## Question 1 (60\%)

Given a directed graph, where the values indicate upper bounds:

a. (15\%) List all cuts between node 1 and node 7 . Find the minimum cut (or cuts).
b. ( $15 \%$ ) Find the maximum flow between 1 and 7 using the Augmenting Algorithm. List all algorithmic steps.
c. ( $15 \%$ ) Find the maximum flow between 1 and 7 using the Simplex Algorithm. Show the objective function and constraints. List the algorithmic steps. You can use any available software (Solver, Lindo, etc.)
d. $(10 \%)$ Formulate the dual problem. Show the objective function and constraints.
e. $(5 \%)$ find the range of the capacity of arc $(3,4)$ that does NOT change the maximum flow.
Question 2 (40\%)
The following table lists the arcs of a directed graph:

| Arc capacity | Cost of Flow $^{1}$ | To Node | From Node |
| :---: | :---: | :---: | :---: |
| 40 | 2 | 2 | 1 |
| 90 | 3 | 4 | 1 |
| 90 | 3 | 3 | 2 |
| 20 | 1 | 5 | 2 |
| 40 | 2 | 6 | 3 |
| 40 | 2 | 5 | 4 |
| 160 | 4 | 7 | 4 |
| 20 | 1 | 6 | 5 |
| 40 | 2 | 8 | 5 |
| 40 | 2 | 9 | 6 |
| 90 | 3 | 8 | 7 |
| 40 | 2 | 9 | 8 |

a. ( $10 \%$ ) List all simple paths between 1 and 9 and calculate each path cost.
b. ( $10 \%$ ) Find the maximum flow between 1 and 9 and the flow distribution in the network.
c. ( $10 \%$ ) In which arc (or arcs) you should increase the capacity, in order to increase the maximum flow? Take into account the cost of each arc.
d. $(10 \%)$ Is it possible to decrease the total cost in the solution found in item (b) without decreasing the maximum flow?

[^0]
[^0]:    ${ }^{1}$ Each use of a specific arc will incur the mentioned cost, regardless of the volume of flow.
