{\text {p1094 }}\) up to node, including node, then stop these steps.
3. Otherwise, if node is in the special \({ }^{\text {p1094 }}\) category, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token, and return.
4. Set node to the previous entry in the stack of open elements \({ }^{\text {p1093 }}\).
5. Return to the step labeled loop.

When the steps above say the user agent is to close a p element, it means that the user agent must run the following steps:
1. Generate implied end tags \({ }^{\text {p1132 }}\), except for \(p^{p 211}\) elements.
2. If the current node \({ }^{\text {p1094 }}\) is not a \(p^{p 211}\) element, then this is a parse error \({ }^{\text {p1081 }}\).
3. Pop elements from the stack of open elements \({ }^{p 1093}\) until a \(p^{p 211}\) element has been popped from the stack.

The adoption agency algorithm, which takes as its only argument a token token for which the algorithm is being run, consists of the following steps:
1. Let subject be token's tag name.
2. If the current node \({ }^{\text {p1094 }}\) is an HTML element \({ }^{\text {p44 }}\) whose tag name is subject, and the current node \({ }^{\text {p1094 }}\) is not in the list of active formatting elements \({ }^{\text {p1095 }}\), then pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\), and return.
3. Let outer loop counter be zero.
4. Outer loop: If outer loop counter is greater than or equal to eight, then return.
5. Increment outer loop counter by one.
6. Let formatting element be the last element in the list of active formatting elements \({ }^{\text {p1095 }}\) that:
- is between the end of the list and the last marker \({ }^{\text {p1095 }}\) in the list, if any, or the start of the list otherwise, and
- has the tag name subject.

If there is no such element, then return and instead act as described in the "any other end tag" entry above.
7. If formatting element is not in the stack of open elements \({ }^{\text {p1093 }}\), then this is a parse error \({ }^{\text {p1081 }}\); remove the element from the list, and return.
8. If formatting element is in the stack of open elements \({ }^{\text {p1093 }}\), but the element is not in scope \({ }^{\text {p1094 }}\), then this is a parse error \({ }^{\text {p1081 }}\); return.
9. If formatting element is not the current node \({ }^{\text {p1094 }}\), this is a parse error \({ }^{\text {p1081 }}\). (But do not return.)
10. Let furthest block be the topmost node in the stack of open elements \({ }^{\text {p1093 }}\) that is lower in the stack than formatting element, and is an element in the special \({ }^{\text {p1094 }}\) category. There might not be one.
11. If there is no furthest block, then the UA must first pop all the nodes from the bottom of the stack of open elements \({ }^{\text {p1093 }}\), from the current node \({ }^{\text {p1094 }}\) up to and including formatting element, then remove formatting element from the list of active formatting elements \({ }^{\text {p1095 }}\), and finally return.
12. Let common ancestor be the element immediately above formatting element in the stack of open elements \({ }^{\text {p1093 }}\).
13. Let a bookmark note the position of formatting element in the list of active formatting elements \({ }^{\text {p1095 }}\) relative to the elements on either side of it in the list.
14. Let node and last node be furthest block. Follow these steps:
1. Let inner loop counter be zero.
2. Inner loop: Increment inner loop counter by one.
3. Let node be the element immediately above node in the stack of open elements \({ }^{\text {p1093 }}\), or if node is no longer in the stack of open elements \({ }^{\text {p1093 }}\) (e.g. because it got removed by this algorithm), the element that was immediately above node in the stack of open elements \({ }^{\text {p1093 }}\) before node was removed.
4. If node is formatting element, then go to the next step in the overall algorithm.
5. If inner loop counter is greater than three and node is in the list of active formatting elements \({ }^{\text {p1095 }}\), then remove node from the list of active formatting elements \({ }^{\text {p1095 }}\).
6. If node is not in the list of active formatting elements \({ }^{\mathrm{p} 1095}\), then remove node from the stack of open elements \({ }^{\text {p1093 }}\) and then go back to the step labeled inner loop.
7. Create an element for the token \({ }^{\text {p1127 }}\) for which the element node was created, in the HTML namespace, with common ancestor as the intended parent; replace the entry for node in the list of active formatting elements \({ }^{\text {p1095 }}\) with an entry for the new element, replace the entry for node in the stack of open elements \({ }^{\text {p1093 }}\) with an entry for the new element, and let node be the new element.
8. If last node is furthest block, then move the aforementioned bookmark to be immediately after the new node in the list of active formatting elements \({ }^{\text {p1095 }}\).
9. Insert last node into node, first removing it from its previous parent node if any.
10. Let last node be node.
11. Return to the step labeled inner loop.
15. Insert whatever last node ended up being in the previous step at the appropriate place for inserting a node \({ }^{\text {p1126 }}\), but using common ancestor as the override target.
16. Create an element for the token \({ }^{\text {p1127 }}\) for which formatting element was created, in the HTML namespace, with furthest block as the intended parent.
17. Take all of the child nodes of furthest block and append them to the element created in the last step.
18. Append that new element to furthest block.
19. Remove formatting element from the list of active formatting elements \({ }^{\text {p1095 }}\), and insert the new element into the list of active formatting elements \({ }^{\text {p1095 }}\) at the position of the aforementioned bookmark.
20. Remove formatting element from the stack of open elements \({ }^{\text {p1093 }}\), and insert the new element into the stack of open elements \({ }^{\text {p1093 }}\) immediately below the position of furthest block in that stack.
21. Jump back to the step labeled outer loop.

\section*{Note}

This algorithm's name, the "adoption agency algorithm", comes from the way it causes elements to change parents, and is in contrast with other possible algorithms for dealing with misnested content.

\subsection*{12.2.6.4.8 The "text" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "text \({ }^{\text {p1148" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\rightarrow\) A character token}

Insert the token's character \({ }^{\text {p1130 }}\).

\section*{Note}

This can never be a U+0000 NULL character; the tokenizer converts those to U+FFFD REPLACEMENT CHARACTER characters.

Parse error \({ }^{\text {p1081 }}\).
If the current node \({ }^{\text {p1094 }}\) is a script \({ }^{\text {p614 }}\) element, mark the script \({ }^{\text {p614 }}\) element as "already started" \({ }^{\text {p619 }}\).
Pop the current node \({ }^{p 1094}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to the original insertion mode \({ }^{\text {p1092 }}\) and reprocess the token.

\section*{\(\hookrightarrow\) An end tag whose tag name is "script"}

If the JavaScript execution context stack is empty, perform a microtask checkpoint \({ }^{\text {p949 }}\).
Let script be the current node \({ }^{\text {p1094 }}\) (which will be a script \({ }^{\text {p614 }}\) element).
Pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{p 1093}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to the original insertion mode \({ }^{\text {p1092 }}\).
Let the old insertion point have the same value as the current insertion point \({ }^{\text {p1092 }}\). Let the insertion point \({ }^{\text {p1092 }}\) be just before the next input character \({ }^{\text {p1092 }}\).

Increment the parser's script nesting level \({ }^{\text {p1081 }}\) by one.
Prepare \({ }^{\text {p620 }}\) the script. This might cause some script to execute, which might cause new characters to be inserted into the tokenizer \({ }^{\text {p970 }}\), and might cause the tokenizer to output more tokens, resulting in a reentrant invocation of the parser \({ }^{\text {p1080 }}\).

Decrement the parser's script nesting level \({ }^{\text {p1081 }}\) by one. If the parser's script nesting level \({ }^{\text {p1081 }}\) is zero, then set the parser pause flag \({ }^{\text {p1081 }}\) to false.

Let the insertion point \({ }^{\text {p1092 }}\) have the value of the old insertion point. (In other words, restore the insertion point \({ }^{\text {p1092 }}\) to its previous value. This value might be the "undefined" value.)

At this stage, if there is a pending parsing-blocking script \({ }^{\text {p623 }}\), then:
\(\rightarrow\) If the script nesting level \({ }^{\text {p1081 }}\) is not zero:
Set the parser pause flag \({ }^{\text {p1081 }}\) to true, and abort the processing of any nested invocations of the tokenizer, yielding control back to the caller. (Tokenization will resume when the caller returns to the "outer" tree construction stage.)

\section*{Note}

The tree construction stage of this particular parser is being called reentrantly \({ }^{\text {p1080 }}\), say from a call to document.write() \({ }^{\text {p97e }}\).
\(\hookrightarrow\) Otherwise:
Run these steps:
1. Let the script be the pending parsing-blocking script \({ }^{\text {p623 }}\). There is no longer a pending parsing-blocking script \({ }^{\text {p623 }}\).
2. Block the tokenizer \({ }^{\text {p1097 }}\) for this instance of the HTML parser \({ }^{\text {p1079 }}\), such that the event loop \({ }^{\text {p944 }}\) will not run tasks \({ }^{\text {p944 }}\) that invoke the tokenizer \({ }^{\text {p1097 }}\).
3. If the parser's Document \({ }^{p 114}\) has a style sheet that is blocking scripts \({ }^{\text {p178 }}\) or the script's "ready to be parserexecuted" \({ }^{p 619}\) flag is not set: spin the event loop \({ }^{\text {p949 }}\) until the parser's Document \({ }^{\text {p114 }}\) has no style sheet that is blocking scripts \({ }^{\text {p178 }}\) and the script's "ready to be parser-executed" p619 flag is set.
4. If this parser has been aborted \({ }^{\mathrm{p} 1165}\) in the meantime, return.

\section*{Note}

This could happen if, e.g., while the spin the event loop \({ }^{\text {p949 }}\) algorithm is running, the browsing context \({ }^{p 811}\) gets closed, or the document. open () \({ }^{\text {p969 }}\) method gets invoked on the Document \({ }^{\text {p114 }}\).
5. Unblock the tokenizer \({ }^{\text {p1097 }}\) for this instance of the HTML parser \({ }^{\text {p1079 }}\), such that tasks \({ }^{\text {p944 }}\) that invoke the tokenizer \({ }^{\text {p1097 }}\) can again be run.
6. Let the insertion point \({ }^{\text {p1092 }}\) be just before the next input character \({ }^{\text {p1092 }}\).
7. Increment the parser's script nesting level \({ }^{\text {p1081 }}\) by one (it should be zero before this step, so this sets it to one).
8. Execute \({ }^{p 623}\) the script.
9. Decrement the parser's script nesting level \({ }^{\text {p1081 }}\) by one. If the parser's script nesting level \({ }^{\text {p1081 }}\) is zero (which it always should be at this point), then set the parser pause flag \({ }^{\text {p1081 }}\) to false.
10. Let the insertion point \({ }^{\text {p1092 }}\) be undefined again.
11. If there is once again a pending parsing-blocking script \({ }^{\mathrm{p} 623}\), then repeat these steps from step 1.

\section*{Any other end tag}

Pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to the original insertion mode \({ }^{\text {p1092 }}\).

\subsection*{12.2.6.4.9 The "in table" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "in table \({ }^{p 1150}\) " insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\hookrightarrow\) A character token, if the current node \({ }^{\text {p1094 }}\) is \(\underline{\text { table }}{ }^{\text {p450 }}\), tbody \({ }^{\text {p461 }}\), tfoot \(^{\text {p463 }}\), thead \({ }^{\text {p462 }}\), or tr \(^{\text {p464 }}\) element} Let the pending table character tokens be an empty list of tokens.

Let the original insertion mode \({ }^{\text {p1092 }}\) be the current insertion mode \({ }^{\text {p1092 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table text \({ }^{\text {p1152" }}\) and reprocess the token.

\section*{\(\rightarrow\) A comment token}

Insert a comment \({ }^{\text {p1131 }}\).

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\hookrightarrow\) A start tag whose tag name is "caption"}

Clear the stack back to a table context \({ }^{\text {p1152 }}\). (See below.)
Insert a marker \({ }^{\text {p1095 }}\) at the end of the list of active formatting elements \({ }^{\text {p1095 }}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in caption \({ }^{\text {p1152". }}\).
\(\hookrightarrow\) A start tag whose tag name is "colgroup"
Clear the stack back to a table context \({ }^{\text {p1152 }}\). (See below.)

Insert an HTML element \({ }^{\text {p1129 }}\) for the token, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in column group \({ }^{\text {p1153" }}\).
\(\rightarrow\) A start tag whose tag name is "col"
Clear the stack back to a table context \({ }^{\text {p1152 }}\). (See below.)
Insert an HTML element \({ }^{\text {p1129 }}\) for a "colgroup" start tag token with no attributes, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in column group \({ }^{\text {p1153". }}\).

Reprocess the current token.
\(\leftrightarrow\) A start tag whose tag name is one of: "tbody", "tfoot", "thead"
Clear the stack back to a table context \({ }^{\text {p1152 }}\). (See below.)
Insert an HTML element \({ }^{\text {p1129 }}\) for the token, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in table body \({ }^{\text {p1154". }}\).
\(\leftrightarrow\) A start tag whose tag name is one of: "td", "th", "tr"
Clear the stack back to a table context \({ }^{\text {p1152 }}\). (See below.)

Insert an HTML element \({ }^{\text {p1129 }}\) for a "tbody" start tag token with no attributes, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in table body \({ }^{\text {p1154" }}\).

Reprocess the current token.
\(\hookrightarrow\) A start tag whose tag name is "table"
Parse error \({ }^{\text {p1081 }}\).
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a table element in table scope \({ }^{\text {p1095 }}\), ignore the token.

Otherwise:

Pop elements from this stack until a table \({ }^{p 450}\) element has been popped from the stack.
Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).
Reprocess the token.

\section*{\(\hookrightarrow\) An end tag whose tag name is "table"}

If the stack of open elements \({ }^{\text {p1093 }}\) does not have a table element in table scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token.
Otherwise:
Pop elements from this stack until a table \({ }^{p 450}\) element has been popped from the stack.
Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"

Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is one of: "style", "script", "template"
\(\rightarrow\) An end tag whose tag name is "template"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) A start tag whose tag name is "input"
If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII caseinsensitive match for the string "hidden", then: act as described in the "anything else" entry below.

Otherwise:

Parse error \({ }^{\text {p1081 }}\).
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
Pop that input \({ }^{\text {p493 }}\) element off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
\(\hookrightarrow\) A start tag whose tag name is "form"
Parse error \({ }^{\text {p1081 }}\).

If there is a template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), or if the form element pointer \({ }^{\text {p1096 }}\) is not null, ignore the token.

Otherwise:
Insert an HTML element \({ }^{\text {p1129 }}\) for the token, and set the form element pointer \({ }^{\text {p1096 }}\) to point to the element created.
Pop that form \({ }^{\text {p486 }}\) element off the stack of open elements \({ }^{\text {p1093 }}\).

\section*{\(\rightarrow\) An end-of-file token}

Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).

\section*{\(\rightarrow\) Anything else}

Parse error \({ }^{\text {p1081 }}\). Enable foster parenting \({ }^{\text {p1126 }}\), process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\), and then disable foster parenting \({ }^{\text {p1126 }}\).

When the steps above require the UA to clear the stack back to a table context, it means that the UA must, while the current node \({ }^{\text {p1094 }}\) is not a table \({ }^{\text {p45 }}\), template \({ }^{p 629}\), or html \({ }^{\text {p152 }}\) element, pop elements from the stack of open elements \({ }^{\text {p1093 }}\).

\section*{Note}

This is the same list of elements as used in the has an element in table scope \({ }^{\text {p1095 }}\) steps.

\section*{Note}

The current node \({ }^{\text {p1094 }}\) being an html \({ }^{\text {p152 }}\) element after this process is a fragment case \({ }^{\text {p1177 }}\).

\subsection*{12.2.6.4.10 The "in table text" insertion mode \({ }^{p 11}\)}

When the user agent is to apply the rules for the "in table text \({ }^{\text {p1152" } " ~ i n s e r t i o n ~ m o d e ~}{ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\rightarrow\) A character token that is U+0000 NULL}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\rightarrow\) Any other character token}

Append the character token to the pending table character tokens \({ }^{p 1150}\) list.

\section*{\(\rightarrow\) Anything else}

If any of the tokens in the pending table character tokens \({ }^{\text {p1150 }}\) list are character tokens that are not ASCII whitespace, then this is a parse error \({ }^{\text {p1081 }}\) : reprocess the character tokens in the pending table character tokens \({ }^{\text {p1150 }}\) list using the rules given in the "anything else" entry in the "in table \({ }^{\text {p1150" }}\) insertion mode.

Otherwise, insert the characters \({ }^{\text {p1130 }}\) given by the pending table character tokens \({ }^{\text {p1150 }}\) list.
Switch the insertion mode \({ }^{\text {p1092 }}\) to the original insertion mode \({ }^{\text {p1092 }}\) and reprocess the token.

\subsection*{12.2.6.4.11 The "in caption" insertion mode \(\S_{52}^{p 11}\)}

When the user agent is to apply the rules for the "in caption \({ }^{\text {p1152" } " ~ i n s e r t i o n ~ m o d e ~}{ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\leftrightarrow\) An end tag whose tag name is "caption"}

If the stack of open elements \({ }^{\text {p1093 }}\) does not have a caption element in table scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise:

Generate implied end tags \({ }^{\text {p1132 }}\).
Now, if the current node \({ }^{\text {p1094 }}\) is not a caption \({ }^{\text {p458 }}\) element, then this is a parse error \({ }^{\text {p1081 }}\).
Pop elements from this stack until a caption \({ }^{\text {p458 }}\) element has been popped from the stack.
Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150" } " . ~}\)
\(\rightarrow\) A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"
\(\hookrightarrow\) An end tag whose tag name is "table"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a caption element in table scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise:

Generate implied end tags \({ }^{\text {p1132 }}\)
Now, if the current node \({ }^{\text {p1094 }}\) is not a caption \({ }^{\text {p458 }}\) element, then this is a parse error \({ }^{\text {p1081 }}\).

Pop elements from this stack until a caption \({ }^{p 458}\) element has been popped from the stack.
Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).

Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150" }}\).

Reprocess the token.
\(\leftrightarrow\) An end tag whose tag name is one of: "body", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr" Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\rightarrow\) Anything else}

Process the token using the rules for \({ }^{p 1092}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).

\subsection*{12.2.6.4.12 The "in column group" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "in column group \({ }^{\text {p1153" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\rightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character \({ }^{\text {p1130 }}\).
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\).

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\rightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\leftrightarrow\) A start tag whose tag name is "col"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), if it is set.
\(\leftrightarrow\) An end tag whose tag name is "colgroup"
If the current node \({ }^{p 1094}\) is not a colgroup \({ }^{p 459}\) element, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.
Otherwise, pop the current node \({ }^{\text {p1094 }}\) from the stack of open elements \({ }^{\text {p1093 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150" }}\).
\(\rightarrow\) An end tag whose tag name is "col"
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is "template"
\(\rightarrow\) An end tag whose tag name is "template"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\rightarrow\) An end-of-file token
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138 " }}\) insertion mode \({ }^{\text {p1092 }}\).

\section*{\(\rightarrow\) Anything else}

If the current node \({ }^{\text {p1094 }}\) is not a colgroup \({ }^{\text {p459 }}\) element, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise, pop the current node \({ }^{\text {p1094 }}\) from the stack of open elements \({ }^{\text {p1093 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150" }}\).

Reprocess the token.

\subsection*{12.2.6.4.13 The "in table body" insertion mode \(\S_{54}^{\text {p11 }}\)}

When the user agent is to apply the rules for the "in table body \({ }^{\text {p1154" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\rightarrow\) A start tag whose tag name is "tr"
Clear the stack back to a table body context \({ }^{\text {p1154 }}\). (See below.)
Insert an HTML element \({ }^{\text {p1129 }}\) for the token, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in row \({ }^{\text {p1155". }}\)
\(\rightarrow\) A start tag whose tag name is one of: "th", "td"
Parse error \({ }^{\text {p1081 }}\).
Clear the stack back to a table body context \({ }^{\text {p1154 }}\). (See below.)
Insert an HTML element \({ }^{\text {p1129 }}\) for a "tr" start tag token with no attributes, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in row \({ }^{\text {p1155". }}\)

Reprocess the current token.
\(\hookrightarrow\) An end tag whose tag name is one of: "tbody", "tfoot", "thead"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in table scope \({ }^{\text {p1095 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token, this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise:

Clear the stack back to a table body context \({ }^{\text {p1154 }}\). (See below.)
Pop the current node \({ }^{\text {p1094 }}\) from the stack of open elements \({ }^{\text {p1093 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150". }}\).
\(\leftrightarrow\) A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead"
\(\hookrightarrow\) An end tag whose tag name is "table"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a tbody, thead, or tfoot element in table scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise:
Clear the stack back to a table body context \({ }^{\text {p1154 }}\). (See below.)
Pop the current node \({ }^{\text {p1094 }}\) from the stack of open elements \({ }^{\text {p1093 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150". } .}\)
Reprocess the token.
\(\rightarrow\) An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th", "tr"
Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\hookrightarrow\) Anything else}

Process the token using the rules for \({ }^{\mathrm{p} 1092}\) the " \(\underline{i n}\) table \({ }^{\mathrm{p} 1150 "}\) insertion mode \({ }^{\text {p1092 }}\).
When the steps above require the UA to clear the stack back to a table body context, it means that the UA must, while the current node \({ }^{p 1094}\) is not a tbody \({ }^{p 461}\), tfoot \({ }^{p 463}\), thead \({ }^{p 462}\), template \({ }^{p 629}\), or html \({ }^{p 152}\) element, pop elements from the stack of open elements \({ }^{\text {p1093 }}\).

\section*{Note}

The current node \({ }^{p 1094}\) being an html \({ }^{p 152}\) element after this process is a fragment case \({ }^{p 1177}\).

\subsection*{12.2.6.4.14 The "in row" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "in row \({ }^{\text {p1155" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\hookrightarrow\) A start tag whose tag name is one of: "th", "td"}

Clear the stack back to a table row context \({ }^{\text {p1155 }}\). (See below.)

Insert an HTML element \({ }^{\text {p1129 }}\) for the token, then switch the insertion mode \({ }^{\text {p1092 }}\) to "in cell \({ }^{\text {p1156". }}\).
Insert a marker \({ }^{\text {p1095 }}\) at the end of the list of active formatting elements \({ }^{\text {p1095 }}\).
\(\rightarrow\) An end tag whose tag name is "tr"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a tr element in table scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise:

Clear the stack back to a table row context \({ }^{\text {p1155 }}\). (See below.)
Pop the current node \({ }^{\text {p1094 }}\) (which will be a tr \({ }^{\text {p464 }}\) element) from the stack of open elements \({ }^{\text {p1093 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table body \({ }^{\text {p1154" }}\).
\(\hookrightarrow\) A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead", "tr"
\(\leftrightarrow\) An end tag whose tag name is "table"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a tr element in table scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise:

Clear the stack back to a table row context \({ }^{\text {p1155 }}\). (See below.)

Pop the current node \({ }^{\text {p1094 }}\) (which will be a \(\underline{t^{p 464}}\) element) from the stack of open elements \({ }^{\text {p1093 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table body \({ }^{\text {p1154" }}\).

Reprocess the token

\section*{\(\rightarrow\) An end tag whose tag name is one of: "tbody", "tfoot", "thead"}

If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in table scope \({ }^{\text {p1095 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token, this is a parse error \({ }^{\mathrm{p} 1081}\); ignore the token.

If the stack of open elements \({ }^{\text {p1093 }}\) does not have a tr element in table scope \({ }^{\text {p1095 }}\), ignore the token.

Otherwise:

Clear the stack back to a table row context \({ }^{\text {p1155 }}\). (See below.)

Pop the current node \({ }^{\text {p1094 }}\) (which will be a tr \(r^{\text {p464 }}\) element) from the stack of open elements \({ }^{\text {p1093 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table body \({ }^{\text {p1154" }}\).

Reprocess the token
\(\leftrightarrow\) An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th"
Parse error \({ }^{\text {p1081 }} . ~ I g n o r e ~ t h e ~ t o k e n . ~\)

\section*{\(\rightarrow\) Anything else}

Process the token using the rules for \({ }^{\text {p1092 }}\) the "in table \({ }^{\text {p1150" }}\) insertion mode \({ }^{\text {p1092 }}\).

When the steps above require the UA to clear the stack back to a table row context, it means that the UA must, while the current \(\underline{\text { node }}{ }^{p 1094}\) is not a \(\mathrm{tr}^{\mathrm{p} 464}\), template \({ }^{\mathrm{p} 629}\), or html \({ }^{\mathrm{p} 152}\) element, pop elements from the stack of open elements \({ }^{\text {p1093 }}\).

\section*{Note}

The current node \({ }^{p 1094}\) being an html \({ }^{p 152}\) element after this process is a fragment case \({ }^{p 1177}\)

When the user agent is to apply the rules for the "in cell \({ }^{\text {p1156" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\leftrightarrow\) An end tag whose tag name is one of: "td", "th"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in table scope \({ }^{\text {p1095 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise:

Generate implied end tags \({ }^{\text {p1132 }}\).
Now, if the current node \({ }^{\text {p1094 }}\) is not an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token, then this is a parse error \({ }^{\text {p1081 }}\).
Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) stack until an HTML element \({ }^{\text {p44 }}\) with the same tag name as the token has been popped from the stack.

Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in row \({ }^{\text {p1155". }}\).
\(\rightarrow\) A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a td or th element in table scope \({ }^{\text {p1095 }}\), then this is a parse error \({ }^{\text {p1081 }}\); ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise, close the cell \({ }^{\text {p1156 }}\) (see below) and reprocess the token.
\(\rightarrow\) An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html"
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\leftrightarrow\) An end tag whose tag name is one of: "table", "tbody", "tfoot", "thead", "tr"
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in table scope \({ }^{\text {p1095 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

Otherwise, close the cell \({ }^{\text {p1156 }}\) (see below) and reprocess the token.
\(\rightarrow\) Anything else
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
Where the steps above say to close the cell, they mean to run the following algorithm:
1. Generate implied end tags \({ }^{\text {p1132 }}\).
2. If the current node \({ }^{p 1094}\) is not now \(a \underline{t d^{p 465}}\) element or a th \({ }^{p 467}\) element, then this is a parse error \({ }^{p 1081}\).
3. Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) stack until a \(t d^{p 465}\) element or a th \(h^{p 467}\) element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).
5. Switch the insertion mode \({ }^{\mathrm{p} 1092}\) to "in row \({ }^{\mathrm{p} 1155 \text { ". }}\)

\section*{Note}

The stack of open elements \({ }^{p 1093}\) cannot have both a \(t d^{p 465}\) and a th \({ }^{p 467}\) element in table scope \({ }^{\text {p1095 }}\) at the same time, nor can it have neither when the close the cell \({ }^{p 1156}\) algorithm is invoked.

\subsection*{12.2.6.4.16 The "in select" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "in select \({ }^{\text {p1156" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\hookrightarrow\) A character token that is U+0000 NULL}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\section*{\(\rightarrow\) A comment token}

Insert a comment \({ }^{\text {p1131 }}\).

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{p 1081}\). Ignore the token.
\(\leftrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{p 1092}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\leftrightarrow\) A start tag whose tag name is "option"
If the current node \({ }^{\text {p1094 }}\) is an option \({ }^{\text {p545 }}\) element, pop that node from the stack of open elements \({ }^{\text {p1093 }}\).
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\hookrightarrow\) A start tag whose tag name is "optgroup"
If the current node \({ }^{\text {p1094 }}\) is an option \({ }^{p 545}\) element, pop that node from the stack of open elements \({ }^{\text {p1093 }}\).

If the current node \({ }^{\text {p1094 }}\) is an optgroup \({ }^{\text {p544 }}\) element, pop that node from the stack of open elements \({ }^{\text {p1093 }}\).

Insert an HTML element \({ }^{\text {p1129 }}\) for the token.

\section*{\(\leftrightarrow\) An end tag whose tag name is "optgroup"}

First, if the current node \({ }^{\text {p1094 }}\) is an option \({ }^{p 545}\) element, and the node immediately before it in the stack of open elements \({ }^{\text {p1093 }}\) is an optgroup \({ }^{\text {p544 }}\) element, then pop the current node \({ }^{\text {p1094 }}\) from the stack of open elements \({ }^{\text {p1093 }}\).

If the current node \({ }^{p 1094}\) is an optgroup \({ }^{p 544}\) element, then pop that node from the stack of open elements \({ }^{\text {p1093 }}\). Otherwise, this is a parse error \({ }^{\text {p1081 }}\); ignore the token.
\(\leftrightarrow\) An end tag whose tag name is "option"
If the current node \({ }^{\text {p1094 }}\) is an option \({ }^{p 545}\) element, then pop that node from the stack of open elements \({ }^{\text {p1093 }}\). Otherwise, this is a parse error \({ }^{\text {p1081 }}\); ignore the token.

\section*{\(\rightarrow\) An end tag whose tag name is "select"}

If the stack of open elements \({ }^{\text {p1093 }}\) does not have a select element in select scope \({ }^{\text {p1095 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise:

Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a select \({ }^{\text {p537 }}\) element has been popped from the stack.
Reset the insertion mode appropriately \({ }^{\text {p1092 }}\)

\section*{\(\rightarrow\) A start tag whose tag name is "select"}

Parse error \({ }^{\text {p1081 }}\).
If the stack of open elements \({ }^{\text {p1093 }}\) does not have a select element in select scope \({ }^{\text {p1095 }}\), ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise:
Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a select \({ }^{\text {p537 }}\) element has been popped from the stack.

Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).

Note
It just gets treated like an end tag.

\section*{\(\rightarrow\) A start tag whose tag name is one of: "input", "keygen", "textarea"}

Parse error \({ }^{\text {p1081 }}\).

If the stack of open elements \({ }^{\text {p1093 }}\) does not have a select element in select scope \({ }^{\text {p1095 }}\), ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise:
Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a select \({ }^{\text {p537 }}\) element has been popped from the stack.

Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).
Reprocess the token.
\(\hookrightarrow\) A start tag whose tag name is one of: "script", "template"
\(\leftrightarrow\) An end tag whose tag name is "template"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end-of-file token
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) Anything else
Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\subsection*{12.2.6.4.17 The "in select in table" insertion mode \(\S_{58}^{p 11}\)}

When the user agent is to apply the rules for the "in select in table \({ }^{\text {p1158" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\rightarrow\) A start tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"
Parse error \({ }^{\text {p1081 }}\).
Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a select \({ }^{\text {p537 }}\) element has been popped from the stack.
Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).

Reprocess the token.
\(\hookrightarrow\) An end tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"
Parse error \({ }^{\text {p1081 }}\).
If the stack of open elements \({ }^{\text {p1093 }}\) does not have an element in table scope \({ }^{\text {p1095 }}\) that is an HTML element \({ }^{\text {p44 }}\) with the same tag name as that of the token, then ignore the token.

Otherwise:
Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a select \({ }^{\text {p537 }}\) element has been popped from the stack.

Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).

Reprocess the token.
\(\hookrightarrow\) Anything else
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in select \({ }^{\text {p1156" }}\) insertion mode \({ }^{\text {p1092 }}\).

\subsection*{12.2.6.4.18 The "in template" insertion mode \(\S_{58}^{p 11}\)}

When the user agent is to apply the rules for the "in template \({ }^{p 1158 "}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\leftrightarrow\) A character token}
\(\leftrightarrow\) A comment token
\(\rightarrow\) A DOCTYPE token
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"
\(\leftrightarrow\) An end tag whose tag name is "template"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135 " }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) A start tag whose tag name is one of: "caption", "colgroup", "tbody", "tfoot", "thead"
Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
Push "in table \({ }^{\text {p1150" }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in table \({ }^{\text {p1150" }}\), and reprocess the token.
\(\rightarrow\) A start tag whose tag name is "col"
Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
Push "in column group \({ }^{\text {p1153" }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).

Switch the insertion mode \({ }^{\text {p1092 }}\) to "in column group \({ }^{\text {p1153" }}\), and reprocess the token.
\(\rightarrow\) A start tag whose tag name is "tr"
Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
Push "in table body \({ }^{\text {p1154" }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).

Switch the insertion mode \({ }^{p 1092}\) to "in table body \({ }^{p 1154 "}\) ", and reprocess the token.
\(\rightarrow\) A start tag whose tag name is one of: "td", "th"
Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
Push "in row \({ }^{\text {p1155" }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in row \({ }^{\text {p1155" ", and reprocess the token. }}\)

\section*{\(\leftrightarrow\) Any other start tag}

Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
Push "in body \({ }^{\text {p1138" }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).
Switch the insertion mode \({ }^{\text {p1092 }}\) to "in body \({ }^{p 1138 "}\) ", and reprocess the token.

\section*{Any other end tag}

Parse error \({ }^{p 1081}\). Ignore the token.

\section*{\(\hookrightarrow\) An end-of-file token}

If there is no template \({ }^{\text {p629 }}\) element on the stack of open elements \({ }^{\text {p1093 }}\), then stop parsing \({ }^{\text {p1165 }}\). (fragment case \({ }^{\text {p1177 }}\) )
Otherwise, this is a parse error \({ }^{p 1081}\).
Pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until a template \({ }^{\text {p629 }}\) element has been popped from the stack.
Clear the list of active formatting elements up to the last marker \({ }^{\text {p1096 }}\).
Pop the current template insertion mode \({ }^{\text {p1092 }}\) off the stack of template insertion modes \({ }^{\text {p1092 }}\).
Reset the insertion mode appropriately \({ }^{\text {p1092 }}\).
Reprocess the token.

When the user agent is to apply the rules for the "after body \({ }^{\text {p1160" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:

\section*{\(\rightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED} (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138 " }}\) insertion mode \({ }^{\text {p1092 }}\).

\section*{\(\rightarrow\) A comment token}

Insert a comment \({ }^{\text {p1131 }}\) as the last child of the first element in the stack of open elements \({ }^{\text {p1093 }}\) (the html \({ }^{\text {p152 }}\) element).
\(\hookrightarrow\) A DOCTYPE token
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\leftrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\rightarrow\) An end tag whose tag name is "html"
If the parser was created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), this is a parse error \({ }^{\text {p1081 }}\); ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise, switch the insertion mode \({ }^{\text {p1092 }}\) to "after after body \({ }^{\text {p1161". }}\).
\(\hookrightarrow\) An end-of-file token
Stop parsing \({ }^{\text {p1165 }}\).
\(\hookrightarrow\) Anything else
Parse error \({ }^{\mathrm{p} 1081}\). Switch the insertion mode \({ }^{\mathrm{p} 1092}\) to "in body \({ }^{\mathrm{p} 1138 \text { " }}\) and reprocess the token.

\subsection*{12.2.6.4.20 The "in frameset" insertion mode \(\S^{p 11}\)}

When the user agent is to apply the rules for the "in frameset \({ }^{p 1160}\) " insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\rightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character \({ }^{\text {p1130 }}\).
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\).
\(\hookrightarrow\) A DOCTYPE token
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{p 1092}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) A start tag whose tag name is "frameset"
Insert an HTML element \({ }^{\text {p1129 }}\) for the token.
\(\leftrightarrow\) An end tag whose tag name is "frameset"
If the current node \({ }^{\text {p1094 }}\) is the root html \({ }^{\text {p152 }}\) element, then this is a parse error \({ }^{\text {p1081 }}\); ignore the token. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise, pop the current node \({ }^{\text {p1094 }}\) from the stack of open elements \({ }^{\text {p1093 }}\).
If the parser was not created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\) (fragment case \({ }^{\text {p1177 }}\) ), and the current node \({ }^{\text {p1094 }}\) is no longer a frameset \({ }^{\text {p1239 }}\) element, then switch the insertion mode \({ }^{\text {p1092 }}\) to "after frameset \({ }^{\text {p1161". }}\).

\section*{\(\rightarrow\) A start tag whose tag name is "frame"}

Insert an HTML element \({ }^{\text {p1129 }}\) for the token. Immediately pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\).
\(\rightarrow\) A start tag whose tag name is "noframes"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\leftrightarrow\) An end-of-file token
If the current node \({ }^{p 1094}\) is not the root html \({ }^{p 152}\) element, then this is a parse error \({ }^{\text {p1081 }}\).

\section*{Note}

The current node \({ }^{p 1094}\) can only be the root html \({ }^{p 152}\) element in the fragment case \({ }^{\text {p1177 }}\).

Stop parsing \({ }^{\text {p1165 }}\).
\(\hookrightarrow\) Anything else
Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\subsection*{12.2.6.4.21 The "after frameset" insertion mode \(\S_{61}^{p 11}\)}

When the user agent is to apply the rules for the "after frameset \({ }^{\text {p1161" } " ~ i n s e r t i o n ~ m o d e ~}{ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\leftrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character \({ }^{\text {p1130 }}\).
\(\rightarrow\) A comment token
Insert a comment \({ }^{\mathrm{pl131}}\).

\section*{\(\rightarrow\) A DOCTYPE token}

Parse error \({ }^{\text {p1081 }}\). Ignore the token.
\(\rightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{p 1092}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end tag whose tag name is "html"
Switch the insertion mode \({ }^{\text {p1092 }}\) to "after after frameset \({ }^{\text {p1162 " }}\).
\(\leftrightarrow\) A start tag whose tag name is "noframes"
Process the token using the rules for \({ }^{p 1092}\) the "in head \({ }^{\text {p1135 } " ~ i n s e r t i o n ~ m o d e ~}{ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end-of-file token
Stop parsing \({ }^{\text {p1165 }}\).
\(\rightarrow\) Anything else
Parse error \({ }^{\text {p1081 }}\). Ignore the token.

\subsection*{12.2.6.4.22 The "after after body" insertion mode \(\begin{gathered}\S_{61}^{p 11} \\ \xi^{p 1}\end{gathered}\)}

When the user agent is to apply the rules for the "after after body \({ }^{\text {p1161" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\rightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\) as the last child of the Document \({ }^{\text {p114 }}\) object.
\(\hookrightarrow\) A DOCTYPE token
\(\rightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
\(\leftrightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end-of-file token
Stop parsing \({ }^{\text {p1165 }}\).
\(\rightarrow\) Anything else
Parse error \({ }^{\text {p1081 }}\). Switch the insertion mode \({ }^{\text {p1092 }}\) to "in body \({ }^{\text {p1138" }}\) and reprocess the token.

\section*{}

When the user agent is to apply the rules for the "after after frameset \({ }^{\text {p1162" }}\) insertion mode \({ }^{\text {p1092 }}\), the user agent must handle the token as follows:
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\text {p1131 }}\) as the last child of the Document \({ }^{\text {p114 }}\) object.

\section*{\(\hookrightarrow\) A DOCTYPE token}
\(\leftrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE
\(\rightarrow\) A start tag whose tag name is "html"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in body \({ }^{\text {p1138" }}\) insertion mode \({ }^{\text {p1092 }}\).
\(\hookrightarrow\) An end-of-file token
Stop parsing \({ }^{\text {p1165 }}\).
\(\leftrightarrow\) A start tag whose tag name is "noframes"
Process the token using the rules for \({ }^{\text {p1092 }}\) the "in head \({ }^{\text {p1135 } " ~ i n s e r t i o n ~ m o d e ~}{ }^{\text {p1092 }}\).
\(\hookrightarrow\) Anything else
Parse error \({ }^{\text {p1081 }}\). Ignore the token.
12.2.6.5 The rules for parsing tokens in foreign content \(\$_{62}^{\text {p11 }}\)

When the user agent is to apply the rules for parsing tokens in foreign content, the user agent must handle the token as follows:
\(\leftrightarrow\) A character token that is U+0000 NULL
Parse error \({ }^{\text {p1081 }}\). Insert a U+FFFD REPLACEMENT CHARACTER character \({ }^{\text {p1130 }}\).
\(\leftrightarrow\) A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the token's character \({ }^{\text {p1130 }}\).
\(\hookrightarrow\) Any other character token
Insert the token's character \({ }^{\text {p1130 }}\).
Set the frameset-ok flag \({ }^{\text {p1097 }}\) to "not ok".
\(\hookrightarrow\) A comment token
Insert a comment \({ }^{\mathrm{p} 1131}\).
\(\rightarrow\) A DOCTYPE token
Parse error \({ }^{p 1081}\). Ignore the token.
\(\hookrightarrow\) A start tag whose tag name is one of: "b", "big", "blockquote", "body", "br", "center", "code", "dd", "div", "dl", "dt",
"em", "embed", "h1", "h2", "h3", "h4", "h5", "h6", "head", "hr", "i", "img", "li", "listing", "menu", "meta", "nobr", "ol", "p", "pre", "ruby", "s", "small", "span", "strong", "strike", "sub", "sup", "table", "tt", "u", "ul", "var"
\(\rightarrow\) A start tag whose tag name is "font", if the token has any attributes named "color", "face", or "size"
Parse error \({ }^{p 1081}\).
If the parser was created as part of the HTML fragment parsing algorithm \({ }^{\text {p1177 }}\), then act as described in the "any other start tag" entry below. (fragment case \({ }^{\text {p1177 }}\) )

Otherwise:

Pop an element from the stack of open elements \({ }^{\text {p1093 }}\), and then keep popping more elements from the stack of open elements \({ }^{\text {p1093 }}\) until the current node \({ }^{\text {p1094 }}\) is a MathML text integration point \({ }^{\text {p1126 }}\), an HTML integration point \({ }^{\text {p1126 }}\), or an element in the HTML namespace.

Then, reprocess the token.

\section*{\(\rightarrow\) Any other start tag}

If the adjusted current node \({ }^{\text {p1094 }}\) is an element in the MathML namespace, adjust MathML attributes \({ }^{\text {p1129 }}\) for the token. (This fixes the case of MathML attributes that are not all lowercase.)

If the adjusted current node \({ }^{\text {p1094 }}\) is an element in the SVG namespace, and the token's tag name is one of the ones in the first column of the following table, change the tag name to the name given in the corresponding cell in the second column. (This fixes the case of SVG elements that are not all lowercase.)
\begin{tabular}{|c|c|}
\hline Tag name & Element name \\
\hline altglyph & altGlyph \\
\hline altglyphdef & altGlyphDef \\
\hline altglyphitem & altGlyphItem \\
\hline animatecolor & animateColor \\
\hline animatemotion & animateMotion \\
\hline animatetransform & animateTransform \\
\hline clippath & clipPath \\
\hline feblend & feBlend \\
\hline fecolormatrix & feColorMatrix \\
\hline fecomponenttransfer & feComponentTransfer \\
\hline fecomposite & feComposite \\
\hline feconvolvematrix & feConvolveMatrix \\
\hline fediffuselighting & feDiffuseLighting \\
\hline fedisplacementmap & feDisplacementMap \\
\hline fedistantlight & feDistantLight \\
\hline fedropshadow & feDropShadow \\
\hline feflood & feFlood \\
\hline fefunca & feFuncA \\
\hline fefuncb & feFuncB \\
\hline fefuncg & feFuncG \\
\hline fefuncr & feFuncR \\
\hline fegaussianblur & feGaussianBlur \\
\hline feimage & feImage \\
\hline femerge & feMerge \\
\hline femergenode & feMergeNode \\
\hline femorphology & feMorphology \\
\hline feoffset & fe0ffset \\
\hline fepointlight & fePointLight \\
\hline fespecularlighting & feSpecularLighting \\
\hline fespotlight & feSpotLight \\
\hline fetile & feTile \\
\hline feturbulence & feTurbulence \\
\hline foreignobject & foreign0bject \\
\hline glyphref & glyphRef \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\multicolumn{1}{c|}{ Tag name } & \multicolumn{1}{|c}{ Element name } \\
\hline lineargradient & linearGradient \\
\hline radialgradient & radialGradient \\
\hline textpath & textPath \\
\hline
\end{tabular}

If the adjusted current node \({ }^{\text {p1094 }}\) is an element in the SVG namespace, adjust SVG attributes \({ }^{\text {p1129 }}\) for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes \({ }^{\text {p1130 }}\) for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.) Insert a foreign element \({ }^{\text {p1128 }}\) for the token, in the same namespace as the adjusted current node \({ }^{\text {p1094 }}\).

If the token has its self-closing flag \({ }^{\text {p1097 }}\) set, then run the appropriate steps from the following list:

\section*{\(\rightarrow\) If the token's tag name is "script", and the new current node \({ }^{\text {p1094 }}\) is in the SVG namespace}

Acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\), and then act as described in the steps for a "script" end tag below.

\section*{\(\hookrightarrow\) Otherwise}

Pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{\text {p1093 }}\) and acknowledge the token's self-closing flag \({ }^{\text {p1097 }}\).
\(\leftrightarrow\) An end tag whose tag name is "script", if the current node \({ }^{\text {p1094 }}\) is an SVG script element
Pop the current node \({ }^{\text {p1094 }}\) off the stack of open elements \({ }^{11093}\).
Let the old insertion point have the same value as the current insertion point \({ }^{\text {p1092 }}\). Let the insertion point \({ }^{p 1092}\) be just before the next input character \({ }^{\text {p1092 }}\).

Increment the parser's script nesting level \({ }^{\text {p1081 }}\) by one. Set the parser pause flag \({ }^{\text {p1081 }}\) to true.
Process the SVG script element according to the SVG rules, if the user agent supports SVG. [SVG] \({ }^{\text {p1291 }}\)

\section*{Note}

Even if this causes new characters to be inserted into the tokenizer \({ }^{p 970}\), the parser will not be executed reentrantly, since the parser pause flag \({ }^{\text {p1081 }}\) is true.

Decrement the parser's script nesting level \({ }^{\text {p1081 }}\) by one. If the parser's script nesting level \({ }^{\text {p1081 }}\) is zero, then set the parser pause flag \({ }^{\text {p1081 }}\) to false.

Let the insertion point \({ }^{\text {p1092 }}\) have the value of the old insertion point. (In other words, restore the insertion point \({ }^{\text {p1092 }}\) to its previous value. This value might be the "undefined" value.)

\section*{\(\rightarrow\) Any other end tag}

Run these steps:
1. Initialize node to be the current node \({ }^{\text {p1094 }}\) (the bottommost node of the stack).
2. If node's tag name, converted to ASCII lowercase, is not the same as the tag name of the token, then this is a parse error \({ }^{\text {p1081 }}\).
3. Loop: If node is the topmost element in the stack of open elements \({ }^{\text {p1093 }}\), then return. (fragment case \({ }^{\text {p1177 }}\) )
4. If node's tag name, converted to ASCII lowercase, is the same as the tag name of the token, pop elements from the stack of open elements \({ }^{\text {p1093 }}\) until node has been popped from the stack, and then return.
5. Set node to the previous entry in the stack of open elements \({ }^{\text {p1093 }}\).
6. If node is not an element in the HTML namespace, return to the step labeled loop.
7. Otherwise, process the token according to the rules given in the section corresponding to the current insertion mode \({ }^{p 1092}\) in HTML content.

Once the user agent stops parsing the document, the user agent must run the following steps:
1. Set the current document readiness \({ }^{\text {p117 }}\) to "interactive" and the insertion point \({ }^{\text {p1092 }}\) to undefined.
2. Pop all the nodes off the stack of open elements \({ }^{\text {p1093 }}\).
3. If the list of scripts that will execute when the document has finished parsing \({ }^{\text {p622 }}\) is not empty, run these substeps:
1. Spin the event loop \({ }^{p 949}\) until the first script \({ }^{p 614}\) in the list of scripts that will execute when the document has finished parsing \({ }^{\text {p622 }}\) has its "ready to be parser-executed" \({ }^{\text {p619 }}\) flag set and the parser's Document \({ }^{\text {p114 }}\) has no style sheet that is blocking scripts \({ }^{\text {p178 }}\).
2. Execute \({ }^{\text {p623 }}\) the first script \({ }^{\text {p614 }}\) in the list of scripts that will execute when the document has finished parsing \({ }^{\text {p622 }}\).
3. Remove the first script \({ }^{\text {p614 }}\) element from the list of scripts that will execute when the document has finished parsing \({ }^{\text {p622 }}\) (i.e. shift out the first entry in the list).
4. If the list of scripts that will execute when the document has finished parsing \({ }^{\text {p622 }}\) is still not empty, repeat these substeps again from substep 1.
4. Queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the Document \({ }^{\text {p114 }}\) 's relevant global object \({ }^{\text {p924 }}\) to run the following substeps:
1. Fire an event named DOMContentLoaded \({ }^{p 1281}\) at the Document \({ }^{p 114}\) object, with its bubbles attribute initialized to true.
2. Enable the client message queue of the ServiceWorkerContainer object whose associated service worker client is the Document \({ }^{\text {p114 }}\) object's relevant settings object \({ }^{\text {p924 }}\).
5. Spin the event loop \({ }^{\text {p949 }}\) until the set of scripts that will execute as soon as possible \({ }^{\text {p623 }}\) and the list of scripts that will execute in order as soon as possible \({ }^{\text {p623 }}\) are empty.
6. Spin the event loop \({ }^{\text {p949 }}\) until there is nothing that delays the load event in the Document \({ }^{\text {p114 }}\).
7. Queue a global task \({ }^{\text {p945 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the Document \({ }^{\text {p114 }}\) 's relevant global object \({ }^{\text {p924 }}\) to run the following substeps:
1. Set the current document readiness \({ }^{\text {p117 }}\) to "complete".
2. Load event: If the Document \({ }^{\text {p114 }}\) object's browsing context \({ }^{\text {p811 }}\) is non-null, then fire an event named load \({ }^{p 1282}\) at the Document \({ }^{p 114}\) object's relevant global object \({ }^{\text {p924 }}\), with legacy target override flag set.
8. If the Document \({ }^{\text {p114 }}\) object's browsing context \({ }^{p 811}\) is non-null, then queue a global task \({ }^{\mathrm{p945}}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the Document \({ }^{\text {p114 }}\) 's relevant global object \({ }^{\text {p924 }}\) to run these steps:
1. If the Document \({ }^{p 114}\) 's page showing \({ }^{\text {p885 }}\) flag is true, then return (i.e. don't fire the event below).
2. Set the Document \({ }^{\text {p114 }}\) 's page showing \({ }^{\text {p885 }}\) flag to true.
3. Fire an event named pageshow \({ }^{p 1282}\) at the Document \({ }^{p 114}\) object's relevant global object \({ }^{\text {p924 }}\), using PageTransitionEvent \({ }^{\text {p884 }}\), with the persisted \({ }^{p 885}\) attribute initialized to false, and legacy target override flag set.
9. If the Document \({ }^{\text {p114 }}\) has any pending application cache download process tasks \({ }^{\text {p906 }}\), then queue \({ }^{\text {p945 }}\) each such task \({ }^{\text {p944 }}\) in the order they were added to the list of pending application cache download process tasks \({ }^{\text {p906 }}\), and then empty the list of pending application cache download process tasks \({ }^{\text {p906 }}\). The task source \({ }^{\text {p945 }}\) for these tasks \({ }^{\text {p944 }}\) is the networking task source \({ }^{\text {p952 }}\).
10. If the Document \({ }^{\text {p114 }}\) 's print when loaded \({ }^{\text {p978 }}\) flag is set, then run the printing steps \({ }^{\text {p979 }}\).
11. The Document \({ }^{\text {p114 }}\) is now ready for post-load tasks.
12. Completely finish loading \({ }^{\mathrm{p} 885}\) the Document \({ }^{\mathrm{p} 114}\).

When the user agent is to abort a parser, it must run the following steps:
1. Throw away any pending content in the input stream \({ }^{\text {p1091 }}\), and discard any future content that would have been added to it.
2. Set the current document readiness \({ }^{\text {p117 }}\) to "interactive".
3. Pop all the nodes off the stack of open elements \({ }^{\text {p1093 }}\).
4. Set the current document readiness \({ }^{\text {p117 }}\) to "complete".

\subsection*{12.2.8 Coercing an HTML DOM into an infoset \(\S^{p 11}\)}

When an application uses an HTML parser \({ }^{\text {p1079 }}\) in conjunction with an XML pipeline, it is possible that the constructed DOM is not compatible with the XML tool chain in certain subtle ways. For example, an XML toolchain might not be able to represent attributes with the name xmlns, since they conflict with the Namespaces in XML syntax. There is also some data that the HTML parser \({ }^{\text {p1079 }}\) generates that isn't included in the DOM itself. This section specifies some rules for handling these issues.

If the XML API being used doesn't support DOCTYPEs, the tool may drop DOCTYPEs altogether.
If the XML API doesn't support attributes in no namespace that are named "xmlns", attributes whose names start with "xmlns:", or attributes in the XMLNS namespace, then the tool may drop such attributes.

The tool may annotate the output with any namespace declarations required for proper operation.
If the XML API being used restricts the allowable characters in the local names of elements and attributes, then the tool may map all element and attribute local names that the API wouldn't support to a set of names that are allowed, by replacing any character that isn't supported with the uppercase letter \(U\) and the six digits of the character's code point when expressed in hexadecimal, using digits 0-9 and capital letters A-F as the symbols, in increasing numeric order.

Example
For example, the element name foo<bar, which can be output by the HTML parser \({ }^{\text {p1079 }}\), though it is neither a legal HTML element name nor a well-formed XML element name, would be converted into fooU00003Cbar, which is a well-formed XML element name (though it's still not legal in HTML by any means).

\section*{Example}

As another example, consider the attribute xlink:href. Used on a MathML element, it becomes, after being adjusted \({ }^{p 1130}\), an attribute with a prefix "xlink" and a local name "href". However, used on an HTML element, it becomes an attribute with no prefix and the local name "xlink:href", which is not a valid NCName, and thus might not be accepted by an XML API. It could thus get converted, becoming "xlinkU00003Ahref".

\section*{Note}

The resulting names from this conversion conveniently can't clash with any attribute generated by the HTML parser \({ }^{\text {p1079 }}\), since those are all either lowercase or those listed in the adjust foreign attributes \({ }^{\text {p1130 }}\) algorithm's table.

If the XML API restricts comments from having two consecutive U+002D HYPHEN-MINUS characters (--), the tool may insert a single U+0020 SPACE character between any such offending characters.

If the XML API restricts comments from ending in a U+002D HYPHEN-MINUS character ( - ), the tool may insert a single U+0020 SPACE character at the end of such comments.

If the XML API restricts allowed characters in character data, attribute values, or comments, the tool may replace any U+000C FORM FEED (FF) character with a U+0020 SPACE character, and any other literal non-XML character with a U+FFFD REPLACEMENT CHARACTER.

If the tool has no way to convey out-of-band information, then the tool may drop the following information:
- Whether the document is set to no-quirks mode, limited-quirks mode, or quirks mode
- The association between form controls and forms that aren't their nearest form \({ }^{\text {p486 }}\) element ancestor (use of the form element pointer \({ }^{p 1096}\) in the parser)
- The template contents \({ }^{\text {p631 }}\) of any template \({ }^{\text {p629 }}\) elements.

The mutations allowed by this section apply after the HTML parser \({ }^{p 1079}\) 's rules have been applied. For example, a <a: :> start tag will be closed by a </a : :> end tag, and never by a </aU00003AU00003A> end tag, even if the user agent is using the rules above to then generate an actual element in the DOM with the name aU00003AU00003A for that start tag.

\section*{}

This section is non-normative.
This section examines some erroneous markup and discusses how the HTML parser \({ }^{\text {p1079 }}\) handles these cases.

\subsection*{12.2.9.1 Misnested tags: \(\left\langle\boldsymbol{b}><\boldsymbol{i}></ b></ i>\S_{67}^{\text {p11 }}\right.\)}

This section is non-normative.
The most-often discussed example of erroneous markup is as follows:
```

<p>1<b>2<i>3</b>4</i>5</p>

```

The parsing of this markup is straightforward up to the " 3 ". At this point, the DOM looks like this:

Here, the stack of open elements \({ }^{p 1093}\) has five elements on it: \(\underline{h t m} 2^{p 152}, \underline{b o d y} y^{p 178}, \underline{p}^{p 211}, \underline{b}^{p 273}\), and \(\underline{i}^{p 272}\). The list of active formatting elements \({ }^{\text {p1095 }}\) just has two: \(\underline{b}^{\text {p273 }}\) and \(\underline{i}^{\text {p272 }}\). The insertion mode \({ }^{\text {p1092 }}\) is "in body \({ }^{\text {p1138 } " . ~}\)

Upon receiving the end tag token with the tag name "b", the "adoption agency algorithm \({ }^{\text {p1147" }}\) is invoked. This is a simple case, in that the formatting element is the \(\underline{b^{p 273}}\) element, and there is no furthest block. Thus, the stack of open elements \({ }^{\text {p1093 }}\) ends up with just three elements: \(h t m l^{p 152}\), body \({ }^{p 178}\), and \(p^{p 211}\), while the list of active formatting elements \({ }^{p 1095}\) has just one: \(\underline{i}^{p 272}\). The DOM tree is unmodified at this point.

The next token is a character ("4"), triggers the reconstruction of the active formatting elements \({ }^{\mathrm{p} 1096}\), in this case just the \(\underline{\underline{\mathrm{p}}^{p 272}}\) element. A new \(\underline{i}^{p 272}\) element is thus created for the " 4 " Text node. After the end tag token for the " \(i\) " is also received, and the " 5 " Text node is inserted, the DOM looks as follows:
```

$L_{h t m l^{p 152}}$
-head $^{\text {p153 }}{ }^{\text {body }}{ }^{\text {p178 }}$
$\mathrm{L}_{p^{p 211}}$
\#text: 1
$b^{\text {p273 }}$
-\#text: 2
$i^{\text {p272 }}$
\#text: 3
$-\underline{i}^{\mathrm{p} 272}$
L\#text: 4
\#text: 5

```

\subsection*{12.2.9.2 Misnested tags: \(\langle\boldsymbol{b}\rangle\langle\boldsymbol{p}\rangle</ \boldsymbol{b}\rangle</ \boldsymbol{p}\rangle \S_{68}^{\text {p11 }}\)}

This section is non-normative.
A case similar to the previous one is the following:
\(<b>1<p>2</ b>3</ p>\)

Up to the " 2 " the parsing here is straightforward:

The interesting part is when the end tag token with the tag name "b" is parsed.
Before that token is seen, the stack of open elements \({ }^{p 1093}\) has four elements on it: html \({ }^{p 152}\), body \({ }^{p 178}, \underline{b}^{p 273}\), and \(p^{p 211}\). The list of active formatting elements \({ }^{p 1095}\) just has the one: \(\underline{b^{p 273}}\). The insertion mode \({ }^{\text {p1092 }}\) is "in body \({ }^{p 1138 " .}\).

Upon receiving the end tag token with the tag name " b ", the "adoption agency algorithm \({ }^{\text {p1147" }}\) is invoked, as in the previous example. However, in this case, there is a furthest block, namely the p p211 element. Thus, this time the adoption agency algorithm isn't skipped over.

The common ancestor is the body \({ }^{p 178}\) element. A conceptual "bookmark" marks the position of the \(\underline{b}^{p 273}\) in the list of active formatting elements \({ }^{\text {p1095 }}\), but since that list has only one element in it, the bookmark won't have much effect.

As the algorithm progresses, node ends up set to the formatting element ( \(\underline{b}^{\mathrm{p} 273}\) ), and last node ends up set to the furthest block ( \(\mathrm{p}^{\mathrm{p} 211}\) ).
The last node gets appended (moved) to the common ancestor, so that the DOM looks like:

A new \(\underline{b^{p 273}}\) element is created, and the children of the \(\underline{p}^{p 211}\) element are moved to it:

Finally, the new \(\underline{b^{p 273}}\) element is appended to the \(\underline{p}^{p 211}\) element, so that the DOM looks like:

The \(\underline{b^{p 273}}\) element is removed from the list of active formatting elements \({ }^{\text {p1095 }}\) and the stack of open elements \({ }^{\text {p1093 }}\), so that when the " 3 " is parsed, it is appended to the \(\mathrm{p}^{\text {p211 }}\) element:
\(L_{h t m l^{p 152}}\)

\subsection*{12.2.9.3 Unexpected markup in tables \(\S_{69}^{\text {p11 }}\)}

This section is non-normative.
Error handling in tables is, for historical reasons, especially strange. For example, consider the following markup:
<table><b><tr><td>aaa</td></tr>bbb</table>ccc

The highlighted \(\underline{b}^{p 273}\) element start tag is not allowed directly inside a table like that, and the parser handles this case by placing the element before the table. (This is called foster parenting \({ }^{p 1126}\).) This can be seen by examining the DOM tree as it stands just after the \(t a b l e^{\text {p450 }}\) element's start tag has been seen:
\(\mathrm{L}_{\text {html }^{\text {p152 }}}\)
Lhead \(^{\text {p153 }}\)
\(\frac{\text { body }^{\text {p178 }}}{L_{\text {table }}{ }^{\text {p450 }}}\)
...and then immediately after the \(\underline{b}^{p 273}\) element start tag has been seen:

At this point, the stack of open elements \({ }^{p 1093}\) has on it the elements \(h t m l^{p 152}\), body \({ }^{p 178}\), \(t a b l e^{p 450}\), and \(\underline{b}^{p 273}\) (in that order, despite the resulting DOM tree); the list of active formatting elements \({ }^{\text {p1095 }}\) just has the \(\underline{b^{p 273}}\) element in it; and the insertion mode \({ }^{p 1092}\) is "in table \({ }^{\text {p1150". }}\).

The \(t r^{p 464}\) start tag causes the \(b^{p 273}\) element to be popped off the stack and a tbody \({ }^{p 461}\) start tag to be implied; the tbody \({ }^{p 461}\) and \(t r^{p 464}\) elements are then handled in a rather straight-forward manner, taking the parser through the "in table body \({ }^{\text {p1154" }}\) and "in row \({ }^{\text {p1155" }}\) insertion modes, after which the DOM looks as follows:
```

$\mathrm{L}_{\mathrm{html}}{ }^{\mathrm{p} 152}$
- head $^{\text {p153 }}$
$\underline{\text { body }^{\text {p178 }}}$
$-b^{\text {p273 }}$
table ${ }^{\text {p450 }}$
$L_{\text {tbody }}{ }^{\text {p461 }}$
$\mathrm{L}_{\underline{t r^{p 464}}}$

```

Here, the stack of open elements \({ }^{p 1093}\) has on it the elements \(\underline{h t m} l^{p 152}\), body \(y^{p 178}\), table \(e^{p 456}, \underline{t b o d y}{ }^{p 461}\), and \(\underline{t^{p 464}}\); the list of active formatting elements \({ }^{\text {p1095 }}\) still has the \(b^{\text {p273 }}\) element in it; and the insertion mode \({ }^{\text {p1092 }}\) is "in row \({ }^{\text {p1155 " }}\).

The \(t d^{p 465}\) element start tag token, after putting a \(\underline{t d^{p 465}}\) element on the tree, puts a marker \({ }^{p 1095}\) on the list of active formatting elements \({ }^{p 1095}\) (it also switches to the "in cell \({ }^{\text {p1156" }}\) insertion mode \({ }^{\text {p1092 }}\) ).
\(\mathrm{L}_{\mathrm{htm}}{ }^{\text {p152 }}\)
```

head p153
body\mp@subsup{}{}{\mathrm{ p178}}
-b
table }\mp@subsup{}{}{\mathrm{ p450}
L tbody }\mp@subsup{}{}{\mathrm{ p461 }
Ltr
Ltd

```

The marker \({ }^{\text {p1095 }}\) means that when the "aaa" character tokens are seen, no \(b^{p 273}\) element is created to hold the resulting Text node:
```

Lhtml }\mp@subsup{}{}{\textrm{p152}
-Ghead p153
-b}\mp@subsup{\boldsymbol{b}}{}{\mathrm{ p273}
table\mp@subsup{e}{}{p450}
Ltbody }\mp@subsup{}{}{\mathrm{ p461 }
Ltri
Ltd
L\#text: aaa

```

The end tags are handled in a straight-forward manner; after handling them, the stack of open elements \({ }^{p 1093}\) has on it the elements \(\underline{h t m} l^{p 152}, \underline{\text { body }}{ }^{\text {p178 }}, \underline{t a b l e} e^{\text {p450 }}\), and tbody \({ }^{\text {p461 }}\); the list of active formatting elements \({ }^{\text {p1095 }}\) still has the \(b^{\text {p273 }}\) element in it (the marker \({ }^{\text {p1095 }}\) having been removed by the "td" end tag token); and the insertion mode \({ }^{\text {p1092 }}\) is "in table body \({ }^{\text {p1154" }}\).

Thus it is that the "bbb" character tokens are found. These trigger the "in table text \({ }^{p 1152}\) " insertion mode to be used (with the original
 \(t a g\) ) is seen, they are processed as a group. Since they are not all spaces, they are handled as per the "anything else" rules in the "in table \({ }^{\text {p1150" }}\) insertion mode, which defer to the "in body \({ }^{\text {p1138" }}\) insertion mode but with foster parenting \({ }^{\text {p1126 }}\).

When the active formatting elements are reconstructed \({ }^{\text {p1096 }}\), a \(b^{\text {p273 }}\) element is created and foster parented \({ }^{\text {p1126 }}\), and then the "bbb" Text node is appended to it:
```

$\mathrm{L}_{\mathrm{htm}}{ }^{\mathrm{p} 152}$
-head ${ }^{\text {p153 }}$
body ${ }^{\text {p178 }}$

| $-\underline{b}^{\text {p273 }}$ |
| :--- |
| $-\underline{b}^{\text {p273 }}$ |

            \#\#text: bbb
            table \({ }^{p 45}\)
            \(L_{\text {tbody }}{ }^{\text {p461 }}\)
            \(\mathrm{Ltr}^{\text {p464 }}\)
                    \(\mathrm{L}_{\underline{t^{p}}{ }^{\text {p465 }}}\)
                    ᄂ \#text: aaa
    ```

The stack of open elements \({ }^{\text {p1093 }}\) has on it the elements html \({ }^{\text {p152 }}\), body \({ }^{p 178}\), table \({ }^{p 450}\), tbody \({ }^{p 461}\), and the new \(b^{p 273}\) (again, note that this doesn't match the resulting tree!); the list of active formatting elements \({ }^{p 1095}\) has the new \(\underline{b^{p 273}}\) element in it; and the insertion mode \({ }^{\text {p1092 }}\) is still "in table body \({ }^{\text {p1154". }}\)

Had the character tokens been only ASCII whitespace instead of "bbb", then that ASCII whitespace would just be appended to the tbody \({ }^{\text {p461 }}\) element.

Finally, the table \({ }^{p 450}\) is closed by a "table" end tag. This pops all the nodes from the stack of open elements \({ }^{\text {p1093 }}\) up to and including the table \({ }^{\text {p450 }}\) element, but it doesn't affect the list of active formatting elements \({ }^{\text {p1095 }}\), so the "ccc" character tokens after the table result in yet another \(\underline{b^{p 273}}\) element being created, this time after the table:
```

$L_{h t m l}{ }^{\text {p152 }}$
- head ${ }^{\text {p153 }}$
body ${ }^{\text {p178 }}$
$-\underline{b^{\text {p2 }}}-\underline{b^{\text {p273 }}}$
L\#text: $b b b$
table ${ }^{\text {p450 }}$
$L_{\text {tbody }}{ }^{\text {p461 }}$

```
1170
```

Ltrp
Ltd
L\#text: aaa
\mp@subsup{\boldsymbol{b}}{}{p273}
L\#text:ccc

```

\subsection*{12.2.9.4 Scripts that modify the page as it is being parsed \(\S^{\text {p11 }}\)}

This section is non-normative.
Consider the following markup, which for this example we will assume is the document with URL https://example. com/inner, being rendered as the content of an iframe \({ }^{\text {p361 }}\) in another document with the URL https://example.com/outer:
```

<div id=a>
    <script>
        var div = document.getElementById('a');
        parent.document.body.appendChild(div);
    </script>
    <script>
        alert(document.URL);
    </script>
</div>
<script>
    alert(document.URL);
</script>
```

Up to the first "script" end tag, before the script is parsed, the result is relatively straightforward:
```

$\mathrm{L}_{\mathrm{htm}}{ }^{\mathrm{p} 152}$
head ${ }^{\text {p153 }}$
body ${ }^{\text {p178 }}$
$\mathrm{L}_{\underline{\text { div }}}{ }^{\text {p237 }}$ id $^{\text {p137 }}=" \mathrm{a} "$
-\#text:
script ${ }^{\text {p614 }}$
$\mathrm{L}_{\text {\#text: }}$ var div $=$ document.getElementById('a'); ${ }^{\Delta}$ parent.document.body.appendChild(div);

```

After the script is parsed, though, the \(\underline{\text { div }^{p 237}}\) element and its child script \({ }^{p 614}\) element are gone:
```

Lhtml p152
-head p153

```

They are, at this point, in the Document \({ }^{\text {p114 }}\) of the aforementioned outer browsing context \({ }^{\text {p811 }}\). However, the stack of open elements \({ }^{\text {p1093 }}\) still contains the div \({ }^{\text {p237 }}\) element.

Thus, when the second script \({ }^{\text {p614 }}\) element is parsed, it is inserted into the outer Document \({ }^{\text {p114 }}\) object.
Those parsed into different Document \({ }^{p 114} s\) than the one the parser was created for do not execute, so the first alert does not show.
Once the \(d i v^{p 237}\) element's end tag is parsed, the \(\operatorname{div}^{p 237}\) element is popped off the stack, and so the next script \({ }^{p 614}\) element is in the inner Document \({ }^{p 114}\) :

This script does execute, resulting in an alert that says "https://example.com/inner".

\subsection*{12.2.9.5 The execution of scripts that are moving across multiple documents \(\S_{72}^{p 11}\)}

This section is non-normative.
Elaborating on the example in the previous section, consider the case where the second script \({ }^{p 614}\) element is an external script (i.e. one with a src \({ }^{\text {p615 }}\) attribute). Since the element was not in the parser's Document \({ }^{\text {p114 }}\) when it was created, that external script is not even downloaded.

In a case where a script \({ }^{p 614}\) element with a \(s r c^{p 615}\) attribute is parsed normally into its parser's Document \({ }^{p 114}\), but while the external script is being downloaded, the element is moved to another document, the script continues to download, but does not execute.

\section*{Note}

In general, moving script \({ }^{\text {p614 }}\) elements between Document \({ }^{p 114}\) s is considered a bad practice

\subsection*{12.2.9.6 Unclosed formatting elements \(\S_{72}^{p 11}\)}

This section is non-normative.
The following markup shows how nested formatting elements (such as \(\underline{b}^{\text {p273 }}\) ) get collected and continue to be applied even as the elements they are contained in are closed, but that excessive duplicates are thrown away.
```

<!DOCTYPE html>
<p><b class=x><b class=x><b><b class=x><b class=x><b>X
<p>X
<p><b><b class=x><b>X

<p></b></b></b></b></b></b>X
```

The resulting DOM tree is as follows:
```
-DOCTYPE: html
\(h_{\text {tml }}{ }^{\text {p152 }}\)
    head \({ }^{\text {p153 }}\)
    body \({ }^{\text {p178 }}\)
            \(-\frac{p^{p 211}}{L_{\underline{b}}}\)
                \(\mathrm{L}_{\mathrm{b}^{\mathrm{p} 273}}\) class \(^{\text {p137 }}=" \mathrm{x}\) "
            \(\mathrm{L}_{\boldsymbol{b}^{\text {p273 }}}\) class \({ }^{\text {p137 }}=" x "\)
                \(\mathrm{L}_{\underline{b^{2273}}}\)
                    \(\mathrm{L}_{\boldsymbol{b}^{\mathrm{p} 273}}\) class \(^{\text {p137 }}=" \mathrm{x}\) "
                    \(\mathrm{L}_{\underline{\boldsymbol{b}^{\text {p273 }}}}^{\text {class }^{\text {p137 }}}=" \times "\)
                    \(\mathrm{L}_{\mathbf{b}^{\text {p273 }}}\)
                        \# \#text: \(X{ }^{\boldsymbol{s}}\)
        \(-p^{p 211}\)
        \(\mathrm{L}_{\boldsymbol{b}^{\text {p273 }}}\) class \(^{\text {p137 }}=" \mathrm{x} "\)
            \(L_{\underline{b^{p 273}}}\)
                \(\mathrm{L}^{\text {b }}{ }^{\text {p273 }}\) class \({ }^{\text {p137 }}=" x "\)
                    \(\mathrm{L}^{\boldsymbol{b}^{\text {p273 }}}\) class \({ }^{\text {p137 }}=" x "\)
                        \(\left\llcorner_{b^{p 273}}\right.\)
                        —\#text: \(X\)
        \(-p^{p 211}\)
            \(\mathrm{L}_{\underline{\boldsymbol{b}^{\text {p2 }}}{ }^{\text {2 }}}^{\text {class }}{ }^{\text {p137 }}=" x "\)
            \(L_{b^{p 273}}\)
                \(\mathrm{L}_{\boldsymbol{b}^{\text {p273 }}}\) class \(^{\text {p137 }}=" \mathrm{x} "\)
                    \(L_{b^{p 273}}\) class \(^{\text {p137 }}=" x "\)
                    \(\left\llcorner^{\boldsymbol{b}^{\mathrm{p} 273}}\right.\)
                        \(\left\llcorner^{\boldsymbol{b}^{\mathrm{p} 273}}\right.\)
                            \(\mathrm{L}^{\text {b }}{ }^{\text {2273 }}\) class \({ }^{\text {p137 }}=" x\) "
                                    \(\left\llcorner_{\underline{b^{p 273}}}\right.\)
                                    —\#text: \(X^{\prime \prime}\)
        \(\frac{p^{p 211}}{L_{\# t e x t}} X_{s}\)
1172
```

Note how the second \(\underline{p}^{p 211}\) element in the markup has no explicit \(\underline{b^{p 273}}\) elements, but in the resulting DOM, up to three of each kind of formatting element (in this case three \(\underline{b}^{p 273}\) elements with the class attribute, and two unadorned \(\underline{b}^{p 273}\) elements) get reconstructed before the element's "X".

Also note how this means that in the final paragraph only six \(\underline{b}^{p 273}\) end tags are needed to completely clear the list of active formatting elements \({ }^{\text {p1095 }}\), even though nine \(b^{p 273}\) start tags have been seen up to this point.

\subsection*{12.3 Serializing HTML fragments \(\S_{73}^{\S^{p 11}}\)}

For the purposes of the following algorithm, an element serializes as void if its element type is one of the void elements \({ }^{\text {p1068 }}\), or is basefont \({ }^{\text {p1233 }}\), bgsound \({ }^{\text {p1232 }}\), frame \({ }^{\text {p1240 }}\), or keygen \({ }^{\text {p1232 }}\).

The following steps form the HTML fragment serialization algorithm. The algorithm takes as input a DOM Element, Document \({ }^{\text {p114 }}\), or DocumentFragment referred to as the node, and returns a string.

Note
This algorithm serializes the children of the node being serialized, not the node itself.
1. If the node serializes as void \({ }^{\text {p1173 }}\), then return the empty string.
2. Let \(s\) be a string, and initialize it to the empty string.
3. If the node is a template \({ }^{p 629}\) element, then let the node instead be the template \({ }^{p 629}\) element's template contents \({ }^{p 631}\) (a DocumentFragment node).
4. For each child node of the node, in tree order, run the following steps:
1. Let current node be the child node being processed.
2. Append the appropriate string from the following list to \(s\) :
\(\hookrightarrow\) If current node is an Element
If current node is an element in the HTML namespace, the MathML namespace, or the SVG namespace, then let tagname be current node's local name. Otherwise, let tagname be current node's qualified name.

Append a U+003C LESS-THAN SIGN character (<), followed by tagname.
Note
For HTML elements \({ }^{p 44}\) created by the HTML parser \({ }^{p 1079}\) or createElement(), tagname will be lowercase.

If current node's is value is not null, and the element does not have an \(\underline{\underline{s^{p 703}}}\) attribute in its attribute list, then append the string " is="", followed by current node's is value escaped as described below \({ }^{\text {p1177 }}\) in attribute mode, followed by a U+0022 QUOTATION MARK character (").

For each attribute that the element has, append a U+0020 SPACE character, the attribute's serialized name as described below \({ }^{\text {p1173 }}\), a U+003D EQUALS SIGN character (=), a U+0022 QUOTATION MARK character ("), the attribute's value, escaped as described below \({ }^{\text {p1177 }}\) in attribute mode, and a second U+0022 QUOTATION MARK character (").

An attribute's serialized name for the purposes of the previous paragraph must be determined as follows:

\section*{\(\rightarrow\) If the attribute has no namespace}

The attribute's serialized name is the attribute's local name.

\section*{Note}

For attributes on HTML elements \({ }^{p 44}\) set by the HTML parser \({ }^{p 1079}\) or by setAttribute(), the local name will be lowercase.

\section*{\(\rightarrow\) If the attribute is in the XML namespace}

The attribute's serialized name is the string "xml:" followed by the attribute's local name.
\(\rightarrow\) If the attribute is in the XMLNS namespace and the attribute's local name is xmlns The attribute's serialized name is the string "xmlns".
\(\hookrightarrow\) If the attribute is in the XMLNS namespace and the attribute's local name is not xmlns The attribute's serialized name is the string "xmlns:" followed by the attribute's local name.
\(\leftrightarrow\) If the attribute is in the XLink namespace The attribute's serialized name is the string "xlink:" followed by the attribute's local name.
\(\leftrightarrow\) If the attribute is in some other namespace
The attribute's serialized name is the attribute's qualified name.
While the exact order of attributes is implementation-defined, and may depend on factors such as the order that the attributes were given in the original markup, the sort order must be stable, such that consecutive invocations of this algorithm serialize an element's attributes in the same order.

Append a U+003E GREATER-THAN SIGN character ( \(>\) ).
If current node serializes as void \({ }^{\text {p1173 }}\), then continue on to the next child node at this point.
Append the value of running the HTML fragment serialization algorithm \({ }^{\text {p1173 }}\) on the current node element (thus recursing into this algorithm for that element), followed by a U+003C LESS-THAN SIGN character (<), a U+002F SOLIDUS character (/), tagname again, and finally a U+003E GREATER-THAN SIGN character ( \(>\) ).
\(\rightarrow\) If current node is a Text node
If the parent of current node is a style \({ }^{p 174}\), script \({ }^{\text {p614 }}\), xmp \(^{\text {p1233 }}\), iframe \({ }^{\text {p361 }}\), noembed \({ }^{p 1232}\), noframes \({ }^{p 1232}\), or plaintext \({ }^{p 1232}\) element, or if the parent of current node is a noscript \({ }^{p 627}\) element and scripting is enabled \({ }^{\text {p924 }}\) for the node, then append the value of current node's data IDL attribute literally.

Otherwise, append the value of current node's data IDL attribute, escaped as described below \({ }^{\text {p1177 }}\).
\(\rightarrow\) If current node is a Comment
Append the literal string "<!--" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+002D HYPHENMINUS, U+002D HYPHEN-MINUS), followed by the value of current node's data IDL attribute, followed by the literal string " - ->" (U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS, U+003E GREATER-THAN SIGN).
\(\hookrightarrow\) If current node is a ProcessingInstruction
Append the literal string "<?" (U+003C LESS-THAN SIGN, U+003F QUESTION MARK), followed by the value of current node's target IDL attribute, followed by a single U+0020 SPACE character, followed by the value of current node's data IDL attribute, followed by a single U+003E GREATER-THAN SIGN character ( \(>\) ).
\(\leftrightarrow\) If current node is a DocumentType
Append the literal string " <! DOCTYPE" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+0044 LATIN CAPITAL LETTER D, U+004F LATIN CAPITAL LETTER O, U+0043 LATIN CAPITAL LETTER C, U+0054 LATIN CAPITAL LETTER T, U+0059 LATIN CAPITAL LETTER Y, U+0050 LATIN CAPITAL LETTER P, U+0045 LATIN CAPITAL LETTER E), followed by a space (U+0020 SPACE), followed by the value of current node's name IDL attribute, followed by the literal string ">" (U+003E GREATER-THAN SIGN).
5. Return s .

\section*{\(\triangle\) Warning!}

It is possible that the output of this algorithm, if parsed with an HTML parser \({ }^{\text {p1079 }}\), will not return the original tree structure. Tree structures that do not roundtrip a serialize and reparse step can also be produced by the HTML parser \({ }^{\text {p1079 }}\) itself, although such cases are typically non-conforming.

\section*{Example}

For instance, if a textarea \({ }^{p 548}\) element to which a Comment node has been appended is serialized and the output is then reparsed, the comment will end up being displayed in the text control. Similarly, if, as a result of DOM manipulation, an element contains a comment that contains the literal string " - ->", then when the result of serializing the element is parsed, the comment will be
truncated at that point and the rest of the comment will be interpreted as markup. More examples would be making a script \({ }^{\text {p614 }}\) element contain a Text node with the text string "</script>", or having a \(p^{\text {p211 }}\) element that contains a \(u t^{p 222}\) element (as the \(u^{p 222}\) element's start tag \({ }^{\text {p1069 }}\) would imply the end tag for the \(p^{p 211}\) ).

This can enable cross-site scripting attacks. An example of this would be a page that lets the user enter some font family names that are then inserted into a CSS style \({ }^{\text {p174 }}\) block via the DOM and which then uses the innerHTML IDL attribute to get the HTML serialization of that style \({ }^{p 174}\) element: if the user enters "</style><script>attack</script>" as a font family name, innerHTML will return markup that, if parsed in a different context, would contain a script \({ }^{\text {p614 }}\) node, even though no script \({ }^{\text {p614 }}\) node existed in the original DOM.

\section*{Example}

For example, consider the following markup:
```
<form id="outer"><div></form><form id="inner"><input>
```

This will be parsed into:
```
\(L_{\text {html }}{ }^{\text {p152 }}\)
    head \({ }^{\text {p153 }}\)
    body \({ }^{\text {p178 }}\)
        \(\mathrm{L}_{\text {form }}{ }^{\text {p486 }}\) id \(^{\text {p137 }}=\) "outer"
            \(\mathrm{L}_{\text {div }^{\text {p237 }}}\)
                \(L_{\underline{\text { form }}}{ }^{\text {p486 }} \underline{i d}^{\text {p137 }}=\) "inner"
                \(\mathrm{L}_{\text {input }}{ }^{\text {p493 }}\)
```

The input \({ }^{\text {p493 }}\) element will be associated with the inner form \({ }^{\text {p486 }}\) element. Now, if this tree structure is serialized and reparsed, the <form id="inner"> start tag will be ignored, and so the input \({ }^{\text {p493 }}\) element will be associated with the outer form \({ }^{\text {p486 }}\) element instead.
```
<html><head></head><body><form id="outer"><div><form
```
id="inner"><input></form></div></form></body></html>
\(\mathrm{L}_{\underline{h t m} \mathrm{l}^{\text {p152 }}}\)
    head \({ }^{\text {p153 }}\)
    body \({ }^{\text {p178 }}\)
        \(\mathrm{L}_{\text {form }^{\text {p486 }}}\) id \(^{\text {p137 }}=\) "outer"
            \(\mathrm{L}_{\text {div }}{ }^{\text {p237 }}\)
            \(\mathrm{L}_{\text {input }}{ }^{\text {p493 }}\)

\section*{Example}

As another example, consider the following markup:
<a><table><a>

This will be parsed into:
```
\(L_{\text {html }}{ }^{\text {p152 }}\)
    head \({ }^{\text {p153 }}\)
    body \({ }^{\text {p178 }}\)
        \(\mathrm{L}_{\underline{a^{p 238}}}\)
            \(-a^{\text {p238 }}\)
            table \({ }^{\text {p450 }}\)
```

That is, the \(a^{p 238}\) elements are nested, because the second \(a^{p 238}\) element is foster parented \({ }^{\mathrm{p} 1126}\). After a serialize-reparse roundtrip, the \(a^{p 238}\) elements and the table \({ }^{p 450}\) element would all be siblings, because the second <a> start tag implicitly closes the first \(a^{p 238}\) element.
```
<html><head></head><body><a><a></a><table></table></a></body></html>
```

For historical reasons, this algorithm does not round-trip an initial U+000A LINE FEED (LF) character in pre \({ }^{\text {p216 }}\), textarea \({ }^{\text {p548 }}\), or listing \({ }^{\text {p1232 }}\) elements, even though (in the first two cases) the markup being round-tripped can be conforming. The HTML parser \({ }^{p 1079}\) will drop such a character during parsing, but this algorithm does not serialize an extra U+000A LINE FEED (LF) character.

\section*{Example}

For example, consider the following markup:
<pre>
Hello.</pre>

When this document is first parsed, the pre \({ }^{\text {p216 }}\) element's child text content starts with a single newline character. After a serializereparse roundtrip, the pre \({ }^{\text {p216 }}\) element's child text content is simply "Hello.".

Because of the special role of the is \({ }^{\mathrm{p} 703}\) attribute in signaling the creation of customized built-in elements \({ }^{\mathrm{p} 703}\), in that it provides a mechanism for parsed HTML to set the element's is value, we special-case its handling during serialization. This ensures that an element's is value is preserved through serialize-parse roundtrips.

\section*{Example}

When creating a customized built-in element \({ }^{\mathrm{p} 703}\) via the parser, a developer uses the is \({ }^{\mathrm{p} 703}\) attribute directly; in such cases serialize-parse roundtrips work fine.
```
<script>
window.SuperP = class extends HTMLParagraphElement {};
customElements.define("super-p", SuperP, { extends: "p" });
</script>
<div id="container"><p is="super-p">Superb!</p></div>
<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>
```

But when creating a customized built-in element via its constructor \({ }^{\mathrm{p703}}\) or via createElement (), the is \({ }^{\mathrm{p} 703}\) attribute is not added. Instead, the is value (which is what the custom elements machinery uses) is set without intermediating through an attribute.
```
<script>
container.innerHTML = "";
const p = document.createElement("p", { is: "super-p" });
container.appendChild(p);
// The is attribute is not present in the DOM:
console.assert(!p.hasAttribute("is"));
// But the element is still a super-p:
console.assert(p instanceof SuperP);
</script>
```

To ensure that serialize-parse roundtrips still work, the serialization process explicitly writes out the element's is value as an is \({ }^{\text {p703 }}\) attribute:
```
<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>
```

Escaping a string (for the purposes of the algorithm above) consists of running the following steps:
1. Replace any occurrence of the " \(\delta\) " character by the string "\&amp;".
2. Replace any occurrences of the U+00AO NO-BREAK SPACE character by the string "\&nbsp;".
3. If the algorithm was invoked in the attribute mode, replace any occurrences of the "" " character by the string "\&quot;".
4. If the algorithm was not invoked in the attribute mode, replace any occurrences of the "<" character by the string "\&lt;", and any occurrences of the ">" character by the string "\&gt;".

\subsection*{12.4 Parsing HTML fragments \(\S^{p 11}\)}

The following steps form the HTML fragment parsing algorithm. The algorithm takes as input an Element node, referred to as the context element, which gives the context for the parser, as well as input, a string to parse, and returns a list of zero or more nodes.

\section*{Note}

Parts marked fragment case in algorithms in the parser section are parts that only occur if the parser was created for the purposes of this algorithm. The algorithms have been annotated with such markings for informational purposes only; such markings have no normative weight. If it is possible for a condition described as a fragment case \({ }^{\text {pl177 }}\) to occur even when the parser wasn't created for the purposes of handling this algorithm, then that is an error in the specification.
1. Create a new Document \({ }^{\text {p114 }}\) node, and mark it as being an HTML document.
2. If the node document of the context \({ }^{p 1177}\) element is in quirks mode, then let the Document \({ }^{p 114}\) be in quirks mode. Otherwise, the node document of the context \({ }^{p 1177}\) element is in limited-quirks mode, then let the Document \({ }^{p 114}\) be in limited-quirks mode. Otherwise, leave the Document \({ }^{\text {p114 }}\) in no-quirks mode.
3. Create a new HTML parser \({ }^{\text {p1079 }}\), and associate it with the just created Document \({ }^{\text {p114 }}\) node.
4. Set the state of the HTML parser \({ }^{\text {p1079' }}\) 's tokenization \({ }^{\text {p1097 }}\) stage as follows, switching on the context \({ }^{\text {p1177 }}\) element:
\(\rightarrow\) title \({ }^{\text {p154 }}\)
\(\rightarrow\) textarea \({ }^{\text {p548 }}\)
Switch the tokenizer to the RCDATA state \({ }^{p 1098}\).
```
style}\mp@subsup{}{}{p174
xmp}\mp@subsup{}{}{p1233
iframe }\mp@subsup{}{}{P361
@noembed}\mp@subsup{}{}{p1232
noframes }\mp@subsup{}{}{\mathrm{ p1232}
```

Switch the tokenizer to the RAWTEXT state \({ }^{\text {p1098 }}\).
\(\rightarrow\) script \({ }^{p 614}\)
Switch the tokenizer to the script data state \({ }^{p 1098}\).
```
|noscript }\mp@subsup{}{}{p627
```

If the scripting flag \({ }^{\text {p1096 }}\) is enabled, switch the tokenizer to the RAWTEXT state \({ }^{\text {p1098 }}\). Otherwise, leave the tokenizer in
the data state \({ }^{\text {p1098 }}\).
\(\rightarrow\) plaintext \({ }^{\text {p1232 }}\)
Switch the tokenizer to the PLAINTEXT state \({ }^{\text {p1099 }}\).

\section*{\(\rightarrow\) Any other element}

Leave the tokenizer in the data state \({ }^{\text {p1098 }}\).
Note
For performance reasons, an implementation that does not report errors and that uses the actual state machine described in this specification directly could use the PLAINTEXT state instead of the RAWTEXT and script data states where those are mentioned in the list above. Except for rules regarding parse errors, they are equivalent, since there is no appropriate end tag token \({ }^{p 1097}\) in the fragment case, yet they involve far fewer state transitions.
5. Let root be a new html \({ }^{p 152}\) element with no attributes.
6. Append the element root to the Document \({ }^{\text {p114 }}\) node created above.
7. Set up the parser's stack of open elements \({ }^{\text {p1093 }}\) so that it contains just the single element root.
8. If the context \({ }^{p 1177}\) element is a template \({ }^{\text {p629 }}\) element, push "in template \({ }^{\text {p1158" }}\) onto the stack of template insertion modes \({ }^{\text {p1092 }}\) so that it is the new current template insertion mode \({ }^{\text {p1092 }}\).
9. Create a start tag token whose name is the local name of context \({ }^{p 1177}\) and whose attributes are the attributes of context \({ }^{p 1177}\).

Let this start tag token be the start tag token of the context \({ }^{p 1177}\) node, e.g. for the purposes of determining if it is an \(\underline{H T M L}\) integration point \({ }^{\text {p1126 }}\).
10. Reset the parser's insertion mode appropriately \({ }^{\text {p1092 }}\).

Note
The parser will reference the context \({ }^{\text {p1177 }}\) element as part of that algorithm.
11. Set the parser's form element pointer \({ }^{\text {p1096 }}\) to the nearest node to the context \({ }^{p 1177}\) element that is a form \({ }^{\text {p486 }}\) element (going straight up the ancestor chain, and including the element itself, if it is a form \({ }^{\text {p486 }}\) element), if any. (If there is no such form \({ }^{\text {p486 }}\) element, the form element pointer \({ }^{\text {p1096 }}\) keeps its initial value, null.)
12. Place the input into the input stream \({ }^{\text {p1091 }}\) for the HTML parser \({ }^{\text {p1079 }}\) just created. The encoding confidence \({ }^{\text {p1086 }}\) is irrelevant.
13. Start the parser and let it run until it has consumed all the characters just inserted into the input stream.
14. Return the child nodes of root, in tree order.

\subsection*{12.5 Named character references \(\S^{p 11}\)}

This table lists the character reference names that are supported by HTML, and the code points to which they refer. It is referenced by the previous sections.

\section*{Note}

It is intentional, for legacy compatibility, that many code points have multiple character reference names. For example, some appear both with and without the trailing semicolon, or with different capitalizations.

This data is also available as a JSON file.
The glyphs displayed above are non-normative. Refer to Unicode for formal definitions of the characters listed above.

\section*{Note}

The character reference names originate from XML Entity Definitions for Characters, though only the above is considered normative. [XMLENTITY] \({ }^{\text {p1293 }}\)

\title{
13 The XML syntax \(\S^{\S_{88}^{11}}\)
}

\section*{Note}

This section only describes the rules for \(X M L\) resources. Rules for text/html \({ }^{\text {p1250 }}\) resources are discussed in the section above entitled "The HTML syntax \({ }^{\text {p10677 }}\) ".

\subsection*{13.1 Writing documents in the XML syntax \(\S^{\text {p11 }}\)}

\section*{Note}

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The syntax for XML is defined in XML and Namespaces in XML. [XML] \({ }^{\text {p1293 }}[\mathrm{XMLNS}]^{\text {p1293 }}\)
This specification does not define any syntax-level requirements beyond those defined for XML proper.
XML documents may contain a DOCTYPE if desired, but this is not required to conform to this specification. This specification does not define a public or system identifier, nor provide a formal DTD.

\section*{Note}

According to XML, XML processors are not guaranteed to process the external DTD subset referenced in the DOCTYPE. This means, for example, that using entity references for characters in XML documents is unsafe if they are defined in an external file (except for \&lt;, \&gt;, \&amp ; \&quot; and \&apos;).

\subsection*{13.2 Parsing XML documents \(\S^{\text {p11 }}\) \\ 88}

This section describes the relationship between XML and the DOM, with a particular emphasis on how this interacts with HTML.
An XML parser, for the purposes of this specification, is a construct that follows the rules given in \(X M L\) to map a string of bytes or characters into a Document \({ }^{p 114}\) object.

\section*{Note}

At the time of writing, no such rules actually exist.

An XML parser \({ }^{\text {p1188 }}\) is either associated with a Document \({ }^{\text {p114 }}\) object when it is created, or creates one implicitly.
This Document \({ }^{\text {p114 }}\) must then be populated with DOM nodes that represent the tree structure of the input passed to the parser, as defined by XML, Namespaces in XML, and DOM. When creating DOM nodes representing elements, the create an element for a token \({ }^{\text {p1127 }}\) algorithm or some equivalent that operates on appropriate XML datastructures must be used, to ensure the proper element interfaces are created and that custom elements \({ }^{\mathrm{p} 703}\) are set up correctly.

DOM mutation events must not fire for the operations that the XML parser \({ }^{p 1188}\) performs on the Document \({ }^{\text {p114 }}\) 's tree, but the user agent must act as if elements and attributes were individually appended and set respectively so as to trigger rules in this specification regarding what happens when an element is inserted into a document or has its attributes set, and DOM's requirements regarding mutation observers mean that mutation observers are fired (unlike mutation events). [XML] \({ }^{\text {p1293 }}[\text { XMLNS }]^{p 1293}[D O M]^{p 1287}\) [UIEVENTS] \({ }^{\text {p1292 }}\)

Between the time an element's start tag is parsed and the time either the element's end tag is parsed or the parser detects a wellformedness error, the user agent must act as if the element was in a stack of open elements \({ }^{\text {p1093 }}\).

This is used, e.g. by the object \({ }^{\text {p373 }}\) element to avoid instantiating plugins before the param \({ }^{\text {p378 }}\) element children have been parsed.

This specification provides the following additional information that user agents should use when retrieving an external entity: the public identifiers given in the following list all correspond to the URL given by this link. (This URL is a DTD containing the entity declarations for the names listed in the named character references \({ }^{\text {p1178 }}\) section.) [XML] \({ }^{\text {p1293 }}\)
- -//W3C//DTD XHTML 1.0 Transitional//EN
- -//W3C//DTD XHTML 1.1//EN
- -//W3C//DTD XHTML 1.0 Strict//EN
- -//W3C//DTD XHTML 1.0 Frameset//EN
- -//W3C//DTD XHTML Basic 1.0//EN
- -//W3C//DTD XHTML 1.1 plus MathML 2.0//EN
- -//W3C//DTD XHTML 1.1 plus MathML 2.0 plus SVG 1.1//EN
- -//W3C//DTD MathML 2.0//EN
- -//WAPFORUM//DTD XHTML Mobile 1.0//EN

Furthermore, user agents should attempt to retrieve the above external entity's content when one of the above public identifiers is used, and should not attempt to retrieve any other external entity's content.

\section*{Note}

This is not strictly a violation \({ }^{p 27}\) of XML, but it does contradict the spirit of XML's requirements. This is motivated by a desire for user agents to all handle entities in an interoperable fashion without requiring any network access for handling external subsets. \([X M L]^{p 1293}\)

XML parsers can be invoked with XML scripting support enabled or XML scripting support disabled. Except where otherwise specified, XML parsers are invoked with XML scripting support enabled \({ }^{\text {p1189 }}\).

When an XML parser \({ }^{\text {p1188 }}\) with XML scripting support enabled \({ }^{\text {p1189 }}\) creates a script \({ }^{\text {p614 }}\) element, it must have its parser document \({ }^{\text {p619 }}\) set and its "non-blocking" \({ }^{\text {p619 }}\) flag must be unset. If the parser was created as part of the XML fragment parsing algorithm \({ }^{\text {p11911 }}\), then the element must be marked as "already started" 0619 also. When the element's end tag is subsequently parsed, the user agent must perform a microtask checkpoint \({ }^{\text {p949 }}\), and then prepare \({ }^{\text {p620 }}\) the script \({ }^{\text {p614 }}\) element. If this causes there to be a pending parsing-blocking script \({ }^{\text {p623 }}\), then the user agent must run the following steps:
1. Block this instance of the XML parser \({ }^{\text {p1188 }}\), such that the event loop \({ }^{\text {p944 }}\) will not run tasks \({ }^{\text {p944 }}\) that invoke it.
2. Spin the event loop \({ }^{\text {p949 }}\) until the parser's Document \({ }^{\text {p114 }}\) has no style sheet that is blocking scripts \({ }^{p 178}\) and the pending parsingblocking script \({ }^{\text {p623 }}\) 's "ready to be parser-executed" \({ }^{p 619}\) flag is set.
3. Unblock this instance of the XML parser \({ }^{\text {p1188 }}\), such that tasks \({ }^{\text {p944 }}\) that invoke it can again be run.
4. Execute \({ }^{\text {p623 }}\) the pending parsing-blocking script \({ }^{\text {p623 }}\).
5. There is no longer a pending parsing-blocking script \({ }^{p 623}\).

\section*{Note}

Since the document. write() \({ }^{\text {p97e }}\) API is not available for XML documents, much of the complexity in the HTML parser \({ }^{\text {p1079 }}\) is not needed in the XML parser \({ }^{\text {p1188 }}\)

\section*{Note}

When the XML parser \({ }^{\text {p1188 }}\) has XML scripting support disabled \({ }^{p 1189}\) none of this happens.

When an XML parser \({ }^{\text {p1188 }}\) would append a node to a template \({ }^{\text {p629 }}\) element, it must instead append it to the template \({ }^{\text {p629 }}\) element's template contents \({ }^{\text {p631 }}\) (a DocumentFragment node).

\section*{Note}

This is a willful violation \({ }^{p 27}\) of XML; unfortunately, XML is not formally extensible in the manner that is needed for template \({ }^{\text {p629 }}\) processing. \([X M L]^{p 1293}\)

When an XML parser \({ }^{\text {p1188 }}\) creates a Node object, its node document must be set to the node document of the node into which the newly created node is to be inserted.

Certain algorithms in this specification spoon-feed the parser characters one string at a time. In such cases, the XML parser \({ }^{p 1188}\)
must act as it would have if faced with a single string consisting of the concatenation of all those characters.
When an XML parser \({ }^{\text {p1188 }}\) reaches the end of its input, it must stop parsing \({ }^{\text {p1165 }}\), following the same rules as the HTML parser \({ }^{\text {p1079 }}\). An XML parser \({ }^{p 1188}\) can also be aborted \({ }^{\text {p1165 }}\), which must again be done in the same way as for an HTML parser \({ }^{\text {p1079 }}\).

For the purposes of conformance checkers, if a resource is determined to be in the XML syntax \({ }^{\text {p1188 }}\), then it is an XML document.

\subsection*{13.3 Serializing XML fragments \(\S^{p 11}\)}

The XML fragment serialization algorithm for a Document \({ }^{\text {p114 }}\) or Element node either returns a fragment of XML that represents that node or throws an exception.

For Document \({ }^{p 114} \mathrm{~s}\), the algorithm must return a string in the form of a document entity, if none of the error cases below apply.
For Elements, the algorithm must return a string in the form of an internal general parsed entity, if none of the error cases below apply.
In both cases, the string returned must be XML namespace-well-formed and must be an isomorphic serialization of all of that node's relevant child nodes \({ }^{p 1190}\), in tree order. User agents may adjust prefixes and namespace declarations in the serialization (and indeed might be forced to do so in some cases to obtain namespace-well-formed XML). User agents may use a combination of regular text and character references to represent Text nodes in the DOM.

A node's relevant child nodes are those that apply given the following rules:

\section*{For template \({ }^{p 629}\) elements}

The relevant child nodes \({ }^{\text {p1190 }}\) are the child nodes of the template \({ }^{\text {p629 }}\) element's template contents \({ }^{\text {p631 }}\), if any.

\section*{For all other nodes}

The relevant child nodes \({ }^{\text {p1190 }}\) are the child nodes of node itself, if any.
For Elements, if any of the elements in the serialization are in no namespace, the default namespace in scope for those elements must be explicitly declared as the empty string. (This doesn't apply in the Document \({ }^{\text {p114 }}\) case.) [XML] \({ }^{\text {p1293 }}\) [XMLNS] \({ }^{\text {p1293 }}\)

For the purposes of this section, an internal general parsed entity is considered XML namespace-well-formed if a document consisting of an element with no namespace declarations whose contents are the internal general parsed entity would itself be XML namespace-well-formed.

If any of the following error cases are found in the DOM subtree being serialized, then the algorithm must throw an
"InvalidStateError" DOMException instead of returning a string:
- A Document \({ }^{\text {p114 }}\) node with no child element nodes.
- A DocumentType node that has an external subset public identifier that contains characters that are not matched by the XML PubidChar production. [XML] \(]^{\text {p1293 }}\)
- A DocumentType node that has an external subset system identifier that contains both a U+0022 QUOTATION MARK (") and a U+0027 APOSTROPHE (') or that contains characters that are not matched by the XML Char production. [XML] \({ }^{\text {p1293 }}\)
- A node with a local name containing a U+003A COLON (:).
- A node with a local name that does not match the XML Name production. [XML] \({ }^{\text {p1293 }}\)
- An Attr node with no namespace whose local name is the lowercase string "xmlns". [XMLNS] \({ }^{p 1293}\)
- An Element node with two or more attributes with the same local name and namespace.
- An Attr node, Text node, Comment node, or ProcessingInstruction node whose data contains characters that are not matched by the XML Char production. [XML] \({ }^{\text {p1293 }}\)
- A Comment node whose data contains two adjacent U+002D HYPHEN-MINUS characters (-) or ends with such a character.
- A ProcessingInstruction node whose target name is an ASCII case-insensitive match for the string "xml".
- A ProcessingInstruction node whose target name contains a U+003A COLON (:).
- A ProcessingInstruction node whose data contains the string "?>".

These are the only ways to make a DOM unserialisable. The DOM enforces all the other XML constraints; for example, trying to append two elements to a Document \({ }^{\text {p114 }}\) node will throw a "HierarchyRequestError" DOMException.

\subsection*{13.4 Parsing XML fragments \(\S^{\text {p11 }}\)}

The XML fragment parsing algorithm either returns a Document \({ }^{\text {p114 }}\) or throws a "SyntaxError" DOMException. Given a string input and a context element context \({ }^{\text {p1177 }}\), the algorithm is as follows:
1. Create a new XML parser \({ }^{\text {p1188 }}\).
2. Feed the parser \({ }^{\text {p1189 }}\) just created the string corresponding to the start tag of the context \({ }^{\text {p1177 }}\) element, declaring all the namespace prefixes that are in scope on that element in the DOM, as well as declaring the default namespace (if any) that is in scope on that element in the DOM.

A namespace prefix is in scope if the DOM lookupNamespaceURI () method on the element would return a non-null value for that prefix.

The default namespace is the namespace for which the DOM isDefaultNamespace() method on the element would return true.

\section*{Note}

No DOCTYPE is passed to the parser, and therefore no external subset is referenced, and therefore no entities will be recognized.
3. Feed the parser \({ }^{\text {p1189 }}\) just created the string input.
4. Feed the parser \({ }^{\text {p1189 }}\) just created the string corresponding to the end tag of the context \({ }^{p 1177}\) element.
5. If there is an XML well-formedness or XML namespace well-formedness error, then throw a "SyntaxError" DOMException.
6. If the document element of the resulting Document \({ }^{\text {p114 }}\) has any sibling nodes, then throw a "SyntaxError" DOMException.
7. Return the child nodes of the document element of the resulting Document \({ }^{\text {p114 }}\), in tree order.

\section*{14 Rendering \({ }^{\text {pp11 }}\)}

User agents are not required to present HTML documents in any particular way. However, this section provides a set of suggestions for rendering HTML documents that, if followed, are likely to lead to a user experience that closely resembles the experience intended by the documents' authors. So as to avoid confusion regarding the normativity of this section, "must" has not been used. Instead, the term "expected" is used to indicate behavior that will lead to this experience. For the purposes of conformance for user agents designated as supporting the suggested default rendering \({ }^{p 47}\), the term "expected" in this section has the same conformance implications as "must".

\subsection*{14.1 Introduction \(\S^{\text {p11 }}\) \\ 92}

In general, user agents are expected to support CSS, and many of the suggestions in this section are expressed in CSS terms. User agents that use other presentation mechanisms can derive their expected behavior by translating from the CSS rules given in this section.

In the absence of style-layer rules to the contrary (e.g. author style sheets), user agents are expected to render an element so that it conveys to the user the meaning that the element represents \({ }^{\text {p123 }}\), as described by this specification.

The suggestions in this section generally assume a visual output medium with a resolution of 96dpi or greater, but HTML is intended to apply to multiple media (it is a media-independent language). User agent implementers are encouraged to adapt the suggestions in this section to their target media.

An element is being rendered if it has any associated CSS layout boxes, SVG layout boxes, or some equivalent in other styling languages.

\section*{Note}

Just being off-screen does not mean the element is not being rendered \({ }^{p 1192}\). The presence of the hidden \({ }^{\text {p765 }}\) attribute normally means the element is not being rendered \({ }^{p 1192}\), though this might be overridden by the style sheets.

An element is said to intersect the viewport when it is being rendered \({ }^{\text {p1192 }}\) and its associated CSS layout box intersects the viewport.

\section*{Note}

This specification does not define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API. [INTERSECTIONOBSERVER] \({ }^{\text {p1288 }}\)

User agents that do not honor author-level CSS style sheets are nonetheless expected to act as if they applied the CSS rules given in these sections in a manner consistent with this specification and the relevant CSS and Unicode specifications. [CSS] \({ }^{\text {p1285 }}\) [UNICODE] \({ }^{\text {p1292 }}[\text { BIDI] }]^{\text {p1285 }}\)

\section*{Note}

This is especially important for issues relating to the 'display', 'unicode-bidi', and 'direction' properties.

\subsection*{14.2 The CSS user agent style sheet and presentational hints \(\S^{\text {p11 }}\)}

The CSS rules given in these subsections are, except where otherwise specified, expected to be used as part of the user-agent level style sheet defaults for all documents that contain HTML elements \({ }^{\text {p44 }}\).

Some rules are intended for the author-level zero-specificity presentational hints part of the CSS cascade; these are explicitly called out as presentational hints.

When the text below says that an attribute attribute on an element element maps to the pixel length property (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute's value using the rules for parsing nonnegative integers \({ }^{\text {p69 }}\) doesn't generate an error, then the user agent is expected to use the parsed value as a pixel length for a presentational hint \({ }^{\mathrm{p} 1192}\) for properties.

When the text below says that an attribute attribute on an element element maps to the dimension property (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute's value using the rules for parsing dimension values \({ }^{\mathrm{p71}}\) doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hint \({ }^{\text {p1192 }}\) for properties, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that an attribute attribute on an element element maps to the dimension property (ignoring zero) (or properties) properties, it means that if element has an attribute attribute set, and parsing that attribute's value using the rules for parsing nonzero dimension values \({ }^{\mathrm{p72}}\) doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hint \({ }^{\text {p1192 }}\) for properties, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When a user agent is to align descendants of a node, the user agent is expected to align only those descendants that have both their 'margin-inline-start' and 'margin-inline-end' properties computing to a value other than 'auto', that are over-constrained and that have one of those two margins with a used value forced to a greater value, and that do not themselves have an applicable align attribute. When multiple elements are to align \({ }^{\text {p1193 }}\) a particular descendant, the most deeply nested such element is expected to override the others. Aligned elements are expected to be aligned by having the used values of their margins on the line-left and lineright sides be set accordingly. [CSSLOGICAL] \({ }^{1286}\) [CSSWM] \({ }^{12887}\)

\subsection*{14.3 Non-replaced elements \(\S^{p 11}\)}

\subsection*{14.3.1 Hidden elements \(\S^{p 11}\)}

93
CSS
```
@namespace url(http://www.w3.org/1999/xhtml);
[hidden], area, base, basefont, datalist, head, link, meta, noembed,
noframes, param, rp, script, source, style, template, track, title {
    display: none;
}
embed[hidden] { display: inline; height: 0; width: 0; }
input[type=hidden i] { display: none !important; }
@media (scripting) {
    noscript { display: none !important; }
}
```

\subsection*{14.3.2 The page \(\S^{p 11}\)}

CSS
@namespace url(http://www.w3.org/1999/xhtml);
html, body \{ display: block; \}

For each property in the table below, given a body \({ }^{\text {p178 }}\) element, the first attribute that exists maps to the pixel length property \({ }^{\text {p1193 }}\) on the body \({ }^{p 178}\) element. If none of the attributes for a property are found, or if the value of the attribute that was found cannot be parsed successfully, then a default value of \(8 p x\) is expected to be used for that property instead.
\begin{tabular}{|c|c|}
\hline Property & Source \\
\hline \multirow[t]{3}{*}{'margin-top'} & The body \({ }^{\text {p178 }}\) element's marginheight \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's topmargin \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's container frame element \({ }^{\text {p1194's }}\) s marginheight \({ }^{\text {p1236 }}\) attribute \\
\hline
\end{tabular}
\begin{tabular}{|c|c|}
\hline Property & Source \\
\hline \multirow[t]{3}{*}{'margin-right'} & The body \({ }^{\text {p178 }}\) element's marginwidth \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's rightmargin \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's container frame element \({ }^{\text {p1194 }}\) 's marginwidth \({ }^{\text {p1236 }}\) attribute \\
\hline \multirow[t]{3}{*}{'margin-bottom'} & The body \({ }^{\text {p178 }}\) element's marginheight \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's bottommargin \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's container frame element \({ }^{\text {p1194 }}\) 's marginheight \({ }^{\text {p1236 }}\) attribute \\
\hline \multirow[t]{3}{*}{'margin-left'} & The body \({ }^{\text {p178 }}\) element's marginwidth \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's leftmargin \({ }^{\text {p1236 }}\) attribute \\
\hline & The body \({ }^{\text {p178 }}\) element's container frame element \({ }^{\text {p1194 }}\) 's marginwidth \({ }^{\text {p1236 }}\) attribute \\
\hline
\end{tabular}

If the body \({ }^{\text {p178 }}\) element's node document's browsing context \({ }^{\text {p811 }}\) is a child browsing context \({ }^{\text {p814 }}\), and the container \({ }^{\text {p814 }}\) of that browsing context \({ }^{\mathrm{p} 811}\) is a frame \({ }^{\mathrm{p} 124 \theta}\) or iframe \({ }^{\mathrm{p} 361}\) element, then the container frame element of the body \({ }^{\text {p178 }}\) element is that frame \({ }^{\text {p1240 }}\) or iframe \({ }^{\mathrm{p} 361}\) element. Otherwise, there is no container frame element \({ }^{\mathrm{p} 1194}\).

\section*{\(\triangle\) Warning!}

The above requirements imply that a page can change the margins of another page (including one from another origin \({ }^{p 837}\) ) using, for example, an iframe \({ }^{p 361}\). This is potentially a security risk, as it might in some cases allow an attack to contrive a situation in which a page is rendered not as the author intended, possibly for the purposes of phishing or otherwise misleading the user.

If a Document \({ }^{p 114}\) 's browsing context \({ }^{\text {p811 }}\) is a child browsing context \({ }^{\mathrm{p} 814}\), then it is expected to be positioned and sized to fit inside the content box of the container \({ }^{\mathrm{p} 814}\) of that browsing context \({ }^{\mathrm{p} 811}\). If the container \({ }^{\mathrm{p} 814}\) is not being rendered \({ }^{\mathrm{p} 1192}\), the browsing context \({ }^{\mathrm{p} 811}\) is expected to have a viewport with zero width and zero height.

If a Document \({ }^{p 114}\) 's browsing context \({ }^{p 811}\) is a child browsing context \({ }^{\text {p814 }}\), the container \({ }^{p 814}\) of that browsing context \({ }^{p 811}\) is a frame \({ }^{p 124 \theta}\) or iframe \({ }^{\mathrm{p} 361}\) element, that element has a scrolling attribute, and that attribute's value is an ASCII case-insensitive match for the string "off", "noscroll", or "no", then the user agent is expected to prevent any scrollbars from being shown for the viewport of the Document \({ }^{\text {p114 }}\) 's browsing context \({ }^{\text {p811 }}\), regardless of the 'overflow' property that applies to that viewport.

When a body \({ }^{\text {p178 }}\) element has a background \({ }^{p 1237}\) attribute set to a non-empty value, the new value is expected to be parsed \({ }^{p 89}\) relative to the element's node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'background-image' property to the resulting URL string \({ }^{\mathrm{p89}}\).

When a body \({ }^{\text {p178 }}\) element has a bgcolor \(r^{p 1236}\) attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\text {p86 }}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'background-color' property to the resulting color.

When a body \({ }^{\text {p178 }}\) element has a text \({ }^{\text {p1236 }}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\text {p86 }}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'color' property to the resulting color.

When a body \({ }^{\text {p178 }}\) element has a link \({ }^{\text {p1236 }}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\text {p86 }}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the 'color' property of any element in the Document \({ }^{p 114}\) matching the \(:\) link \(^{\text {p725 }}\) pseudo-class to the resulting color.

When a body \({ }^{\text {p178 }}\) element has a \(\underline{v^{2} i n k^{p 1236}}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\mathrm{p86}}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the 'color' property of any element in the Document \({ }^{\text {p114 }}\) matching the :visited \({ }^{\text {p725 }}\) pseudo-class to the resulting color.

When a body \({ }^{\text {p178 }}\) element has an alink \({ }^{\text {p1236 }}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\mathrm{p86}}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the 'color' property of any element in the Document \({ }^{\text {p114 }}\) matching the :active \({ }^{\text {p725 }}\) pseudo-class and either the :link \({ }^{\text {p725 }}\) pseudo-class or the : visited \({ }^{\text {p725 }}\) pseudo-class to the resulting color.

CsS @namespace url(http://www.w3.org/1999/xhtml);

The following rules are also expected to apply, as presentational hints \({ }^{\text {p1192 }}\) :
CsS
@namespace url(http://www.w3.org/1999/xhtml);
pre[wrap] \{ white-space: pre-wrap; \}

In quirks mode, the following rules are also expected to apply:

Css anamespace url(http://www.w3.org/1999/xhtml) ;
form \{ margin-block-end: lem; \}

The center \({ }^{p 1233}\) element, and the div \({ }^{p 237}\) element when it has an align \({ }^{p 1236}\) attribute whose value is an ASCII case-insensitive match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their 'text-align' property set to 'center' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the center.

The div \({ }^{p 237}\) element, when it has an align \({ }^{p 1236}\) attribute whose value is an ASCII case-insensitive match for the string "left", is expected to left-align text within itself, as if it had its 'text-align' property set to 'left' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{p 1193}\) to the left.

The div \({ }^{p 237}\) element, when it has an align \({ }^{p 1236}\) attribute whose value is an ASCII case-insensitive match for the string "right", is expected to right-align text within itself, as if it had its 'text-align' property set to 'right' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the right.

The div \({ }^{\text {p237 }}\) element, when it has an align \({ }^{\text {p1236 }}\) attribute whose value is an ASCII case-insensitive match for the string "justify", is expected to full-justify text within itself, as if it had its 'text-align' property set to 'justify' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the left.

\subsection*{14.3.4 Phrasing content \({ }^{86}{ }_{96}^{p 11}\)}

CSS
```
@namespace url(http://www.w3.org/1999/xhtml);
cite, dfn, em, i, var { font-style: italic; }
b, strong { font-weight: bolder; }
code, kbd, samp, tt { font-family: monospace; }
big { font-size: larger; }
small { font-size: smaller; }
sub { vertical-align: sub; }
sup { vertical-align: super; }
sub, sup { line-height: normal; font-size: smaller; }
ruby { display: ruby; }
rt { display: ruby-text; }
:link { color: #0000EE; }
:visited { color: #551A8B; }
:link:active, :visited:active { color: #FF0000; }
:link, :visited { text-decoration: underline; cursor: pointer; }
:focus { outline: auto; }
mark { background: yellow; color: black; } /* this color is just a suggestion and can be changed based
on implementation feedback */
abbr[title], acronym[title] { text-decoration: dotted underline; }
ins, u { text-decoration: underline; }
del, s, strike { text-decoration: line-through; }
q::before { content: open-quote; }
q::after { content: close-quote; }
br { display-outside: newline; } /* this also has bidi implications */
nobr { white-space: nowrap; }
wbr { display-outside: break-opportunity; } /* this also has bidi implications */
nobr wbr { white-space: normal; }
```

The following rules are also expected to apply, as presentational hints \({ }^{\text {p1192 }}\) :
```
Css @namespace url(http://www.w3.org/1999/xhtml);
br[clear=left i] { clear: left; }
br[clear=right i] { clear: right; }
br[clear=all i], br[clear=both i] { clear: both; }
```

For the purposes of the CSS ruby model, runs of children of ruby \({ }^{p 252}\) elements that are not \(r t^{p 258}\) or \(r^{p 258}\) elements are expected to be wrapped in anonymous boxes whose 'display' property has the value 'ruby-base'. [CSSRUBY] \({ }^{\text {p1286 }}\)

When a particular part of a ruby has more than one annotation, the annotations should be distributed on both sides of the base text so as to minimize the stacking of ruby annotations on one side.

When it becomes possible to do so, the preceding requirement will be updated to be expressed in terms of CSS ruby. (Currently, CSS ruby does not handle nested ruby \({ }^{\text {p252 }}\) elements or multiple sequential rt \({ }^{\text {p258 }}\) elements, which is how this semantic is expressed.)

User agents that do not support correct ruby rendering are expected to render parentheses around the text of \(r t^{p 258}\) elements in the absence of \(r p^{p 258}\) elements.

User agents are expected to support the 'clear' property on inline elements (in order to render br \({ }^{\text {p288 }}\) elements with \(c l e a r r^{p 1236}\) attributes) in the manner described in the non-normative note to this effect in CSS.

The initial value for the 'color' property is expected to be black. The initial value for the 'background-color' property is expected to be 'transparent'. The canvas's background is expected to be white.

When a font \({ }^{\text {p1233 }}\) element has a color attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\text {p86 }}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'color' property to the resulting color.

The font \({ }^{\text {p1233 }}\) element is expected to override the color of any text decoration that spans the text of the element to the used value of the element's 'color' property.

When a font \({ }^{p 1233}\) element has a face attribute, the user agent is expected to treat the attribute as a presentational hint \({ }^{p 1192}\) setting the element's 'font-family' property to the attribute's value.

When a font \({ }^{p 1233}\) element has a size attribute, the user agent is expected to use the following steps, known as the rules for parsing a legacy font size, to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'font-size' property:
1. Let input be the attribute's value.
2. Let position be a pointer into input, initially pointing at the start of the string.
3. Skip ASCII whitespace within input given position.
4. If position is past the end of input, there is no presentational hint \({ }^{\mathrm{p} 1192}\). Return.
5. If the character at position is a U+002B PLUS SIGN character (+), then let mode be relative-plus, and advance position to the next character. Otherwise, if the character at position is a U+002D HYPHEN-MINUS character (-), then let mode be relativeminus, and advance position to the next character. Otherwise, let mode be absolute.
6. Collect a sequence of code points that are ASCII digits from input given position, and let the resulting sequence be digits.
7. If digits is the empty string, there is no presentational hint \({ }^{\text {p1192 }}\). Return.
8. Interpret digits as a base-ten integer. Let value be the resulting number.
9. If mode is relative-plus, then increment value by 3 . If mode is relative-minus, then let value be the result of subtracting value from 3.
10. If value is greater than 7 , let it be 7 .
11. If value is less than 1 , let it be 1 .
12. Set 'font-size' to the keyword corresponding to the value of value according to the following table:
\begin{tabular}{l|l} 
value & 'font-size' keyword \\
\hline 1 & 'x-small' \\
\hline 2 & 'small' \\
\hline 3 & 'medium' \\
\hline 4 & 'large' \\
\hline 5 & 'x-large' \\
\hline 6 & 'xx-large' \\
\hline 7 & 'xxx-large' \\
\hline
\end{tabular}

CSS @namespace url(http://www.w3.org/1999/xhtml);
```
[dir]:dir(ltr), bdi:dir(ltr), input[type=tel i]:dir(ltr) { direction: ltr; }
```
[dir]:dir(rtl), bdi:dir(rtl) \{ direction: rtl; \}
address, blockquote, center, div, figure, figcaption, footer, form, header, hr,
legend, listing, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2,
h3, h4, h5, h6, hgroup, nav, section, table, caption, colgroup, col, thead,
tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, bdi, output,
[dir=ltr i], [dir=rtl i], [dir=auto i] \{
    unicode-bidi: isolate;
\}
bdo, bdo[dir] \{ unicode-bidi: isolate-override; \}
input[dir=auto i]:is([type=search i], [type=tel i], [type=url i],
[type=email i]), textarea[dir=auto i], pre[dir=auto i] \{
    unicode-bidi: plaintext;
\}
/* see prose for input elements whose type attribute is in the Text state */
/* the rules setting the 'content' property on br and wbr elements also has bidi implications */

When an input \({ }^{\text {p493 }}\) element's \(\underline{\text { dir }}{ }^{p 142}\) attribute is in the auto \({ }^{p 142}\) state and its type \({ }^{\text {p495 }}\) attribute is in the Text \({ }^{\text {p499 }}\) state, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'unicode-bidi' property to 'plaintext'.

Input fields (i.e. textarea \({ }^{\text {p548 }}\) elements, and input \({ }^{\text {p493 }}\) elements when their type \({ }^{\text {p495 }}\) attribute is in the Text \({ }^{\text {p499 }}\), Search \({ }^{\text {p499 }}\), Telephone \({ }^{\mathrm{p500}}, \underline{U R L^{\mathrm{L} 501}}\), or Email \({ }^{p 502}\) state) are expected to present an editing user interface with a directionality that matches the element's 'direction' property.

When the document's character encoding is ISO-8859-8, the following rules are additionally expected to apply, following those above: [ENCODING] \({ }^{\text {p1287 }}\)
```

    unicode-bidi: normal;
}
```

\subsection*{14.3.6 Quotes \(\S^{\text {pl1 }}\)}

This block is automatically generated from the Unicode Common Locale Data Repository. [CLDR] \({ }^{\text {p1285 }}\)
User agents are expected to use either the block below (which will be regularly updated) or to automatically generate their own copy directly from the source material. The language codes are derived from the CLDR file names. The quotes are derived from the delimiter blocks, with fallback handled as specified in the CLDR documentation.

\section*{14．3．7 Sections and headings §}

CsS＠namespace url（http：／／www．w3．org／1999／xhtml）；
```
article, aside, h1, h2, h3, h4, h5, h6, hgroup, nav, section {
    display: block;
}
h1 { margin-block-start: 0.67em; margin-block-end: 0.67em; font-size: 2.00em; font-weight: bold; }
h2 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; font-weight: bold; }
h3 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; font-weight: bold; }
h4 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; font-weight: bold; }
h5 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; font-weight: bold; }
h6 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; font-weight: bold; }
```

In the following CSS block，\(x\) is shorthand for the following selector：：is（article，aside，nav，section）

Css＠namespace url（http：／／www．w3．org／1999／xhtml）；
1204
```
x h1 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; }
x x h1 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; }
x x x h1 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x x x h1 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x x x h1 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
x hgroup > h1 ~ h2 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; }
x x hgroup > h1 ~ h2 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x x hgroup > h1 ~ h2 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x x hgroup > h1 ~ h2 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
x hgroup > h1 ~ h3 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x hgroup > h1 ~ h3 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x hgroup > h1 ~ h3 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
hgroup > h1 ~ h4 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x hgroup > h1 ~ h4 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
hgroup > h1 ~ h5 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
```

\section*{Note}

The shorthand is used to keep this block at least mildly readable.

\subsection*{14.3.8 Lists \(\S^{p 12}\)}

CSS @namespace url(http://www.w3.org/1999/xhtml);
```
dir, dd, dl, dt, menu, ol, ul { display: block; }
li { display: list-item; }
dir, dl, menu, ol, ul { margin-block-start: lem; margin-block-end: lem; }
:is(dir, dl, menu, ol, ul) :is(dir, dl, menu, ol, ul) {
    margin-block-start: 0; margin-block-end: 0;
}
dd { margin-inline-start: 40px; }
dir, menu, ol, ul { padding-inline-start: 40px; }
ol { list-style-type: decimal; }
dir, menu, ul {
    list-style-type: disc;
}
:is(dir, menu, ol, ul) :is(dir, menu, ul) {
    list-style-type: circle;
}
:is(dir, menu, ol, ul) :is(dir, menu, ol, ul) :is(dir, menu, ul) {
    list-style-type: square;
}
```

The following rules are also expected to apply, as presentational hints \({ }^{\text {p11922 }}\) :
ol[type=a s], li[type=a s] \{ list-style-type: lower-alpha; \}
```
ol[type=A s], li[type=A s] { list-style-type: upper-alpha; }
ol[type=i s], li[type=i s] { list-style-type: lower-roman; }
ol[type=I s], li[type=I s] { list-style-type: upper-roman; }
ul[type=none i], li[type=none i] { list-style-type: none; }
ul[type=disc i], li[type=disc i] { list-style-type: disc; }
ul[type=circle i], li[type=circle i] { list-style-type: circle; }
ul[type=square i], li[type=square i] { list-style-type: square; }
```

When rendering \(l i^{p 224}\) elements, non-CSS user agents are expected to use the ordinal value \({ }^{p 225}\) of the \(l i^{p 224}\) element to render the counter in the list item marker.

This specification does not yet define the CSS-specific rules for rendering \(l^{1 i^{2224}}\) elements, because CSS doesn't yet provide sufficient hooks for this purpose.

\subsection*{14.3.9 Tables \(\S^{p 12}\)}

CSS @namespace url(http://www.w3.org/1999/xhtml);
```
table { display: table; }
```
caption \{ display: table-caption; \}

    border-block-end-style: none;
    border-inline-start-style: solid;
}
table[rules=all i] > tr > td, table[rules=all i] > tr > th,
table[rules=all i] > thead > tr > td, table[rules=all i] > thead > tr > th,
table[rules=all i] > tbody > tr > td, table[rules=all i] > tbody > tr > th,
table[rules=all i] > tfoot > tr > td, table[rules=all i] > tfoot > tr > th {
    border-width: lpx;
    border-style: solid;
}
table[rules=groups i] > colgroup {
    border-inline-start-width: 1px;
    border-inline-start-style: solid;
```
```
    border-inline-end-width: lpx;
    border-inline-end-style: solid;
}
table[rules=groups i] > thead,
table[rules=groups i] > tbody,
table[rules=groups i] > tfoot {
    border-block-start-width: 1px;
    border-block-start-style: solid;
    border-block-end-width: 1px;
    border-block-end-style: solid;
}
table[rules=rows i] > tr, table[rules=rows i] > thead > tr,
table[rules=rows i] > tbody > tr, table[rules=rows i] > tfoot > tr {
    border-block-start-width: 1px;
    border-block-start-style: solid;
    border-block-end-width: 1px;
    border-block-end-style: solid;
}
```

In quirks mode, the following rules are also expected to apply:

CSS
```
@namespace url(http://www.w3.org/1999/xhtml);
table {
    font-weight: initial;
    font-style: initial;
    font-variant: initial;
    font-size: initial;
    line-height: initial;
    white-space: initial;
    text-align: initial;
}
```

For the purposes of the CSS table model, the col \({ }^{\text {p460 }}\) element is expected to be treated as if it was present as many times as its span \({ }^{\text {p460 }}\) attribute specifies \({ }^{\text {p69 }}\).

For the purposes of the CSS table model, the colgroup \({ }^{\text {p459 }}\) element, if it contains no col \({ }^{\text {p460 }}\) element, is expected to be treated as if it had as many such children as its span \({ }^{\text {p460 }}\) attribute specifies \({ }^{\text {p69 }}\).

For the purposes of the CSS table model, the colspan \({ }^{\text {p469 }}\) and rowspan \({ }^{\mathrm{p} 469}\) attributes on \(\mathrm{td}^{\mathrm{p} 465}\) and \(\mathrm{th}^{\mathrm{p} 467}\) elements are expected to provide \({ }^{\text {p69 }}\) the special knowledge regarding cells spanning rows and columns.

In HTML documents, the following rules are also expected to apply:

CSS @namespace url(http://www.w3.org/1999/xhtml);
:is(table, thead, tbody, tfoot, tr) > form \{ display: none !important; \}

The table \({ }^{\text {p450 }}\) element's cellspacing \({ }^{\text {p1237 }}\) attribute maps to the pixel length property \({ }^{\text {p1193 }}\) 'border-spacing' on the element.
The table \({ }^{\text {p450 }}\) element's cellpadding \({ }^{\text {p1237 }}\) attribute maps to the pixel length properties \({ }^{\text {p1193 }}\) 'padding-top', 'padding-right', 'paddingbottom', and 'padding-left' of any \(\underline{t d^{p 465}}\) and \(\underline{t h}^{\mathrm{p} 467}\) elements that have corresponding cells \({ }^{\mathrm{p} 470}\) in the table \({ }^{\mathrm{p} 470}\) corresponding to the table \({ }^{\text {p450 }}\) element.

The table \({ }^{\text {p450 }}\) element's height \({ }^{\text {p1237 }}\) attribute maps to the dimension property (ignoring zero) \({ }^{\text {p1193 }}\) 'height' on the table \({ }^{\text {p450 }}\) element. The table \({ }^{\text {p450 }}\) element's width \({ }^{p 1237}\) attribute maps to the dimension property (ignoring zero) \({ }^{\text {p1193 }}\) 'width' on the table \({ }^{\text {p450 }}\) element.

The \(c 0 t^{p 460}\) element's \(\underline{\text { width }^{p 1236}}\) attribute maps to the dimension property \({ }^{\text {p1193 }}\) 'width' on the \(c l^{\text {p466 }}\) element.
The thead \({ }^{p 462}, \underline{t b o d y^{p 461}}\), and \(\underline{\text { ffoot }^{p 463}}\) elements' height \(t^{p 1237}\) attribute maps to the dimension property \({ }^{p 1193}\) 'height' on the element.
The \(\underline{t r^{p 464}}\) element's height \(t^{p 1237}\) attribute maps to the dimension property (ignoring zero) \({ }^{\text {p1193 }}\) 'height' on the \(\underline{t^{p 464}}\) element.
The \(\underline{t d^{p 465}}\) and \(\underline{t h^{p 467}}\) elements' height \({ }^{\text {p1237 }}\) attributes map to the dimension property (ignoring zero) \({ }^{\text {p1193 }}\) 'height' on the element.
The \(\underline{t d^{p 465}}\) and \(\underline{t h^{\mathrm{p} 467}}\) elements' \(\underline{\text { width }^{\mathrm{p} 1237}}\) attributes map to the dimension property (ignoring zero) \({ }^{\mathrm{p} 1193}\) 'width' on the element.

The \(t h e a d^{p 462}, ~ t b o d y y^{p 461}, ~ t f o o t^{p 463}, ~ t r^{p 464}, ~ t d^{\text {p465 }}\), and \(t h^{\text {p467 }}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their 'text-align' property set to 'center' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the center.

The \(\underline{t h e a d}{ }^{\mathrm{p} 462}, \underline{t b o d y}{ }^{\mathrm{p} 461}, \underline{t f o o t^{\mathrm{p} 463}}, \underline{\mathrm{tr}^{\mathrm{p} 464}}, \underline{\mathrm{td}^{\mathrm{p} 465}}\), and \(\underline{\mathrm{th}^{\mathrm{p} 467}}\) elements, when they have an align attribute whose value is an \(\underline{\text { ASCII }}\) case-insensitive match for the string "left", are expected to left-align text within themselves, as if they had their 'text-align' property set to 'left' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the left.

The thead \({ }^{p 462}\), \(t\) body \(y^{p 461}, \underline{t f o o t} t^{p 463}, \underline{t r^{p 464}}, \underline{t d^{p 465}}\), and \(t^{p 467}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for the string "right", are expected to right-align text within themselves, as if they had their 'text-align' property set to 'right' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the right.

The \(t h e a d^{p 462}, \underline{t b o d y} y^{p 461}, \underline{t f o o t^{p 463}}, \underline{t r^{p 464}}, \underline{t d^{p 465}}\), and \(\underline{t h^{p 467}}\) elements, when they have an align attribute whose value is an ASCII case-insensitive match for the string "justify", are expected to full-justify text within themselves, as if they had their 'text-align' property set to 'justify' in a presentational hint \({ }^{\text {p1192 }}\), and to align descendants \({ }^{\text {p1193 }}\) to the left.

User agents are expected to have a rule in their user agent style sheet that matches \(t h^{\text {p467 }}\) elements that have a parent node whose computed value for the 'text-align' property is its initial value, whose declaration block consists of just a single declaration that sets the 'text-align' property to the value 'center'.

When a \(t a b l e^{p 450}, t h e a d^{p 462}, t b o d y y^{p 461}, ~ t f o o t^{p 463}, t r^{p 464}, t d^{p 465}\), or \(t h^{p 467}\) element has a background \({ }^{p 1237}\) attribute set to a non-empty value, the new value is expected to be parsed \({ }^{p 89}\) relative to the element's node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'background-image' property to the resulting URL string \({ }^{\text {p89 }}\).

When a \(t a b l e^{p 450}, ~ t h e a d^{p 462}, ~ t b o d y y^{p 461}, ~ t f o o t^{p 463}, \underline{t r}{ }^{p 464}, \underline{t d^{p 465}}\), or \(\underline{t h}{ }^{p 467}\) element has a bgcolor attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\mathrm{p} 86}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{p 1192}\) setting the element's 'background-color' property to the resulting color.

When a table \({ }^{\text {p450 }}\) element has a bordercolor \({ }^{p 1237}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\text {p86 }}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'border-top-color', 'border-right-color', 'border-bottom-color', and 'border-left-color' properties to the resulting color.

The table \({ }^{\text {p450 }}\) element's border \({ }^{p 1237}\) attribute maps to the pixel length properties \({ }^{\text {p1193 }}\) 'border-top-width', 'border-right-width', 'border-bottom-width', 'border-left-width' on the element. If the attribute is present but parsing the attribute's value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) generates an error, a default value of \(1 p x\) is expected to be used for that property instead.

Rules marked "only if border is not equivalent to zero" in the CSS block above is expected to only be applied if the border \({ }^{\text {p1237 }}\) attribute mentioned in the selectors for the rule is not only present but, when parsed using the rules for parsing non-negative integers \({ }^{\text {p69 }}\), is also found to have a value other than zero or to generate an error.

In quirks mode, a \(t d^{p 465}\) element or ath \(h^{p 467}\) element that has a nowrap \({ }^{p 1237}\) attribute but also has a width \({ }^{p 1237}\) attribute whose value, when parsed using the rules for parsing nonzero dimension values \({ }^{\mathrm{p72}}\), is found to be a length (not an error or a number classified as a percentage), is expected to have a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'white-space' property to 'normal', overriding the rule in the CSS block above that sets it to 'nowrap'.

\subsection*{14.3.10 Margin collapsing quirks \(\S^{p 12}\)}

A node is substantial if it is a text node that is not inter-element whitespace \({ }^{\text {p129 }}\), or if it is an element node.
A node is blank if it is an element that contains no substantial \({ }^{\text {p1211 }}\) nodes.
The elements with default margins are the following elements: blockquote \({ }^{\mathrm{p} 217}, ~ d i r^{p 1232}, ~ \underset{l^{p 226}}{ }, ~ h 1^{\mathrm{p} 199}, ~ h 2^{\mathrm{p} 199}, ~ h 3^{\mathrm{p} 199}, ~ h 4^{\mathrm{p} 199}, ~ h 5^{\mathrm{p} 199}\), \(h^{p 196}\), listing \({ }^{p 1232}\), menu \(^{p 223}\), ol \(^{p 22 \theta}, p^{p 211}\), plaintext \({ }^{p 1232}\), pre \(^{p 216}, \underline{u^{p 222}}\), xmp \(^{p 1233}\)

In quirks mode, any element with default margins \({ }^{\text {p1211 }}\) that is the child of a body \({ }^{p 178}\), \(\underline{t d^{p 465}}\), or \(t^{\text {p467 }}\) element and has no substantial \({ }^{\text {p1211 }}\) previous siblings is expected to have a user-agent level style sheet rule that sets its 'margin-block-start' property to zero.

In quirks mode, any element with default margins \({ }^{\mathrm{p} 1211}\) that is the child of a body \({ }^{\mathrm{p} 178}\), \(\underline{\mathrm{td}^{\mathrm{p} 465}}\), or \(\underline{\mathrm{h}}^{\mathrm{p} 467}\) element, has no substantial \({ }^{\mathrm{p} 1211}\) previous siblings, and is blank \({ }^{\text {p1211 }}\), is expected to have a user-agent level style sheet rule that sets its 'margin-block-end' property to zero also.

In quirks mode, any element with default margins \({ }^{\text {p1211 }}\) that is the child of a \(\underline{t^{p 465}}\) or \(\underline{t^{p 467}}\) element, has no substantial \({ }^{p 1211}\) following siblings, and is blank \({ }^{\text {p1211 }}\), is expected to have a user-agent level style sheet rule that sets its 'margin-block-start' property to zero.

In quirks mode, any \(p^{p 211}\) element that is the child of a \(t d^{p 465}\) or \(t h^{p 467}\) element and has no substantial \({ }^{p 1211}\) following siblings, is expected to have a user-agent level style sheet rule that sets its 'margin-block-end' property to zero.

\subsection*{14.3.11 Form controls \(\S^{p 12}\)}

11
CSS
```
@namespace url(http://www.w3.org/1999/xhtml);
input, select, button, textarea {
    letter-spacing: initial;
    word-spacing: initial;
    line-height: initial;
    text-transform: initial;
    text-indent: initial;
    text-shadow: initial;
}
input, select, textarea {
    text-align: initial;
}
input:is([type=reset i], [type=button i], [type=submit i]), button {
    text-align: center;
}
input:is([type=reset i], [type=button i], [type=submit i], [type=color i]), button {
    display: inline-block;
}
input:is([type=radio i], [type=checkbox i], [type=reset i], [type=button i],
[type=submit i], [type=color i], [type=search i]), select, button {
    box-sizing: border-box;
}
textarea { white-space: pre-wrap; }
```

In quirks mode, the following rules are also expected to apply:
@namespace url(http://www.w3.org/1999/xhtml);
input:not([type=image i]), textarea \{ box-sizing: border-box; \}

Each kind of form control is also described in the Widgets \({ }^{\text {p1219 }}\) section, which describes the look and feel of the control.
14.3.12 The \(\mathrm{hr}^{\mathrm{p} 214}\) element \(\S^{\mathrm{p} 12}\)

CSS @namespace url(http://www.w3.org/1999/xhtml);
hr \{
color: gray;
border-style: inset;
border-width: lpx;
margin-block-start: 0.5em;
margin-inline-end: auto;
margin-block-end: 0.5 em ;
margin-inline-start: auto;
overflow: hidden;
\}

The following rules are also expected to apply, as presentational hints \({ }^{\text {p1192 }}\) :
css
```
@namespace url(http://www.w3.org/1999/xhtml);
hr[align=left i] { margin-left: 0; margin-right: auto; }
hr[align=right i] { margin-left: auto; margin-right: 0; }
hr[align=center i] { margin-left: auto; margin-right: auto; }
hr[color], hr[noshade] { border-style: solid; }
```

If an \(h r^{p 214}\) element has either a color \(r^{p 1236}\) attribute or a noshade \({ }^{\text {p1236 }}\) attribute, and furthermore also has a size \({ }^{p 1236}\) attribute, and parsing that attribute's value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) doesn't generate an error, then the user agent is expected to use the parsed value divided by two as a pixel length for presentational hints \({ }^{\text {p1192 }}\) for the properties 'border-top-width', 'border-right-width', 'border-bottom-width', and 'border-left-width' on the element.

Otherwise, if an \(h r^{p 214}\) element has neither a color \({ }^{p 1236}\) attribute nor a noshade \({ }^{p 1236}\) attribute, but does have a size \({ }^{p 1236}\) attribute, and parsing that attribute's value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) doesn't generate an error, then: if the parsed value is one, then the user agent is expected to use the attribute as a presentational hint \({ }^{\mathrm{p1192}}\) setting the element's 'border-bottom-width' to 0; otherwise, if the parsed value is greater than one, then the user agent is expected to use the parsed value minus two as a pixel length for presentational hints \({ }^{\text {p1192 }}\) for the 'height' property on the element.

The width \({ }^{\mathrm{p} 1236}\) attribute on an \(\mathrm{hr}^{\mathrm{p} 214}\) element maps to the dimension property \({ }^{\text {p1193 }}\) 'width' on the element.
When an \(h^{r^{p 214}}\) element has a color \({ }^{p 1236}\) attribute, its value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\text {p86 }}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'color' property to the resulting color.

\subsection*{14.3.13 The fieldset \({ }^{p 562}\) and legend \({ }^{p 565}\) elements \(\S_{12}^{p 12}\)}
fieldset \{
    display: block;
    margin-inline-start: 2px;
    margin-inline-end: \(2 p x\);
    border: groove 2px ThreeDFace;
    padding-block-start: 0.35 em ;
    padding-inline-end: 0.75 em ;
    padding-block-end: 0.625 em ;
    padding-inline-start: 0.75 em ;
    min-inline-size: min-content;
```
}
legend {
    padding-inline-start: 2px; padding-inline-end: 2px;
}
legend[align=left i] {
    justify-self: left;
}
legend[align=center i] {
    justify-self: center;
}
legend[align=right i] {
    justify-self: right;
}
```

The fieldset \({ }^{\mathrm{p562}}\) element, when it generates a CSS box, is expected to act as follows:
- The element is expected to establish a new block formatting context.
- The 'display' property is expected to act as follows:
- If the computed value of 'display' is a value such that the outer display type is 'inline', then behave as 'inlineblock'.
- Otherwise, behave as 'flow-root'.

\section*{Note}

This does not change the computed value.
- If the element's box has a child box that matches the conditions in the list below, then the first such child box is the 'fieldset' element's rendered legend:
- The child is a legend \({ }^{p 565}\) element.
- The child's used value of 'float' is 'none'.
- The child's used value of 'position' is not 'absolute' or 'fixed'.
- If the element has a rendered legend \({ }^{p 1213}\), then the border is expected to not be painted behind the rectangle defined as follows, using the writing mode of the fieldset:
1. The block-start edge of the rectangle is the smaller of the block-start edge of the rendered legend \({ }^{\text {p1213 }}\) 's margin rectangle at its static position (ignoring transforms), and the block-start outer edge of the fieldset \({ }^{\text {p562' }}\) s border.
2. The block-end edge of the rectangle is the larger of the block-end edge of the rendered legend \({ }^{p 1213}\) 's margin rectangle at its static position (ignoring transforms), and the block-end outer edge of the fieldset \({ }^{\mathrm{p} 562}\) 's border.
3. The inline-start edge of the rectangle is the smaller of the inline-start edge of the rendered legend \({ }^{\text {p1213 }}\) 's border rectangle at its static position (ignoring transforms), and the inline-start outer edge of the fieldset \({ }^{p 562}\) 's border.
4. The inline-end edge of the rectangle is the larger of the inline-end edge of the rendered legend \({ }^{p 1213}\) ' \(s\) border rectangle at its static position (ignoring transforms), and the inline-end outer edge of the fieldset \({ }^{\text {p562' }} \mathrm{s}\) border.
- The space allocated for the element's border on the block-start side is expected to be the element's 'border-block-start-width' or the rendered legend \({ }^{\text {p1213 }}\) 's margin box size in the fieldset \({ }^{p 562}\) 's block-flow direction, whichever is greater.
- For the purpose of calculating the used 'block-size', if the computed 'block-size' is not 'auto', the space allocated for the rendered legend \({ }^{\text {p1213 }}\) 's margin box that spills out past the border, if any, is expected to be substracted from the 'block-size'. If the content box's block-size would be negative, then let the content box's block-size be zero instead.
- If the element has a rendered legend \({ }^{\text {p1213 }}\), then that element is expected to be the first child box.
- The anonymous fieldset content box \({ }^{p 1214}\) is expected to appear after the rendered legend \({ }^{p 1213}\) and is expected to contain the content (including the '::before' and '::after' pseudo-elements) of the fieldset \({ }^{p 562}\) element except for the rendered legend \({ }^{p 1213}\), if there is one.
- The used value of the 'padding-top', 'padding-right', 'padding-bottom', and 'padding-left' properties are expected to be zero.
- For the purpose of calculating the min-content inline size, use the greater of the min-content inline size of the rendered legend \({ }^{\text {p1213 }}\) and the min-content inline size of the anonymous fieldset content box \({ }^{\text {p1214 }}\).
- For the purpose of calculating the max-content inline size, use the greater of the max-content inline size of the rendered legend \({ }^{\text {p1213 }}\) and the max-content inline size of the anonymous fieldset content box \({ }^{\text {p1214 }}\).

A fieldset \({ }^{\text {p562 }}\) element's rendered legend \({ }^{p 1213}\), if any, is expected to act as follows:
- The element is expected to establish a new formatting context for its contents. The type of this formatting context is determined by its 'display' value, as usual.
- The 'display' property is expected to behave as if its computed value was blockified.

\section*{Note}

This does not change the computed value.
- If the computed value of 'inline-size' is 'auto', then the used value is the fit-content inline size.
- The element is expected to be positioned in the inline direction as is normal for blocks (e.g., taking into account margins and the 'justify-self' property).
- The element's box is expected to be constrained in the inline direction by the inline content size of the fieldset \({ }^{p 562}\) as if it had used its computed inline padding.

\section*{Example}

For example, if the fieldset \({ }^{p 562}\) has a specified padding of 50 px , then the rendered legend \({ }^{\text {p1213 }}\) will be positioned 50 px in from the fieldset \({ }^{p 562}\) 's border. The padding will further apply to the anonymous fieldset content box \({ }^{\text {p1214 }}\) instead of the fieldset \({ }^{\text {p562 }}\) element itself.
- The element is expected to be positioned in the block-flow direction such that its border box is centered over the border on the block-start side of the fieldset \({ }^{p 562}\) element.

A fieldset \({ }^{\text {p562 }}\) element's anonymous fieldset content box is expected to act as follows:
- The 'display' property is expected to act as follows:
- If the computed value of 'display' on the fieldset \({ }^{p 562}\) element is 'grid' or 'inline-grid', then set the used value to 'grid'.
- If the computed value of 'display' on the fieldset \({ }^{\text {p562 }}\) element is 'flex' or 'inline-flex', then set the used value to 'flex'.
- Otherwise, set the used value to 'flow-root'.
- The following properties are expected to inherit from the fieldset \({ }^{\text {p562 }}\) element:
```
'align-content'
'align-items'
'border-radius'
'column-count'
'column-fill'
'column-gap'
'column-rule'
'column-width'
'flex-direction'
'flex-wrap'
'grid-auto-columns'
'grid-auto-flow'
'grid-auto-rows'
'grid-column-gap'
'grid-row-gap'
'grid-template-areas'
'grid-template-columns'
'grid-template-rows'
'justify-content'
'justify-items'
'overflow'
'padding-bottom'
'padding-left'
- 'padding-right'
```
- The 'block-size' property is expected to be set to ' \(100 \%\) '.
- For the purpose of calculating percentage padding, act as if the padding was calculated for the fieldset \({ }^{\text {p562 }}\) element.

The legend is rendered over the top border, and the top border area reserves vertical space for the legend. The fieldset's top margin starts at the top margin edge of the legend. The legend's horizontal margins, or the 'justify-self property, gives its horizontal position. The anonymous fieldset content box \({ }^{p 1214}\) appears below the legend.

\subsection*{14.4 Replaced elements \(\S^{p 12}\)}

\section*{Note}
 video \({ }^{\text {p380 }}\).

\subsection*{14.4.1 Embedded content \(\S^{\text {p12 }}\) \\ 15}

The embed \({ }^{\mathrm{p} 369}\), iframe \({ }^{\mathrm{p} 361}\), and video \({ }^{\mathrm{p} 338}\) elements are expected to be treated as replaced elements.
A canvas \({ }^{p 634}\) element that represents \({ }^{\text {p123 }}\) embedded content \(^{p 132}\) is expected to be treated as a replaced element; the contents of such elements are the element's bitmap, if any, or else a transparent black bitmap with the same intrinsic dimensions as the element. Other canvas \({ }^{\text {p634 }}\) elements are expected to be treated as ordinary elements in the rendering model.

An object \({ }^{\text {p373 }}\) element that represents \({ }^{\text {p123 }}\) an image, plugin, or its nested browsing context \({ }^{\text {p814 }}\) is expected to be treated as a replaced element. Other object \({ }^{\text {p373 }}\) elements are expected to be treated as ordinary elements in the rendering model.

The audio \({ }^{\text {p384 }}\) element, when it is exposing a user interface \({ }^{\text {p436 }}\), is expected to be treated as a replaced element about one line high, as wide as is necessary to expose the user agent's user interface features. When an audio \({ }^{\text {p384 }}\) element is not exposing a user interface \({ }^{\text {p436 }}\), the user agent is expected to force its 'display' property to compute to 'none', irrespective of CSS rules.

Whether a video \({ }^{\text {p388 }}\) element is exposing a user interface \({ }^{\text {p436 }}\) is not expected to affect the size of the rendering; controls are expected to be overlaid above the page content without causing any layout changes, and are expected to disappear when the user does not need them.

When a video \({ }^{\text {p388 }}\) element represents a poster frame or frame of video, the poster frame or frame of video is expected to be rendered at the largest size that maintains the aspect ratio of that poster frame or frame of video without being taller or wider than the video \({ }^{\text {p380 }}\) element itself, and is expected to be centered in the video \({ }^{\text {p388 }}\) element.

Any subtitles or captions are expected to be overlayed directly on top of their video \({ }^{\text {p380 }}\) element, as defined by the relevant rendering rules; for WebVTT, those are the rules for updating the display of WebVTT text tracks. [WEBVTT] \({ }^{\text {p1292 }}\)

When the user agent starts exposing a user interface \({ }^{\text {p436 }}\) for a video \({ }^{p 388}\) element, the user agent should run the rules for updating the text track rendering \({ }^{\mathrm{p} 423}\) of each of the text tracks \({ }^{\mathrm{p} 421}\) in the \({\underline{\text { video }}{ }^{\mathrm{p} 380}}^{\text {element's }}\) list of text tracks \({ }^{\text {p421 }}\) that are showing \({ }^{\text {p423 }}\) and whose text track kind \({ }^{\mathrm{p} 421}\) is one of subtitles \({ }^{\mathrm{p} 422}\) or captions \({ }^{\mathrm{p} 422}\) (e.g., for text tracks \({ }^{\mathrm{p} 421}\) based on WebVTT, the rules for updating the display of WebVTT text tracks). [WEBVTT] \({ }^{\text {p1292 }}\)

\section*{Note}

Resizing video \({ }^{\text {p380 }}\) and canvas \({ }^{\text {p634 }}\) elements does not interrupt video playback or clear the canvas.

The following CSS rules are expected to apply:
css
@namespace url(http://www.w3.org/1999/xhtml);
iframe \{ border: 2px inset; \}
video \{ object-fit: contain; \}

\subsection*{14.4.2 Images \(\S^{p 12}\) \\ 16}

User agents are expected to render \(\underline{i m g}{ }^{\text {p320 }}\) elements and input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attributes are in the Image Button \({ }^{\text {p518 }}\) state, according to the first applicable rules from the following list:

\section*{\(\rightarrow\) If the element represents \({ }^{\text {p123 }}\) an image}

The user agent is expected to treat the element as a replaced element and render the image according to the rules for doing so defined in CSS.
\(\hookrightarrow\) If the element does not represent \({ }^{\text {p123 }}\) an image and either:
- the user agent has reason to believe that the image will become available \({ }^{\text {p336 }}\) and be rendered in due course, or
- the element has no alt attribute, or
- the Document \({ }^{p 114}\) is in quirks mode, and the element already has intrinsic dimensions (e.g., from the dimension attributes \({ }^{\text {p449 }}\) or CSS rules)

The user agent is expected to treat the element as a replaced element whose content is the text that the element represents, if any, optionally alongside an icon indicating that the image is being obtained (if applicable). For input \({ }^{\text {p493 }}\) elements, the element is expected to appear button-like to indicate that the element is a button \({ }^{\text {p486 }}\).
\(\hookrightarrow\) If the element is an img \({ }^{\text {p326 }}\) element that represents \({ }^{\text {p123 }}\) some text and the user agent does not expect this to change
The user agent is expected to treat the element as a non-replaced phrasing element whose content is the text, optionally with an icon indicating that an image is missing, so that the user can request the image be displayed or investigate why it is not rendering. In non-graphical contexts, such an icon should be omitted.
\(\hookrightarrow\) If the element is an \(\underline{\mathrm{img}}^{\mathrm{p} 329}\) element that represents \({ }^{\text {p123 }}\) nothing and the user agent does not expect this to change The user agent is expected to treat the element as a replaced element whose intrinsic dimensions are 0 . (In the absence of further styles, this will cause the element to essentially not be rendered.)
\(\leftrightarrow\) If the element is an input \({ }^{\text {p493 }}\) element that does not represent \({ }^{\text {p123 }}\) an image and the user agent does not expect this to change

The user agent is expected to treat the element as a replaced element consisting of a button whose content is the element's alternative text. The intrinsic dimensions of the button are expected to be about one line in height and whatever width is necessary to render the text on one line.

The icons mentioned above are expected to be relatively small so as not to disrupt most text but be easily clickable. In a visual environment, for instance, icons could be 16 pixels by 16 pixels square, or 1 em by 1 em if the images are scalable. In an audio environment, the icon could be a short bleep. The icons are intended to indicate to the user that they can be used to get to whatever options the UA provides for images, and, where appropriate, are expected to provide access to the context menu that would have
come up if the user interacted with the actual image.

All animated images with the same absolute URL and the same image data are expected to be rendered synchronized to the same timeline as a group, with the timeline starting at the time of the least recent addition to the group.

\section*{Note}

In other words, when a second image with the same absolute URL and animated image data is inserted into a document, it jumps to the point in the animation cycle that is currently being displayed by the first image.

When a user agent is to restart the animation for an img \({ }^{\text {p320 }}\) element showing an animated image, all animated images with the same absolute URL and the same image data in that img \({ }^{\text {p320 }}\) element's node document are expected to restart their animation from the beginning.

The following CSS rules are expected to apply when the Document \({ }^{\text {p114 }}\) is in quirks mode:

CSS @namespace url(http://www.w3.org/1999/xhtml)
```
img[align=left i] { margin-right: 3px; }
```
img[align=right i] \{ margin-left: 3px; \}

\subsection*{14.4.3 Attributes for embedded content and images \(\S_{17}^{172}\)}

The following CSS rules are expected to apply as presentational hints \({ }^{\text {p1192 }}\) :

CSS @namespace url(http://www.w3.org/1999/xhtml);
```
iframe[frameborder='0'], iframe[frameborder=no i] { border: none; }
embed[align=left i], iframe[align=left i], img[align=left i],
input[type=image i][align=left i], object[align=left i] {
    float: left;
}
embed[align=right i], iframe[align=right i], img[align=right i],
input[type=image i][align=right i], object[align=right i] {
    float: right;
}
embed[align=top i], iframe[align=top i], img[align=top i],
input[type=image i][align=top i], object[align=top i] {
    vertical-align: top
}
embed[align=baseline i], iframe[align=baseline i], img[align=baseline i],
input[type=image i][align=baseline i], object[align=baseline i] {
    vertical-align: baseline;
}
embed[align=texttop i], iframe[align=texttop i], img[align=texttop i],
input[type=image i][align=texttop i], object[align=texttop i] {
    vertical-align: text-top;
}
```
embed[align=absmiddle i], iframe[align=absmiddle i], img[align=absmiddle i],
input[type=image i][align=absmiddle i], object[align=absmiddle i],
embed[align=abscenter i], iframe[align=abscenter i], img[align=abscenter i],
```
input[type=image i][align=abscenter i], object[align=abscenter i] {
    vertical-align: middle;
}
embed[align=bottom i], iframe[align=bottom i], img[align=bottom i],
input[type=image i][align=bottom i], object[align=bottom i] {
    vertical-align: bottom;
}
```

When an embed \({ }^{\text {p369 }}\), iframe \({ }^{\text {p361 }}\), img \({ }^{\text {p329 }}\), or object \({ }^{\text {p373 }}\) element, or an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Image Button \({ }^{\text {p518 }}\) state, has an align attribute whose value is an ASCII case-insensitive match for the string "center" or the string "middle", the user agent is expected to act as if the element's 'vertical-align' property was set to a value that aligns the vertical middle of the element with the parent element's baseline.

The hspace attribute of embed \({ }^{\text {p369 }}\), \(\underline{\text { img }}{ }^{\text {p329 }}\), or object \(t^{\text {p373 }}\) elements, and input \({ }^{\text {p493 }}\) elements with a type \({ }^{\text {p495 }}\) attribute in the Image Button \({ }^{\text {p518 }}\) state, maps to the dimension properties \({ }^{\text {p1193 }}\) 'margin-left' and 'margin-right' on the element.

The vspace attribute of embed \({ }^{\mathrm{p} 369}\), \(\underline{i m g}^{\mathrm{p} 329}\), or object \(\mathrm{t}^{\mathrm{p} 373}\) elements, and input \({ }^{\text {p493 }}\) elements with a type \({ }^{\text {p495 }}\) attribute in the Image Button \({ }^{\text {p518 }}\) state, maps to the dimension properties \({ }^{\text {p1193 }}\) 'margin-top' and 'margin-bottom' on the element.

When an \(\underline{i m g}^{\text {p326 }}\) element, object \({ }^{\text {p373 }}\) element, or input \({ }^{\text {p493 }}\) element with a typp \({ }^{\text {p495 }}\) attribute in the Image Button \({ }^{\text {p518 }}\) state has a border attribute whose value, when parsed using the rules for parsing non-negative integers \({ }^{\text {p69 }}\), is found to be a number greater than zero, the user agent is expected to use the parsed value for eight presentational hints \({ }^{\text {p1192 }}\) : four setting the parsed value as a pixel length for the element's 'border-top-width', 'border-right-width', 'border-bottom-width', and 'border-left-width' properties, and four setting the element's 'border-top-style', 'border-right-style', 'border-bottom-style', and 'border-left-style' properties to the value 'solid'.

The width \({ }^{\text {p449 }}\) and height \({ }^{\text {p449 }}\) attributes on embed \({ }^{\text {p369 }}\), iframe \({ }^{\text {p361 }}\), img \(^{\text {p320 }}\), object \(t^{\text {p373 }}\) or video \({ }^{\text {p389 }}\) elements, and input \({ }^{\text {p493 }}\) elements with a type \({ }^{\text {p495 }}\) attribute in the Image Button \({ }^{\text {p518 }}\) state and that either represents an image or that the user expects will eventually represent an image, map to the dimension properties \({ }^{\text {p1193 }}\) 'width' and 'height' on the element respectively.

The intrinsic aspect ratio for an \(\underline{\mathrm{img}^{\mathrm{p} 32 \theta}}\) element img is computed as follows:
1. If img's current request \({ }^{\mathrm{p} 336}\) is available \({ }^{\mathrm{p} 336}\) and has an intrinsic aspect ratio, then use that intrinsic aspect ratio.
2. If img's width \({ }^{p 449}\) and height \({ }^{\text {p449 }}\) attribute values, when parsed using the rules for parsing dimension values \({ }^{\text {p71 }}\), are both not an error, not a percentage, and non-zero, then use the ratio resulting from dividing the width \({ }^{\text {p449 }}\) attribute value by the height \({ }^{\text {p449 }}\) attribute value.
3. Otherwise, img has no intrinsic aspect ratio.

\subsection*{14.4.4 Image maps \(\S^{p 12}\)}

Shapes on an image map \({ }^{\text {p445 }}\) are expected to act, for the purpose of the CSS cascade, as elements independent of the original area \({ }^{\text {p443 }}\) element that happen to match the same style rules but inherit from the \(i^{\text {mg }^{\text {p320 }}}\) or object \({ }^{p 373}\) element.

For the purposes of the rendering, only the 'cursor' property is expected to have any effect on the shape.

\section*{Example}

Thus, for example, if an area \({ }^{\text {p443 }}\) element has a style \({ }^{p 144}\) attribute that sets the 'cursor' property to 'help', then when the user designates that shape, the cursor would change to a Help cursor.

\section*{Example}

Similarly, if an area \({ }^{\text {p443 }}\) element had a CSS rule that set its 'cursor' property to 'inherit' (or if no rule setting the 'cursor' property matched the element at all), the shape's cursor would be inherited from the img \(^{\text {p320 }}\) or object \({ }^{\text {p373 }}\) element of the image map \({ }^{\text {p445 }}\), not from the parent of the area \({ }^{\text {p443 }}\) element.

\subsection*{14.5 Widgets \(\S^{p 12}\)}

\subsection*{14.5.1 Introduction \(\S_{19}^{\text {p12 }}\)}

The elements defined in this section can be rendered in a variety of manners, within the guidelines provided below. User agents are encouraged to set the 'appearance' CSS property appropriately to achieve platform-native appearances for widgets, and are expected to implement any relevant animations, etc, that are appropriate for the platform.

\subsection*{14.5.2 Button layout \({ }_{19}^{\text {p12 }}\)}

Button layout is as follows:
- The 'display' property is expected to act as follows:
- If the computed value of 'display' is 'inline-grid', 'grid', 'inline-flex', or 'flex', then behave as the computed value.
- Otherwise, if the computed value of 'display' is a value such that the outer display type is 'inline', then behave as 'inline-block'.
- Otherwise, behave as 'flow-root'.
- The element is expected to establish a new formatting context for its contents. The type of this formatting context is determined by its 'display' value, as usual.
- If the element is absolutely positioned, then for the purpose of the CSS visual formatting model, act as if the element is a replaced element. [CSS] \({ }^{\text {p1285 }}\)
- If the computed value of 'inline-size' is 'auto', then the used value is the fit-content inline size.
- For the purpose of the 'normal' keyword of the 'align-self' property, act as if the element is a replaced element.
- If the element is an input \({ }^{p 493}\) element, or if it is a button \({ }^{p 535}\) element and its computed value for 'display' is not 'inline-grid', 'grid', 'inline-flex', or 'flex', then the element's box has a child anonymous button content box with the following behaviors:
- The box is a block-level block container that establishes a new block formatting context (i.e., 'display' is 'flow-root').
- If the box does not overflow in the horizontal axis, then it is centered horizontally.
- If the box does not overflow in the vertical axis, then it is centered vertically.

Otherwise, there is no anonymous button content box \({ }^{p 1219}\).
14.5.3 The button \({ }^{\text {p535 }}\) element \(\S_{19}^{p 12}\)

The button \({ }^{\text {p535 }}\) element, when it generates a CSS box, is expected to depict a button and to use button layout \({ }^{\text {p1219 }}\) whose anonymous button content box \({ }^{\text {p1219 }}\) 's contents (if there is an anonymous button content box \({ }^{\text {p1219 }}\) ) are the child boxes the element's box would otherwise have.
14.5.4 The details \({ }^{\text {p604 }}\) and summary \({ }^{\text {p607 }}\) elements \(\S^{\text {p12 }}\)
```
@namespace url(http://www.w3.org/1999/xhtml);
```
summary \{
    display: list-item;
    counter-increment: list-item 0;
    list-style: disclosure-closed inside;
\}
details[open] > summary \{
    list-style-type: disclosure-open;

The details \({ }^{\text {p604 }}\) element is expected to render as a block box. The element is also expected to have an internal shadow tree with two slots, both rendered as a block box. The first slot is expected to take the details \({ }^{p 604}\) element's first summary \({ }^{p 607}\) element child, if any. The second slot is expected to take the details \({ }^{\text {p604 }}\) element's remaining descendants, if any.

The first slot is expected to allow the user to request the details be shown or hidden.
The second slot is expected to be removed from the rendering when the details \({ }^{\text {p664 }}\) element does not have an open \({ }^{\text {p604 }}\) attribute.

\subsection*{14.5.5 The input \({ }^{\text {p493 }}\) element as a text entry widget \(\S^{\text {p12 }}\)}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Text \({ }^{\text {p499 }}\), Search \({ }^{\text {p499 }}\), Telephone \({ }^{\text {p500 }}\), URL \({ }^{\text {p501 }}\), or Email \({ }^{\text {p502 }}\) state, is expected to render as an 'inline-block' box depicting a text control. Additionally, the 'line-height' property, if it has a computed value equivalent to a value that is less than 1.0, must have a used value of 1.0.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Password \({ }^{\text {p503 }}\) state is expected to render as an 'inline-block' box depicting a text control that obscures data entry.

If these text controls provide a text selection, then, when the user changes the current selection, the user agent is expected to queue an element task \({ }^{\text {p946 }}\) on the user interaction task source \({ }^{\text {p952 }}\) given the input \({ }^{\text {p493 }}\) element to fire an event named select \({ }^{\text {p1282 }}\) at the element, with the bubbles attribute initialized to true.

If an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in one of the above states has a size \({ }^{p 522}\) attribute, and parsing that attribute's value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint \({ }^{\text {p1192 }}\) for the 'width' property on the element, with the value obtained from applying the converting a character width to pixels \({ }^{\text {p1220 }}\) algorithm to the value of the attribute.

If an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in one of the above states does not have a size \({ }^{\text {p522 }}\) attribute, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'width' property on the element to the value obtained from applying the converting a character width to pixels \({ }^{\text {p1220 }}\) algorithm to the number 20.

The converting a character width to pixels algorithm returns (size-1) \(\times a v g+m a x\), where size is the character width to convert, \(a v g\) is the average character width of the primary font for the element for which the algorithm is being run, in pixels, and max is the maximum character width of that same font, also in pixels. (The element's 'letter-spacing' property does not affect the result.)

\section*{}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Date \({ }^{\text {p504 }}\) state is expected to render as an 'inline-block' box depicting a date control.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Month \({ }^{\text {p505 }}\) state is expected to render as an 'inline-block' box depicting a month control.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Week \({ }^{\text {p506 }}\) state is expected to render as an 'inline-block' box depicting a week control.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Time \({ }^{\text {p507 }}\) state is expected to render as an 'inline-block' box depicting a time control.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Local Date and Time \({ }^{\text {p508 }}\) state is expected to render as an 'inline-block' box depicting a local date and time control.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Number \({ }^{\text {p509 }}\) state is expected to render as an 'inline-block' box depicting a number control.

These controls are all expected to be about one line high, and about as wide as necessary to show the widest possible value.

\subsection*{14.5.7 The input \({ }^{\text {p493 }}\) element as a range control \(\S^{\text {p12 }}\)}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Range \({ }^{\text {p510 }}\) state is expected to render as an 'inline-block' box depicting a slider control.

When the control is wider than it is tall (or square), the control is expected to be a horizontal slider, with the lowest value on the right if the 'direction' property on this element has a computed value of 'rtl', and on the left otherwise. When the control is taller than it is wide, it is expected to be a vertical slider, with the lowest value on the bottom.

Predefined suggested values (provided by the list \({ }^{p 528}\) attribute) are expected to be shown as tick marks on the slider, which the slider can snap to.

User agents are expected to use the used value of the 'direction' property on the element to determine the direction in which the slider operates. Typically, a left-to-right ('Itr') horizontal control would have the lowest value on the left and the highest value on the right, and vice versa.

\subsection*{14.5.8 The input \({ }^{\text {p493 }}\) element as a color well \(\S^{\text {p12 }}\)}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{p 495}\) attribute is in the Color \({ }^{\text {p513 }}\) state is expected to depict a color well, which, when activated, provides the user with a color picker (e.g. a color wheel or color palette) from which the color can be changed. The element, when it generates a CSS box, is expected to use button layout \({ }^{\text {p1219 }}\), that has no child boxes of the anonymous button content box \({ }^{\text {p1219 }}\). The anonymous button content box \({ }^{\text {p1219 }}\) is expected to have a presentational hint \({ }^{\mathrm{p} 1192}\) setting the 'background-color' property to the element's value \({ }^{\text {p566 }}\).

Predefined suggested values (provided by the list \({ }^{p 528}\) attribute) are expected to be shown in the color picker interface, not on the color well itself.

\subsection*{14.5.9 The input \({ }^{\text {p493 }}\) element as a checkbox and radio button widgets \(\S^{\text {p12 }}\)}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Checkbox \({ }^{\text {p513 }}\) state is expected to render as an 'inline-block' box containing a single checkbox control, with no label.

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Radio Button \({ }^{\text {p514 }}\) state is expected to render as an 'inline-block' box containing a single radio button control, with no label.

\subsection*{14.5.10 The input \({ }^{\text {p493 }}\) element as a file upload control \(\S_{21}^{\text {p12 }}\)}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the File Upload \({ }^{\text {p515 }}\) state, when it generates a CSS box, is expected to render as an 'inline-block' box containing a span of text giving the file name(s) of the selected files \({ }^{\text {p515 }}\), if any, followed by a button that, when activated, provides the user with a file picker from which the selection can be changed. The button is expected to use button layout \({ }^{\text {p1219 }}\) and the contents of the anonymous button content box \({ }^{\text {p1219 }}\) are expected to be implementation-defined (and possibly localespecific) text, for example "Choose file".

\subsection*{14.5.11 The input \({ }^{\text {p493 }}\) element as a button \(\S^{\text {p12 }}\)}

An input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Submit Button \({ }^{\text {p518 }}\), Reset Button \({ }^{\text {p520 }}\), or Button \({ }^{\text {p521 }}\) state, when it generates a CSS box, is expected to depict a button and use button layout \({ }^{\text {p1219 }}\) and the contents of the anonymous button content box \({ }^{\text {p1219 }}\) are expected to be the text of the element's value \({ }^{\text {p497 }}\) attribute, if any, or text derived from the element's type \({ }^{\text {p495 }}\) attribute in an implementation-defined (and probably locale-specific) fashion, if not.

CSS @namespace url(http://www.w3.org/1999/xhtml);
marquee \{
display: inline-block;
text-align: initial;
\}

The marquee \({ }^{\text {p1237 }}\) element, while turned on \({ }^{\text {p1238 }}\), is expected to render in an animated fashion according to its attributes as follows:
If the element's behavior \({ }^{\text {p1238 }}\) attribute is in the scroll \({ }^{\text {p1238 }}\) state
Slide the contents of the element in the direction described by the direction \({ }^{p 1238}\) attribute as defined below, such that it begins off the start side of the marquee \({ }^{p 1237}\), and ends flush with the inner end side.

Example
For example, if the direction \({ }^{p 1238}\) attribute is left \({ }^{\text {p1238 }}\) (the default), then the contents would start such that their left edge are off the side of the right edge of the marquee \({ }^{\text {p1237' }}\) s content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the marquee \({ }^{\text {p1237' }} \mathrm{s}\) content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index \({ }^{\text {p1239 }}\). If the element is still turned on \({ }^{\text {p1238 }}\) after this, then the user agent is expected to restart the animation.

If the element's behavior \({ }^{\text {p1238 }}\) attribute is in the slide \({ }^{\text {p1238 }}\) state
Slide the contents of the element in the direction described by the direction \({ }^{p 1238}\) attribute as defined below, such that it begins off the start side of the marquee \({ }^{\text {p1237 }}\), and ends off the end side of the marquee \({ }^{\text {p1237 }}\).

\section*{Example}

For example, if the direction \({ }^{p 1238}\) attribute is left \({ }^{p 1238}\) (the default), then the contents would start such that their left edge are off the side of the right edge of the marquee \({ }^{\text {p1237' }} \mathrm{s}\) content area, and the contents would then slide up to the point where the right edge of the contents are flush with the left inner edge of the marquee \({ }^{\mathrm{p} 1237}\) 's content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index \({ }^{\text {p1239 }}\). If the element is still turned on \({ }^{\text {p1238 }}\) after this, then the user agent is expected to restart the animation.

If the element's behavior \({ }^{\text {p1238 }}\) attribute is in the alternate \({ }^{\text {p1238 }}\) state
When the marquee current loop index \({ }^{\text {p1239 }}\) is even (or zero), slide the contents of the element in the direction described by the direction \({ }^{\text {p1238 }}\) attribute as defined below, such that it begins flush with the start side of the marquee \({ }^{\text {p1237 }}\), and ends flush with the end side of the marquee \({ }^{\text {p1237 }}\).

When the marquee current loop index \({ }^{\text {p1239 }}\) is odd, slide the contents of the element in the opposite direction than that described by the direction \({ }^{\text {p1238 }}\) attribute as defined below, such that it begins flush with the end side of the marquee \({ }^{\text {p1237 }}\), and ends flush with the start side of the marquee \({ }^{p 1237}\).

\section*{Example}

For example, if the direction \({ }^{p 1238}\) attribute is left \({ }^{p 1238}\) (the default), then the contents would with their right edge flush with the right inner edge of the marquee \({ }^{\text {p1237 }}\) 's content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the marquee \({ }^{\text {p1237' }}\) 's content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index \({ }^{\text {p1239 }}\). If the element is still turned on \({ }^{\text {p1238 }}\) after this, then the user agent is expected to continue the animation.

The direction \({ }^{\text {p1238 }}\) attribute has the meanings described in the following table:
\begin{tabular}{l|l|l|l|l} 
direction \(^{\text {p1238 }}\) attribute state & Direction of animation & Start edge & End edge & Opposite direction \\
\hline left \(^{\text {p1238 }}\) & \(\leftarrow\) Right to left & Right & Left & \(\rightarrow\) Left to Right \\
\hline right \(^{\text {p1238 }}\) & \(\rightarrow\) Left to Right & Left & Right & \(\leftarrow\) Right to left \\
\hline up \(^{\text {p1238 }}\) & \(\uparrow\) Up (Bottom to Top) & Bottom & Top & \(\downarrow\) Down (Top to Bottom) \\
\hline down \(^{\text {p1238 }}\) & \(\downarrow\) Down (Top to Bottom) & Top & Bottom & \(\uparrow\) Up (Bottom to Top) \\
\hline
\end{tabular}

In any case, the animation should proceed such that there is a delay given by the marquee scroll interval \({ }^{\text {p1238 }}\) between each frame, and such that the content moves at most the distance given by the marquee scroll distance \({ }^{\text {p1239 }}\) with each frame.

When a marquee \({ }^{p 1237}\) element has a bgcolor attribute set, the value is expected to be parsed using the rules for parsing a legacy color value \({ }^{\mathrm{p86}}\), and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint \({ }^{\text {p1192 }}\) setting the element's 'background-color' property to the resulting color.

The width and height attributes on a marquee \({ }^{p 1237}\) element map to the dimension properties \({ }^{\text {p1193 }}\) 'width' and 'height' on the element respectively.

The intrinsic height of a marquee \({ }^{\text {p1237 }}\) element with its direction \({ }^{\text {p1238 }}\) attribute in the up \({ }^{\text {p1238 }}\) or down \({ }^{\text {p1238 }}\) states is 200 CSS pixels.
The vspace attribute of a marquee \({ }^{\text {p1237 }}\) element maps to the dimension properties \({ }^{p 1193}\) 'margin-top' and 'margin-bottom' on the element. The hspace attribute of a marquee \({ }^{\text {p1237 }}\) element maps to the dimension properties \({ }^{\text {p1193 }}\) 'margin-left' and 'margin-right' on the element.

The 'overflow' property on the marquee \({ }^{\text {p1237 }}\) element is expected to be ignored; overflow is expected to always be hidden.

\subsection*{14.5.13 The meter \({ }^{\text {p557 }}\) element \(\S^{\text {p12 }}\)}

The meter \({ }^{p 557}\) element is expected to render as an 'inline-block' box with a 'height' of ' 1 em ' and a 'width' of '5em', a 'vertical-align' of '-0.2em', and with its contents depicting a gauge.

When the element is wider than it is tall (or square), the depiction is expected to be of a horizontal gauge, with the minimum value on the right if the 'direction' property on this element has a computed value of 'rtl', and on the left otherwise. When the element is taller than it is wide, it is expected to depict a vertical gauge, with the minimum value on the bottom.

User agents are expected to use a presentation consistent with platform conventions for gauges, if any.

\section*{Note}

Requirements for what must be depicted in the gauge are included in the definition of the meter \({ }^{\text {p557 }}\) element.

\subsection*{14.5.14 The progress \({ }^{p 555}\) element \(\S^{\text {p12 }}\)}

The progress \({ }^{p 555}\) element is expected to render as an 'inline-block' box with a 'height' of '1em' and a 'width' of '10em', and a 'verticalalign' of '-0.2em'.

When the element is wider than it is tall, the element is expected to be depicted as a horizontal progress bar, with the start on the right and the end on the left if the 'direction' property on this element has a computed value of 'rtl', and with the start on the left and the end on the right otherwise. When the element is taller than it is wide, it is expected to be depicted as a vertical progress bar, with the lowest value on the bottom. When the element is square, it is expected to be depicted as a directionindependent progress widget (e.g. a circular progress ring).

User agents are expected to use a presentation consistent with platform conventions for progress bars. In particular, user agents are expected to use different presentations for determinate and indeterminate progress bars. User agents are also expected to vary the presentation based on the dimensions of the element.

\section*{Example}

For example, on some platforms for showing indeterminate progress there is a "spinner" progress indicator with square dimensions, which could be used when the element is square, and an indeterminate progress bar, which could be used when the element is wide.

Requirements for how to determine if the progress bar is determinate or indeterminate, and what progress a determinate progress bar is to show, are included in the definition of the progress \({ }^{p 555}\) element.

\subsection*{14.5.15 The select \({ }^{\text {p537 }}\) element \({ }_{24}^{\text {p12 }}\)}

A select \({ }^{\text {p537 }}\) element is either a list box or a drop-down box, depending on its attributes.
A select \({ }^{\text {p537 }}\) element whose multiple \({ }^{p 539}\) attribute is present is expected to render as a multi-select list box \({ }^{\text {p1224 }}\).
A select \({ }^{p 537}\) element whose multiple \({ }^{p 539}\) attribute is absent, and whose display size \({ }^{p 539}\) is greater than 1 , is expected to render as a single-select list box \({ }^{\text {p1224 }}\).

When the element renders as a list box \({ }^{\text {p1224 }}\), it is expected to render as an 'inline-block' box whose 'height' is the height necessary to contain as many rows for items as given by the element's display size \({ }^{\text {p539 }}\), or four rows if the attribute is absent, and whose 'width' is the width of the select's labels \({ }^{\text {p1224 }}\) plus the width of a scrollbar.

A select \({ }^{\text {p537 }}\) element whose multiple \({ }^{\text {p539 }}\) attribute is absent, and whose display size \({ }^{\text {p539 }}\) is 1 , is expected to render as a one-line dropdown box \({ }^{\text {p1224 }}\) whose width is the width of the select's labels \({ }^{\text {p1224 }}\).

In either case (list box \({ }^{\text {p1224 }}\) or drop-down box \({ }^{\text {p1224 }}\) ), the element's items are expected to be the element's list of options \({ }^{p 539}\), with the element's optgroup \({ }^{p 544}\) element children providing headers for groups of options where applicable.

An optgroup \({ }^{\mathrm{p} 544}\) element is expected to be rendered by displaying the element's label \({ }^{\mathrm{p} 545}\) attribute.
An option \({ }^{\text {p545 }}\) element is expected to be rendered by displaying the element's label \({ }^{p 546}\), indented under its optgroup \({ }^{\text {p544 }}\) element if it has one.

The width of the select's labels is the wider of the width necessary to render the widest optgroup \({ }^{p 544}\), and the width necessary to render the widest option \({ }^{\mathrm{p} 545}\) element in the element's list of options \({ }^{\mathrm{p} 539}\) (including its indent, if any).

If a select \({ }^{\text {p537 }}\) element contains a placeholder label option \({ }^{\text {p539 }}\), the user agent is expected to render that option \({ }^{\text {p545 }}\) in a manner that conveys that it is a label, rather than a valid option of the control. This can include preventing the placeholder label option \({ }^{\text {p539 }}\) from being explicitly selected by the user. When the placeholder label option \({ }^{\text {p539' }}\) s selectedness \({ }^{\text {p547 }}\) is true, the control is expected to be displayed in a fashion that indicates that no valid option is currently selected.

User agents are expected to render the labels in a select \({ }^{\text {p537 }}\) in such a manner that any alignment remains consistent whether the label is being displayed as part of the page or in a menu control.

\subsection*{14.5.16 The textarea \({ }^{\text {p548 }}\) element \({ }_{{ }_{24}{ }^{\text {p12 }}}\)}

The textarea \({ }^{p 548}\) element is expected to render as an 'inline-block' box depicting a multiline text control. If this multiline text control provides a selection, then, when the user changes the current selection, the user agent is expected to queue an element task \({ }^{\text {p946 }}\) on the user interaction task source \({ }^{p 952}\) given the textarea \({ }^{p 548}\) element to fire an event named select \({ }^{p 1282}\) at the element, with the bubbles attribute initialized to true.

If the element has a cols \({ }^{p 550}\) attribute, and parsing that attribute's value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint \({ }^{p 1192}\) for the 'width' property on the element, with the value being the textarea effective width \({ }^{\text {p1224 }}\) (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'width' property on the element to the textarea effective width \({ }^{\text {p1224 }}\).

The textarea effective width of a textarea \({ }^{p 548}\) element is size \(\times a v g+s b w\), where size is the element's character width \({ }^{\mathrm{p550}}\), \(a v g\) is the average character width of the primary font of the element, in CSS pixels, and sbw is the width of a scrollbar, in CSS pixels. (The element's 'letter-spacing' property does not affect the result.)

If the element has a rows \({ }^{\mathrm{p} 550}\) attribute, and parsing that attribute's value using the rules for parsing non-negative integers \({ }^{\mathrm{p} 69}\) doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint \({ }^{\text {p1192 }}\) for the 'height' property on the element, with the value being the textarea effective height \({ }^{p 1225}\) (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'height' property on the element to the textarea effective height \({ }^{\text {p1225 }}\).

The textarea effective height of a textarea \({ }^{p 548}\) element is the height in CSS pixels of the number of lines specified the element's character height \({ }^{\text {p550 }}\), plus the height of a scrollbar in CSS pixels.

User agents are expected to apply the 'white-space' CSS property to textarea \({ }^{\mathrm{p548}}\) elements. For historical reasons, if the element has a wrap \({ }^{\text {p551 }}\) attribute whose value is an ASCII case-insensitive match for the string "off", then the user agent is expected to treat the attribute as a presentational hint \({ }^{p 1192}\) setting the element's 'white-space' property to 'pre'.

\subsection*{14.6 Frames and framesets \(\S^{\text {p12 }}\)}

User agent are expected to render frameset \({ }^{\text {p1239 }}\) elements as a box with the height and width of the viewport, with a surface rendered according to the following layout algorithm:
1. The cols and rows variables are lists of zero or more pairs consisting of a number and a unit, the unit being one of percentage, relative, and absolute.

Use the rules for parsing a list of dimensions \({ }^{\mathrm{p73}}\) to parse the value of the element's cols attribute, if there is one. Let cols be the result, or an empty list if there is no such attribute.

Use the rules for parsing a list of dimensions \({ }^{\text {p73 }}\) to parse the value of the element's rows attribute, if there is one. Let rows be the result, or an empty list if there is no such attribute.
2. For any of the entries in cols or rows that have the number zero and the unit relative, change the entry's number to one.
3. If cols has no entries, then add a single entry consisting of the value 1 and the unit relative to cols.

If rows has no entries, then add a single entry consisting of the value 1 and the unit relative to rows.
4. Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values \({ }^{p 1226}\) using cols as the input list, and the width of the surface that the frameset \({ }^{\text {p1239 }}\) is being rendered into, in CSS pixels, as the input dimension. Let sized cols be the resulting list.

Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values \({ }^{\text {p1226 }}\) using rows as the input list, and the height of the surface that the frameset \({ }^{\text {p1239 }}\) is being rendered into, in CSS pixels, as the input dimension. Let sized rows be the resulting list.
5. Split the surface into a grid of \(w \times h\) rectangles, where \(w\) is the number of entries in sized cols and \(h\) is the number of entries in sized rows.

Size the columns so that each column in the grid is as many CSS pixels wide as the corresponding entry in the sized cols list.
Size the rows so that each row in the grid is as many CSS pixels high as the corresponding entry in the sized rows list.
6. Let children be the list of frame \({ }^{p 124 \theta}\) and frameset \(t^{p 1239}\) elements that are children of the frameset \({ }^{p 1239}\) element for which the algorithm was invoked.
7. For each row of the grid of rectangles created in the previous step, from top to bottom, run these substeps:
1. For each rectangle in the row, from left to right, run these substeps:
1. If there are any elements left in children, take the first element in the list, and assign it to the rectangle.

If this is a frameset \({ }^{p 1239}\) element, then recurse the entire frameset \({ }^{p 1239}\) layout algorithm for that frameset \({ }^{p 1239}\) element, with the rectangle as the surface.

Otherwise, it is a frame \({ }^{\text {p1248 }}\) element; render its nested browsing context \({ }^{\text {p814 }}\), positioned and sized to fit the rectangle.
2. If there are any elements left in children, remove the first element from children.
8. If the frameset \(t^{p 1239}\) element has a border \({ }^{\text {p1226 }}\), draw an outer set of borders around the rectangles, using the element's frame border color \({ }^{\text {p1226 }}\).

For each rectangle, if there is an element assigned to that rectangle, and that element has a border \({ }^{\text {p1226 }}\), draw an inner set of borders around that rectangle, using the element's frame border color \({ }^{\text {p1226 }}\).

For each (visible) border that does not abut a rectangle that is assigned a frame \({ }^{\text {p1240 }}\) element with a noresize attribute
(including rectangles in further nested frameset \({ }^{p 1239}\) elements), the user agent is expected to allow the user to move the border, resizing the rectangles within, keeping the proportions of any nested frameset \({ }^{\text {p1239 }}\) grids.

A frameset \({ }^{p 1239}\) or frame \({ }^{p 124 \theta}\) element has a border if the following algorithm returns true:
1. If the element has a frameborder attribute whose value is not the empty string and whose first character is either a U+0031 DIGIT ONE (1) character, a U+0079 LATIN SMALL LETTER Y character (y), or a U+0059 LATIN CAPITAL LETTER \(Y\) character \((\mathrm{Y})\), then return true.
2. Otherwise, if the element has a frameborder attribute, return false.
3. Otherwise, if the element has a parent element that is a frameset \({ }^{\text {p1239 }}\) element, then return true if that element has a border \({ }^{\text {p1226 }}\), and false if it does not.
4. Otherwise, return true.

The frame border color of a frameset \({ }^{p 1239}\) or \(f r a m e^{p 124 \theta}\) element is the color obtained from the following algorithm:
1. If the element has a bordercolor attribute, and applying the rules for parsing a legacy color value \({ }^{\text {p86 }}\) to that attribute's value does not result in an error, then return the color so obtained.
2. Otherwise, if the element has a parent element that is a frameset \({ }^{\text {p1239 }}\) element, then return the frame border color \({ }^{\text {p1226 }}\) of that element.
3. Otherwise, return gray.

The algorithm to convert a list of dimensions to a list of pixel values consists of the following steps:
1. Let input list be the list of numbers and units passed to the algorithm.

Let output list be a list of numbers the same length as input list, all zero.
Entries in output list correspond to the entries in input list that have the same position.
2. Let input dimension be the size passed to the algorithm.
3. Let count percentage be the number of entries in input list whose unit is percentage.

Let total percentage be the sum of all the numbers in input list whose unit is percentage.
Let count relative be the number of entries in input list whose unit is relative.
Let total relative be the sum of all the numbers in input list whose unit is relative.
Let count absolute be the number of entries in input list whose unit is absolute.
Let total absolute be the sum of all the numbers in input list whose unit is absolute.
Let remaining space be the value of input dimension.
4. If total absolute is greater than remaining space, then for each entry in input list whose unit is absolute, set the corresponding value in output list to the number of the entry in input list multiplied by remaining space and divided by total absolute. Then, set remaining space to zero.

Otherwise, for each entry in input list whose unit is absolute, set the corresponding value in output list to the number of the entry in input list. Then, decrement remaining space by total absolute.
5. If total percentage multiplied by the input dimension and divided by 100 is greater than remaining space, then for each entry in input list whose unit is percentage, set the corresponding value in output list to the number of the entry in input list multiplied by remaining space and divided by total percentage. Then, set remaining space to zero.

Otherwise, for each entry in input list whose unit is percentage, set the corresponding value in output list to the number of the entry in input list multiplied by the input dimension and divided by 100. Then, decrement remaining space by total percentage multiplied by the input dimension and divided by 100.
6. For each entry in input list whose unit is relative, set the corresponding value in output list to the number of the entry in input list multiplied by remaining space and divided by total relative.
7. Return output list.

User agents working with integer values for frame widths (as opposed to user agents that can lay frames out with subpixel accuracy)
are expected to distribute the remainder first to the last entry whose unit is relative, then equally (not proportionally) to each entry whose unit is percentage, then equally (not proportionally) to each entry whose unit is absolute, and finally, failing all else, to the last entry.

The contents of a frame \({ }^{p 124 \theta}\) element that does not have a frameset \({ }^{p 1239}\) parent are expected to be rendered as transparent black; the user agent is expected to not render its nested browsing context \({ }^{\text {p814 }}\) in this case, and its nested browsing context \({ }^{\text {p814 }}\) is expected to have a viewport with zero width and zero height.

\subsection*{14.7 Interactive media \(\S^{\text {p12 }}\)}

\subsection*{14.7.1 Links, forms, and navigation \(\S^{p 12}\)}

User agents are expected to allow the user to control aspects of hyperlink \({ }^{\text {p283 }}\) activation and form submission \({ }^{\text {p595 }}\), such as which browsing context \({ }^{\text {p811 }}\) is to be used for the subsequent navigation \({ }^{\text {p866 }}\).

User agents are expected to allow users to discover the destination of hyperlinks \({ }^{\mathrm{p} 283}\) and of forms \({ }^{\text {p486 }}\) before triggering their navigation \({ }^{\text {p866 }}\).

User agents are expected to inform the user of whether a hyperlink \({ }^{\text {p283 }}\) includes hyperlink auditing \({ }^{\text {p293 }}\), and to let them know at a minimum which domains will be contacted as part of such auditing.

User agents may allow users to navigate \({ }^{p 866}\) browsing contexts \({ }^{\text {p811 }}\) to the URLs indicated \({ }^{p 89}\) by the cite attributes on \(q^{p 247}\), blockquote \({ }^{\mathrm{p} 217}\), ins \({ }^{\mathrm{p} 311}\), and del \({ }^{\mathrm{p312}}\) elements.

User agents may surface hyperlinks \({ }^{\text {p283 }}\) created by link \({ }^{p 157}\) elements in their user interface.

\section*{Note}

While link \({ }^{p 157}\) elements that create hyperlinks \({ }^{p 283}\) will match the : link \(^{p 725}\) or : visited \({ }^{p 725}\) pseudo-classes, will react to clicks if visible, and so forth, this does not extend to any browser interface constructs that expose those same links. Activating a link through the browser's interface, rather than in the page itself, does not trigger click events and the like.

\subsection*{14.7.2 The title \({ }^{\text {p139 }}\) attribute \(\S^{\S^{p 12}}\)}

User agents are expected to expose the advisory information \({ }^{\text {p139 }}\) of elements upon user request, and to make the user aware of the presence of such information.

On interactive graphical systems where the user can use a pointing device, this could take the form of a tooltip. When the user is unable to use a pointing device, then the user agent is expected to make the content available in some other fashion, e.g. by making the element a focusable area \({ }^{\mathrm{p} 770}\) and always displaying the advisory information \({ }^{\mathrm{p} 139}\) of the currently focused \({ }^{\mathrm{p} 771}\) element, or by showing the advisory information \({ }^{\text {p139 }}\) of the elements under the user's finger on a touch device as the user pans around the screen.

U+000A LINE FEED (LF) characters are expected to cause line breaks in the tooltip; U+0009 CHARACTER TABULATION (tab) characters are expected to render as a nonzero horizontal shift that lines up the next glyph with the next tab stop, with tab stops occurring at points that are multiples of 8 times the width of a U+0020 SPACE character.

\section*{Example}

For example, a visual user agent could make elements with a title \({ }^{\text {p139 }}\) attribute focusable \({ }^{\text {p772 }}\), and could make any focused \({ }^{\text {p771 }}\) element with a title \({ }^{\text {p139 }}\) attribute show its tooltip under the element while the element has focus. This would allow a user to tab around the document to find all the advisory text.

\section*{Example}

As another example, a screen reader could provide an audio cue when reading an element with a tooltip, with an associated key to read the last tooltip for which a cue was played.

\subsection*{14.7.3 Editing hosts \(\S^{p 12}\) \\ 28}

The current text editing caret (i.e. the active range, if it is empty and in an editing host \({ }^{\text {p789 }}\) ), if any, is expected to act like an inline replaced element with the vertical dimensions of the caret and with zero width for the purposes of the CSS rendering model.

\section*{Note}

This means that even an empty block can have the caret inside it, and that when the caret is in such an element, it prevents margins from collapsing through the element.

\subsection*{14.7.4 Text rendered in native user interfaces \(\S^{\text {p12 }}\)}

User agents are expected to honor the Unicode semantics of text that is exposed in user interfaces, for example supporting the bidirectional algorithm in text shown in dialogs, title bars, popup menus, and tooltips. Text from the contents of elements is expected to be rendered in a manner that honors the directionality \({ }^{\text {p142 }}\) of the element from which the text was obtained. Text from attributes is expected to be rendered in a manner that honours the directionality of the attribute \({ }^{\text {p143 }}\).

\section*{Example}

Consider the following markup, which has Hebrew text asking for a programming language, the languages being text for which a left-to-right direction is important given the punctuation in some of their names:
```
<p dir="rtl" lang="he">
    <label>
        בחר שפת תכנות:
> select>
        <option dir="ltr">C++</option>
        <option dir="ltr">C#</option>
        <option dir="ltr">FreePascal</option>
        <option dir="ltr">F#</option>
    </select>
    </label>
</p>
```

If the select \({ }^{\text {p537 }}\) element was rendered as a drop down box, a correct rendering would ensure that the punctuation was the same both in the drop down, and in the box showing the current selection.

\section*{Example}

The directionality of attributes depends on the attribute and on the element's dir \({ }^{\text {p142 }}\) attribute, as the following example demonstrates. Consider this markup:
```

<table>
    <tr>
    <th abbr="(א" dir=ltr>A
    <th abbr="(א" dir=rtl>A
    <th abbr="(א" dir=auto>A
</table>
```

If the abbr \({ }^{p 468}\) attributes are rendered, e.g. in a tooltip or other user interface, the first will have a left parenthesis (because the direction is 'Itr'), the second will have a right parenthesis (because the direction is 'rtl'), and the third will have a right parenthesis (because the direction is determined from the attribute value to be 'rtl').

However, if instead the attribute was not a directionality-capable attribute \({ }^{\text {p143 }}\), the results would be different:
```

<table>
    <tr>
    <th data-abbr="(א" dir=ltr>A
    <th data-abbr="(א" dir=rtl>A
    <th data-abbr="(א" dir=auto>A
</table>
```

In this case, if the user agent were to expose the data-abbr attribute in the user interface (e.g. in a debugging environment), the last case would be rendered with a left parenthesis, because the direction would be determined from the element's contents.

A string provided by a script (e.g. the argument to window. alert ( \()^{\text {p977 }}\) ) is expected to be treated as an independent set of one or more bidirectional algorithm paragraphs when displayed, as defined by the bidirectional algorithm, including, for instance, supporting the paragraph-breaking behavior of U+000A LINE FEED (LF) characters. For the purposes of determining the paragraph level of such text in the bidirectional algorithm, this specification does not provide a higher-level override of rules P2 and P3. [BIDI] \({ }^{\text {p1285 }}\)

When necessary, authors can enforce a particular direction for a given paragraph by starting it with the Unicode U+200E LEFT-TORIGHT MARK or U+200F RIGHT-TO-LEFT MARK characters.

\section*{Example}

Thus, the following script:
```

alert('\u05DC\u05DE\u05D3 HTML \u05D4\u05D9\u05D5\u05DD!')

```
...would always result in a message reading "למד HTML (המד" היום HTML היום "), regardless of the language of the user agent interface or the direction of the page or any of its elements.

\section*{Example}

For a more complex example, consider the following script:
```

/* Warning: this script does not handle right-to-left scripts correctly */
var s;
if (s = prompt('What is your name?')) {
alert(s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
}

```

When the user enters "Kitty", the user agent would alert "Kitty! Ok, Fred, Kitty, and Wilma will get the car.".
However, if the user enters "لا أ فهم", then the bidirectional algorithm will determine that the direction of the paragraph is right-to-

To force an alert that starts with user-provided text (or other text of unknown directionality) to render left-to-right, the string can be prefixed with a U+200E LEFT-TO-RIGHT MARK character:
```

var s;
if (s = prompt('What is your name?')) {
alert('\u200E' + s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
}

```

\subsection*{14.8 Print media \(\S^{\text {p12 }}\)}

User agents are expected to allow the user to request the opportunity to obtain a physical form (or a representation of a physical form) of a Document \({ }^{\text {p114 }}\). For example, selecting the option to print a page or convert it to PDF format. [PDF] \({ }^{\text {p1289 }}\)

When the user actually obtains a physical form \({ }^{\text {p1229 }}\) (or a representation of a physical form) of a Document \({ }^{\text {p114 }}\), the user agent is
expected to create a new rendering of the Document \({ }^{\text {p114 }}\) for the print media.

\subsection*{14.9 Unstyled XML documents \(\S_{30}^{p 12}\)}

HTML user agents may, in certain circumstances, find themselves rendering non-HTML documents that use vocabularies for which they lack any built-in knowledge. This section provides for a way for user agents to handle such documents in a somewhat useful manner.

While a Document \({ }^{\text {p114 }}\) is an unstyled document \({ }^{p 1230}\), the user agent is expected to render an unstyled document view \({ }^{\text {p1230 }}\).
A Document \({ }^{p 114}\) is an unstyled document while it matches the following conditions:
- The Document \({ }^{p 114}\) has no author style sheets (whether referenced by HTTP headers, processing instructions, elements like link \({ }^{\text {p157 }}\), inline elements like style \({ }^{\text {p174 }}\), or any other mechanism).
- None of the elements in the Document \({ }^{\mathrm{p} 114}\) have any presentational hints \({ }^{\mathrm{p} 1192}\).
- None of the elements in the Document \({ }^{p 114}\) have any style attributes.
- None of the elements in the Document \({ }^{p 114}\) are in any of the following namespaces: HTML namespace, SVG namespace, MathML namespace
- The Document \({ }^{\text {p114 }}\) has no focusable area \({ }^{\text {p770 }}\) (e.g. from XLink) other than the viewport.
- The Document \({ }^{\text {p114 }}\) has no hyperlinks \({ }^{\text {p283 }}\) (e.g. from XLink).
- There exists no script \({ }^{p 925}\) whose settings object \({ }^{p 925}\) specifies this Document \({ }^{p 114}\) as the responsible document \({ }^{\text {p917 }}\).
- None of the elements in the Document \({ }^{\text {p114 }}\) have any registered event listeners.

An unstyled document view is one where the DOM is not rendered according to CSS (which would, since there are no applicable styles in this context, just result in a wall of text), but is instead rendered in a manner that is useful for a developer. This could consist of just showing the Document \({ }^{\text {p114 }}\) object's source, maybe with syntax highlighting, or it could consist of displaying just the DOM tree, or simply a message saying that the page is not a styled document.

\section*{Note}

If a Document \({ }^{p 114}\) stops being an unstyled document \({ }^{p 1230}\), then the conditions above stop applying, and thus a user agent following these requirements will switch to using the regular CSS rendering.

\section*{15 Obsolete features \(\S^{p 12}\)}

\subsection*{15.1 Obsolete but conforming features \(\S^{p 12}\) \\ 31}

Features listed in this section will trigger warnings in conformance checkers.
Authors should not specify a border \({ }^{p 1236}\) attribute on an \(\underline{i m g}{ }^{p 326}\) element. If the attribute is present, its value must be the string " 0 ". CSS should be used instead.

Authors should not specify a charset \({ }^{p 1233}\) attribute on a script \({ }^{p 614}\) element. If the attribute is present, its value must be an ASCII caseinsensitive match for "utf-8". (This has no effect in a document that conforms to the requirements elsewhere in this standard of being encoded as UTF-8.)

Authors should not specify a language \({ }^{p 1235}\) attribute on a script \({ }^{\text {p614 }}\) element. If the attribute is present, its value must be an ASCII case-insensitive match for the string "JavaScript" and either the type \({ }^{\text {p615 }}\) attribute must be omitted or its value must be an ASCII case-insensitive match for the string "text/javascript". The attribute should be entirely omitted instead (with the value "JavaScript", it has no effect), or replaced with use of the type \({ }^{\text {p615 }}\) attribute.

Authors should not specify a value for the type \({ }^{\text {p615 }}\) attribute on script \({ }^{p 614}\) elements that is the empty string or a JavaScript MIME type essence match. Instead, they should omit the attribute, which has the same effect.

Authors should not specify a type \({ }^{p 1235}\) attribute on a style \({ }^{p 174}\) element. If the attribute is present, its value must be an ASCII caseinsensitive match for "text/css \({ }^{\text {p1283 }}\) ".

Authors should not specify the name \({ }^{p 1233}\) attribute on \(a^{p 238}\) elements. If the attribute is present, its value must not be the empty string and must neither be equal to the value of any of the IDs in the element's tree other than the element's own ID, if any, nor be equal to the value of any of the other name \({ }^{p 1233}\) attributes on \(a^{p 238}\) elements in the element's tree. If this attribute is present and the element has an ID, then the attribute's value must be equal to the element's ID. In earlier versions of the language, this attribute was intended as a way to specify possible targets for fragments in URLs. The \(\underline{i d^{p 137}}\) attribute should be used instead.

Authors should not, but may despite requirements to the contrary elsewhere in this specification, specify the maxlength \({ }^{\mathrm{p} 522}\) and size \({ }^{\text {p522 }}\) attributes on input \({ }^{\text {p493 }}\) elements whose type \({ }^{\text {p495 }}\) attributes are in the Number \({ }^{\text {p509 }}\) state. One valid reason for using these attributes regardless is to help legacy user agents that do not support input \({ }^{\text {p493 }}\) elements with type="number" to still render the text control with a useful width.

\subsection*{15.1.1 Warnings for obsolete but conforming features \(\S^{\text {p12 }}\)}

To ease the transition from HTML4 Transitional documents to the language defined in this specification, and to discourage certain features that are only allowed in very few circumstances, conformance checkers must warn the user when the following features are used in a document. These are generally old obsolete features that have no effect, and are allowed only to distinguish between likely mistakes (regular conformance errors) and mere vestigial markup or unusual and discouraged practices (these warnings).

The following features must be categorized as described above:
- The presence of a border \({ }^{p 1236}\) attribute on an \(\underline{i m g}{ }^{\text {p320 }}\) element if its value is the string " 0 ".
- The presence of a charset \({ }^{p 1233}\) attribute on a script \({ }^{\text {p614 }}\) element if its value is an ASCII case-insensitive match for "utf-8".
- The presence of a language \({ }^{p 1235}\) attribute on a script \({ }^{p 614}\) element if its value is an ASCII case-insensitive match for the string "JavaScript" and if there is no type \({ }^{\text {p615 }}\) attribute or there is and its value is an ASCII case-insensitive match for the string "text/javascript".
- The presence of a type \({ }^{\text {p1235 }}\) attribute on a script \({ }^{p 614}\) element if its value is a JavaScript MIME type essence match.
- The presence of a type \({ }^{\text {p1235 }}\) attribute on a style \({ }^{\text {p174 }}\) element if its value is an ASCII case-insensitive match for "text/ CSS \({ }^{\text {p1283" }}\).
- The presence of a name \({ }^{p 1233}\) attribute on an \(a^{p 238}\) element, if its value is not the empty string.
- The presence of a maxlength \({ }^{\text {p522 }}\) attribute on an \(\underline{\text { input }^{p 493}}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Number \({ }^{\text {p509 }}\) state.
- The presence of a size \({ }^{p 522}\) attribute on an input \({ }^{\text {p493 }}\) element whose type \({ }^{\text {p495 }}\) attribute is in the Number \({ }^{\text {p509 }}\) state.

Conformance checkers must distinguish between pages that have no conformance errors and have none of these obsolete features, and pages that have no conformance errors but do have some of these obsolete features.

\section*{Example}

For example, a validator could report some pages as "Valid HTML" and others as "Valid HTML with warnings".

\subsection*{15.2 Non-conforming features \(\S_{32}^{p 12}\)}

Elements in the following list are entirely obsolete, and must not be used by authors:
applet
Use embed \({ }^{\text {p369 }}\) or object \({ }^{\text {p373 }}\) instead.
acronym
Use abbr \({ }^{p 250}\) instead.
bgsound
Use audio \({ }^{\text {p384 }}\) instead.
dir
Use \(u l^{p 222}\) instead.
frame \({ }^{\text {p124e }}\)
frameset \({ }^{\text {p1239 }}\)
noframes
Either use iframe \({ }^{\mathrm{p} 361}\) and CSS instead, or use server-side includes to generate complete pages with the various invariant parts merged in.
isindex
Use an explicit form \({ }^{\text {p486 }}\) and text control \({ }^{\text {p499 }}\) combination instead.
keygen
For enterprise device management use cases, use native on-device management capabilities.
For certificate enrollment use cases, use the Web Cryptography API to generate a keypair for the certificate, and then export the certificate and key to allow the user to install them manually. [WEBCRYPTO] \({ }^{\text {p1292 }}\)
listing
Use pre \({ }^{\text {p216 }}\) and code \({ }^{\text {p267 }}\) instead.
menuitem
To implement a custom context menu, use script to handle the contextmenu \({ }^{\text {p1281 }}\) event.
nextid
Use GUIDs instead.
noembed
Use object \({ }^{\text {p373 }}\) instead of embed \({ }^{\text {p369 }}\) when fallback is necessary.
plaintext
Use the "text/plain" MIME type instead.
rb
rtc
Providing the ruby base directly inside the ruby \({ }^{\mathrm{p} 252}\) element or using nested ruby \({ }^{\mathrm{p} 252}\) elements is sufficient.
```

strike
Use det l p312 instead if the element is marking an edit,otherwise use s}\mp@subsup{s}{}{p245}\mathrm{ instead.

```
xmp
    Use pre \({ }^{\text {p216 }}\) and code \({ }^{\text {p267 }}\) instead, and escape "<" and "\&" characters as "\&lt;" and "\&amp;" respectively.
basefont
big
blink
center
font
marquee \({ }^{\text {p1237 }}\)
multicol
nobr
spacer
tt
    Use appropriate elements or CSS instead.
    Where the \(t t^{\mathrm{p} 1233}\) element would have been used for marking up keyboard input, consider the \(\mathrm{kbd}^{\mathrm{p} 27 \mathrm{\theta}}\) element; for variables,
    consider the var \({ }^{p 268}\) element; for computer code, consider the code \({ }^{\mathrm{p} 267}\) element; and for computer output, consider the samp \({ }^{\mathrm{p} 269}\)
    element.
    Similarly, if the big \(\underline{b}^{p 1233}\) element is being used to denote a heading, consider using the \(h 1^{p 19 \theta}\) element; if it is being used for marking
    up important passages, consider the strong \({ }^{\mathrm{p242}}\) element; and if it is being used for highlighting text for reference purposes, consider
    the mark \({ }^{\text {p275 }}\) element.
    See also the text-level semantics usage summary \({ }^{\text {p282 }}\) for more suggestions with examples.

The following attributes are obsolete (though the elements are still part of the language), and must not be used by authors:
charset on \(a^{\text {p238 }}\) elements
charset on link \({ }^{\text {p157 }}\) elements
Use an HTTP `Content-Type \({ }^{\text {p99`` }}\) header on the linked resource instead.
charset on script \({ }^{\text {p614 }}\) elements (except as noted in the previous section)
Omit the attribute. Both documents and scripts are required to use UTF-8, so it is redundant to specify it on the script \({ }^{\text {p614 }}\) element since it inherits from the document.
coords on a \({ }^{\text {p238 }}\) elements
shape on \(a^{\text {p238 }}\) elements
Use area \({ }^{p 443}\) instead of \(a^{p 238}\) for image maps.
methods on \(a^{p 238}\) elements
methods on link \({ }^{\text {p157 }}\) elements
Use the HTTP OPTIONS feature instead.
name on \(a^{\text {p238 }}\) elements (except as noted in the previous section)
name on embed \({ }^{\text {p369 }}\) elements
name on img \({ }^{\text {p320 }}\) elements
name on option \({ }^{\text {p545 }}\) elements
Use the \(i d^{p 137}\) attribute instead.
rev on \(a^{\text {p238 }}\) elements
rev on link \({ }^{\text {p157 }}\) elements
Use the rel \({ }^{p 284}\) attribute instead, with an opposite term. (For example, instead of rev="made", use rel="author".)
urn on \(a^{\text {p238 }}\) elements
urn on link \({ }^{\text {p157 }}\) elements
Specify the preferred persistent identifier using the href \(f^{\text {p284 }}\) attribute instead.
accept on form \({ }^{\text {p486 }}\) elements
Use the accept \({ }^{\text {p516 }}\) attribute directly on the input \({ }^{\text {p493 }}\) elements instead.
hreflang on area \({ }^{\text {p443 }}\) elements
type on area \({ }^{\text {p443 }}\) elements
These attributes do not do anything useful, and for historical reasons there are no corresponding IDL attributes on area \({ }^{\text {p443 }}\) elements. Omit them altogether.
nohref on area \({ }^{\text {p443 }}\) elements
Omitting the href \({ }^{p 284}\) attribute is sufficient; the nohref \(f^{p 1234}\) attribute is unnecessary. Omit it altogether.
profile on head \({ }^{\text {p153 }}\) elements
Unnecessary. Omit it altogether.
version on html \({ }^{\text {p152 }}\) elements
Unnecessary. Omit it altogether.
ismap on input \({ }^{\text {p493 }}\) elements
Unnecessary. Omit it altogether. All input \({ }^{\text {p493 }}\) elements with a type \({ }^{\text {p495 }}\) attribute in the Image Button \({ }^{\text {p518 }}\) state are processed as server-side image maps.
usemap on input \({ }^{\text {p493 }}\) elements
Use img \({ }^{\text {p320 }}\) instead of input \({ }^{\text {p493 }}\) for image maps.
longdesc on iframe \({ }^{\text {p361 }}\) elements
longdesc on img \({ }^{\text {p320 }}\) elements
Use a regular \(\underline{a}^{\text {p238 }}\) element to link to the description, or (in the case of images) use an image map \({ }^{\text {p445 }}\) to provide a link from the image to the image's description.
lowsrc on img \({ }^{\text {p32e }}\) elements
Use a progressive JPEG image (given in the \(\mathrm{src}^{\mathrm{p321}}\) attribute), instead of using two separate images.
target on link \({ }^{\text {p157 }}\) elements
Unnecessary. Omit it altogether.
type on menu \({ }^{\text {p223 }}\) elements
To implement a custom context menu, use script to handle the contextmenu \({ }^{p 1281}\) event. For toolbar menus, omit the attribute.
label on menu \({ }^{\text {p223 }}\) elements
contextmenu on all elements
onshow on all elements
To implement a custom context menu, use script to handle the contextmenu \({ }^{\text {p1281 }}\) event.
scheme on meta \({ }^{\text {p164 }}\) elements
Use only one scheme per field, or make the scheme declaration part of the value.
archive on object \({ }^{\text {p373 }}\) elements
classid on object \({ }^{\text {p373 }}\) elements
code on object \({ }^{\text {p373 }}\) elements
codebase on object \({ }^{\text {p373 }}\) elements
codetype on object \({ }^{\text {p373 }}\) elements
Use the data \({ }^{\text {p374 }}\) and type \({ }^{\text {p374 }}\) attributes to invoke plugins \({ }^{\text {p45 }}\). To set parameters with these names in particular, the param \({ }^{\text {p378 }}\) element can be used.

\section*{declare on object \({ }^{\text {p373 }}\) elements}

Repeat the object \({ }^{\text {p373 }}\) element completely each time the resource is to be reused.
standby on object \({ }^{\text {p373 }}\) elements
Optimize the linked resource so that it loads quickly or, at least, incrementally.
typemustmatch on object \({ }^{\text {p373 }}\) elements
Avoid using object \({ }^{\text {p373 }}\) elements with untrusted resources.
type on param \({ }^{\text {p378 }}\) elements
valuetype on param \({ }^{\text {p378 }}\) elements
Use the name \({ }^{p 379}\) and value \({ }^{p 379}\) attributes without declaring value types.
language on script \({ }^{\mathrm{p} 614}\) elements (except as noted in the previous section)
Omit the attribute for JavaScript; for data blocks \({ }^{\mathrm{p} 615}\), use the type \({ }^{\mathrm{p} 615}\) attribute instead.
event on script \({ }^{\text {p614 }}\) elements
for on script \({ }^{\mathrm{p} 614}\) elements
Use DOM events mechanisms to register event listeners. [DOM] \({ }^{\text {p1287 }}\)
type on style \({ }^{\text {p174 }}\) elements (except as noted in the previous section)
Omit the attribute for CSS; for data blocks \({ }^{p 615}\), use script \({ }^{p 614}\) as the container instead of style \(e^{p 174}\).
datapagesize on table \({ }^{\text {p450 }}\) elements
Unnecessary. Omit it altogether.
summary on table \({ }^{\text {p450 }}\) elements
Use one of the techniques for describing tables \({ }^{\text {p455 }}\) given in the table \({ }^{\text {p450 }}\) section instead.
abbr on \(t d^{\text {p465 }}\) elements
Use text that begins in an unambiguous and terse manner, and include any more elaborate text after that. The title \({ }^{p 139}\) attribute can also be useful in including more detailed text, so that the cell's contents can be made terse. If it's a heading, use th \({ }^{\text {p467 }}\) (which has an abbr \(r^{p 468}\) attribute).
axis on \(t^{\text {p465 }}\) and th \({ }^{\text {p467 }}\) elements
Use the scope \({ }^{\text {p467 }}\) attribute on the relevant \(t t^{p 467}\).

\section*{scope on td \({ }^{\text {p465 }}\) elements}

Use th \({ }^{\text {p467 }}\) elements for heading cells.

```

option }\mp@subsup{}{}{\textrm{p}545}\mathrm{ , select }\mp@subsup{}{}{\textrm{p}537}\mathrm{ , span }\mp@subsup{}{}{\textrm{p}279}\mathrm{ , table }\mp@subsup{}{}{\textrm{p}450}\mathrm{ , and textarea }\mp@subsup{}{}{\textrm{p}548}\mathrm{ elements

\subsection*{15.3 Requirements for implementations \(\S^{p 12}\)}

\subsection*{15.3.1 The marquee element \(\S_{37}^{p 12}\)}

The marquee \({ }^{p 1237}\) element is a presentational element that animates content. CSS transitions and animations are a more appropriate mechanism. [CSSANIMATIONS] \({ }^{\text {p1286 }}\) [CSSTRANSITIONS] \({ }^{\text {p1287 }}\)

IDL
```

[Exposed=Window]
interface HTMLMarqueeElement : HTMLElement {
[HTMLConstructor] constructor();
[CEReactions] attribute DOMString behavior;
[CEReactions] attribute DOMString bgColor;
[CEReactions] attribute DOMString direction;

```
```

[CEReactions] attribute DOMString height;
[CEReactions] attribute unsigned long hspace;
[CEReactions] attribute long loop;
[CEReactions] attribute unsigned long scrollAmount;
[CEReactions] attribute unsigned long scrollDelay;
[CEReactions] attribute boolean trueSpeed;
[CEReactions] attribute unsigned long vspace;
[CEReactions] attribute DOMString width;
attribute EventHandler onbounce;
attribute EventHandler onfinish;
attribute EventHandler onstart;
undefined start();
undefined stop();
};

```

A marquee \({ }^{\text {p1237 }}\) element can be turned on or turned off. When it is created, it is turned on \({ }^{\text {p1238 }}\).
When the start() method is called, the marquee \({ }^{\text {p1237 }}\) element must be turned on \({ }^{\text {p1238 }}\).
When the stop() method is called, the marquee \({ }^{p 1237}\) element must be turned off \({ }^{p 1238}\).
When a marquee \({ }^{\text {p1237 }}\) element is created, the user agent must queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the marquee \({ }^{\text {p1237 }}\) element to fire an event named start at the element.

The behavior content attribute on marquee \({ }^{p 1237}\) elements is an enumerated attribute \({ }^{\text {p68 }}\) with the following keywords (all nonconforming):
\begin{tabular}{l|l} 
Keyword & \multicolumn{1}{c}{ State } \\
\hline scroll & scroll \\
\hline slide & slide \\
\hline alternate & alternate \\
\hline
\end{tabular}

The missing value default \(t^{p 68}\) and invalid value default \(t^{p 68}\) are the scroll \({ }^{p 1238}\) state.

The direction content attribute on marquee \({ }^{p 1237}\) elements is an enumerated attribute \({ }^{\text {p68 }}\) with the following keywords (all nonconforming):
\begin{tabular}{l|l} 
Keyword & State \\
\hline left & left \\
\hline right & right \\
\hline up & up \\
\hline down & down \\
\hline
\end{tabular}

The missing value default \({ }^{p 68}\) and invalid value default \({ }^{p 68}\) are the left \({ }^{p 1238}\) state.

The truespeed content attribute on marquee \({ }^{\text {p1237 }}\) elements is a boolean attribute \({ }^{\text {p67 }}\).

A marquee \({ }^{\text {p1237 }}\) element has a marquee scroll interval, which is obtained as follows:
1. If the element has a scrolldelay attribute, and parsing its value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) does not return an error, then let delay be the parsed value. Otherwise, let delay be 85 .
2. If the element does not have a truespeed \({ }^{\text {p1238 }}\) attribute, and the delay value is less than 60 , then let delay be 60 instead.
3. The marquee scroll interval \({ }^{\text {p1238 }}\) is delay, interpreted in milliseconds.

A marquee \({ }^{\text {p1237 }}\) element has a marquee scroll distance, which, if the element has a scrollamount attribute, and parsing its value using the rules for parsing non-negative integers \({ }^{\text {p69 }}\) does not return an error, is the parsed value interpreted in CSS pixels, and otherwise is 6 CSS pixels.

A marquee \({ }^{p 1237}\) element has a marquee loop count, which, if the element has a loop attribute, and parsing its value using the rules for parsing integers \({ }^{\text {p68 }}\) does not return an error or a number less than 1 , is the parsed value, and otherwise is -1 .

The loop IDL attribute, on getting, must return the element's marquee loop count \({ }^{\text {p1239 }}\); and on setting, if the new value is different than the element's marquee loop count \({ }^{\text {p1239 }}\) and either greater than zero or equal to -1 , must set the element's \(l^{\text {loop }}{ }^{\text {p1239 }}\) content attribute (adding it if necessary) to the valid integer \({ }^{\rho 68}\) that represents the new value. (Other values are ignored.)

A marquee \({ }^{\text {p1237 }}\) element also has a marquee current loop index, which is zero when the element is created.
The rendering layer will occasionally increment the marquee current loop index, which must cause the following steps to be run:
1. If the marquee loop count \({ }^{\text {p1239 }}\) is -1 , then return.
2. Increment the marquee current loop index \({ }^{\text {p1239 }}\) by one.
3. If the marquee current loop index \({ }^{\text {p1239 }}\) is now equal to or greater than the element's marquee loop count \({ }^{\text {p1239 }}\), turn off \({ }^{\text {p1238 }}\) the marquee \({ }^{\text {p1237 }}\) element and queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the marquee \({ }^{\text {p1237 }}\) element to fire an event named finish at the marquee \({ }^{\text {p1237 }}\) element.

Otherwise, if the behavior \({ }^{p 1238}\) attribute is in the alternate \({ }^{\text {p1238 }}\) state, then queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the marquee \({ }^{\text {p1237 }}\) element to fire an event named bounce at the marquee \({ }^{\text {p1237 }}\) element. Otherwise, queue an element task \({ }^{\text {p946 }}\) on the DOM manipulation task source \({ }^{\text {p952 }}\) given the marquee \({ }^{\text {p1237 }}\) element to fire an event named start at the marquee \({ }^{\text {p1237 }}\) element.

The following are the event handlers \({ }^{\text {p954 }}\) (and their corresponding event handler event types \({ }^{\text {p957 }}\) ) that must be supported, as event handler content attributes \({ }^{\text {p955 }}\) and event handler IDL attributes \({ }^{\text {p955 }}\), by marquee \({ }^{\text {p1237 }}\) elements:
\begin{tabular}{l|l} 
Event handler \({ }^{\text {p954 }}\) & Event handler event type \({ }^{\text {p957 }}\) \\
\hline onbounce & bounce \\
\hline onfinish & finish \\
\hline onstart & start \\
\hline
\end{tabular}

The behavior, direction, height, hspace, vspace, and width IDL attributes must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.

The bgColor IDL attribute must reflect \({ }^{\mathrm{p94}}\) the bgcolor content attribute.
The scrollAmount IDL attribute must reflect \({ }^{\text {p94 }}\) the scrollamount content attribute. The default value is 6 .
The scrolldelay IDL attribute must reflect \({ }^{\text {p94 }}\) the scrolldelay content attribute. The default value is 85 .
The trueSpeed IDL attribute must reflect \({ }^{\text {p94 }}\) the truespeed \({ }^{\text {p1238 }}\) content attribute.

\subsection*{15.3.2 Frames \({ }_{39}^{\S^{\text {pl2 }}}\)}

The frameset element acts as the body element \({ }^{\text {p118 }}\) in documents that use frames.
The frameset \({ }^{\text {p1239 }}\) element must implement the HTMLFrameSetElement \({ }^{\text {p1239 }}\) interface.
IDL
```

[Exposed=Window]
interface HTMLFrameSetElement : HTMLElement {
[HTMLConstructor] constructor();

```
```

    [CEReactions] attribute DOMString cols;
    [CEReactions] attribute DOMString rows;
    };
HTMLFrameSetElement includes WindowEventHandlers;

```

The cols and rows IDL attributes of the frameset \({ }^{p 1239}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name．
The frameset \({ }^{\text {p1239 }}\) element exposes as event handler content attributes \({ }^{\text {p955 }}\) a number of the event handlers \({ }^{\text {p954 }}\) of the Window \({ }^{\text {p824 }}\) object． It also mirrors their event handler IDL attributes \({ }^{\text {p955 }}\) ．

The event handlers \({ }^{\text {p954 }}\) of the Window \({ }^{p 824}\) object named by the Window－reflecting body element event handler set \({ }^{\text {p962 }}\) ，exposed on the frameset \({ }^{\text {p1239 }}\) element，replace the generic event handlers \({ }^{\text {p954 }}\) with the same names normally supported by HTML elements \({ }^{\text {p44 }}\) ．

The frame element has a nested browsing context \({ }^{\mathrm{p814}}\) similar to the iframe \({ }^{\mathrm{p} 361}\) element，but rendered within a frameset \({ }^{p 1239}\) element．
A frame \({ }^{\text {p124日 }}\) element is said to be an active frame element when it is in a document．
When a frame \({ }^{\text {p1240 }}\) element element is created as an active frame element \({ }^{p 1240}\) ，or becomes an active frame element \({ }^{\text {p1240 }}\) after not having been one，the user agent must run these steps：

1．Create a new nested browsing context \({ }^{\mathrm{p} 814}\) for element．
2．Process the frame attributes \({ }^{p 1240}\) for element，with initiallnsertion \({ }^{p 1240}\) set to true．
When a frame \({ }^{p 124 \theta}\) element stops being an active frame element \({ }^{p 1240}\) ，the user agent must discard \({ }^{p 831}\) the element＇s nested browsing context \({ }^{\text {p814 }}\) ，and then set the element＇s nested browsing context \({ }^{\text {p814 }}\) to null．

Whenever a frame \({ }^{\text {p124日 }}\) element with a non－null nested browsing context \({ }^{\text {p814 }}\) has its src attribute set，changed，or removed，the user agent must process the frame attributes \({ }^{\text {p1240 }}\) ．

To process the frame attributes for an element element，with an optional boolean initiallnsertion：
1．If initiallnsertion is true，then do nothing．
2．Otherwise，run the otherwise steps for if rame or frame elements \({ }^{\mathrm{p} 364}\) given element．
The frame \({ }^{\text {p1240 }}\) element potentially delays the load event \({ }^{\text {p365 }}\) ．
The frame \({ }^{\text {p124日 }}\) element must implement the HTMLFrameElement \({ }^{\text {p124日 }}\) interface．

IDL
```

[Exposed=Window]
interface HTMLFrameElement : HTMLElement {
[HTMLConstructor] constructor();
[CEReactions] attribute DOMString name;
[CEReactions] attribute DOMString scrolling;
[CEReactions] attribute USVString src;
[CEReactions] attribute DOMString frameBorder;
[CEReactions] attribute USVString longDesc;
[CEReactions] attribute boolean noResize;
readonly attribute Document? contentDocument;
readonly attribute WindowProxy? contentWindow;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};

```

The name，scrolling，and src IDL attributes of the frame \({ }^{\text {p1248 }}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name．For the purposes of reflection，the frame \({ }^{\text {p124日 }}\) element＇s src content attribute is defined as containing a URL．

The frameBorder IDL attribute of the frame \({ }^{p 124 \theta}\) element must reflect \({ }^{\mathrm{p94}}\) the element＇s frameborder content attribute．

The longDesc IDL attribute of the frame \({ }^{\text {p124日 }}\) element must reflect \({ }^{\text {p94 }}\) the element's longdesc content attribute, which for the purposes of reflection is defined as containing a URL.

The noResize IDL attribute of the frame \({ }^{p 124 \theta}\) element must reflect \({ }^{\mathrm{p94}}\) the element's noresize content attribute.
The contentDocument IDL attribute, on getting, must return the frame \({ }^{\text {p1248 }}\) element's content document \({ }^{\mathrm{p815}}\).
The contentWindow IDL attribute must return the WindowProxy \({ }^{\text {p834 }}\) object of the frame \({ }^{\text {p1248 }}\) element's nested browsing context \({ }^{\text {p814 }}\), if the element's nested browsing context \({ }^{\mathrm{p} 814}\) is non-null, or return null otherwise.

The marginHeight IDL attribute of the frame \({ }^{\text {p1248 }}\) element must reflect \({ }^{\text {p94 }}\) the element's marginheight content attribute.
The marginWidth IDL attribute of the frame \({ }^{p 124 \theta}\) element must reflect \({ }^{p 94}\) the element's marginwidth content attribute.

\subsection*{15.3.3 Other elements, attributes and APIs \(\S_{41}^{\text {p12 }}\)}

User agents must treat acronym \({ }^{p 1232}\) elements in a manner equivalent to abbr \({ }^{p 250}\) elements in terms of semantics and for purposes of rendering.

IDL
```

partial interface HTMLAnchorElement {
[CEReactions] attribute DOMString coords;
[CEReactions] attribute DOMString charset;
[CEReactions] attribute DOMString name;
[CEReactions] attribute DOMString rev;
[CEReactions] attribute DOMString shape;
};

```

The coords, charset, name, rev, and shape IDL attributes of the \(a^{p 238}\) element must reflect \({ }^{p 94}\) the respective content attributes of the same name.

IDL partial interface HTMLAreaElement \{
[CEReactions] attribute boolean noHref;
\};

The noHref IDL attribute of the area \({ }^{\text {p443 }}\) element must reflect \({ }^{\text {p94 }}\) the element's nohref \({ }^{\text {p1234 }}\) content attribute.

IDL
```

partial interface HTMLBodyElement {
[CEReactions] attribute [LegacyNullToEmptyString] DOMString text;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString link;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString vLink;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString aLink;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
[CEReactions] attribute DOMString background;
};

```

The link IDL attribute of the body \({ }^{\text {p178 }}\) element must reflect \({ }^{\text {p94 }}\) the element's link \(^{p 1236}\) content attribute.
The aLink IDL attribute of the body \({ }^{\text {p178 }}\) element must reflect \({ }^{\text {p94 }}\) the element's alink \({ }^{\text {p1236 }}\) content attribute.
The vLink IDL attribute of the body \({ }^{\text {p178 }}\) element must reflect \({ }^{\text {p94 }}\) the element's vlink \({ }^{p 1236}\) content attribute.
The bgColor IDL attribute of the body \({ }^{\text {p178 }}\) element must reflect \({ }^{\text {p94 }}\) the element's bgcolor \({ }^{\text {p1236 }}\) content attribute.
The background IDL attribute of the body \({ }^{p 178}\) element must reflect \({ }^{p 94}\) the element's background \({ }^{p 1237}\) content attribute. (The content is not defined to contain a URL, despite rules regarding its handling in the rendering section above.)
```

IDL partial interface HTMLBRElement {
[CEReactions] attribute DOMString clear;
};

```

The clear IDL attribute of the \(b r^{p 288}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.
```

IDL partial interface HTMLTableCaptionElement {
[CEReactions] attribute DOMString align;
};

```

The align IDL attribute of the caption \({ }^{\text {p458 }}\) element must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.

IDL partial interface HTMLTableColElement \{
    [CEReactions] attribute DOMString align;
    [CEReactions] attribute DOMString ch;
    [CEReactions] attribute DOMString chOff;
    [CEReactions] attribute DOMString vAlign;
    [CEReactions] attribute DOMString width;
\};

The align and width IDL attributes of the \(c o t^{p 460}\) element must reflect \({ }^{\mathrm{p94}}\) the respective content attributes of the same name.
The ch IDL attribute of the \(\cot ^{p 460}\) element must reflect \({ }^{\text {p94 }}\) the element's char \({ }^{\text {p1236 }}\) content attribute.
The ch0ff IDL attribute of the \(c o 2^{p 460}\) element must reflect \({ }^{p 94}\) the element's charoff \(f^{p 1236}\) content attribute.
The vAlign IDL attribute of the \(\operatorname{col}^{p 46 \theta}\) element must reflect \({ }^{p 94}\) the element's valign \({ }^{\text {p1236 }}\) content attribute.

User agents must treat dir \({ }^{p 1232}\) elements in a manner equivalent to \(u l^{p 222}\) elements in terms of semantics and for purposes of rendering.

The dir \({ }^{p 1232}\) element must implement the HTMLDirectoryElement \({ }^{\text {p1242 }}\) interface.

IDL [Exposed=Window]
interface HTMLDirectoryElement : HTMLElement \{
[HTMLConstructor] constructor();
[CEReactions] attribute boolean compact;
\};

The compact IDL attribute of the dir \(r^{p 1232}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.

IDL partial interface HTMLDivElement \{
[CEReactions] attribute DOMString align;
\};

The align IDL attribute of the div \({ }^{p 237}\) element must reflect \({ }^{\mathrm{p94}}\) the content attribute of the same name.
```

IDL partial interface HTMLDListElement {
[CEReactions] attribute boolean compact;
};

```
1242

The compact IDL attribute of the \(\underline{d l^{p 226}}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.

IDL partial interface HTMLEmbedElement \{
```

    [CEReactions] attribute DOMString align;
    ```
    [CEReactions] attribute DOMString name;
\};

The name and align IDL attributes of the embed \({ }^{\text {p369 }}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.

The font \({ }^{\text {p1233 }}\) element must implement the HTMLFontElement \({ }^{\text {p1243 }}\) interface.
IDL [Exposed=Window]
```

interface HTMLFontElement : HTMLElement {
[HTMLConstructor] constructor();
[CEReactions] attribute [LegacyNullToEmptyString] DOMString color;
[CEReactions] attribute DOMString face;
[CEReactions] attribute DOMString size;
};

```

The color, face, and size IDL attributes of the font \({ }^{\text {p1233 }}\) element must reflect \({ }^{\mathrm{p94}}\) the respective content attributes of the same name.
```

IDL partial interface HTMLHeadingElement {
[CEReactions] attribute DOMString align;
};

```

The align IDL attribute of the \(h 1^{p 19 \theta}-h 6^{p 198}\) elements must reflect \({ }^{p 94}\) the content attribute of the same name.

\section*{Note}

The profile IDL attribute on head \({ }^{\text {p153 }}\) elements (with the HTMLHeadElement \({ }^{\text {p153 }}\) interface) is intentionally omitted. Unless so required by another applicable specification \({ }^{\text {p65 }}\), implementations would therefore not support this attribute. (It is mentioned here as it was defined in a previous version of DOM.)

IDL partial interface HTMLHRElement \{
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString color;
[CEReactions] attribute boolean noShade;
[CEReactions] attribute DOMString size;
[CEReactions] attribute DOMString width;
\};

The align, color, size, and width IDL attributes of the \(h r^{p 214}\) element must reflect \({ }^{\mathrm{p} 94}\) the respective content attributes of the same name.

The noShade IDL attribute of the \(\mathrm{hr}^{\mathrm{p214}}\) element must reflect \({ }^{\text {p94 }}\) the element's noshade \({ }^{\text {p1236 }}\) content attribute.
```

IDL partial interface HTMLHtmlElement {
[CEReactions] attribute DOMString version;
};

```

The version IDL attribute of the \(h t m 2^{p 152}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.
```

partial interface HTMLIFrameElement {
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString scrolling;
[CEReactions] attribute DOMString frameBorder;
[CEReactions] attribute USVString longDesc;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};

```

The align and scrolling IDL attributes of the iframe \({ }^{p 361}\) element must reflect \({ }^{p 94}\) the respective content attributes of the same name.
The frameBorder IDL attribute of the iframe \({ }^{\mathrm{p} 361}\) element must reflect \({ }^{\mathrm{p94}}\) the element's frameborder \({ }^{\text {p1236 }}\) content attribute.

The longDesc IDL attribute of the iframe \({ }^{\text {p361 }}\) element must reflect \({ }^{p 94}\) the element's longdesc \({ }^{\text {p1234 }}\) content attribute, which for the purposes of reflection is defined as containing a URL.

The marginHeight IDL attribute of the iframe \({ }^{\mathrm{p} 361}\) element must reflect \({ }^{\mathrm{p94}}\) the element's marginheight \({ }^{\text {p1236 }}\) content \(^{\text {attribute. }}\)
The marginWidth IDL attribute of the iframe \({ }^{\text {p361 }}\) element must reflect \({ }^{p 94}\) the element's marginwidth \({ }^{\text {p1236 }}\) content attribute.
```

IDL partial interface HTMLImageElement {
[CEReactions] attribute DOMString name;
[CEReactions] attribute USVString lowsrc;
[CEReactions] attribute DOMString align;
[CEReactions] attribute unsigned long hspace;
[CEReactions] attribute unsigned long vspace;
[CEReactions] attribute USVString longDesc;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString border;
};

```

The name, align, border, hspace, and vspace IDL attributes of the img \({ }^{\text {p320 }}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.

The longDesc IDL attribute of the img \({ }^{p 320}\) element must reflect \({ }^{p 94}\) the element's longdesc \({ }^{p 1234}\) content attribute, which for the purposes of reflection is defined as containing a URL.

The lowsrc IDL attribute of the img \({ }^{\mathrm{p320}}\) element must reflect \({ }^{\text {p94 }}\) the element's lowsrc \({ }^{\text {p1234 }}\) content attribute, which for the purposes of reflection is defined as containing a URL.

IDL partial interface HTMLInputElement \{
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString useMap; \};

The align IDL attribute of the input \({ }^{p 493}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.

The useMap IDL attribute of the input \({ }^{p 493}\) element must reflect \({ }^{p 94}\) the element's usemap \({ }^{\text {p1234 }}\) content attribute.
```

IDL partial interface HTMLLegendElement {
[CEReactions] attribute DOMString align;
};

```

The align IDL attribute of the legend \({ }^{p 565}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.
```

IDL partial interface HTMLLIElement {
[CEReactions] attribute DOMString type;
};

```

The type IDL attribute of the \(\underline{l}^{p 224}\) element must reflect \({ }^{\mathrm{p} 94}\) the content attribute of the same name.
```

IDL partial interface HTMLLinkElement {
[CEReactions] attribute DOMString charset;
[CEReactions] attribute DOMString rev;
[CEReactions] attribute DOMString target;
};

```

The charset, rev, and target IDL attributes of the link \({ }^{\text {p157 }}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.

User agents must treat listing \({ }^{p 1232}\) elements in a manner equivalent to pre \({ }^{\text {p216 }}\) elements in terms of semantics and for purposes of rendering.
```

IDL partial interface HTMLMenuElement {
[CEReactions] attribute boolean compact;
};

```

The compact IDL attribute of the menu \({ }^{\mathrm{p} 223}\) element must reflect \({ }^{\mathrm{p94}}\) the content attribute of the same name.
```

IDL partial interface HTMLMetaElement {
[CEReactions] attribute DOMString scheme;
};

```

User agents may treat the scheme \({ }^{\text {p1234 }}\) content attribute on the meta \({ }^{\text {p164 }}\) element as an extension of the element's name \({ }^{p 166}\) content attribute when processing a meta \({ }^{p 164}\) element with a name \({ }^{p 166}\) attribute whose value is one that the user agent recognizes as supporting the scheme \({ }^{\text {p1234 }}\) attribute.

User agents are encouraged to ignore the scheme \({ }^{\text {p1234 }}\) attribute and instead process the value given to the metadata name as if it had been specified for each expected value of the scheme \({ }^{\text {p1234 }}\) attribute.

\section*{Example}

For example, if the user agent acts on meta \({ }^{p 164}\) elements with name \({ }^{\text {p166 }}\) attributes having the value "eGMS.subject.keyword", and knows that the scheme \({ }^{\text {p1234 }}\) attribute is used with this metadata name, then it could take the scheme \({ }^{\text {p1234 }}\) attribute into account, acting as if it was an extension of the name \({ }^{p 166}\) attribute. Thus the following two meta \({ }^{\text {p164 }}\) elements could be treated as two elements giving values for two different metadata names, one consisting of a combination of "eGMS.subject.keyword" and "LGCL", and the other consisting of a combination of "eGMS.subject.keyword" and "ORLY":
```

<!-- this markup is invalid -->

<meta name="eGMS.subject.keyword" scheme="LGCL" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" scheme="ORLY" content="Mah car: kthxbye">
```

The suggested processing of this markup, however, would be equivalent to the following:
```

<meta name="eGMS.subject.keyword" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" content="Mah car: kthxbye">
```

The scheme IDL attribute of the meta \({ }^{\text {p164 }}\) element must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.
```

partial interface HTMLObjectElement {
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString archive;
[CEReactions] attribute DOMString code;
[CEReactions] attribute boolean declare;
[CEReactions] attribute unsigned long hspace;
[CEReactions] attribute DOMString standby;
[CEReactions] attribute unsigned long vspace;
[CEReactions] attribute DOMString codeBase;
[CEReactions] attribute DOMString codeType;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString border;
};

```

The align, archive, border, code, declare, hspace, standby, and vspace IDL attributes of the object \({ }^{\text {p373 }}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.

The codeBase IDL attribute of the object \({ }^{p 373}\) element must reflect \({ }^{p 94}\) the element's codebase \({ }^{\text {p1234 }}\) content attribute, which for the purposes of reflection is defined as containing a URL.

The codeType IDL attribute of the object \({ }^{p 373}\) element must reflect \({ }^{p 94}\) the element's codetype \({ }^{\text {p1234 }}\) content attribute.
```

IDL partial interface HTMLOListElement {
[CEReactions] attribute boolean compact;
};

```

The compact IDL attribute of the \(o l^{p 22 \theta}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.
```

IDL partial interface HTMLParagraphElement {
[CEReactions] attribute DOMString align;
};

```

The align IDL attribute of the \(p^{p 211}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.
```

IDL partial interface HTMLParamElement {
[CEReactions] attribute DOMString type;
[CEReactions] attribute DOMString valueType;
};

```

The type IDL attribute of the param \({ }^{\text {p378 }}\) element must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.

The valueType IDL attribute of the param \({ }^{p 378}\) element must reflect \({ }^{\text {p94 }}\) the element's valuetype \({ }^{\text {p1235 }}\) content attribute.

User agents must treat plaintext \({ }^{\text {p1232 }}\) elements in a manner equivalent to pre \({ }^{\text {p216 }}\) elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element, though.)
```

IDL partial interface HTMLPreElement {
[CEReactions] attribute long width;
};

```

The width IDL attribute of the pre \({ }^{\text {p216 }}\) element must reflect \({ }^{p 94}\) the content attribute of the same name.
```

IDL partial interface HTMLStyleElement {
[CEReactions] attribute DOMString type;
};

```

The type IDL attribute of the style \({ }^{\text {p174 }}\) element must reflect \({ }^{\text {p94 }}\) the element's type \({ }^{\text {p1235 }}\) content attribute.

IDL partial interface HTMLScriptElement \{
[CEReactions] attribute DOMString charset;
[CEReactions] attribute DOMString event;
[CEReactions] attribute DOMString htmlFor;
\};

The charset and event IDL attributes of the script \({ }^{\text {p614 }}\) element must reflect \({ }^{p 94}\) the respective content attributes of the same name.
The htmlFor IDL attribute of the script \({ }^{p 614}\) element must reflect \({ }^{p 94}\) the element's for \({ }^{p 1235}\) content attribute.

IDL
```

partial interface HTMLTableElement {
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString border;
[CEReactions] attribute DOMString frame;
[CEReactions] attribute DOMString rules;
[CEReactions] attribute DOMString summary;
[CEReactions] attribute DOMString width;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString cellPadding;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString cellSpacing;
};

```

The align, border, frame, summary, rules, and width, IDL attributes of the table \({ }^{\text {p450 }}\) element must reflect \({ }^{\text {p94 }}\) the respective content attributes of the same name.

The bgColor IDL attribute of the table \({ }^{\mathrm{p} 450}\) element must reflect \({ }^{\mathrm{p} 94}\) the element's bgcolor \(^{p 1237}\) content attribute.
The cellPadding IDL attribute of the table \({ }^{\text {p450 }}\) element must reflect \({ }^{\mathrm{p94}}\) the element's cellpadding \({ }^{\text {p1237 }}\) content attribute.
The cellSpacing IDL attribute of the table \({ }^{\mathrm{p} 450}\) element must reflect \({ }^{\mathrm{p} 94}\) the element's cellspacing \({ }^{\text {p1237 }}\) content attribute.

IDL partial interface HTMLTableSectionElement \{
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString ch;
[CEReactions] attribute DOMString chOff;
[CEReactions] attribute DOMString vAlign;
\};

The align IDL attribute of the tbody \({ }^{\text {p461 }}\), thead \({ }^{\text {p462 }}\), and \(t^{\text {foot }}{ }^{\text {p463 }}\) elements must reflect \({ }^{p 94}\) the content attribute of the same name.
The ch IDL attribute of the tbody \({ }^{p 461}\), thead \({ }^{\mathrm{p} 462}\), and \(t\) foot \(t^{\text {p463 }}\) elements must reflect \({ }^{\mathrm{p} 94}\) the elements' char \(r^{p 1237}\) content attributes.
The ch0ff IDL attribute of the \(\mathrm{tbody}^{\text {p461 }}\), thead \({ }^{\text {p462 }}\), and \(\mathrm{tfoot}^{\text {p463 }}\) elements must reflect \({ }^{\text {p94 }}\) the elements' charoff \(\mathrm{f}^{\text {p1237 }}\) content attributes.
 attributes.
```

partial interface HTMLTableCellElement {
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString axis;
[CEReactions] attribute DOMString height;
[CEReactions] attribute DOMString width;
[CEReactions] attribute DOMString ch;
[CEReactions] attribute DOMString chOff;
[CEReactions] attribute boolean noWrap;
[CEReactions] attribute DOMString vAlign;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
};

```

The align, axis, height, and width IDL attributes of the \(t d^{\mathrm{p465}}\) and \(t h^{\mathrm{p} 467}\) elements must reflect \({ }^{\mathrm{p94}}\) the respective content attributes of the same name.

The ch IDL attribute of the \(t d^{\text {p465 }}\) and \(\underline{t h^{p 467}}\) elements must reflect \({ }^{p 94}\) the elements' char \(r^{p 1237}\) content attributes.
The ch0ff IDL attribute of the \(\underline{t d}^{p 465}\) and \(\underline{t h}^{\mathrm{p} 467}\) elements must reflect \({ }^{\mathrm{p94}}\) the elements' charoff \({ }^{\mathrm{p} 1237}\) content attributes.
The noWrap IDL attribute of the \(\underline{t d}^{p 465}\) and \(t^{\text {p467 }}\) elements must reflect \({ }^{p 94}\) the elements' nowrap \({ }^{p 1237}\) content attributes.
The vAlign IDL attribute of the \(\underline{t d^{p 465}}\) and \(\underline{t h^{p 467}}\) elements must reflect \({ }^{\mathrm{p94}}\) the elements' valign \({ }^{\mathrm{p} 1237}\) content attributes.
The bgColor IDL attribute of the \(\underline{t d^{p 465}}\) and \(\underline{t h^{p 467}}\) elements must reflect \({ }^{\text {p94 }}\) the elements' bgcolor \({ }^{p 1237}\) content attributes.

IDL
```

partial interface HTMLTableRowElement {
[CEReactions] attribute DOMString align;
[CEReactions] attribute DOMString ch;
[CEReactions] attribute DOMString chOff;
[CEReactions] attribute DOMString vAlign;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
};

```

The align IDL attribute of the \(t r^{\text {p464 }}\) element must reflect \({ }^{\text {p94 }}\) the content attribute of the same name.
The ch IDL attribute of the \(t r^{p 464}\) element must reflect \({ }^{\text {p94 }}\) the element's char \({ }^{p 1237}\) content attribute.
The ch0ff IDL attribute of the \(t r^{p 464}\) element must reflect \({ }^{\text {p94 }}\) the element's charoff \({ }^{\text {p1237 }}\) content attribute.
The vAlign IDL attribute of the \(\operatorname{tr}^{\text {p464 }}\) element must reflect \({ }^{\text {p94 }}\) the element's valign \({ }^{p 1237}\) content attribute.
The bgColor IDL attribute of the \(\underline{t r}^{\mathrm{p} 464}\) element must reflect \({ }^{\text {p94 }}\) the element's bgcolor \({ }^{p 1237}\) content attribute.

IDL partial interface HTMLUListElement \{
[CEReactions] attribute boolean compact;
[CEReactions] attribute DOMString type;
\};

The compact and type IDL attributes of the \(\underline{u^{p 222}}\) element must reflect \({ }^{p 94}\) the respective content attributes of the same name.

User agents must treat xmp \({ }^{p 1233}\) elements in a manner equivalent to pre \({ }^{\text {p216 }}\) elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element though.)
```

partial interface Document {
[CEReactions] attribute [LegacyNullToEmptyString] DOMString fgColor;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString linkColor;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString vlinkColor;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString alinkColor;
[CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
[SameObject] readonly attribute HTMLCollection anchors;
[SameObject] readonly attribute HTMLCollection applets;
undefined clear();
undefined captureEvents();
undefined releaseEvents();
[SameObject] readonly attribute HTMLAllCollection all;
};

```

The attributes of the Document \({ }^{\text {p114 }}\) object listed in the first column of the following table must reflect \({ }^{\text {p94 }}\) the content attribute on the body element \({ }^{\text {p118 }}\) with the name given in the corresponding cell in the second column on the same row, if the body element \({ }^{\text {p118 }}\) is a \(\underline{\text { body }}{ }^{\text {p178 }}\) element (as opposed to a frameset \({ }^{\text {p1239 }}\) element). When there is no body element \({ }^{p 118}\) or if it is a frameset \({ }^{\text {p1239 }}\) element, the attributes must instead return the empty string on getting and do nothing on setting.
\begin{tabular}{l|l|l} 
IDL attribute & Content attribute \\
\hline
\end{tabular}
\begin{tabular}{l|l}
\hline fgColor & text \(^{\text {p1236 }}\) \\
\hline linkColor & link \(^{\text {p1236 }}\) \\
\hline vlinkColor & \(\underline{\text { Vlink }^{p 1236}}\) \\
\hline alinkColor & alink \(^{p 1236}\) \\
\hline bgColor & bgcolor \(^{\text {p1236 }}\) \\
\hline
\end{tabular}

The anchors attribute must return an \(\underline{H T M L C o l l e c t i o n ~ r o o t e d ~ a t ~ t h e ~ D o c u m e n t ~}{ }^{\text {p114 }}\) node, whose filter matches only \(\underline{a}^{\text {p238 }}\) elements with name \({ }^{\text {p1233 }}\) attributes.

The applets attribute must return an HTMLCollection rooted at the Document \({ }^{\text {p114 }}\) node, whose filter matches nothing. (It exists for historical reasons.)

The clear(), captureEvents(), and releaseEvents() methods must do nothing.

The all attribute must return an HTMLALlCollection \({ }^{\text {p97 }}\) rooted at the Document \({ }^{\text {p114 }}\) node, whose filter matches all elements.
```

IDL partial interface Window {
undefined captureEvents();
undefined releaseEvents();
[Replaceable, SameObject] readonly attribute External external;
};

```

The captureEvents() and releaseEvents() methods must do nothing.
The external attribute of the Window \({ }^{\text {p824 }}\) interface must return an instance of the External \({ }^{p 1249}\) interface:
```

[Exposed=Window]
interface External {
undefined AddSearchProvider();
undefined IsSearchProviderInstalled();
};

```

The AddSearchProvider() and IsSearchProviderInstalled() methods must do nothing.

\section*{16 IANA considerations \(\S_{50}^{\text {p12 }}\)}

\section*{16.1 text/html \(\S^{p 12}\) \\ 50}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
text

\section*{Subtype name:}
html

\section*{Required parameters:}

No required parameters

\section*{Optional parameters:}
charset
The charset parameter may be provided to specify the document's character encoding, overriding any character encoding declarations \({ }^{\mathrm{p} 173}\) in the document other than a Byte Order Mark (BOM). The parameter's value must be an ASCII case-insensitive match for the string "utf-8". [ENCODING] \({ }^{\text {p1287 }}\)

\section*{Encoding considerations:}

8bit (see the section on character encoding declarations \({ }^{\text {p173 }}\) )

\section*{Security considerations:}

Entire novels have been written about the security considerations that apply to HTML documents. Many are listed in this document, to which the reader is referred for more details. Some general concerns bear mentioning here, however:

HTML is scripted language, and has a large number of APIs (some of which are described in this document). Script can expose the user to potential risks of information leakage, credential leakage, cross-site scripting attacks, cross-site request forgeries, and a host of other problems. While the designs in this specification are intended to be safe if implemented correctly, a full implementation is a massive undertaking and, as with any software, user agents are likely to have security bugs.

Even without scripting, there are specific features in HTML which, for historical reasons, are required for broad compatibility with legacy content but that expose the user to unfortunate security problems. In particular, the img \({ }^{\text {p320 }}\) element can be used in conjunction with some other features as a way to effect a port scan from the user's location on the Internet. This can expose local network topologies that the attacker would otherwise not be able to determine.

HTML relies on a compartmentalization scheme sometimes known as the same-origin policy. An origin \({ }^{\text {p837 }}\) in most cases consists of all the pages served from the same host, on the same port, using the same protocol.

It is critical, therefore, to ensure that any untrusted content that forms part of a site be hosted on a different origin \({ }^{\text {p837 }}\) than any sensitive content on that site. Untrusted content can easily spoof any other page on the same origin, read data from that origin, cause scripts in that origin to execute, submit forms to and from that origin even if they are protected from cross-site request forgery attacks by unique tokens, and make use of any third-party resources exposed to or rights granted to that origin.

\section*{Interoperability considerations:}

Rules for processing both conforming and non-conforming content are defined in this specification.

\section*{Published specification:}

This document is the relevant specification. Labeling a resource with the text/html \({ }^{p 1250}\) type asserts that the resource is an HTML document using the HTML syntax \({ }^{\text {p1067 }}\).

\section*{Applications that use this media type:}

Web browsers, tools for processing web content, HTML authoring tools, search engines, validators.

\section*{Additional information:}

\section*{Magic number(s):}

No sequence of bytes can uniquely identify an HTML document. More information on detecting HTML documents is available in MIME Sniffing. [MIMESNIFF] \({ }^{\text {p1289 }}\)

\section*{File extension(s):}
"html" and "htm" are commonly, but certainly not exclusively, used as the extension for HTML documents.

\section*{Macintosh file type code(s):}

\section*{Intended usage:}

Common

\section*{Restrictions on usage:}

No restrictions apply.

\section*{Author:}

Ian Hickson <ian@hixie.ch>

\section*{Change controller:}

W3C

Fragments used with text/html \({ }^{p 1250}\) resources either refer to the indicated part of the document \({ }^{p 880}\) or provide state information for inpage scripts.

\section*{16.2 multipart/x-mixed-replace \(\S_{51}^{p 12}\)}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
multipart
Subtype name:
x-mixed-replace

\section*{Required parameters:}
- boundary (defined in RFC2046) [RFC2046] \({ }^{\text {p1290 }}\)

\section*{Optional parameters:}

No optional parameters.
Encoding considerations:
binary

\section*{Security considerations:}

Subresources of a multipart/x-mixed-replace \({ }^{\text {p1251 }}\) resource can be of any type, including types with non-trivial security implications such as text/html \({ }^{\text {p1250 }}\).

Interoperability considerations:
None.
Published specification:
This specification describes processing rules for web browsers. Conformance requirements for generating resources with this type are the same as for multipart/mixed \({ }^{\text {p1283 }}\). \([\text { RFC2046] }]^{\text {p1290 }}\)

\section*{Applications that use this media type:}

This type is intended to be used in resources generated by web servers, for consumption by web browsers.

\section*{Additional information:}

Magic number(s):
No sequence of bytes can uniquely identify a multipart/x-mixed-replace \({ }^{p 1251}\) resource.
File extension(s):
No specific file extensions are recommended for this type.
Macintosh file type code(s):
No specific Macintosh file type codes are recommended for this type.

\section*{Person \& email address to contact for further information:}

Ian Hickson <ian@hixie.ch>

\section*{Intended usage:}

Common

\section*{Restrictions on usage:}

No restrictions apply.

\section*{Author:}

Ian Hickson <ian@hixie.ch>

\section*{Change controller:}

W3C
Fragments used with multipart/x-mixed-replace \({ }^{\text {p1251 }}\) resources apply to each body part as defined by the type used by that body part.

\section*{16.3 application/xhtml+xml \(\S^{p 12}\)}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
application

\section*{Subtype name:}
xhtml+xml

\section*{Required parameters:}

Same as for application/xml \({ }^{p 1283}[\text { RFC7303] }]^{p 1291}\)

\section*{Optional parameters:}

Same as for application/xml \({ }^{\text {p1283 }}\) [RFC7303] \({ }^{\text {p1291 }}\)

\section*{Encoding considerations:}

Same as for application/xml \({ }^{\text {p1283 }}\) [RFC7303] \(]^{\text {p1291 }}\)

\section*{Security considerations:}

Same as for application/xml \({ }^{\text {p1283 }}[\text { RFC7303] }]^{\text {p1291 }}\)

\section*{Interoperability considerations:}

Same as for application/xml \({ }^{\text {p1283 }}\left[\right.\) RFC7303] \({ }^{\text {p1291 }}\)

\section*{Published specification:}

Labeling a resource with the application/xhtml+xml \({ }^{p 1252}\) type asserts that the resource is an XML document that likely has a document element from the HTML namespace. Thus, the relevant specifications are XML, Namespaces in XML, and this specification. [XML] \({ }^{\text {p1293 }}[\text { XMLNS }]^{p 1293}\)

\section*{Applications that use this media type:}

Same as for application/xml \({ }^{\text {p1283 }}\) [RFC7303] \({ }^{\text {p1291 }}\)

\section*{Additional information:}

Magic number(s):
Same as for application/xml \({ }^{\text {p1283 }}\left[\right.\) RFC7303] \({ }^{1291}\)
File extension(s):
"xhtml" and "xht" are sometimes used as extensions for XML resources that have a document element from the HTML namespace.
Macintosh file type code(s):
TEXT

\section*{Person \& email address to contact for further information:}

Ian Hickson <ian@hixie.ch>
Intended usage:
Common

\section*{Restrictions on usage:}

No restrictions apply.

\section*{Author:}

Ian Hickson <ian@hixie.ch>

\section*{Change controller:}

W3C
Fragments used with application/xhtml+xml \({ }^{p 1252}\) resources have the same semantics as with any XML MIME type. [RFC7303] \({ }^{\text {p1291 }}\)

\section*{16.4 text/cache-manifest \(\S^{\text {p12 }}\)}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
text

\section*{Subtype name:}
cache-manifest

\section*{Required parameters:}

No parameters

\section*{Optional parameters:}
charset
The charset parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

\section*{Encoding considerations:}

8bit (always UTF-8)

\section*{Security considerations:}

Cache manifests themselves pose no immediate risk unless sensitive information is included within the manifest. Implementations, however, are required to follow specific rules when populating a cache based on a cache manifest, to ensure that certain originbased restrictions are honored. Failure to correctly implement these rules can result in information leakage, cross-site scripting attacks, and the like.

\section*{Interoperability considerations:}

Rules for processing both conforming and non-conforming content are defined in this specification.
Published specification:
This document is the relevant specification.
Applications that use this media type:
Web browsers.

\section*{Additional information:}

Magic number(s):
Cache manifests begin with the string "CACHE MANIFEST", followed by either a U+0020 SPACE character, a U+0009 CHARACTER TABULATION (tab) character, a U+000A LINE FEED (LF) character, or a U+000D CARRIAGE RETURN (CR) character.

\section*{File extension(s):}
"appcache"

\section*{Macintosh file type code(s):}

No specific Macintosh file type codes are recommended for this type.

\section*{Person \& email address to contact for further information:}

Ian Hickson <ian@hixie.ch>

\section*{Intended usage:}

Common

\section*{Restrictions on usage:}

No restrictions apply.

\section*{Author:}

Ian Hickson <ian@hixie.ch>

\section*{Change controller:}

W3C
Fragments have no meaning with text/cache-manifest \({ }^{p 1253}\) resources.

\section*{16.5 text/ping \(\S^{p 12}\) \\ 54}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
text
Subtype name:
ping

\section*{Required parameters:}

No parameters

\section*{Optional parameters:}
charset
The charset parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

\section*{Encoding considerations:}

Not applicable.

\section*{Security considerations:}

If used exclusively in the fashion described in the context of hyperlink auditing \({ }^{\mathrm{p} 293}\), this type introduces no new security concerns.

\section*{Interoperability considerations:}

Rules applicable to this type are defined in this specification.

\section*{Published specification:}

This document is the relevant specification.

\section*{Applications that use this media type:}

Web browsers.

\section*{Additional information:}

Magic number(s):
text/ping \({ }^{\text {p1254 }}\) resources always consist of the four bytes \(0 \times 500 \times 490 \times 4 \mathrm{E} 0 \times 47\) (`PING`).
File extension(s):
No specific file extension is recommended for this type.
Macintosh file type code(s):
No specific Macintosh file type codes are recommended for this type.

\section*{Person \& email address to contact for further information:}

Ian Hickson <ian@hixie.ch>

\section*{Intended usage:}

Common

\section*{Restrictions on usage:}

Only intended for use with HTTP POST requests generated as part of a web browser's processing of the ping \({ }^{\text {p284 }}\) attribute.

\section*{Author:}

Ian Hickson <ian@hixie.ch>

\section*{Change controller:}

W3C
Fragments have no meaning with text/ping \({ }^{\text {p1254 }}\) resources.

\section*{16.6 application/microdata+json \(\S^{112}\)}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
application

\section*{Subtype name:}
microdata+json

\section*{Required parameters:}

Same as for application/json \({ }^{\text {p1283 }}\) [JSON \(]^{\text {p1288 }}\)

\section*{Optional parameters:}

Same as for application/json \({ }^{\text {p1283 }}\) [JSON] \({ }^{\text {p1288 }}\)
Encoding considerations:
8bit (always UTF-8)

\section*{Security considerations:}

Same as for application/json \({ }^{\text {p1283 }}\) [JSON] \({ }^{\text {p1288 }}\)

\section*{Interoperability considerations:}

Same as for application/json \({ }^{\text {p1283 }}\) [JSON] \({ }^{\text {p1288 }}\)

\section*{Published specification:}

Labeling a resource with the application/microdata+json \({ }^{\text {p1255 }}\) type asserts that the resource is a JSON text that consists of an object with a single entry called "items" consisting of an array of entries, each of which consists of an object with an entry called "id" whose value is a string, an entry called "type" whose value is another string, and an entry called "properties" whose value is an object whose entries each have a value consisting of an array of either objects or strings, the objects being of the same form as the objects in the aforementioned "items" entry. Thus, the relevant specifications are JSON and this specification. [JSON] \({ }^{\text {p1288 }}\)

\section*{Applications that use this media type:}

Applications that transfer data intended for use with HTML's microdata feature, especially in the context of drag-and-drop, are the primary application class for this type.

\section*{Additional information:}

Magic number(s):
Same as for application/json \({ }^{\text {p1283 }}\) [JSON] \({ }^{\text {p1288 }}\)
File extension(s):
Same as for application/json \({ }^{\text {p1283 }}[J S O N]^{\text {p1288 }}\)
Macintosh file type code(s):
Same as for application/json \({ }^{\text {p1283 }}\left[\right.\) [JSON] \({ }^{\text {p1288 }}\)
Person \& email address to contact for further information:
Ian Hickson <ian@hixie.ch>

\section*{Intended usage:}

Common

\section*{Restrictions on usage:}

No restrictions apply.

\section*{Author:}

Ian Hickson <ian@hixie.ch>
Change controller:
W3C

Fragments used with application/microdata+json \({ }^{\text {p1255 }}\) resources have the same semantics as when used with application/ json \({ }^{\text {p1283 }}\) (namely, at the time of writing, no semantics at all). [JSON] \({ }^{p 1288}\)

\section*{16.7 text/event-stream \(\S^{p 12}\) \\ 56}

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

\section*{Type name:}
text
Subtype name:
event-stream

\section*{Required parameters:}

No parameters

\section*{Optional parameters:}
charset
The charset parameter may be provided. The parameter's value must be "utf-8". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

\section*{Encoding considerations:}

8bit (always UTF-8)

\section*{Security considerations:}

An event stream from an origin distinct from the origin of the content consuming the event stream can result in information leakage. To avoid this, user agents are required to apply CORS semantics. [FETCH] \({ }^{\text {p1287 }}\)

Event streams can overwhelm a user agent; a user agent is expected to apply suitable restrictions to avoid depleting local resources because of an overabundance of information from an event stream.

Servers can be overwhelmed if a situation develops in which the server is causing clients to reconnect rapidly. Servers should use a \(5 x x\) status code to indicate capacity problems, as this will prevent conforming clients from reconnecting automatically.

\section*{Interoperability considerations:}

Rules for processing both conforming and non-conforming content are defined in this specification.

\section*{Published specification:}

This document is the relevant specification.

\section*{Applications that use this media type:}

Web browsers and tools using web services.

\section*{Additional information:}

Magic number(s):
No sequence of bytes can uniquely identify an event stream.
File extension(s):
No specific file extensions are recommended for this type.

\section*{Macintosh file type code(s):}

No specific Macintosh file type codes are recommended for this type.

\section*{Person \& email address to contact for further information:}

Ian Hickson <ian@hixie.ch>

\section*{Intended usage:}

Common

\section*{Restrictions on usage:}

This format is only expected to be used by dynamic open-ended streams served using HTTP or a similar protocol. Finite resources are not expected to be labeled with this type.

\section*{Author:}

Ian Hickson <ian@hixie.ch>

\section*{Change controller:}

W3C
Fragments have no meaning with text/event-stream \({ }^{\text {p1256 }}\) resources.

\subsection*{16.17 web+ scheme prefix \(\S^{p 12}\) \\ 60}

This section describes a convention for use with the IANA URI scheme registry. It does not itself register a specific scheme. [RFC7595] \({ }^{\text {p1290 }}\)

\section*{Scheme name:}

Schemes starting with the four characters "web+" followed by one or more letters in the range a-z.

\section*{Status:}

Permanent

\section*{Scheme syntax:}

Scheme-specific.

\section*{Scheme semantics:}

Scheme-specific.

\section*{Encoding considerations:}

All "web+" schemes should use UTF-8 encodings where relevant.
Applications/protocols that use this scheme name:
Scheme-specific.

\section*{Interoperability considerations:}

The scheme is expected to be used in the context of web applications.

\section*{Security considerations:}

Any web page is able to register a handler for all "web+" schemes. As such, these schemes must not be used for features intended to be core platform features (e.g. network transfer protocols like HTTP or FTP). Similarly, such schemes must not store confidential information in their URLs, such as usernames, passwords, personal information, or confidential project names.

\end{tabular}

An asterisk \(\left(^{*}\right)\) in a cell indicates that the actual rules are more complicated than indicated in the table above.
\(\dagger\) Categories in the "Parents" column refer to parents that list the given categories in their content model, not to elements that themselves are in those categories. For example, the \(a^{p 238}\) element's "Parents" column says "phrasing", so any element whose content model contains the "phrasing" category could be a parent of an \(\underline{a^{p 238}}\) element. Since the "flow" category includes all the "phrasing" elements, that means the th \({ }^{\text {p467 }}\) element could be a parent to an \(a^{p 238}\) element.

\section*{Attributes \(\S^{p 12}\) \\ 69}

This section is non-normative.
\begin{tabular}{|c|c|c|c|}
\hline \multicolumn{4}{|c|}{List of attributes (excluding event handler content attributes)} \\
\hline Attribute & Element(s) & Description & Value \\
\hline abbr & \(\mathrm{th}^{\text {p468 }}\) & Alternative label to use for the header cell when referencing the cell in other contexts & Text \({ }^{\text {p129 }}\) * \\
\hline accept & input \({ }^{\text {p516 }}\) & Hint for expected file type in file upload controls \({ }^{\text {p515 }}\) & Set of comma-separated tokens \({ }^{\text {p87 }} *\) consisting of valid MIME type strings with no parameters or audio/*, video/*, or image/* \\
\hline accept-charset & form \({ }^{\text {p887 }}\) & Character encodings to use for form submission \({ }^{\text {p595 }}\) & ASCII case-insensitive match for "UTF-8" \\
\hline accesskey & HTML elements \({ }^{\text {p785 }}\) & Keyboard shortcut to activate or focus element & Ordered set of unique space-separated tokens \({ }^{\mathrm{p} 87}\), none of which are identical to another, each consisting of one code point in length \\
\hline action & form \({ }^{\text {p571 }}\) & URL to use for form submission \({ }^{\text {p595 }}\) & Valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline allow & iframe \({ }^{\text {p367 }}\) & Permissions policy to be applied to the iframe \({ }^{\text {p361 }}\) 's contents & Serialized permissions policy \\
\hline allowfullscreen & iframe \({ }^{\text {P367 }}\) & Whether to allow the iframe \({ }^{\text {p361' }}\) 's contents to use requestFullscreen() & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline allowpaymentrequest & iframe \({ }^{\text {P367 }}\) & Whether the iframe \({ }^{\text {p361' }} \mathrm{s}\) contents are allowed to use the PaymentRequest interface to make payment requests & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline alt & \[
\begin{aligned}
& \text { area }^{\text {p444 }} ; \text { img }^{\text {p321 }} ; \\
& \text { input }^{\text {p519 }}
\end{aligned}
\] & Replacement text for use when images are not available & Text \({ }^{\text {p129 }}\) * \\
\hline as & link \({ }^{\text {p161 }}\) & \begin{tabular}{l}
Potential destination for a preload request (for \\
rel \(^{p 158}=\) "preload \({ }^{\text {p305" }}\) and \\
\(r l^{p 158}="\) modulepreload \({ }^{\text {p301" }}\) ")
\end{tabular} & Potential destination, for rel \({ }^{\text {p158 }}=" p r e l o a d^{p 305 "}\); script-like destination, for \(r e l^{p 158}="\) modulepreload \({ }^{\text {p301 }}\) " \\
\hline async & Script \({ }^{\text {p615 }}\) & Execute script when available, without blocking while fetching & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline autocapitalize & HTML elements \({ }^{\text {p791 }}\) & Recommended autocapitalization behavior (for supported input methods) & "on \({ }^{\text {p791 }}\) "; "off \({ }^{\text {p791 }}\) "; "none \({ }^{\text {p791 }}\) "; "sentences \({ }^{\text {p792 }}\) "; "words \({ }^{\text {p792 }}\); "characters \({ }^{\text {p792 } "}\) \\
\hline autocomplete & form \({ }^{\text {p488 }}\) & Default setting for autofill feature for controls in the form & "on"; "off" \\
\hline autocomplete & input \({ }^{\text {p573 }}\); select \({ }^{\text {p573 }}\); textarea \({ }^{\text {p573 }}\) & Hint for form autofill feature & Autofill field \({ }^{\text {p575 }}\) name and related tokens* \\
\hline autofocus & HTML elements \({ }^{\text {p782 }}\) & Automatically focus the element when the page is loaded & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline autoplay & \(\underline{\text { audio }}{ }^{\text {p407 }} ; \underline{\text { video }}{ }^{\text {p487 }}\) & Hint that the media resource \({ }^{\text {p389 }}\) can be started automatically when the page is loaded & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline charset & meta \(^{1165}\) & Character encoding declaration \({ }^{\text {p173 }}\) & "utf-8" \\
\hline checked & input \({ }^{\text {p497 }}\) & Whether the control is checked & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline cite & blockquote \({ }^{\text {p218 }}\); del \({ }^{\text {p313 }}\); ins \(^{\text {p313 }} ; q^{\text {p248 }}\) & Link to the source of the quotation or more information about the edit & Valid URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline class & HTML elements \({ }^{\text {p137 }}\) & Classes to which the element belongs & Set of space-separated tokens \({ }^{\text {p87 }}\) \\
\hline color & link \({ }^{1161}\) & Color to use when customizing a site's icon (for rel \({ }^{\mathrm{p158}}={ }^{\prime \prime}\) maskicon") & CSS \(\leq\) color \(>\) \\
\hline cols & textarea \({ }^{\text {p550 }}\) & Maximum number of characters per line & Valid non-negative integer \({ }^{\text {p69 }}\) greater than zero \\
\hline colspan & \(\underline{\mathrm{td}^{\text {p469 }} ; \mathrm{th}^{\text {p469 }}}\) & Number of columns that the cell is to span & Valid non-negative integer \({ }^{\text {p69 }}\) greater than zero \\
\hline content & meta \({ }^{\text {p165 }}\) & Value of the element & Text \({ }^{\text {p129* }}\) \\
\hline contenteditable & HTML elements \({ }^{\text {p787 }}\) & Whether the element is editable & "true"; "false" \\
\hline controls & audio \({ }^{\text {p436 }}\); video \({ }^{\text {p436 }}\) & Show user agent controls & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline coords & area \({ }^{\text {p445 }}\) & Coordinates for the shape to be created in an image map \({ }^{\text {p445 }}\) & Valid list of floating-point numbers \({ }^{\text {p72 }}\) * \\
\hline crossorigin & \[
\begin{aligned}
& \text { audio }^{\text {p390 }} ; \text { img }^{\text {p321 }} ; \\
& \text { link }^{\text {p158 }} ; \text { script }^{\text {p616 }} ; \\
& \underline{\text { video }^{\text {p390 }}}
\end{aligned}
\] & How the element handles crossorigin requests & "anonymous \({ }^{\text {p91 }}\) "; "use-credentials \({ }^{\text {p91 }}\) " \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline Attribute & Element(s) & Description & Value \\
\hline data & object \({ }^{\text {P374 }}\) & Address of the resource & Valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline datetime & del \({ }^{\text {p313 }}\); ins \(^{\text {p313 }}\) & Date and (optionally) time of the change & Valid date string with optional time \({ }^{\text {p85 }}\) \\
\hline datetime & time \({ }^{\text {2261 }}\) & Machine-readable value & Valid month string \({ }^{\mathrm{p74}}\), valid date string \({ }^{\mathrm{p74}}\), valid yearless date string \({ }^{\mathrm{p75}}\), valid time string \({ }^{\mathrm{p} 76}\), valid local date and time string \({ }^{\mathrm{p} 77}\), valid time-zone offset string \({ }^{\mathrm{p} 78}\), valid global date and time string \({ }^{\mathrm{p} 79}\), valid week string \({ }^{\mathrm{p} 81}\), valid nonnegative integer \({ }^{\text {p69 }}\), or valid duration string \({ }^{\text {p82 }}\) \\
\hline decoding & img \(^{\text {p321 }}\) & Decoding hint to use when processing this image for presentation & "sync \({ }^{\text {P338 }}\) "; "async \({ }^{\text {p338 " }}\); "auto \({ }^{\text {p338. }}\) \\
\hline loading & img \(^{\text {P321 }}\); iframe \({ }^{\text {p368 }}\) & Used when determining loading deferral & "lazy \({ }^{\text {p93 }}\) "; "eager \({ }^{\text {p93." }}\) \\
\hline default & track \({ }^{\text {p386 }}\) & Enable the track if no other text track \({ }^{\text {p421 }}\) is more suitable & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline defer & script \({ }^{\text {p615 }}\) & Defer script execution & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline dir & HTML elements \({ }^{\text {p142 }}\) & The text directionality \({ }^{\text {p142 }}\) of the element & "ltr \({ }^{p 142}\) "; "rtl \({ }^{\text {p142 }}\); "auto \({ }^{\text {p142 } "}\) \\
\hline dir & \(\mathrm{bdo}^{\text {p279 }}\) & The text directionality \({ }^{\text {p142 }}\) of the element & "ltr \({ }^{\text {p142 }}\); "rttl \({ }^{\text {p142n }}\) \\
\hline dirname & input \({ }^{\text {p568 }}\); textarea \({ }^{\text {p568 }}\) & Name of form control to use for sending the element's directionality \({ }^{\text {p142 }}\) in form submission \({ }^{\text {p595 }}\) & Text \({ }^{\text {p129 }}\) * \\
\hline disabled & button \({ }^{\text {p579 }}\); input \({ }^{\text {p577 }}\); optgroup \({ }^{\text {p545 }}\); option \({ }^{\text {p546 }}\); select \({ }^{\text {p570 }}\); textarea \({ }^{\text {p570 }}\); form-associated custom elements \({ }^{\text {p570 }}\) & Whether the form control is disabled & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline disabled & fieldset \({ }^{\text {p563 }}\) & Whether the descendant form controls, except any inside legend \({ }^{\text {p565 }}\), are disabled & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline disabled & link \({ }^{\text {p161 }}\) & Whether the link is disabled & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline download & \(\underline{a}^{\text {p284 }}\); area \({ }^{\text {p284 }}\) & Whether to download the resource instead of navigating to it, and its file name if so & Text \\
\hline draggable & HTML elements \({ }^{\text {p809 }}\) & Whether the element is draggable & "true"; "false" \\
\hline enctype & form \({ }^{\text {p572 }}\) & Entry list encoding type to use for form submission \({ }^{\text {p595 }}\) & "application/x-www-form-urlencoded \({ }^{\text {p572 }}\); "multipart/form-data \({ }^{\text {p572" }}\); "text/plain \({ }^{\text {p572" }}\) \\
\hline enterkeyhint & HTML elements \({ }^{\text {p793 }}\) & Hint for selecting an enter key action &  \\
\hline for & label \({ }^{\text {p491 }}\) & Associate the label with form control & ID* \\
\hline for & output \({ }^{\text {p554 }}\) & Specifies controls from which the output was calculated & Unordered set of unique space-separated tokens \({ }^{\text {p877 }}\) consisting of IDs* \\
\hline form & button \({ }^{\text {p566 }}\); fieldset \({ }^{\text {p566 }}\); input \({ }^{\text {p566 }}\); object \({ }^{\text {p566 }}\); output \({ }^{\text {p566 }}\); select \({ }^{\text {p566 }}\); textarea \({ }^{\text {p566 }}\); formassociated custom elements \({ }^{\text {p566 }}\) & Associates the element with a form \({ }^{\text {p486 }}\) element & ID* \\
\hline formaction & button \({ }^{\text {p571] }}\); input \({ }^{\text {p5711 }}\) & URL to use for form submission \({ }^{\text {p595 }}\) & Valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline formenctype & button \({ }^{\text {p5722 }}\); input \({ }^{\text {p572 }}\) & Entry list encoding type to use for form submission \({ }^{\text {p595 }}\) & "application/x-www-form-urlencoded \({ }^{\text {p572" }}\); "multipart/form-data \({ }^{\text {p572" }}\); "text/plain \({ }^{\text {p572" }}\) \\
\hline formmethod & button \({ }^{\text {p571 }}\); input \({ }^{\text {p571 }}\) & Variant to use for form submission \({ }^{\text {p595 }}\) & "GET"; "POST"; "dialog" \\
\hline formnovalidate & button \({ }^{\text {p572 }}\); input \({ }^{\text {p572 }}\) & Bypass form control validation for form submission \({ }^{\text {p595 }}\) & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline formtarget & button \({ }^{\text {p5722 }}\); input \({ }^{\text {p572 }}\) & Browsing context \({ }^{\text {p811 }}\) for form submission \({ }^{\text {p595 }}\) & Valid browsing context name or keyword \({ }^{\text {p819 }}\) \\
\hline headers & \(\underline{t^{\text {p469 }}} ;\) th \(^{\text {p469 }}\) & The header cells for this cell & Unordered set of unique space-separated tokens \({ }^{\text {p877 }}\) consisting of IDs* \\
\hline height & \[
\begin{aligned}
& \text { canvas }^{\text {p635 }} ; \text { embed }^{\text {p449 }} ; \\
& \text { iframe }^{\text {p449 }} ; \text { img }^{\text {p449 }} ;
\end{aligned}
\] & Vertical dimension & Valid non-negative integer \({ }^{\text {p69 }}\) \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline Attribute & Element(s) & Description & Value \\
\hline & \[
\begin{aligned}
& \text { input }^{\text {p449 }} ; \text { object }^{\text {p449 }} ; \\
& \text { video }^{\text {p449 }}
\end{aligned}
\] & & \\
\hline hidden & HTML elements \({ }^{\text {p765 }}\) & Whether the element is relevant & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline high & meter \({ }^{\text {p558 }}\) & Low limit of high range & Valid floating-point number \({ }^{\text {p69 }}\) * \\
\hline href & \(a^{\text {p2844 }}\); area \({ }^{\text {p284 }}\) & Address of the hyperlink \({ }^{\text {p283 }}\) & Valid URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline href & link \({ }^{\text {p1588 }}\) & Address of the hyperlink \({ }^{\text {p283 }}\) & Valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline href & base \({ }^{\text {p156 }}\) & Document base URL \({ }^{\text {p88 }}\) & Valid URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline hreflang & \({\underline{ }{ }^{\text {p2844 }} ; \text { link }^{\text {p159 }}}^{\text {Pr }}\) & Language of the linked resource & Valid BCP 47 language tag \\
\hline http-equiv & meta \(^{\text {p169 }}\) & Pragma directive & "content-type \({ }^{\text {p170" }}\); "default-style \({ }^{\text {p170" }}\); "refresh \({ }^{\text {p170" }}\); "x-uacompatible \({ }^{\text {p170" }}\); "content-security-policy \({ }^{\text {p170" }}\) \\
\hline id & HTML elements \({ }^{\text {p1377 }}\) & The element's ID & Text \({ }^{\text {p129 }}\) * \\
\hline imagesizes & link \({ }^{1160}\) & Image sizes for different page layouts (for \(\mathrm{rel}^{\mathrm{p} 158}=\) "preload \({ }^{\mathrm{p} 305}{ }^{\text {" }}\) ) & Valid source size list \({ }^{\text {P335 }}\) \\
\hline imagesrcset & link \({ }^{1160}\) & Images to use in different situations, e.g., high-resolution displays, small monitors, etc. (for rel \({ }^{\text {p158 }}=\) "preload \({ }^{\text {p305" " }}\) ) & Comma-separated list of image candidate strings \({ }^{\text {p335 }}\) \\
\hline inputmode & HTML elements \({ }^{\text {p792 }}\) & Hint for selecting an input modality &  "decimal \({ }^{\text {p793" }}\); "search \({ }^{\text {p793." }}\) \\
\hline integrity & link \({ }^{\text {p159 }}\); script \({ }^{\text {p616 }}\) & Integrity metadata used in Subresource Integrity checks [SRI] \({ }^{\text {p1291 }}\) & Text \({ }^{\text {p129 }}\) \\
\hline is & HTML elements \({ }^{\text {p703 }}\) & Creates a customized built-in element \({ }^{\text {p } 703}\) & Valid custom element name \({ }^{\text {p704 }}\) of a defined customized built-in element \({ }^{\text {p703 }}\) \\
\hline ismap & \(\mathrm{img}^{\text {P323 }}\) & Whether the image is a serverside image map & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline itemid & HTML elements \({ }^{\text {p735 }}\) & Global identifier \({ }^{\text {p735 }}\) for a microdata item & Valid URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline itemprop & HTML elements \({ }^{\text {p736 }}\) & Property names \({ }^{\mathrm{p} 737}\) of a microdata item & Unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) consisting of valid absolute URLs, defined property names \({ }^{\mathrm{p} 737}\), or text* \\
\hline itemref & HTML elements \({ }^{\text {p735 }}\) & Referenced \({ }^{\text {p123 }}\) elements & Unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) consisting of IDs* \\
\hline itemscope & HTML elements \({ }^{\text {p734 }}\) & Introduces a microdata item & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline itemtype & HTML elements \({ }^{\text {p734 }}\) & Item types \({ }^{\mathrm{p} 734}\) of a microdata item & Unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) consisting of valid absolute URLs* \\
\hline kind & track \({ }^{\text {p386 }}\) & The type of text track & "subtitles \({ }^{\text {p386" }}\); "captions \({ }^{\text {p386" }}\); "descriptions \({ }^{\text {p386" }}\) " "chapters \({ }^{\text {p386" }}\); "metadata \({ }^{\text {p386" }}\) \\
\hline label & optgroup \({ }^{\text {p545 }}\); option \({ }^{\text {p546 }}\); track \({ }^{\text {p386 }}\) & User-visible label & Text \({ }^{\text {p129 }}\) \\
\hline lang & HTML elements \({ }^{\text {p140 }}\) & Language \({ }^{\text {p140 }}\) of the element & Valid BCP 47 language tag or the empty string \\
\hline list & input \({ }^{\text {p528 }}\) & List of autocomplete options & ID* \\
\hline loop & audio \({ }^{\text {p405 }}\); video \({ }^{\text {p405 }}\) & Whether to loop the media resource \({ }^{\text {p389 }}\) & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline low & meter \({ }^{\text {p558 }}\) & High limit of low range & Valid floating-point number \({ }^{\text {p69 * }}\) \\
\hline manifest & html \({ }^{1952}\) & Application cache manifest \({ }^{\text {p892 }}\) & Valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline max & input \({ }^{\text {p526 }}\) & Maximum value & Varies* \\
\hline max & meter \({ }^{\text {p558 }}\); progress \({ }^{\text {p556 }}\) & Upper bound of range & Valid floating-point number \({ }^{\text {p69 }}\) * \\
\hline maxlength & input \({ }^{\text {p522 }}\); textarea \({ }^{\text {p551 }}\) & Maximum length of value & Valid non-negative integer \({ }^{\text {p69 }}\) \\
\hline media & \[
\begin{aligned}
& \text { link }^{\text {p159 }} ; \text { source }{ }^{\text {p318 }} ; \\
& \text { style }{ }^{\text {p175 }}
\end{aligned}
\] & Applicable media & Valid media query list \({ }^{\text {p88 }}\) \\
\hline method & form \({ }^{\text {p571 }}\) & Variant to use for form submission \({ }^{\text {p595 }}\) & "GET \({ }^{\text {p5711 }}\); "P0ST \({ }^{\text {p571] }}\); "dialog \({ }^{\text {p571." }}\) \\
\hline min & input \({ }^{\text {p526 }}\) & Minimum value & Varies* \\
\hline min & meter \({ }^{\text {p558 }}\) & Lower bound of range & Valid floating-point number \({ }^{\text {p69 }}\) * \\
\hline minlength & input \({ }^{\text {p522 }}\); textarea \({ }^{\text {p551 }}\) & Minimum length of value & Valid non-negative integer \({ }^{\text {p69 }}\) \\
\hline multiple & input \({ }^{\text {p524 }}\); select \({ }^{\text {p539 }}\) & Whether to allow multiple values & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline muted & audio \({ }^{\text {p437 }}\); video \({ }^{\text {p437 }}\) & Whether to mute the media resource \({ }^{\text {p389 }}\) by default & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline name & button \(^{\text {p568 }}\); fieldset \({ }^{\text {p568\% }}\); & Name of the element to use for & Text \({ }^{\text {p129 * }}\) \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}

\hline name & map \(^{\text {p443 }}\) & Name of image map \({ }^{\text {p445 }}\) to reference \({ }^{\text {p123 }}\) from the usemap \({ }^{\text {p445 }}\) attribute & Text \({ }^{\text {p129 }}\) * \\
\hline name & meta \({ }^{1166}\) & Metadata name & Text \({ }^{\text {p129 }}\) * \\
\hline name & param \({ }^{\text {p379 }}\) & Name of parameter & Text \({ }^{\text {p129 }}\) \\
\hline name & slot \({ }^{\text {p633 }}\) & Name of shadow tree slot & Text \({ }^{\text {p129 }}\) \\
\hline nomodule & script \({ }^{\text {p615 }}\) & Prevents execution in user agents that support module scripts \({ }^{\text {p925 }}\) & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline nonce & HTML elements \({ }^{\text {p992 }}\) & Cryptographic nonce used in Content Security Policy checks [CSP] \({ }^{\text {p1285 }}\) & Text \({ }^{\text {p129 }}\) \\
\hline novalidate & form \({ }^{\text {p572 }}\) & Bypass form control validation for form submission \({ }^{\text {p595 }}\) & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline open & details \({ }^{\text {p604 }}\) & Whether the details are visible & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline open & \(\mathrm{dialog}^{\text {p611 }}\) & Whether the dialog box is showing & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline optimum & meter \({ }^{\text {p558 }}\) & Optimum value in gauge & Valid floating-point number \({ }^{\text {p69*}}\) \\
\hline pattern & input \({ }^{\text {p525 }}\) & Pattern to be matched by the form control's value & Regular expression matching the JavaScript Pattern production \\
\hline ping & \(\mathrm{a}^{\text {p284 }} ;\) area \(^{\text {p284 }}\) & URLs to ping & Set of space-separated tokens \({ }^{\text {p87 }}\) consisting of valid non-empty URLs \({ }^{\text {p88 }}\) \\
\hline placeholder & input \({ }^{\text {p530 }}\); textarea \({ }^{\text {p551 }}\) & User-visible label to be placed within the form control & Text \({ }^{\text {p129 }}\) * \\
\hline playsinline & video \({ }^{\text {p381 }}\) & Encourage the user agent to display video content within the element's playback area & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline poster & video \({ }^{\text {p381 }}\) & Poster frame to show prior to video playback & Valid non-empty URL potentially surrounded by spaces \({ }^{\text {p88 }}\) \\
\hline preload & \(\underline{\text { audio }}{ }^{\text {p401 }} ; \underline{\text { video }}{ }^{\text {p401 }}\) & Hints how much buffering the media resource \({ }^{\text {p389 }}\) will likely need & "none \({ }^{\text {p402 }}\) "; "metadata \({ }^{\text {p402 }}\) "; "auto \({ }^{\text {p402 }}{ }^{\text {n }}\) \\
\hline readonly & input \({ }^{\text {p522 }}\); textarea \({ }^{\text {p549 }}\) & Whether to allow the value to be edited by the user & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline readonly & form-associated custom elements \({ }^{\text {p704 }}\) & Affects willValidate \({ }^{\text {p593 }}\), plus any behavior added by the custom element author & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline referrerpolicy & \[
\begin{aligned}
& \frac{a^{p 284} ; \text { area }^{\text {p284 }} ;}{} \\
& \text { iframe } \\
& \text { link }{ }^{\text {p159 }} ; \text { script }^{\text {p3621 }} ;
\end{aligned}
\] & Referrer policy for fetches initiated by the element & Referrer policy \\
\hline rel & \(\underline{a}^{\text {p284 }}\); area \({ }^{\text {p284 }}\) & Relationship between the location in the document containing the hyperlink \({ }^{\text {p283 }}\) and the destination resource & Unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) * \\
\hline rel & link \({ }^{1158}\) & Relationship between the document containing the hyperlink \({ }^{\text {p283 }}\) and the destination resource & Unordered set of unique space-separated tokens \({ }^{\text {p87 }}\) * \\
\hline required & \[
\begin{aligned}
& \text { input }^{\text {p523 }} ; \text { select }^{\text {p539 }} ; \\
& \text { textarea }{ }^{\text {p551 }}
\end{aligned}
\] & Whether the control is required for form submission \({ }^{\text {p595 }}\) & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline reversed & op \({ }^{\text {2221 }}\) & Number the list backwards & Boolean attribute \({ }^{\text {p67 }}\) \\
\hline rows & textarea \({ }^{\text {p550 }}\) & Number of lines to show & Valid non-negative integer \({ }^{\text {p69 }}\) greater than zero \\
\hline rowspan & \(\underline{\mathrm{td}^{\text {p469 }} ; \mathrm{th}^{\text {p469 }}}\) & Number of rows that the cell is to span & Valid non-negative integer \({ }^{\text {p69 }}\) \\
\hline sandbox & iframe \({ }^{\text {P365 }}\) & Security rules for nested content & Unordered set of unique space-separated tokens \({ }^{\text {p87 }}\), ASCII case-insensitive, consisting of "allow-forms \({ }^{\text {p844" }}\), "allow-modals \({ }^{\text {p844" }}\) " "allow-orientationlock \({ }^{\text {p844" }}\), "allow-pointer-lock \({ }^{\text {p844" } ", ~ " a l l o w-p o p u p s ~}{ }^{\text {p843" }}\) " "allow-popups - \\
\hline
\end{tabular}

\begin{tabular}{|c|c|c|c|}
\hline \multicolumn{4}{|c|}{List of events} \\
\hline Event & Interface & Interesting targets & Description \\
\hline abort & Event & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) when the download was aborted by the user \\
\hline DOMContentLoaded & Event & Document \({ }^{\text {p114 }}\) & Fired at the Document \({ }^{\text {p114 }}\) once the parser has finished \\
\hline afterprint & Event & Window \({ }^{\text {8824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) after printing \\
\hline beforeprint & Event & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) before printing \\
\hline beforeunload & BeforeUnloadEvent \({ }^{\text {p887 }}\) & Window \({ }^{\text {p } 824}\) & Fired at the Window \({ }^{\text {p824 }}\) when the page is about to be unloaded, in case the page would like to show a warning prompt \\
\hline blur & Event & Window \({ }^{\text {p824 }}\), elements & Fired at nodes when they stop being focused \({ }^{\text {p771 }}\) \\
\hline cancel & Event & dialog \({ }^{\text {p610 }}\) elements & Fired at dialog \({ }^{\text {p610 }}\) elements when they are canceled by the user (e.g. by pressing the Escape key) \\
\hline change & Event & Form controls & Fired at controls when the user commits a value change (see also the input \({ }^{\text {p1281 }}\) event) \\
\hline click & MouseEvent & Elements & Normally a mouse event; also synthetically fired at an element before its activation behavior is run, when an element is activated from a non-pointer input device (e.g. a keyboard) \\
\hline close & Event or CloseEvent \({ }^{\text {p1014 }}\) & dialog \({ }^{\text {p610 }}\) elements, WebSocket \({ }^{\text {p1008 }}\) & Fired at dialog \({ }^{\text {p610 }}\) elements when they are closed, and at WebSocket \({ }^{\text {p1008 }}\) elements when the connection is terminated \\
\hline connect & MessageEvent \({ }^{\text {p998 }}\) & SharedWorkerGlobalScope \({ }^{\text {p1047 }}\) & Fired at a shared worker's global scope when a new client connects \\
\hline contextmenu & MouseEvent & Elements & Fired at elements when the user requests their context menu \\
\hline copy & Event & Elements & Fired at elements when the user copies data to the clipboard \\
\hline cut & Event & Elements & Fired at elements when the user copies the selected data on the clipboard and removes the selection from the document \\
\hline error & Event or ErrorEvent \({ }^{\text {p937 }}\) & Global scope objects, Worker \({ }^{\text {p1053 }}\) objects, elements, networking-related objects & Fired when unexpected errors occur (e.g. networking errors, script errors, decoding errors) \\
\hline focus & Event & Window \({ }^{\text {p824 }}\), elements & Fired at nodes gaining focus \({ }^{\text {p771 }}\) \\
\hline formdata & FormDataEvent \({ }^{\text {p663 }}\) & form \({ }^{\text {p486 }}\) elements & Fired at a form \({ }^{\text {p486 }}\) element when it is constructing the entry list \({ }^{\text {p5999 }}\) \\
\hline hashchange & HashChangeEvent \({ }^{\text {p884 }}\) & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{p 824}\) when the fragment part of the document's URL changes \\
\hline input & Event & Form controls & Fired at controls when the user changes the value (see also the change \({ }^{p 1281}\) event) \\
\hline invalid & Event & Form controls & Fired at controls during form validation if they do not satisfy their constraints \\
\hline languagechange & Event & Global scope objects & Fired at the global scope object when the user's preferred languages change \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|}
\hline Event & Interface & Interesting targets & Description \\
\hline load & Event & Window \({ }^{\text {p } 824}\), elements & Fired at the Window \({ }^{\text {p824 }}\) when the document has finished loading; fired at an element containing a resource (e.g. \(\underline{i m g}^{\text {p320 }}\), embed \({ }^{\text {p369 }}\) ) when its resource has finished loading \\
\hline message & MessageEvent \({ }^{\text {p9988 }}\) & Window \(^{\mathrm{p} 824}\), EventSource \({ }^{\text {p1006 }}\), WebSocket \({ }^{\text {p1008 }}\), MessagePort \({ }^{\text {p1022 }}\), BroadcastChannel \({ }^{\text {p1025 }}\), DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\), Worker \({ }^{\text {p1053 }}\), ServiceWorkerContainer & Fired at an object when it receives a message \\
\hline messageerror & MessageEvent \({ }^{\text {p9988 }}\) & \begin{tabular}{l}
Window \({ }^{\text {p824 }}\), MessagePort \({ }^{\text {p1022 }}\), \\
BroadcastChannel \({ }^{\text {p1025 }}\), \\
DedicatedWorkerGlobalScope \({ }^{\text {p1046 }}\), Worker \({ }^{\text {p1053 }}\), \\
ServiceWorkerContainer
\end{tabular} & Fired at an object when it receives a message that cannot be deserialized \\
\hline offline & Event & Global scope objects & Fired at the global scope object when the network connections fails \\
\hline online & Event & Global scope objects & Fired at the global scope object when the network connections returns \\
\hline open & Event & EventSource \({ }^{\text {p100] }}\), WebSocket \({ }^{\text {p1008 }}\) & Fired at networking-related objects when a connection is established \\
\hline pagehide & PageTransitionEvent \({ }^{\text {p884 }}\) & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) when the page's entry in the session history \({ }^{\text {p849 }}\) stops being the current entry \({ }^{\text {p850 }}\) \\
\hline pageshow & PageTransitionEvent \({ }^{\text {p884 }}\) & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) when the page's entry in the session history \({ }^{\text {p849 }}\) becomes the current entry \({ }^{\text {p850 }}\) \\
\hline paste & Event & Elements & Fired at elements when the user will insert the clipboard data in the most suitable format (if any) supported for the given context \\
\hline popstate & PopStateEvent \({ }^{\text {p883 }}\) & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) when the user navigates the session history \({ }^{\text {p849 }}\) \\
\hline readystatechange & Event & Document \({ }^{\text {p114 }}\) & Fired at the Document \({ }^{\text {p114 }}\) when it finishes parsing and again when all its subresources have finished loading \\
\hline rejectionhandled & PromiseRejectionEvent \({ }^{\text {p938 }}\) & Global scope objects & Fired at global scope objects when a previouslyunhandled promise rejection becomes handled \\
\hline reset & Event & form \({ }^{\text {p486 }}\) elements & Fired at a form \({ }^{\text {p486 }}\) element when it is reset \({ }^{\text {p603 }}\) \\
\hline securitypolicyviolation & Event & Elements & Fired at elements when a Content Security Policy violation is generated [CSP] \({ }^{\text {p1285 }}\) \\
\hline select & Event & Form controls & Fired at form controls when their text selection is adjusted (whether by an API or by the user) \\
\hline slotchange & Event & slot \({ }^{\text {p633 }}\) elements & Fired at slot \({ }^{\text {p633 }}\) elements when their assigned nodes change \\
\hline storage & StorageEvent \({ }^{\text {p1063 }}\) & Window \({ }^{\text {p824 }}\) & Fired at Window \({ }^{\text {p824 }}\) event when the corresponding localStorage \({ }^{\text {p1063 }}\) or sessionStorage \({ }^{\text {p1062 }}\) storage areas change \\
\hline submit & Event & form \({ }^{\text {p486 }}\) elements & Fired at a form \({ }^{\text {p486 }}\) element when it is submitted \({ }^{\text {p596 }}\) \\
\hline toggle & Event & details \({ }^{\text {p664 }}\) element & Fired at details \({ }^{\text {p664 }}\) elements when they open or close \\
\hline unhandledrejection & PromiseRejectionEvent \({ }^{\text {p938 }}\) & Global scope objects & Fired at global scope objects when a promise rejection goes unhandled \\
\hline unload & Event & Window \({ }^{\text {p824 }}\) & Fired at the Window \({ }^{\text {p824 }}\) object when the page is going away \\
\hline
\end{tabular}

Xan Gregg，xenotheme，XhmikosR，Xida Chen，Xidorn Quan，Xue Fuqiao，Yang Chen，Yao Xiao，Yash Handa，Yay295，Ye－Kui Wang， Yehuda Katz，Yi Xu，Yi－An Huang，Yngve Nysaeter Pettersen，Yoav Weiss，Yonathan Randolph，Yury Delendik，平野裕（Yutaka Hirano），Yuzo Fujishima，Zhenbin Xu，张智強（Zhiqiang Zhang），Zoltan Herczeg，and Øistein E．Andersen，for their useful comments，both large and small，that have led to changes to this specification over the years．

Thanks also to everyone who has ever posted about HTML to their blogs，public mailing lists，or forums，including all the contributors to the various W3C HTML WG lists and the various WHATWG lists．

Special thanks to Richard Williamson for creating the first implementation of canvas \({ }^{p 634}\) in Safari，from which the canvas feature was designed．

Special thanks also to the Microsoft employees who first implemented the event－based drag－and－drop mechanism， contenteditable \({ }^{\text {p787 }}\) ，and other features first widely deployed by the Windows Internet Explorer browser．

Special thanks and \(\$ 10,000\) to David Hyatt who came up with a broken implementation of the adoption agency algorithm \({ }^{\text {p1147 }}\) that the editor had to reverse engineer and fix before using it in the parsing section．

Thanks to the participants of the microdata usability study for allowing us to use their mistakes as a guide for designing the microdata feature．

Thanks to the many sources that provided inspiration for the examples used in the specification．

Thanks also to the Microsoft blogging community for some ideas，to the attendees of the W3C Workshop on Web Applications and Compound Documents for inspiration，to the \＃mrt crew，the \＃mrt．no crew，and the \＃whatwg crew，and to Pillar and Hedral for their ideas and support．

Thanks to Igor Zhbanov for generating PDF versions of the specification．
Special thanks to the RICG for developing the picture \({ }^{\text {p316 }}\) element and related features；in particular thanks to Adrian Bateman，Bruce Lawson，David Newton，Ilya Grigorik，John Schoenick，Leon de Rijke，Mat Marquis，Marcos Cáceres，Tab Atkins，Theresa O＇Connor，and Yoav Weiss for their contributions．

Special thanks to the WPWG for incubating the custom elements \({ }^{\text {p696 }}\) feature．In particular，thanks to David Hyatt and lan Hickson for their influence through the XBL specifications，Dimitri Glazkov for the first draft of the custom elements specification，and to Alex Komoroske，Alex Russell，Andres Rios，Boris Zbarsky，Brian Kardell，Daniel Buchner，Dominic Cooney，Erik Arvidsson，Elliott Sprehn， Hajime Morrita，Hayato Ito，Jan Miksovsky，Jonas Sicking，Olli Pettay，Rafael Weinstein，Roland Steiner，Ryosuke Niwa，Scott Miles，Steve Faulkner，Steve Orvell，Tab Atkins，Theresa O＇Connor，Tim Perry，and William Chen for their contributions．

Part of the revision history of the picture \({ }^{\text {p316 }}\) element and related features can be found in the ResponsiveImagesCG／picture－ element repository．

Part of the revision history of the theme－color \({ }^{p 168}\) metadata name can be found in the whatwg／meta－theme－color repository．
Part of the revision history of the custom elements \({ }^{\text {p696 }}\) feature can be found in the w3c／webcomponents repository，which is available under the W3C Permissive Document License．

Part of the revision history of the innerText \({ }^{\text {p148 }}\) getter and setter can be found in the rocallahan／innerText－spec repository．
For about ten years starting in 2003，this standard was almost entirely written by lan Hickson（Google，ian＠hixie．ch）．More recently， Simon Pieters（Bocoup，zcorpan＠gmail．com），Anne van Kesteren（Mozilla，annevk＠annevk．nl），Philip Jägenstedt（Google， philip＠foolip．org），and Domenic Denicola（Google，d＠domenic．me），all previously long－time contributors，have joined lan in editing the text directly．
