

About the MVO of UTR # 50

Comments by Taro Yamamoto

1. Regarding the MVO in General

“2 Introduction” of UTR # 50 wrote:

In East Asia, Kanji and Kana characters are upright, Latin letters of acronyms are upright, while words and sentences in the Latin script are typically sideways, as can be seen in figure 3. The property Mixed Vertical Orientation documents the default orientation of characters in this scenario.

The Mixed Vertical Orientation should be referenced when Japanese texts are composed in vertical lines. The reason for this is simple: in ordinary Japanese, multiple scripts are used, and each script has its own set of conventions for text composition, and the tradition of Japanese typography defines how to compose characters of different source scripts in vertical lines.

However, it should be noted that not all characters of multiple source scripts necessarily have their Japanese vertical mode orientations (or postures: UPRIGHT and ROTATED, etc), because there are cases where any vertical Japanese usages have not yet been well established or stably, widely accepted in the communities of Japanese editors, typographers, and readers. In those cases, the orientation should be aligned to the direction of the parent vertical Japanese line. For example, an English word or sentence composed of multiple Latin alphabet characters tend to be rotated 90 degrees clockwise, although if it is composed of up to three or four characters, the characters’ posture can be UPRIGHT in the so-called TCY (Tate-Chu-Yoko) mode, or if only one character is used, a full-width character separately encoded in the Full-width and Half-width Forms and other sections of Unicode may be used to make it in the UPRIGHT posture.

The text quoted above says, “Latin letters of acronyms are upright, while words and sentences in the Latin script are typically sideways . . .” This seems to be a rather vague description, because even Latin letters of acronyms can be sideways, if such acronyms are followed by some related words or sentences de-

封筒には「To: David Thorogood, Esq.」と書いてあった。
パソコン用いたDTPが普及した。

Figure 1

The right-side line has a rotated acronym, while the left-side line uses the acronym DTP in the upright posture.

scribed in Latin letters. You can see the point, if you look at **Figure 1** on the left side.

2. When can a character be in the UPRIGHT posture in Japanese vertical lines?

2.1. Half-width and Full-width Forms (and similar others)

First, it should be noted that proportional and full-width characters of some Latin alphabet characters and Arabic numbers are encoded, so that one can distinguish the proportional and full-width types by using ordinary Unicode characters. Traditionally, better or worse, with this double encoding policy, it has been possible to compose full-width Latin alphabet characters and Arabic numbers in the UPRIGHT posture in vertical lines, keeping the proportional ones -90 degrees rotated.

1 の h タイ 15 が a ポ 0 始 n グラ 1 年に e フィ 1 まり s すな だ。 G ウチ 2 年代 v エニスの t en ちわ 1 にタリック b er g ちわ 1 印刷者 A g が 1 が 1 う 4 r a 4 う 4 p 0 h y は た M 年代 n な う た u か う た i ば う た u に う た s 昔明 s は た J o

The same thing applies to symbols such as ! and ? listed in the Unicode section of the Half-width and Full-width Forms.

Some people say these Half-width and Full-width Forms should be abandoned, and we should not use these to distinguish the two types of metrics. Some other people insist that the scope of the Half-width and Full-width Forms should be expanded. My view about this is that in order to avoid compatibility problems, we should continue making these separately, doubly encoded characters all available, and keep using them as they are.

2.2. Arabic Numbers and Latin alphabet characters

In what ways can Arabic numbers and Latin alphabet characters be composed in the UPRIGHT posture in Japanese vertical lines? The author thinks the chief usages are limited to the following cases:

2.2.1. Usage 1: Newspapers and magazines

In newspaper and magazine articles, etc. full-width Arabic numbers and Latin alphabet characters are widely used for a range of small numbers or short words such as abbreviations. Still, because the standard line-length tends to be as short as eleven characters long in typical Japanese newspapers, it becomes necessary to rewrite big numbers into Chinese numbers, in order to keep a good level of readability.

Also, look at **Figure 2**. Because full-width numbers and Latin alphabet characters are designed mainly for stand-alone single-digit usages, they look extremely ugly when multiple successive digits are composed in the UPRIGHT posture. The vertical spaces between Arabic numbers have to be uneven and random, because no tuning is made to the vertical metrics of these glyphs in font. Japanese OpenType fonts may use the VORG GPOS feature to control the position of vertical Arabic numbers and Latin alphabet characters, but its main purpose is only to position each glyph within the EM body boundaries, and not to optimize the vertical spacing

Figure 2

Only short words or small numbers can be used in the upright posture, or the spacing between characters look irregular and uneven. In this example, full-width Arabic numbers and Latin alphabet characters are used with the 'VORG' GPOS feature, and character collision was avoided. Without the OpenType® font feature, the result would have been destructively worse than this.

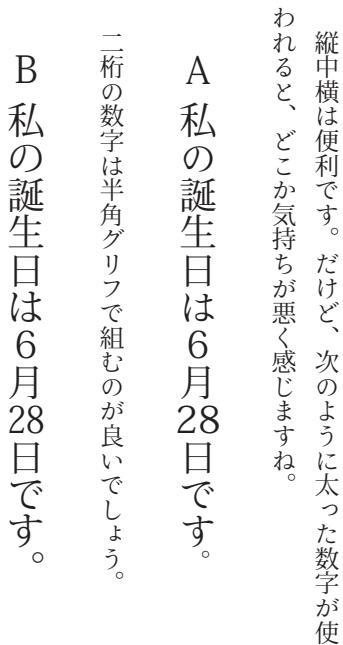

Figure 3

Both of the examples A and B use TCY to set the two-digit number '28'. But A simply uses proportional numbers fail to prevent the numbers exceed the left and right side EM box boundaries, while B with precisely half-width number glyphs accessible from the OpenType 'hwid' GSUB feature, succeeds in preventing the numbers from bloating.

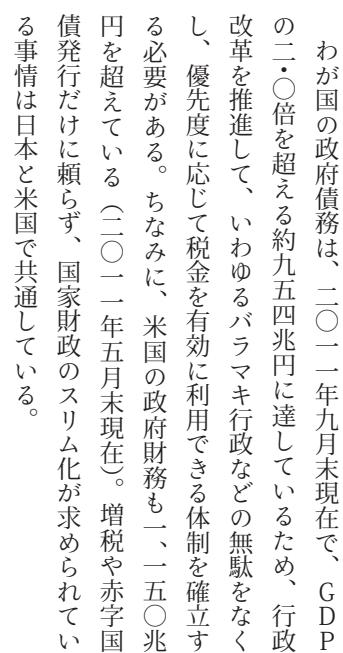

Figure 4

Chinese numbers are typically used in Japanese vertical lines. It is the most authentic style of typesetting numbers in vertical lines.

between multiple Latin alphabet characters composed in the UPRIGHT posture in vertical lines.

Also, today's fonts do not usually have any metrics information to optimally and optically center UPRIGHT Latin alphabet characters in vertical lines. In addition, even if it becomes possible to optimize the spacing of UPRIGHT Latin alphabet glyphs, the resulting composed characters' widths will be all proportional, and this may be a negative factor in optimizing the justification of the parent vertical line based on the Japanese EM-body-based grid system. No consideration about this issue has ever been made in the history of Western typography, because usually Western type has not been composed in the UPRIGHT posture in vertical lines.

2.2.2. Usage 2 TCY

A more widely accepted convention is TCY (Tate-Chu-Yoko), used for a limited number of digits in Arabic numbers or Latin alphabet characters. However, this method has the following problems.

2.2.2.1. Problem 1

As shown in **Figure 3**, this method requires the widths of Arabic number glyphs to be uniformed into precisely half the width of the EM body, or the widths of any two-digit numbers will exceed the left and right side boundaries of the EM body of the parent vertical line. Japanese OpenType supports this half-width capability through the 'hwid' GSUB feature.

2.2.2.2. Problem 2

More importantly, this method has a serious limitation. You cannot put more Arabic numbers than the space between the preceding and succeeding lines can allow. Usually, this method is used for two or three-digit numbers or words, although the limit can vary depending on the available space between lines. How can you handle large numbers?

Common to all these usages of Arabic numbers in the UPRIGHT posture in Japanese vertical lines, it can be said that all these have inherent, serious, typographic limitations. These are widely used as expedient methods, but due to the inherent limitations, these are not thought to be generally applicable methods of composing numbers in Japanese typography, however frequently they may be used.

A stand-alone, one-digit number or a single Latin alphabet character can be set in the UPRIGHT posture. For two or three-digit numbers, you can use TCY. This is true. However, any serious typographers know that, if possible, any numbers should be rewritten or trans-coded into their corresponding Chinese numbers for vertical lines. When Chinese numbers are used, half-width vertical Japanese commas should be used for delimiting digits. A decimal point can be represented by a middle-dot character. Also, use *katakana* characters to describe unit names, instead of using unit symbols or Latin alphabet characters. This is

A

タ イ ポ グ ラ フ ィ 、 す な わ ち t y p o g r a p h y の 歴 史 は 長 い。 J o h a n n e s G u t e n b e r g の 始 ま り だ。 ヴ エ ニ ス の 印 刷 者 A l d u s M a n u t i u s は、 1 5 0 1 年 に イ タ リ ッ ク 体 活 字 を 創 始 し た。

B

Figure 5

The example A has already been introduced in Figure 2. The same text can be better composed as shown in the example B above, which does not use upright vertical characters for Latin alphabet characters. Arabic numbers are rewritten in Chinese numbers.

the most authentic, traditional and generally applicable method of composing numbers in Japanese vertical lines (see **Figure 4**).

Some people may say that how texts should be prepared, rewritten or transcoded should be decided by the editors or typographers who need to compose them, and that it has nothing to do with the vertical orientation that UTR # 50 tries to define.

The author completely agrees with this point. The author does not intend to make the UTR # 50 unnecessarily intervene in any decision making processes on the level of text preparation and writing. But if some people insist that it also should be decided solely by the editors or typographers, what default vertical orientation a character should have, and also that because the methods of using TCY and full-width numbers and Latin alphabet characters are widely used, they should be the standard default methods, and the UPRIGHT posture should be the default orientation for those characters in Japanese vertical lines, The author completely disagrees.

In the paragraphs above, the author has already discussed the reason why the author must disagree with the idea. To express it shortly, the reason is that any of the above-mentioned methods using UPRIGHT Arabic numbers or Latin alphabet characters in Japanese vertical lines are only expedient tricks, which work only for their limited uses, and may be useful only for what they are, and also that Arabic numbers and Latin alphabet characters in the UPRIGHT posture result in bad and ugly arrangements of characters due to the inevitable uneven spacing, when composed in vertical lines. Those characters are inherently not designed to be composed in vertical lines.

If you look at the example of UPRIGHT Arabic numbers and Latin alphabet characters composed in Japanese vertical lines in **Figure 5**, you will clearly see what the author means. It is impossible to compose Arabic numbers and Latin alphabet characters in the UPRIGHT posture with good letter spacing, because they are not designed to support the vertical writing direction from the beginning.

3. Symbols and abbreviations

Next, the author would like to discuss how we should handle symbols and abbreviations in Japanese vertical lines. the author has to admit that there are “gray zones”, where it is difficult to decide whether a symbol should be in the UP-

RIGHT posture or ROTATED in Japanese vertical lines. So, the author thinks it is necessary to have a prioritizing rule set for the decision making.

3.1. “Would be UPRIGHT” priorities

Based on the above-mentioned considerations, the author thinks that characters’ “Would be UPRIGHT” tendencies in Japanese vertical lines can be evaluated according to the following prioritization rule.

3.1.1. “Would be Upright” Priorities:

U1: Chinese characters, Japanese *kana* characters and their related marks that need neither special glyph shapes nor different orientations in Japanese vertical lines.

U2: Full-width characters separately encoded from the proportional characters (in the Unicode Half-width and Full-width Forms section)

U3: Symbols and abbreviations that are mere pictures or geometric shapes without any directionality.

U4: Western-origin ligatures and abbreviations whose decomposed forms can be represented with ordinary Latin alphabet characters or Arabic numbers or symbols that are -90 degrees rotated in vertical lines.

3.1.2. “More Ambiguous” characters

U5 or R5: If a character has one or more similar characters, if the category of the character is narrower or more specialized than the others’, the posture of the others’ should be adopted. For example, if an *emoji* picture and a mathematical symbol resemble each other, but can have different vertical orientations, due to the original source fields (*emoji* and mathematics, etc), choose the greater, more popular field’s vertical orientation.

3.1.3. “Would be Rotated” Priorities

R1: Latin alphabet characters, Arabic numbers, and related proportional punctuations and marks.

R2: Proportional characters separately encoded from the full-width characters (in the Unicode Half-width and Full-width Forms section and others)

R3: Standard multi-purpose, parentheses, punctuations and symbols with directionality (arrows and symbols for musical notations, etc).

R4: Symbols and abbreviations that are originated in Western typography or writing systems.

This rule set is based on the same criteria as those the author has used to decide the vertical postures of Arabic numbers and Latin alphabet characters, viz. to

avoid as many typographically problematic cases as possible, and to avoid as many possibilities of creating aesthetically bad results as possible.

For example, symbols like the c/o (care of) abbreviation character (U+2105) are pure Western-originated symbols. There is no practical usages for this symbol in Japan, except the cases where it is self-referenced in the sentences like: 「この%記号は気付と同じ意味です」 (This % symbol has the same meaning as that of 「気付」 in Japanese). There is no reason for this character's being set in the UPRIGHT posture in vertical lines, in many cases. There are many similar Western-originated symbols like this.

4. Conclusion

The main purpose of this document is to propose a reasonably defined list of Japanese vertical character orientations, which can be referenced as the default character orientations for representing characters in Japanese vertical lines.

As mentioned in one of the previous sections, there are different styles of Japanese character representation for various purposes, and it is impossible to uniform them. Depending on the usages, a character can have different postures or orientations in Japanese vertical lines.

However, it is possible not to select as the default, standard usages the usages that are mere expedient tricks and have inherent limitations, and the usages that tend to result in bad typography for some reason (for example, because of the lack of any traditional conventions to compose the characters in Japanese vertical lines, or the lack of some needed metrics information in font, etc).

In many cases, there have not been established conventional styles for composing Arabic numbers, Latin alphabet characters, and other symbols or abbreviations that were originated in Western typography in Japanese vertical lines. They tend to be badly represented typographically, visually or optically, if they are simply composed and displayed in the UPRIGHT posture in Japanese vertical lines. All these must not be composed in the UPRIGHT posture by default, though the users should be given a method to tailor or customize the character orientations. Instead, their orientations should be defined, so that their original baseline directions can be aligned with the writing direction of the main vertical line. Typically, Latin alphabet characters that are encoded not as full-width characters for Japanese usages should be rotated clockwise.

The author's aim was to find a reasonable set of vertical orientations defined for Unicode characters, with which we can avoid undesirable typographical effects. Once a set of default orientations is defined, people tend to accept it as is, and start regarding it as the standard set of orientations, as time goes by, even if it is possible for them to customize or modify it. For example, if we define all Latin alphabet and Arabic numbers and related symbols to be UPRIGHT in Japanese vertical lines, by default, not a few people will start making Latin alphabet characters and Arabic numbers always in the UPRIGHT posture in Japanese vertical lines, forgetting that the most authentic editorial method to handle Arabic numbers in vertical lines is to rewrite or trans-code them into Chinese numbers. Such people will lose the opportunity to learn and remember

the traditional, authentic style with which they can create better typography in your web applications. On the other hand, they will soon propagate their own style of typography as something “default” or “standard”, and will suffer from the resulting negative effects of abusing UPRIGHT non-Japanese characters in Japanese vertical lines.

Of course, as far as it is done with thorough understanding of Japanese typography, the author agrees that there are many cases where TCY, Latin alphabet and Arabic numbers can be used effectively in the UPRIGHT posture. But such styles should be used by skilled typographers and designers carefully, through the methods of explicit tagging or in some other ways. Such tricks should not be put into the default or standard set exposed to anyone.

Based on these, the author thinks it incredible that some people today insist that most Western-originated, Latin Alphabet characters, Arabic numbers and symbols and abbreviations should have the UPRIGHT posture in Japanese vertical lines by default. Such a proposal will be effective only in amplifying the risk of misleading users and developers about Japanese typography and how to compose characters in vertical lines.

4. Appendix: Vertical Orientations

Here, I would like to try to use the above-mentioned priorities to some characters, which seem to be ambiguous about the vertical orientations.

The last column shows each character's vertical orientation marked as R, U or Tu. The Tu instances are inherited from the original database of UTR # 50, and the priorities from R1 to R5, and from U1 to U5 are marked as R and U respectively.

The first column also shows orientations, but they are the same as those in the original database of UTR # 50, and not part of this proposal.

REMARK:	2012/06/28	Version 1.1.1 (DRAFT STATE)
REMARK:	2012/06/30	Version 1.1.2 (DRAFT STATE)
REMARK:	2012/07/01	Version 1.1.3 (DRAFT STATE)
In this table, Mongolian (U+1800 - U+18AF) and Phags-pa (U+A840 - U+A87F) are defined to be UPRIGHT, based on the standard posture of the characters listed in the Unicode 6.1 Character Code Charts. But, we should pay attention to the fact that it is known that glyphs in Mongolian and Phags-pa fonts are usually +90 degrees pre-rotated in the horizontal writing mode, so that they will be displayed in the UPRIGHT posture when rotated -90 degrees in the vertical writing mode.		
REMARK:	2012/07/01	Version 1.1.4 (DRAFT STATE)
Shinyu Murakami kindly informed me that he found instances of the orientation Tr in the original version were incorrectly changed to Tu, and also two instances of the incorrect orientation identifier "U5" were found in all the versions up to 1.1.3. Also, he pointed out some errors that seemed to be due to some problem in the author's style setting for the Excel fields in the intermediate files. The author corrected these two errors in the version 1.1.4.		
REMARK:	2012/07/02	Version 1.1.2 (DRAFT STATE)
As suggested by Shinyu Murakami, the decision made at the conference on June 7, 2012 needed to be reflected on this document.
