If any null wide-character codes were written into the destination, the *wcpncpy*( ) function shall return the address of the first such null wide-character code. Otherwise, it shall return *&ws1*[*n*].

The *wcsncpy*( ) function shall return *ws1*.

No return values are reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

If there is no null wide-character code in the first *n* wide-character codes of the array pointed to by *ws2*, the result is not null-terminated.

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

wcsrchr — wide-character string scanning operation

SYNOPSIS

```
#include <wchar.h>

wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wcsrchr*( ) function shall locate the last occurrence of *wc* in the wide-character string pointed to by *ws*. The application shall ensure that the value of *wc* is a character representable as a type **wchar_t** and a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code shall be considered to be part of the wide-character string.

RETURN VALUE

Upon successful completion, *wcsrchr*( ) shall return a pointer to the wide-character code or a null pointer if *wc* does not occur in the wide-character string.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

NAME

wcsnrtombs, wcsrtombs — convert a wide-character string to a character string (restartable)

SYNOPSIS

```
#include <wchar.h>

size_t wcsnrtombs(char *restrict dst, const wchar_t **restrict src,
    size_t nwc, size_t len, mbstate_t *restrict ps);
size_t wcsrtombs(char *restrict dst, const wchar_t **restrict src,
    size_t len, mbstate_t *restrict ps);
```

DESCRIPTION

For *wcsrtombs*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wcsrtombs*( ) function shall convert a sequence of wide characters from the array indirectly pointed to by *src* into a sequence of corresponding characters, beginning in the conversion state described by the object pointed to by *ps*. If *dst* is not a null pointer, the converted characters shall then be stored into the array pointed to by *dst*. Conversion continues up to and including a terminating null wide character, which shall also be stored. Conversion shall stop earlier in the following cases:

- When a code is reached that does not correspond to a valid character
- When the next character would exceed the limit of *len* total bytes to be stored in the array pointed to by *dst* (and *dst* is not a null pointer)

Each conversion shall take place as if by a call to the *wcrtomb*( ) function.

If *dst* is not a null pointer, the pointer object pointed to by *src* shall be assigned either a null pointer (if conversion stopped due to reaching a terminating null wide character) or the address just past the last wide character converted (if any). If conversion stopped due to reaching a terminating null wide character, the resulting state described shall be the initial conversion state.

If *ps* is a null pointer, the *wcsrtombs*( ) function shall use its own internal **mbstate_t** object, which is initialized at program start-up to the initial conversion state. Otherwise, the **mbstate_t** object pointed to by *ps* shall be used to completely describe the current conversion state of the associated character sequence.

The *wcsrtombs*( ) function need not be thread-safe if called with a NULL *ps* argument.

The *wcsnrtombs*( ) function shall be equivalent to the *wcsrtombs*( ) function, except that the conversion is limited to the first *nwc* wide characters.

The behavior of these functions shall be affected by the *LC_CTYPE* category of the current locale.

The implementation shall behave as if no function defined in System Interfaces volume of POSIX.1-200x calls these functions.

RETURN VALUE

If conversion stops because a code is reached that does not correspond to a valid character, an encoding error occurs. In this case, these functions shall store the value of the macro [EILSEQ] in *errno* and return (**size_t**)–1; the conversion state is undefined. Otherwise, these functions shall return the number of bytes in the resulting character sequence, not including the terminating null (if any).

69831 **ERRORS**

69832 These functions shall fail if:

69833 [EILSEQ] A wide-character code does not correspond to a valid character.

69834 These functions may fail if:

69835 CX [EINVAL] *ps* points to an object that contains an invalid conversion state.

69836 **EXAMPLES**

69837 None.

69838 **APPLICATION USAGE**

69839 None.

69840 **RATIONALE**

69841 None.

69842 **FUTURE DIRECTIONS**

69843 None.

69847 **CHANGE HISTORY**

69848 First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995
69849 (E).

69850 **Issue 6**

69851 In the DESCRIPTION, a note on using this function in a threaded application is added.

69852 Extensions beyond the ISO C standard are marked.

69853 The normative text is updated to avoid use of the term "must" for application requirements.

69854 The *wcsrtombs*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

69855 **Issue 7**

69856 Austin Group Interpretation 1003.1-2001 #148 is applied, clarifying that the *wcsrtombs*( ) function
69857 need not be thread-safe if called with a NULL *ps* argument.

69858 Austin Group Interpretation 1003.1-2001 #170 is applied.

69859 The *wcnsrtombs*( ) function is added from The Open Group Technical Standard, 2006, Extended
69860 API Set Part 1.

NAME

wcsspn — get the length of a wide substring

SYNOPSIS

```
#include <wchar.h>

size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wcsspn*( ) function shall compute the length (in wide characters) of the maximum initial segment of the wide-character string pointed to by *ws1* which consists entirely of wide-character codes from the wide-character string pointed to by *ws2*.

RETURN VALUE

The *wcsspn*( ) function shall return the length of the initial substring of *ws1*; no return value is reserved to indicate an error.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The RETURN VALUE section is updated to indicate that *wcsspn*( ) returns the length of *ws1* rather that *ws1* itself.

69894 **NAME**

69895 wcsstr — find a wide-character substring

69896 **SYNOPSIS**

69897
```
#include <wchar.h>
```

69898
```
wchar_t *wcsstr(const wchar_t *restrict ws1,
```

69899
```
    const wchar_t *restrict ws2);
```

69900 **DESCRIPTION**

69901 CX The functionality described on this reference page is aligned with the ISO C standard. Any
69902 conflict between the requirements described here and the ISO C standard is unintentional. This
69903 volume of POSIX.1-200x defers to the ISO C standard.

69904 The *wcsstr*( ) function shall locate the first occurrence in the wide-character string pointed to by
69905 *ws1* of the sequence of wide characters (excluding the terminating null wide character) in the
69906 wide-character string pointed to by *ws2*.

69907 **RETURN VALUE**

69908 Upon successful completion, *wcsstr*( ) shall return a pointer to the located wide-character string,
69909 or a null pointer if the wide-character string is not found.

69910 If *ws2* points to a wide-character string with zero length, the function shall return *ws1*.

69911 **ERRORS**

69912 No errors are defined.

69913 **EXAMPLES**

69914 None.

69915 **APPLICATION USAGE**

69916 None.

69928 The *wcsstr*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcstod, wcstof, wcstold — convert a wide-character string to a double-precision number

SYNOPSIS

```
#include <wchar.h>

double wcstod(const wchar_t *restrict nptr, wchar_t **restrict endptr);
float wcstof(const wchar_t *restrict nptr, wchar_t **restrict endptr);
long double wcstold(const wchar_t *restrict nptr,
    wchar_t **restrict endptr);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **double**, **float**, and **long double** representation, respectively. First, they shall decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as a floating-point constant or representing infinity or NaN
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to a floating-point number, and return the result.

The expected form of the subject sequence is an optional `'+'` or `'−'` sign, then one of the following:

- A non-empty sequence of decimal digits optionally containing a radix character; then an optional exponent part consisting of the wide character `'e'` or the wide character `'E'`, optionally followed by a `'+'` or `'−'` wide character, and then followed by one or more decimal digits
- A 0x or 0X, then a non-empty sequence of hexadecimal digits optionally containing a radix character; then an optional binary exponent part consisting of the wide character `'p'` or the wide character `'P'`, optionally followed by a `'+'` or `'−'` wide character, and then followed by one or more decimal digits
- One of INF or INFINITY, or any other wide string equivalent except for case
- One of NAN or NAN(*n-wchar-sequence*$_{opt}$), or any other wide string ignoring case in the NAN part, where:

```
n-wchar-sequence:
    digit
    nondigit
    n-wchar-sequence digit
    n-wchar-sequence nondigit
```

The subject sequence is defined as the longest initial subsequence of the input wide string, starting with the first non-white-space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide string is not of the expected form.

If the subject sequence has the expected form for a floating-point number, the sequence of wide characters starting with the first digit or the radix character (whichever occurs first) shall be interpreted as a floating constant according to the rules of the C language, except that the radix character shall be used in place of a period, and that if neither an exponent part nor a radix character appears in a decimal floating-point number, or if a binary exponent part does not appear in a hexadecimal floating-point number, an exponent part of the appropriate type with value zero shall be assumed to follow the last digit in the string. If the subject sequence begins with a minus-sign, the sequence shall be interpreted as negated. A wide-character sequence INF or INFINITY shall be interpreted as an infinity, if representable in the return type, else as if it were a floating constant that is too large for the range of the return type. A wide-character sequence NAN or NAN(*n-wchar-sequence*$_{opt}$) shall be interpreted as a quiet NaN, if supported in the return type, else as if it were a subject sequence part that does not have the expected form; the meaning of the *n*-wchar sequences is implementation-defined. A pointer to the final wide string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

If the subject sequence has the hexadecimal form and FLT_RADIX is a power of 2, the conversion shall be rounded in an implementation-defined manner.

CX The radix character shall be as defined in the locale of the process (category *LC_NUMERIC*). In the POSIX locale, or in a locale where the radix character is not defined, the radix character shall default to a <period> (`'.'`).

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX The *wcstod*( ) function shall not change the setting of *errno* if successful.

Since 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstod*( ), *wcstof*( ), or *wcstold*( ), then check *errno*.

RETURN VALUE

Upon successful completion, these functions shall return the converted value. If no conversion could be performed, 0 shall be returned CX and *errno* may be set to [EINVAL].

If the correct value is outside the range of representable values, ±HUGE_VAL, ±HUGE_VALF, or ±HUGE_VALL shall be returned (according to the sign of the value), and *errno* shall be set to [ERANGE].

If the correct value would cause underflow, a value whose magnitude is no greater than the smallest normalized positive number in the return type shall be returned and *errno* set to [ERANGE].

ERRORS

The *wcstod*( ) function shall fail if:

[ERANGE] The value to be returned would cause overflow or underflow.

The *wcstod*( ) function may fail if:

CX [EINVAL] No conversion could be performed.

EXAMPLES

None.

APPLICATION USAGE

If the subject sequence has the hexadecimal form and FLT_RADIX is not a power of 2, and the result is not exactly representable, the result should be one of the two numbers in the appropriate internal format that are adjacent to the hexadecimal floating source value, with the extra stipulation that the error should have a correct sign for the current rounding direction.

If the subject sequence has the decimal form and at most DECIMAL_DIG (defined in **<float.h>**) significant digits, the result should be correctly rounded. If the subject sequence *D* has the decimal form and more than DECIMAL_DIG significant digits, consider the two bounding, adjacent decimal strings *L* and *U*, both having DECIMAL_DIG significant digits, such that the values of *L*, *D*, and *U* satisfy `"L <= D <= U"`. The result should be one of the (equal or adjacent) values that would be obtained by correctly rounding *L* and *U* according to the current rounding direction, with the extra stipulation that the error with respect to *D* should have a correct sign for the current rounding direction.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD Chapter 7 (on page 135), **<float.h>**, **<wchar.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO/IEC 9899: 1999 standard:

- The *wcstod*( ) prototype is updated.
- The *wcstof*( ) and *wcstold*( ) functions are added.
- If the correct value for *wcstod*( ) would cause underflow, the return value changed from 0 (as specified in Issue 5) to the smallest normalized positive number.
- The DESCRIPTION, RETURN VALUE, and APPLICATION USAGE sections are extensively updated.

ISO/IEC 9899: 1999 standard, Technical Corrigendum 1 is incorporated.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/66 is applied, correcting the second paragraph in the RETURN VALUE section.

70057 **Issue 7**
70058 Austin Group Interpretation 1003.1-2001 #015 is applied.

70059 **NAME**

70060 wcstoimax, wcstoumax — convert a wide-character string to an integer type

70100 **NAME**

70101 wcstok — split a wide-character string into tokens

70102 **SYNOPSIS**

70103
```
#include <wchar.h>
```

70104
```
wchar_t *wcstok(wchar_t *restrict ws1, const wchar_t *restrict ws2,
```
70105
```
    wchar_t **restrict ptr);
```

70106 **DESCRIPTION**

70107 CX The functionality described on this reference page is aligned with the ISO C standard. Any
70108 conflict between the requirements described here and the ISO C standard is unintentional. This
70109 volume of POSIX.1-200x defers to the ISO C standard.

70110 A sequence of calls to *wcstok*( ) shall break the wide-character string pointed to by *ws1* into a
70111 sequence of tokens, each of which shall be delimited by a wide-character code from the wide-
70112 character string pointed to by *ws2*. The *ptr* argument points to a caller-provided **wchar_t** pointer
70113 into which the *wcstok*( ) function shall store information necessary for it to continue scanning the
70114 same wide-character string.

70115 The first call in the sequence has *ws1* as its first argument, and is followed by calls with a null
70116 pointer as their first argument. The separator string pointed to by *ws2* may be different from call
70117 to call.

70118 The first call in the sequence shall search the wide-character string pointed to by *ws1* for the first
70119 wide-character code that is *not* contained in the current separator string pointed to by *ws2*. If no
70120 such wide-character code is found, then there are no tokens in the wide-character string pointed
70121 to by *ws1* and *wcstok*( ) shall return a null pointer. If such a wide-character code is found, it shall
70122 be the start of the first token.

70123 The *wcstok*( ) function shall then search from there for a wide-character code that *is* contained in
70124 the current separator string. If no such wide-character code is found, the current token extends
70125 to the end of the wide-character string pointed to by *ws1*, and subsequent searches for a token
70126 shall return a null pointer. If such a wide-character code is found, it shall be overwritten by a
70127 null wide character, which terminates the current token. The *wcstok*( ) function shall save a
70128 pointer to the following wide-character code, from which the next search for a token shall start.

70129 Each subsequent call, with a null pointer as the value of the first argument, shall start searching
70130 from the saved pointer and behave as described above.

70131 The implementation shall behave as if no function calls *wcstok*( ).

70132 **RETURN VALUE**

70133 Upon successful completion, the *wcstok*( ) function shall return a pointer to the first wide-
70134 character code of a token. Otherwise, if there is no token, *wcstok*( ) shall return a null pointer.

70135 **ERRORS**

70136 No errors are defined.

CHANGE HISTORY

First released in Issue 4.

Issue 5

Aligned with ISO/IEC 9899:1990/Amendment 1:1995 (E). Specifically, a third argument is added to the definition of *wcstok*( ) in the SYNOPSIS.

Issue 6

The *wcstok*( ) prototype is updated for alignment with the ISO/IEC 9899:1999 standard.

NAME

wcstol, wcstoll — convert a wide-character string to a long integer

SYNOPSIS

```
#include <wchar.h>

long wcstol(const wchar_t *restrict nptr, wchar_t **restrict endptr,
    int base);
long long wcstoll(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

These functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **long** and **long long**, respectively. First, they shall decompose the input string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to an integer, and return the result.

If *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a `'+'` or `'−'` sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix `'0'` optionally followed by a sequence of the digits `'0'` to `'7'` only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters `'a'` (or `'A'`) to `'f'` (or `'F'`) with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a `'+'` or `'−'` sign, but not including an integer suffix. The letters from `'a'` (or `'A'`) to `'z'` (or `'Z'`) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* shall be permitted. If the value of *base* is 16, the wide-character code representations of 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first non-white-space wide-character code that is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and *base* is 0, the sequence of wide-character codes starting with the first digit shall be interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus-sign, the value resulting from the conversion shall be negated. A pointer to the final wide-character string shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX These functions shall not change the setting of *errno* if successful.

Since 0, {LONG_MIN} or {LLONG_MIN} and {LONG_MAX} or {LLONG_MAX} are returned on error and are also valid returns on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstol*( ) or *wcstoll*( ), then check *errno*.

RETURN VALUE

Upon successful completion, these functions shall return the converted value, if any. If no CX conversion could be performed, 0 shall be returned and *errno* may be set to indicate the error. If the correct value is outside the range of representable values, {LONG_MIN}, {LONG_MAX}, {LLONG_MIN}, or {LLONG_MAX} shall be returned (according to the sign of the value), and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [EINVAL] The value of *base* is not supported.

[ERANGE] The value to be returned is not representable.

These functions may fail if:

CX [EINVAL] No conversion could be performed.

NAME

wcstombs — convert a wide-character string to a character string

SYNOPSIS

```
#include <stdlib.h>

size_t wcstombs(char *restrict s, const wchar_t *restrict pwcs,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wcstombs*( ) function shall convert the sequence of wide-character codes that are in the array pointed to by *pwcs* into a sequence of characters that begins in the initial shift state and store these characters into the array pointed to by *s*, stopping if a character would exceed the limit of *n* total bytes or if a null byte is stored. Each wide-character code shall be converted as if by a call to *wctomb*( ), except that the shift state of *wctomb*( ) shall not be affected.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

No more than *n* bytes shall be modified in the array pointed to by *s*. If copying takes place between objects that overlap, the behavior is undefined. CX If *s* is a null pointer, *wcstombs*( ) shall return the length required to convert the entire array regardless of the value of *n*, but no values are stored.

The *wcstombs*( ) function need not be thread-safe.

RETURN VALUE

If a wide-character code is encountered that does not correspond to a valid character (of one or more bytes each), *wcstombs*( ) shall return (**size_t**)–1. Otherwise, *wcstombs*( ) shall return the number of bytes stored in the character array, not including any terminating null byte. The array shall not be null-terminated if the value returned is *n*.

ERRORS

The *wcstombs*( ) function shall fail if:

CX [EILSEQ] A wide-character code does not correspond to a valid character.

CHANGE HISTORY

First released in Issue 4. Derived from the ISO C standard.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION states the effect of when *s* is a null pointer.
- The [EILSEQ] error condition is added.

The *wcstombs*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

Issue 7

Austin Group Interpretations 1003.1-2001 #156 and #170 are applied.

NAME

wcstoul, wcstoull — convert a wide-character string to an unsigned long

SYNOPSIS

```
#include <wchar.h>

unsigned long wcstoul(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
unsigned long long wcstoull(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wcstoul*( ) and *wcstoull*( ) functions shall convert the initial portion of the wide-character string pointed to by *nptr* to **unsigned long** and **unsigned long long** representation, respectively. First, they shall decompose the input wide-character string into three parts:

1. An initial, possibly empty, sequence of white-space wide-character codes (as specified by *iswspace*( ))
2. A subject sequence interpreted as an integer represented in some radix determined by the value of *base*
3. A final wide-character string of one or more unrecognized wide-character codes, including the terminating null wide-character code of the input wide-character string

Then they shall attempt to convert the subject sequence to an unsigned integer, and return the result.

If *base* is 0, the expected form of the subject sequence is that of a decimal constant, octal constant, or hexadecimal constant, any of which may be preceded by a `'+'` or `'−'` sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix `'0'` optionally followed by a sequence of the digits `'0'` to `'7'` only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters `'a'` (or `'A'`) to `'f'` (or `'F'`) with values 10 to 15 respectively.

If the value of *base* is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by *base*, optionally preceded by a `'+'` or `'−'` sign, but not including an integer suffix. The letters from `'a'` (or `'A'`) to `'z'` (or `'Z'`) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of *base* shall be permitted. If the value of *base* is 16, the wide-character codes 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.

The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first wide-character code that is not white space and is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not white space is other than a sign or a permissible letter or digit.

If the subject sequence has the expected form and *base* is 0, the sequence of wide-character codes starting with the first digit shall be interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it shall be used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus-sign, the value resulting from the conversion shall be negated. A pointer to the final wide-character string shall be stored in the object pointed to by *endptr*, provided that *endptr* is

not a null pointer.

CX In other than the C or POSIX locales, other implementation-defined subject sequences may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion shall be performed; the value of *nptr* shall be stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

CX The *wcstoul*( ) function shall not change the setting of *errno* if successful.

Since 0, {ULONG_MAX}, and {ULLONG_MAX} are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set *errno* to 0, then call *wcstoul*( ) or *wcstoull*( ), then check *errno*.

RETURN VALUE

Upon successful completion, the *wcstoul*( ) and *wcstoull*( ) functions shall return the converted CX value, if any. If no conversion could be performed, 0 shall be returned and *errno* may be set to indicate the error. If the correct value is outside the range of representable values, {ULONG_MAX} or {ULLONG_MAX} respectively shall be returned and *errno* set to [ERANGE].

ERRORS

These functions shall fail if:

CX [EINVAL] The value of *base* is not supported.

[ERANGE] The value to be returned is not representable.

These functions may fail if:

CX [EINVAL] No conversion could be performed.

EXAMPLES

Issue 5

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The [EINVAL] error condition is added for when the value of *base* is not supported.

  In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The following changes are made for alignment with the ISO/IEC 9899:1999 standard:

- The *wcstoul*( ) prototype is updated.
- The *wcstoull*( ) function is added.

NAME

wcstoumax — convert a wide-character string to an integer type

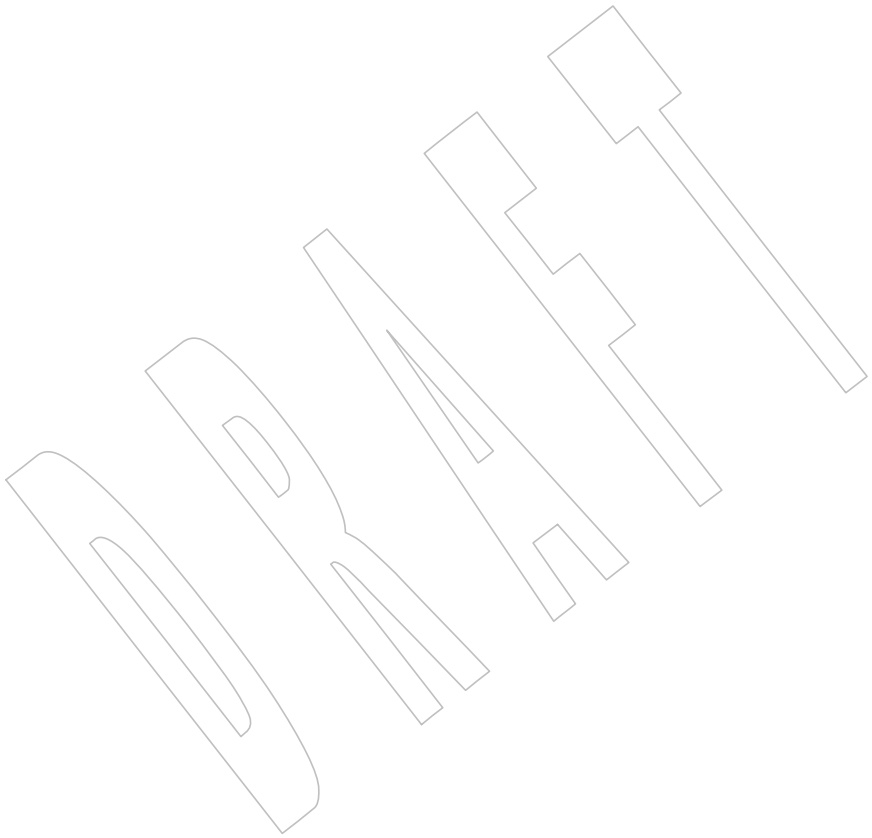
SYNOPSIS

```
#include <stddef.h>
#include <inttypes.h>

uintmax_t wcstoumax(const wchar_t *restrict nptr,
    wchar_t **restrict endptr, int base);
```

DESCRIPTION

Refer to *wcstoimax( )*.



70415 **NAME**

70416 wcswidth — number of column positions of a wide-character string

70417 **SYNOPSIS**

70418 XSI
```
#include <wchar.h>

int wcswidth(const wchar_t *pwcs, size_t n);
```

70420 **DESCRIPTION**

70421 The *wcswidth*( ) function shall determine the number of column positions required for *n* wide-
70422 character codes (or fewer than *n* wide-character codes if a null wide-character code is
70423 encountered before *n* wide-character codes are exhausted) in the string pointed to by *pwcs*.

70424 **RETURN VALUE**

70425 The *wcswidth*( ) function either shall return 0 (if *pwcs* points to a null wide-character code), or
70426 return the number of column positions to be occupied by the wide-character string pointed to by
70427 *pwcs*, or return –1 (if any of the first *n* wide-character codes in the wide-character string pointed
70428 to by *pwcs* is not a printable wide-character code).

70429 **ERRORS**

70430 No errors are defined.

70431 **EXAMPLES**

70432 None.

70433 **APPLICATION USAGE**

70434 This function was removed from the final ISO/IEC 9899:1990/Amendment 1:1995 (E), and the
70435 return value for a non-printable wide character is not specified.

70436 **RATIONALE**

70437 None.

70438 **FUTURE DIRECTIONS**

70439 None.

70440 **SEE ALSO**

70446 The Open Group Corrigendum U021/11 is applied. The function is marked as an extension.

NAME

wcsxfrm, wcsxfrm_l — wide-character string transformation

SYNOPSIS

```
#include <wchar.h>

size_t wcsxfrm(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
CX size_t wcsxfrm_l(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n, locale_t locale);
```

DESCRIPTION

CX For *wcsxfrm*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

CX The *wcsxfrm*( ) and *wcsxfrm_l*( ) functions shall transform the wide-character string pointed to by *ws2* and place the resulting wide-character string into the array pointed to by *ws1*. The transformation shall be such that if *wcscmp*( ) is applied to two transformed wide strings, it shall CX return a value greater than, equal to, or less than 0, corresponding to the result of *wcscoll*( ) and *wcscoll_l*( ) applied to the same two original wide-character strings, and the same *LC_COLLATE* CX category of the locale of the process or the locale object *locale*, respectively. No more than *n* wide-character codes shall be placed into the resulting array pointed to by *ws1*, including the terminating null wide-character code. If *n* is 0, *ws1* is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.

CX The *wcsxfrm*( ) and *wcsxfrm_l*( ) functions shall not change the setting of *errno* if successful.

Since no return value is reserved to indicate an error, an application wishing to check for error situations should set *errno* to 0, then call *wcsxfrm*( ) or *wcsxfrm_l*( ), then check *errno*.

RETURN VALUE

CX The *wcsxfrm*( ) and *wcsxfrm_l*( ) functions shall return the length of the transformed wide-character string (not including the terminating null wide-character code). If the value returned is *n* or more, the contents of the array pointed to by *ws1* are unspecified.

CX On error, the *wcsxfrm*( ) and *wcsxfrm_l*( ) functions may set *errno*, but no return value is reserved to indicate an error.

ERRORS

These functions may fail if:

CX [EINVAL] The wide-character string pointed to by *ws2* contains wide-character codes outside the domain of the collating sequence.

The *wcsxfrm_l*( ) function may fail if:

CX [EINVAL] *locale* is not a valid locale object handle.

EXAMPLES

None.

APPLICATION USAGE

The transformation function is such that two transformed wide-character strings can be ordered by *wcscmp*( ) as appropriate to collating sequence information in the locale of the process (category *LC_COLLATE*).

The fact that when *n* is 0 *ws1* is permitted to be a null pointer is useful to determine the size of the *ws1* array prior to making the transformation.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD **<wchar.h>**

CHANGE HISTORY

First released in Issue 4. Derived from the MSE working draft.

Issue 5

Moved from ENHANCED I18N to BASE and the [ENOSYS] error is removed.

The DESCRIPTION is updated to indicate that *errno* is not changed if the function is successful.

Issue 6

In earlier versions, this function was required to return –1 on error.

Extensions beyond the ISO C standard are marked.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the RETURN VALUE and ERRORS sections, the [EINVAL] optional error condition is added if no conversion could be performed.

The *wcsxfrm*( ) prototype is updated for alignment with the ISO/IEC 9899: 1999 standard.

Issue 7

The *wcsxfrm_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

NAME

wctob — wide-character to single-byte conversion

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int wctob(wint_t c);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wctob*( ) function shall determine whether *c* corresponds to a member of the extended character set whose character representation is a single byte when in the initial shift state.

The behavior of this function shall be affected by the *LC_CTYPE* category of the current locale.

RETURN VALUE

The *wctob*( ) function shall return EOF if *c* does not correspond to a character with length one in the initial shift state. Otherwise, it shall return the single-byte representation of that character as an **unsigned char** converted to **int**.

ERRORS

No errors are defined.

EXAMPLES

CHANGE HISTORY

First released in Issue 5. Included for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E).

70547 **NAME**

70548 wctomb — convert a wide-character code to a character

70549 **SYNOPSIS**

70550
```
#include <stdlib.h>
```

70551
```
int wctomb(char *s, wchar_t wchar);
```

70552 **DESCRIPTION**

70553 CX The functionality described on this reference page is aligned with the ISO C standard. Any
70554 conflict between the requirements described here and the ISO C standard is unintentional. This
70555 volume of POSIX.1-200x defers to the ISO C standard.

70556 The *wctomb*( ) function shall determine the number of bytes needed to represent the character
70557 corresponding to the wide-character code whose value is *wchar* (including any change in the
70558 shift state). It shall store the character representation (possibly multiple bytes and any special
70559 bytes to change shift state) in the array object pointed to by *s* (if *s* is not a null pointer). At most
70560 {MB_CUR_MAX} bytes shall be stored. If *wchar* is 0, a null byte shall be stored, preceded by any
70561 shift sequence needed to restore the initial shift state, and *wctomb*( ) shall be left in the initial shift
70562 state.

70563 CX The behavior of this function is affected by the *LC_CTYPE* category of the current locale. For a
70564 state-dependent encoding, this function shall be placed into its initial state by a call for which its
70565 character pointer argument, *s*, is a null pointer. Subsequent calls with *s* as other than a null
70566 pointer shall cause the internal state of the function to be altered as necessary. A call with *s* as a
70567 null pointer shall cause this function to return a non-zero value if encodings have state
70568 dependency, and 0 otherwise. Changing the *LC_CTYPE* category causes the shift state of this
70569 function to be unspecified.

70570 The *wctomb*( ) function need not be thread-safe.

70571 The implementation shall behave as if no function defined in this volume of POSIX.1-200x calls
70572 *wctomb*( ).

70573 **RETURN VALUE**

70574 If *s* is a null pointer, *wctomb*( ) shall return a non-zero or 0 value, if character encodings,
70575 respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, *wctomb*( )
70576 shall return –1 if the value of *wchar* does not correspond to a valid character, or return the
70577 number of bytes that constitute the character corresponding to the value of *wchar*.

70578 In no case shall the value returned be greater than the value of the {MB_CUR_MAX} macro.

70579 **ERRORS**

70580 The *wctomb*( ) function shall fail if:

70581 CX [EILSEQ] An invalid wide-character code is detected.

70582 **EXAMPLES**

70583 None.

70584 **APPLICATION USAGE**

70585 None.

70586 **RATIONALE**

70587 None.

FUTURE DIRECTIONS

None.

NAME

wctrans, wctrans_l — define character mapping

SYNOPSIS

```
#include <wctype.h>

wctrans_t wctrans(const char *charclass);
wctrans_t wctrans_l(const char *charclass, locale_t locale);
```

DESCRIPTION

For *wctrans*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wctrans*( ) and *wctrans_l*( ) functions are defined for valid character mapping names identified in the current locale. The *charclass* is a string identifying a generic character mapping name for which codeset-specific information is required. The following character mapping names are defined in all locales: **tolower** and **toupper**.

These functions shall return a value of type **wctrans_t**, which can be used as the second argument to subsequent calls of *towctrans*( ) and *towctrans_l*( ).

The *wctrans*( ) and *wctrans_l*( ) functions shall determine values of **wctrans_t** according to the rules of the coded character set defined by character mapping information in the locale of the process or in the locale represented by *locale*, respectively (category *LC_CTYPE*).

The values returned by *wctrans*( ) shall be valid until a call to *setlocale*( ) that modifies the category *LC_CTYPE*.

The values returned by *wctrans_l*( ) shall be valid only in calls to *wctrans_l*( ) with a locale represented by *locale* with the same *LC_CTYPE* category value.

RETURN VALUE

The *wctrans*( ) and *wctrans_l*( ) functions shall return 0 and may set *errno* to indicate the error if the given character mapping name is not valid for the current locale (category *LC_CTYPE*); otherwise, they shall return a non-zero object of type **wctrans_t** that can be used in calls to *towctrans*( ) and *towctrans_l*( ).

ERRORS

These functions may fail if:

[EINVAL] The character mapping name pointed to by *charclass* is not valid in the current locale.

The *wctrans_l*( ) function may fail if:

[EINVAL] *locale* is not a valid locale object handle.

The *wctrans_l*( ) function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

NAME

wctype, wctype_l — define character class

SYNOPSIS

```
#include <wctype.h>

wctype_t wctype(const char *property);
wctype_t wctype_l(const char *property, locale_t locale);
```

DESCRIPTION

For *wctype*( ): The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wctype*( ) and *wctype_l*( ) functions are defined for valid character class names as defined in the current locale or in the locale represented by *locale*, respectively.

The *property* argument is a string identifying a generic character class for which codeset-specific type information is required. The following character class names shall be defined in all locales:

alnum	**digit**	**punct**
alpha	**graph**	**space**
blank	**lower**	**upper**
cntrl	**print**	**xdigit**

Additional character class names defined in the locale definition file (category *LC_CTYPE*) can also be specified.

These functions shall return a value of type **wctype_t**, which can be used as the second argument to subsequent calls of *iswctype*( ) and *iswctype_l*( ).

The *wctype*( ) and *wctype_l*( ) functions shall determine values of **wctype_t** according to the rules of the coded character set defined by character type information in the locale of the process or in the locale represented by *locale*, respectively (category *LC_CTYPE*).

The values returned by *wctype*( ) shall be valid until a call to *setlocale*( ) that modifies the category *LC_CTYPE*.

The values returned by *wctype_l*( ) shall be valid only in calls to *iswctype_l*( ) with a locale represented by *locale* with the same *LC_CTYPE* category value.

RETURN VALUE

The *wctype*( ) and *wctype_l*( ) functions shall return 0 if the given character class name is not valid for the current locale (category *LC_CTYPE*); otherwise, they shall return an object of type **wctype_t** that can be used in calls to *iswctype*( ) and *iswctype_l*( ).

ERRORS

The *wctype_l*( ) function may fail if:

[EINVAL] *locale* is not a valid locale object handle.

First released in Issue 4.

Issue 5

The following change has been made in this version for alignment with ISO/IEC 9899:1990/Amendment 1:1995 (E):

- The SYNOPSIS has been changed to indicate that this function and associated data types are now made visible by inclusion of the **<wctype.h>** header rather than **<wchar.h>**.

Issue 7

The *wctype_l( )* function is added from The Open Group Technical Standard, 2006, Extended API Set Part 4.

70707 **NAME**

70708 wcwidth — number of column positions of a wide-character code

70709 **SYNOPSIS**

70710 XSI
```
#include <wchar.h>

int wcwidth(wchar_t wc);
```

70712 **DESCRIPTION**

70713 The *wcwidth*( ) function shall determine the number of column positions required for the wide
70714 character *wc*. The application shall ensure that the value of *wc* is a character representable as a
70715 **wchar_t**, and is a wide-character code corresponding to a valid character in the current locale.

70716 **RETURN VALUE**

70717 The *wcwidth*( ) function shall either return 0 (if *wc* is a null wide-character code), or return the
70718 number of column positions to be occupied by the wide-character code *wc*, or return –1 (if *wc*
70719 does not correspond to a printable wide-character code).

70720 **ERRORS**

70721 No errors are defined.

70722 **EXAMPLES**

70723 None.

70724 **APPLICATION USAGE**

70725 This function was removed from the final ISO/IEC 9899:1990/Amendment 1:1995 (E), and the
70726 return value for a non-printable wide character is not specified.

70727 **RATIONALE**

70728 None.

70729 **FUTURE DIRECTIONS**

70730 None.

70731 **SEE ALSO**

70732 *wcswidth*( )

70733 XBD **<wchar.h>**

70734 **CHANGE HISTORY**

70735 First released as a World-wide Portability Interface in Issue 4. Derived from the MSE working
70736 draft.

70737 **Issue 6**

70738 The Open Group Corrigendum U021/12 is applied. This function is marked as an extension.

70739 The normative text is updated to avoid use of the term "must" for application requirements.

NAME

wmemchr — find a wide character in memory

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemchr(const wchar_t *ws, wchar_t wc, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wmemchr*( ) function shall locate the first occurrence of *wc* in the initial *n* wide characters of the object pointed to by *ws*. This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially.

If *n* is zero, the application shall ensure that *ws* is a valid pointer and the function behaves as if no valid occurrence of *wc* is found.

RETURN VALUE

The *wmemchr*( ) function shall return a pointer to the located wide character, or a null pointer if the wide character does not occur in the object.

ERRORS

No errors are defined.

NAME

wmemcmp — compare wide characters in memory

SYNOPSIS

```
#include <wchar.h>

int wmemcmp(const wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wmemcmp*( ) function shall compare the first *n* wide characters of the object pointed to by *ws1* to the first *n* wide characters of the object pointed to by *ws2*. This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially.

If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function shall behave as if the two objects compare equal.

RETURN VALUE

The *wmemcmp*( ) function shall return an integer greater than, equal to, or less than zero, respectively, as the object pointed to by *ws1* is greater than, equal to, or less than the object pointed to by *ws2*.

ERRORS

No errors are defined.

NAME

wmemcpy — copy wide characters in memory

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemcpy(wchar_t *restrict ws1, const wchar_t *restrict ws2,
    size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wmemcpy*( ) function shall copy *n* wide characters from the object pointed to by *ws2* to the object pointed to by *ws1*. This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially.

If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function shall copy zero wide characters.

RETURN VALUE

The *wmemcpy*( ) function shall return the value of *ws1*.

NAME

wmemmove — copy wide characters in memory with overlapping areas

SYNOPSIS

```
#include <wchar.h>

wchar_t *wmemmove(wchar_t *ws1, const wchar_t *ws2, size_t n);
```

DESCRIPTION

CX The functionality described on this reference page is aligned with the ISO C standard. Any conflict between the requirements described here and the ISO C standard is unintentional. This volume of POSIX.1-200x defers to the ISO C standard.

The *wmemmove*( ) function shall copy *n* wide characters from the object pointed to by *ws2* to the object pointed to by *ws1*. Copying shall take place as if the *n* wide characters from the object pointed to by *ws2* are first copied into a temporary array of *n* wide characters that does not overlap the objects pointed to by *ws1* or *ws2*, and then the *n* wide characters from the temporary array are copied into the object pointed to by *ws1*.

This function shall not be affected by locale and all **wchar_t** values shall be treated identically. The null wide character and **wchar_t** values not corresponding to valid characters shall not be treated specially.

If *n* is zero, the application shall ensure that *ws1* and *ws2* are valid pointers, and the function shall copy zero wide characters.

RETURN VALUE

The *wmemmove*( ) function shall return the value of *ws1*.

NAME

wordexp, wordfree — perform word expansions

SYNOPSIS

```
#include <wordexp.h>

int wordexp(const char *restrict words, wordexp_t *restrict pwordexp,
    int flags);
void wordfree(wordexp_t *pwordexp);
```

DESCRIPTION

The *wordexp*( ) function shall perform word expansions as described in XCU Section 2.6 (on page 2305), subject to quoting as described in XCU Section 2.2 (on page 2298), and place the list of expanded words into the structure pointed to by *pwordexp*.

The *words* argument is a pointer to a string containing one or more words to be expanded. The expansions shall be the same as would be performed by the command line interpreter if *words* were the part of a command line representing the arguments to a utility. Therefore, the application shall ensure that *words* does not contain an unquoted <newline> character or any of the unquoted shell special characters `'|'`, `'&'`, `';'`, `'<'`, `'>'` except in the context of command substitution as specified in XCU Section 2.6.3 (on page 2309). It also shall not contain unquoted parentheses or braces, except in the context of command or variable substitution. The application shall ensure that every member of *words* which it expects to have expanded by *wordexp*( ) does not contain an unquoted initial comment character. The application shall also ensure that any words which it intends to be ignored (because they begin or continue a comment) are deleted from *words*. If the argument *words* contains an unquoted comment character (<number-sign>) that is the beginning of a token, *wordexp*( ) shall either treat the comment character as a regular character, or interpret it as a comment indicator and ignore the remainder of *words*.

The structure type **wordexp_t** is defined in the **<wordexp.h>** header and includes at least the following members:

Member Type	Member Name	Description
size_t	*we_wordc*	Count of words matched by *words*.
char **	*we_wordv*	Pointer to list of expanded words.
size_t	*we_offs*	Slots to reserve at the beginning of *pwordexp*−>*we_wordv*.

The *wordexp*( ) function shall store the number of generated words into *pwordexp*−>*we_wordc* and a pointer to a list of pointers to words in *pwordexp*−>*we_wordv*. Each individual field created during field splitting (see XCU Section 2.6.5, on page 2311) or pathname expansion (see XCU Section 2.6.6, on page 2311) shall be a separate word in the *pwordexp*−>*we_wordv* list. The words shall be in order as described in XCU Section 2.6 (on page 2305). The first pointer after the last word pointer shall be a null pointer. The expansion of special parameters described in XCU Section 2.5.2 (on page 2302) is unspecified.

It is the caller's responsibility to allocate the storage pointed to by *pwordexp*. The *wordexp*( ) function shall allocate other space as needed, including memory pointed to by *pwordexp*−>*we_wordv*. The *wordfree*( ) function frees any memory associated with *pwordexp* from a previous call to *wordexp*( ).

The *flags* argument is used to control the behavior of *wordexp*( ). The value of *flags* is the bitwise-inclusive OR of zero or more of the following constants, which are defined in **<wordexp.h>**:

WRDE_APPEND Append words generated to the ones from a previous call to *wordexp*( ).

WRDE_DOOFFS — Make use of *pwordexp->we_offs*. If this flag is set, *pwordexp->we_offs* is used to specify how many null pointers to add to the beginning of *pwordexp->we_wordv*. In other words, *pwordexp->we_wordv* shall point to *pwordexp->we_offs* null pointers, followed by *pwordexp->we_wordc* word pointers, followed by a null pointer.

WRDE_NOCMD — If the implementation supports the utilities defined in the Shell and Utilities volume of POSIX.1-200x, fail if command substitution, as specified in XCU Section 2.6.3 (on page 2309), is requested.

WRDE_REUSE — The *pwordexp* argument was passed to a previous successful call to *wordexp*( ), and has not been passed to *wordfree*( ). The result shall be the same as if the application had called *wordfree*( ) and then called *wordexp*( ) without WRDE_REUSE.

WRDE_SHOWERR — Do not redirect *stderr* to **/dev/null**.

WRDE_UNDEF — Report error on an attempt to expand an undefined shell variable.

The WRDE_APPEND flag can be used to append a new set of words to those generated by a previous call to *wordexp*( ). The following rules apply to applications when two or more calls to *wordexp*( ) are made with the same value of *pwordexp* and without intervening calls to *wordfree*( ):

1. The first such call shall not set WRDE_APPEND. All subsequent calls shall set it.
2. All of the calls shall set WRDE_DOOFFS, or all shall not set it.
3. After the second and each subsequent call, *pwordexp->we_wordv* shall point to a list containing the following:
   a. Zero or more null pointers, as specified by WRDE_DOOFFS and *pwordexp->we_offs*
   b. Pointers to the words that were in the *pwordexp->we_wordv* list before the call, in the same order as before
   c. Pointers to the new words generated by the latest call, in the specified order
4. The count returned in *pwordexp->we_wordc* shall be the total number of words from all of the calls.
5. The application can change any of the fields after a call to *wordexp*( ), but if it does it shall reset them to the original value before a subsequent call, using the same *pwordexp* value, to *wordfree*( ) or *wordexp*( ) with the WRDE_APPEND or WRDE_REUSE flag.

If the implementation supports the utilities defined in the Shell and Utilities volume of POSIX.1-200x, and *words* contains an unquoted character—<newline>, `'|'`, `'&'`, `';'`, `'<'`, `'>'`, `'('`, `')'`, `'{'`, `'}'`—in an inappropriate context, *wordexp*( ) shall fail, and the number of expanded words shall be 0.

Unless WRDE_SHOWERR is set in *flags*, *wordexp*( ) shall redirect *stderr* to **/dev/null** for any utilities executed as a result of command substitution while expanding *words*. If WRDE_SHOWERR is set, *wordexp*( ) may write messages to *stderr* if syntax errors are detected while expanding *words*.

The application shall ensure that if WRDE_DOOFFS is set, then *pwordexp->we_offs* has the same value for each *wordexp*( ) call and *wordfree*( ) call using a given *pwordexp*.

The following constants are defined as error return values:

WRDE_BADCHAR	One of the unquoted characters—<newline>, '|', '&', ';', '<', '>', '(', ')', '{', '}'—appears in *words* in an inappropriate context.
WRDE_BADVAL	Reference to undefined shell variable when WRDE_UNDEF is set in *flags*.
WRDE_CMDSUB	Command substitution requested when WRDE_NOCMD was set in *flags*.
WRDE_NOSPACE	Attempt to allocate memory failed.
WRDE_SYNTAX	Shell syntax error, such as unbalanced parentheses or unterminated string.

RETURN VALUE

Upon successful completion, *wordexp*() shall return 0. Otherwise, a non-zero value, as described in **<wordexp.h>**, shall be returned to indicate an error. If *wordexp*() returns the value WRDE_NOSPACE, then *pwordexp*->*we_wordc* and *pwordexp*->*we_wordv* shall be updated to reflect any words that were successfully expanded. In other cases, they shall not be modified.

The *wordfree*() function shall not return a value.

ERRORS

No errors are defined.

EXAMPLES

None.

APPLICATION USAGE

The *wordexp*() function is intended to be used by an application that wants to do all of the shell's expansions on a word or words obtained from a user. For example, if the application prompts for a filename (or list of filenames) and then uses *wordexp*() to process the input, the user could respond with anything that would be valid as input to the shell.

The WRDE_NOCMD flag is provided for applications that, for security or other reasons, want to prevent a user from executing shell commands. Disallowing unquoted shell special characters also prevents unwanted side-effects, such as executing a command or writing a file.

POSIX.1-200x does not require the *wordexp*() function to be thread-safe if passed an expression referencing an environment variable while any other thread is concurrently modifying any environment variable; see *exec* (on page 772).

RATIONALE

This function was included as an alternative to *glob*(). There had been continuing controversy over exactly what features should be included in *glob*(). It is hoped that by providing *wordexp*() (which provides all of the shell word expansions, but which may be slow to execute) and *glob*() (which is faster, but which only performs pathname expansion, without tilde or parameter expansion) this will satisfy the majority of applications.

While *wordexp*() could be implemented entirely as a library routine, it is expected that most implementations run a shell in a subprocess to do the expansion.

Two different approaches have been proposed for how the required information might be presented to the shell and the results returned. They are presented here as examples.

One proposal is to extend the *echo* utility by adding a **−q** option. This option would cause *echo* to add a <backslash> before each <backslash> and <blank> that occurs within an argument. The *wordexp*() function could then invoke the shell as follows:

```
(void) strcpy(buffer, "echo -q");
```

```
(void) strcat(buffer, words);
if ((flags & WRDE_SHOWERR) == 0)
    (void) strcat(buffer, "2>/dev/null");
f = popen(buffer, "r");
```

The *wordexp*( ) function would read the resulting output, remove unquoted <backslash> characters, and break into words at unquoted <blank> characters. If the WRDE_NOCMD flag was set, *wordexp*( ) would have to scan *words* before starting the subshell to make sure that there would be no command substitution. In any case, it would have to scan *words* for unquoted special characters.

Another proposal is to add the following options to *sh*:

–w *wordlist*
This option provides a wordlist expansion service to applications. The words in *wordlist* shall be expanded and the following written to standard output:

1. The count of the number of words after expansion, in decimal, followed by a null byte
2. The number of bytes needed to represent the expanded words (not including null separators), in decimal, followed by a null byte
3. The expanded words, each terminated by a null byte

If an error is encountered during word expansion, *sh* exits with a non-zero status after writing the former to report any words successfully expanded

–P Run in "protected" mode. If specified with the **–w** option, no command substitution shall be performed.

With these options, *wordexp*( ) could be implemented fairly simply by creating a subprocess using *fork*( ) and executing *sh* using the line:

```
execl(<shell path>, "sh", "-P", "-w", words, (char *)0);
```

after directing standard error to **/dev/null**.

It seemed objectionable for a library routine to write messages to standard error, unless explicitly requested, so *wordexp*( ) is required to redirect standard error to **/dev/null** to ensure that no messages are generated, even for commands executed for command substitution. The WRDE_SHOWERR flag can be specified to request that error messages be written.

The WRDE_REUSE flag allows the implementation to avoid the expense of freeing and reallocating memory, if that is possible. A minimal implementation can call *wordfree*( ) when WRDE_REUSE is set.

FUTURE DIRECTIONS

None.

XCU Chapter 2 (on page 2297)

CHANGE HISTORY

First released in Issue 4. Derived from the ISO POSIX-2 standard.

Issue 5

Moved from POSIX2 C-language Binding to BASE.

Issue 6

The normative text is updated to avoid use of the term "must" for application requirements.

The **restrict** keyword is added to the *wordexp*( ) prototype for alignment with the ISO/IEC 9899: 1999 standard.

Issue 7

Austin Group Interpretation 1003.1-2001 #148 is applied, adding APPLICATION USAGE.

71102 **NAME**

71103 wprintf — print formatted wide-character output

71104 **SYNOPSIS**

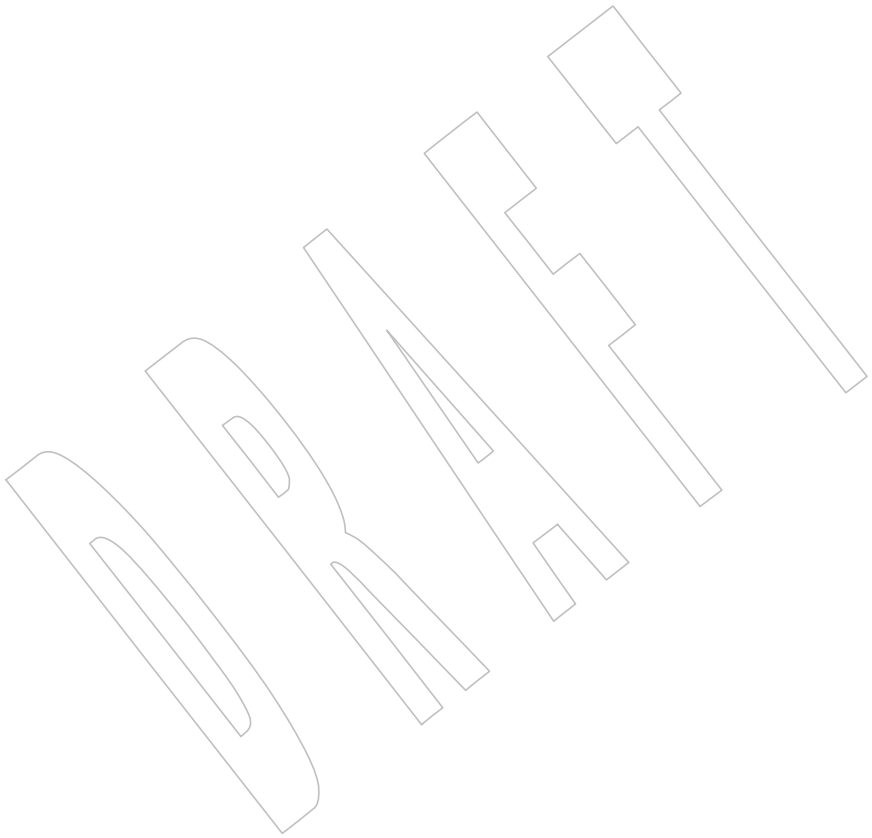
71105 `#include <stdio.h>`

71106 `#include <wchar.h>`

71107 `int wprintf(const wchar_t *restrict format, ...);`

71108 **DESCRIPTION**

71109 Refer to *fwprintf*( ).



71110 **NAME**

71111 pwrite, write — write on a file

71112 **SYNOPSIS**

71113
```
#include <unistd.h>
```

71114
```
ssize_t pwrite(int fildes, const void *buf, size_t nbyte,
```
71115
```
    off_t offset);
```
71116
```
ssize_t write(int fildes, const void *buf, size_t nbyte);
```

71117 **DESCRIPTION**

71118 The *write*( ) function shall attempt to write *nbyte* bytes from the buffer pointed to by *buf* to the
71119 file associated with the open file descriptor, *fildes*.

71120 Before any action described below is taken, and if *nbyte* is zero and the file is a regular file, the
71121 *write*( ) function may detect and return errors as described below. In the absence of errors, or if
71122 error detection is not performed, the *write*( ) function shall return zero and have no other results.
71123 If *nbyte* is zero and the file is not a regular file, the results are unspecified.

71124 On a regular file or other file capable of seeking, the actual writing of data shall proceed from
71125 the position in the file indicated by the file offset associated with *fildes*. Before successful return
71126 from *write*( ), the file offset shall be incremented by the number of bytes actually written. On a
71127 regular file, if the position of the last byte written is greater than or equal to the length of the file,
71128 the length of the file shall be set to this position plus one.

71129 On a file not capable of seeking, writing shall always take place starting at the current position.
71130 The value of a file offset associated with such a device is undefined.

71131 If the O_APPEND flag of the file status flags is set, the file offset shall be set to the end of the file
71132 prior to each write and no intervening file modification operation shall occur between changing
71133 the file offset and the write operation.

71134 XSI If a *write*( ) requests that more bytes be written than there is room for (for example, the file size
71135 limit of the process or the physical end of a medium), only as many bytes as there is room for
71136 shall be written. For example, suppose there is space for 20 bytes more in a file before reaching a
71137 limit. A write of 512 bytes will return 20. The next write of a non-zero number of bytes would
71138 give a failure return (except as noted below).

71139 XSI If the request would cause the file size to exceed the soft file size limit for the process and there
71140 is no room for any bytes to be written, the request shall fail and the implementation shall
71141 generate the SIGXFSZ signal for the thread.

71142 If *write*( ) is interrupted by a signal before it writes any data, it shall return –1 with *errno* set to
71143 [EINTR].

71144 If *write*( ) is interrupted by a signal after it successfully writes some data, it shall return the
71145 number of bytes written.

71146 If the value of *nbyte* is greater than {SSIZE_MAX}, the result is implementation-defined.

71147 After a *write*( ) to a regular file has successfully returned:

71148 • Any successful *read*( ) from each byte position in the file that was modified by that write
71149 shall return the data specified by the *write*( ) for that position until such byte positions are
71150 again modified.

71151 • Any subsequent successful *write*( ) to the same byte position in the file shall overwrite that
71152 file data.

Write requests to a pipe or FIFO shall be handled in the same way as a regular file with the following exceptions:

- There is no file offset associated with a pipe, hence each write request shall append to the end of the pipe.
- Write requests of {PIPE_BUF} bytes or less shall not be interleaved with data from other processes doing writes on the same pipe. Writes of greater than {PIPE_BUF} bytes may have data interleaved, on arbitrary boundaries, with writes by other processes, whether or not the O_NONBLOCK flag of the file status flags is set.
- If the O_NONBLOCK flag is clear, a write request may cause the thread to block, but on normal completion it shall return *nbyte*.
- If the O_NONBLOCK flag is set, *write*( ) requests shall be handled differently, in the following ways:
  - The *write*( ) function shall not block the thread.
  - A write request for {PIPE_BUF} or fewer bytes shall have the following effect: if there is sufficient space available in the pipe, *write*( ) shall transfer all the data and return the number of bytes requested. Otherwise, *write*( ) shall transfer no data and return –1 with *errno* set to [EAGAIN].
  - A write request for more than {PIPE_BUF} bytes shall cause one of the following:
    - When at least one byte can be written, transfer what it can and return the number of bytes written. When all data previously written to the pipe is read, it shall transfer at least {PIPE_BUF} bytes.
    - When no data can be written, transfer no data, and return –1 with *errno* set to [EAGAIN].

When attempting to write to a file descriptor (other than a pipe or FIFO) that supports non-blocking writes and cannot accept the data immediately:

- If the O_NONBLOCK flag is clear, *write*( ) shall block the calling thread until the data can be accepted.
- If the O_NONBLOCK flag is set, *write*( ) shall not block the thread. If some data can be written without blocking the thread, *write*( ) shall write what it can and return the number of bytes written. Otherwise, it shall return –1 and set *errno* to [EAGAIN].

Upon successful completion, where *nbyte* is greater than 0, *write*( ) shall mark for update the last data modification and last file status change timestamps of the file, and if the file is a regular file, the S_ISUID and S_ISGID bits of the file mode may be cleared.

For regular files, no data transfer shall occur past the offset maximum established in the open file description associated with *fildes*.

If *fildes* refers to a socket, *write*( ) shall be equivalent to *send*( ) with no flags set.

SIO If the O_DSYNC bit has been set, write I/O operations on the file descriptor shall complete as defined by synchronized I/O data integrity completion.

If the O_SYNC bit has been set, write I/O operations on the file descriptor shall complete as defined by synchronized I/O file integrity completion.

SHM If *fildes* refers to a shared memory object, the result of the *write*( ) function is unspecified.

71194 TYM If *fildes* refers to a typed memory object, the result of the *write*( ) function is unspecified.

71195 OB XSR If *fildes* refers to a STREAM, the operation of *write*( ) shall be determined by the values of the
71196 minimum and maximum *nbyte* range (packet size) accepted by the STREAM. These values are
71197 determined by the topmost STREAM module. If *nbyte* falls within the packet size range, *nbyte*
71198 bytes shall be written. If *nbyte* does not fall within the range and the minimum packet size value
71199 is 0, *write*( ) shall break the buffer into maximum packet size segments prior to sending the data
71200 downstream (the last segment may contain less than the maximum packet size). If *nbyte* does not
71201 fall within the range and the minimum value is non-zero, *write*( ) shall fail with *errno* set to
71202 [ERANGE]. Writing a zero-length buffer (*nbyte* is 0) to a STREAMS device sends 0 bytes with 0
71203 returned. However, writing a zero-length buffer to a STREAMS-based pipe or FIFO sends no
71204 message and 0 is returned. The process may issue I_SWROPT *ioctl*( ) to enable zero-length
71205 messages to be sent across the pipe or FIFO.

71206 When writing to a STREAM, data messages are created with a priority band of 0. When writing
71207 to a STREAM that is not a pipe or FIFO:

71208 - If O_NONBLOCK is clear, and the STREAM cannot accept data (the STREAM write queue
71209 is full due to internal flow control conditions), *write*( ) shall block until data can be
71210 accepted.

71211 - If O_NONBLOCK is set and the STREAM cannot accept data, *write*( ) shall return –1 and
71212 set *errno* to [EAGAIN].

71213 - If O_NONBLOCK is set and part of the buffer has been written while a condition in which
71214 the STREAM cannot accept additional data occurs, *write*( ) shall terminate and return the
71215 number of bytes written.

71216 In addition, *write*( ) shall fail if the STREAM head has processed an asynchronous error before
71217 the call. In this case, the value of *errno* does not reflect the result of *write*( ), but reflects the prior
71218 error.

71219 The *pwrite*( ) function shall be equivalent to *write*( ), except that it writes into a given position
71220 and does not change the file offset (regardless of whether O_APPEND is set). The first three
71221 arguments to *pwrite*( ) are the same as *write*( ) with the addition of a fourth argument *offset* for
71222 the desired position inside the file.

71223 **RETURN VALUE**

71224 Upon successful completion, these functions shall return the number of bytes actually written to
71225 the file associated with *fildes*. This number shall never be greater than *nbyte*. Otherwise, –1 shall
71226 be returned and *errno* set to indicate the error.

71227 **ERRORS**

71228 These functions shall fail if:

71229 [EAGAIN] The O_NONBLOCK flag is set for the file descriptor and the thread would be
71230 delayed in the *write*( ) operation.

71231 [EBADF] The *fildes* argument is not a valid file descriptor open for writing.

71232 [EFBIG] An attempt was made to write a file that exceeds the implementation-defined
71233 XSI maximum file size or the file size limit of the process, and there was no room
71234 for any bytes to be written.

71235 [EFBIG] The file is a regular file, *nbyte* is greater than 0, and the starting position is
71236 greater than or equal to the offset maximum established in the open file
71237 description associated with *fildes*.

71238 [EINTR] The write operation was terminated due to the receipt of a signal, and no data
71239 was transferred.

71240 [EIO] The process is a member of a background process group attempting to write to
71241 its controlling terminal, TOSTOP is set, the process is neither ignoring nor
71242 blocking SIGTTOU, and the process group of the process is orphaned. This
71243 error may also be returned under implementation-defined conditions.

71244 [ENOSPC] There was no free space remaining on the device containing the file.

71245 [EPIPE] An attempt is made to write to a pipe or FIFO that is not open for reading by
71246 any process, or that only has one end open. A SIGPIPE signal shall also be sent
71247 to the thread.

71248 OB XSR [ERANGE] The transfer request size was outside the range supported by the STREAMS
71249 file associated with *fildes*.

71250 The *write*( ) function shall fail if:

71251 [EAGAIN] or [EWOULDBLOCK]
71252 The file descriptor is for a socket, is marked O_NONBLOCK, and write would
71253 block.

71254 [ECONNRESET] A write was attempted on a socket that is not connected.

71255 [EPIPE] A write was attempted on a socket that is shut down for writing, or is no
71256 longer connected. In the latter case, if the socket is of type SOCK_STREAM, a
71257 SIGPIPE signal shall also be sent to the thread.

71258 These functions may fail if:

71259 OB XSR [EINVAL] The STREAM or multiplexer referenced by *fildes* is linked (directly or
71260 indirectly) downstream from a multiplexer.

71261 [EIO] A physical I/O error has occurred.

71262 [ENOBUFS] Insufficient resources were available in the system to perform the operation.

71263 [ENXIO] A request was made of a nonexistent device, or the request was outside the
71264 capabilities of the device.

71265 OB XSR [ENXIO] A hangup occurred on the STREAM being written to.

71266 OB XSR A write to a STREAMS file may fail if an error message has been received at the STREAM head.
71267 In this case, *errno* is set to the value included in the error message.

71268 The *write*( ) function may fail if:

71269 [EACCES] A write was attempted on a socket and the calling process does not have
71270 appropriate privileges.

71271 [ENETDOWN] A write was attempted on a socket and the local network interface used to
71272 reach the destination is down.

71273 [ENETUNREACH]
71274 A write was attempted on a socket and no route to the network is present.

71275 The *pwrite*( ) function shall fail and the file pointer remain unchanged if:

71276 [EINVAL] The *offset* argument is invalid. The value is negative.

71277 [ESPIPE] *fildes* is associated with a pipe or FIFO.

71278 **EXAMPLES**

71279 **Writing from a Buffer**

71280 The following example writes data from the buffer pointed to by *buf* to the file associated with
71281 the file descriptor *fd*.

```
71282 #include <sys/types.h>
71283 #include <string.h>
71284 ...
71285 char buf[20];
71286 size_t nbytes;
71287 ssize_t bytes_written;
71288 int fd;
71289 ...
71290 strcpy(buf, "This is a test\n");
71291 nbytes = strlen(buf);
71292 bytes_written = write(fd, buf, nbytes);
71293 ...
```

71294 **APPLICATION USAGE**

71295 None.

71296 **RATIONALE**

71297 See also the RATIONALE section in *read*( ).

71298 An attempt to write to a pipe or FIFO has several major characteristics:

71299 • *Atomic/non-atomic*: A write is atomic if the whole amount written in one operation is not
71300 interleaved with data from any other process. This is useful when there are multiple
71301 writers sending data to a single reader. Applications need to know how large a write
71302 request can be expected to be performed atomically. This maximum is called {PIPE_BUF}.
71303 This volume of POSIX.1-200x does not say whether write requests for more than
71304 {PIPE_BUF} bytes are atomic, but requires that writes of {PIPE_BUF} or fewer bytes shall
71305 be atomic.

71306 • *Blocking/immediate*: Blocking is only possible with O_NONBLOCK clear. If there is enough
71307 space for all the data requested to be written immediately, the implementation should do
71308 so. Otherwise, the calling thread may block; that is, pause until enough space is available
71309 for writing. The effective size of a pipe or FIFO (the maximum amount that can be written
71310 in one operation without blocking) may vary dynamically, depending on the
71311 implementation, so it is not possible to specify a fixed value for it.

71312 • *Complete/partial/deferred*: A write request:

```
71313 int fildes;
71314 size_t nbyte;
71315 ssize_t ret;
71316 char *buf;
71317 ret = write(fildes, buf, nbyte);
```

71318 may return:

Complete *ret*=*nbyte*

Partial *ret*<*nbyte*

This shall never happen if *nbyte*≤{PIPE_BUF}. If it does happen (with *nbyte*>{PIPE_BUF}), this volume of POSIX.1-200x does not guarantee atomicity, even if *ret*≤{PIPE_BUF}, because atomicity is guaranteed according to the amount *requested*, not the amount *written*.

Deferred: *ret*=−1, *errno*=[EAGAIN]

This error indicates that a later request may succeed. It does not indicate that it *shall* succeed, even if *nbyte*≤{PIPE_BUF}, because if no process reads from the pipe or FIFO, the write never succeeds. An application could usefully count the number of times [EAGAIN] is caused by a particular value of *nbyte*>{PIPE_BUF} and perhaps do later writes with a smaller value, on the assumption that the effective size of the pipe may have decreased.

Partial and deferred writes are only possible with O_NONBLOCK set.

The relations of these properties are shown in the following tables:

Write to a Pipe or FIFO with O_NONBLOCK *clear*			
Immediately Writable:	**None**	**Some**	*nbyte*
nbyte≤{PIPE_BUF}	Atomic blocking *nbyte*	Atomic blocking *nbyte*	Atomic immediate *nbyte*
nbyte>{PIPE_BUF}	Blocking *nbyte*	Blocking *nbyte*	Blocking *nbyte*

If the O_NONBLOCK flag is clear, a write request shall block if the amount writable immediately is less than that requested. If the flag is set (by *fcntl*( )), a write request shall never block.

Write to a Pipe or FIFO with O_NONBLOCK *set*			
Immediately Writable:	**None**	**Some**	*nbyte*
nbyte≤{PIPE_BUF}	−1, [EAGAIN]	−1, [EAGAIN]	Atomic *nbyte*
nbyte>{PIPE_BUF}	−1, [EAGAIN]	<*nbyte* or −1, [EAGAIN]	≤*nbyte* or −1, [EAGAIN]

There is no exception regarding partial writes when O_NONBLOCK is set. With the exception of writing to an empty pipe, this volume of POSIX.1-200x does not specify exactly when a partial write is performed since that would require specifying internal details of the implementation. Every application should be prepared to handle partial writes when O_NONBLOCK is set and the requested amount is greater than {PIPE_BUF}, just as every application should be prepared to handle partial writes on other kinds of file descriptors.

The intent of forcing writing at least one byte if any can be written is to assure that each write makes progress if there is any room in the pipe. If the pipe is empty, {PIPE_BUF} bytes must be written; if not, at least some progress must have been made.

Where this volume of POSIX.1-200x requires −1 to be returned and *errno* set to [EAGAIN], most historical implementations return zero (with the O_NDELAY flag set, which is the historical predecessor of O_NONBLOCK, but is not itself in this volume of POSIX.1-200x). The error indications in this volume of POSIX.1-200x were chosen so that an application can distinguish these cases from end-of-file. While *write*( ) cannot receive an indication of end-of-file, *read*( ) can, and the two functions have similar return values. Also, some existing systems (for example, Eighth Edition) permit a write of zero bytes to mean that the reader should get an end-of-file

indication; for those systems, a return value of zero from *write*( ) indicates a successful write of an end-of-file indication.

Implementations are allowed, but not required, to perform error checking for *write*( ) requests of zero bytes.

The concept of a {PIPE_MAX} limit (indicating the maximum number of bytes that can be written to a pipe in a single operation) was considered, but rejected, because this concept would unnecessarily limit application writing.

See also the discussion of O_NONBLOCK in *read*( ).

Writes can be serialized with respect to other reads and writes. If a *read*( ) of file data can be proven (by any means) to occur after a *write*( ) of the data, it must reflect that *write*( ), even if the calls are made by different processes. A similar requirement applies to multiple write operations to the same file position. This is needed to guarantee the propagation of data from *write*( ) calls to subsequent *read*( ) calls. This requirement is particularly significant for networked file systems, where some caching schemes violate these semantics.

Note that this is specified in terms of *read*( ) and *write*( ). The XSI extensions *readv*( ) and *writev*( ) also obey these semantics. A new "high-performance" write analog that did not follow these serialization requirements would also be permitted by this wording. This volume of POSIX.1-200x is also silent about any effects of application-level caching (such as that done by *stdio*).

This volume of POSIX.1-200x does not specify the value of the file offset after an error is returned; there are too many cases. For programming errors, such as [EBADF], the concept is meaningless since no file is involved. For errors that are detected immediately, such as [EAGAIN], clearly the pointer should not change. After an interrupt or hardware error, however, an updated value would be very useful and is the behavior of many implementations.

This volume of POSIX.1-200x does not specify behavior of concurrent writes to a file from multiple processes. Applications should use some form of concurrency control.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

The DESCRIPTION is updated for alignment with the POSIX Realtime Extension and the POSIX Threads Extension.

Large File Summit extensions are added.

The *pwrite*( ) function is added.

Issue 6

The DESCRIPTION states that the *write*( ) function does not block the thread. Previously this said "process" rather than "thread".

The DESCRIPTION and ERRORS sections are updated so that references to STREAMS are marked as part of the XSI STREAMS Option Group.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The DESCRIPTION now states that if *write*( ) is interrupted by a signal after it has successfully written some data, it returns the number of bytes written. In the POSIX.1-1988 standard, it was optional whether *write*( ) returned the number of bytes written, or whether it returned –1 with *errno* set to [EINTR]. This is a FIPS requirement.
- The following changes are made to support large files:
  - For regular files, no data transfer occurs past the offset maximum established in the open file description associated with the *fildes*.
  - A second [EFBIG] error condition is added.
- The [EIO] error condition is added.
- The [EPIPE] error condition is added for when a pipe has only one end open.
- The [ENXIO] optional error condition is added.

Text referring to sockets is added to the DESCRIPTION.

The following changes were made to align with the IEEE P1003.1a draft standard:

- The effect of reading zero bytes is clarified.

The DESCRIPTION is updated for alignment with IEEE Std 1003.1j-2000 by specifying that *write*( ) results are unspecified for typed memory objects.

The following error conditions are added for operations on sockets: [EAGAIN], [EWOULDBLOCK], [ECONNRESET], [ENOTCONN], and [EPIPE].

The [EIO] error is made optional.

The [ENOBUFS] error is added for sockets.

The following error conditions are added for operations on sockets: [EACCES], [ENETDOWN], and [ENETUNREACH].

The *writev*( ) function is split out into a separate reference page.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/146 is applied, updating text in the ERRORS section from "a SIGPIPE signal is generated to the calling process" to "a SIGPIPE signal shall also be sent to the thread".

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/147 is applied, making a correction to the RATIONALE.

Issue 7

The *pwrite*( ) function is moved from the XSI option to the Base.

Functionality relating to the XSI STREAMS option is marked obsolescent.

SD5-XSH-ERN-160 is applied, updating the DESCRIPTION to clarify the requirements for the *pwrite*( ) function, and to change the use of the phrase "file pointer" to "file offset".

NAME

writev — write a vector

SYNOPSIS

XSI

```
#include <sys/uio.h>

ssize_t writev(int fildes, const struct iovec *iov, int iovcnt);
```

DESCRIPTION

The *writev*( ) function shall be equivalent to *write*( ), except as described below. The *writev*( ) function shall gather output data from the *iovcnt* buffers specified by the members of the *iov* array: *iov*[0], *iov*[1], ..., *iov*[*iovcnt*–1]. The *iovcnt* argument is valid if greater than 0 and less than or equal to {IOV_MAX}, as defined in **<limits.h>**.

Each *iovec* entry specifies the base address and length of an area in memory from which data should be written. The *writev*( ) function shall always write a complete area before proceeding to the next.

If *fildes* refers to a regular file and all of the *iov_len* members in the array pointed to by *iov* are 0, *writev*( ) shall return 0 and have no other effect. For other file types, the behavior is unspecified.

If the sum of the *iov_len* values is greater than {SSIZE_MAX}, the operation shall fail and no data shall be transferred.

RETURN VALUE

Upon successful completion, *writev*( ) shall return the number of bytes actually written. Otherwise, it shall return a value of –1, the file-pointer shall remain unchanged, and *errno* shall be set to indicate an error.

ERRORS

Refer to *write*( ).

In addition, the *writev*( ) function shall fail if:

[EINVAL] The sum of the *iov_len* values in the *iov* array would overflow an **ssize_t**.

The *writev*( ) function may fail and set *errno* to:

[EINVAL] The *iovcnt* argument was less than or equal to 0, or greater than {IOV_MAX}.

EXAMPLES

Writing Data from an Array

The following example writes data from the buffers specified by members of the *iov* array to the file associated with the file descriptor *fd*.

```
#include <sys/types.h>
#include <sys/uio.h>
#include <unistd.h>
...
ssize_t bytes_written;
int fd;
char *buf0 = "short string\n";
char *buf1 = "This is a longer string\n";
char *buf2 = "This is the longest string in this example\n";
int iovcnt;
struct iovec iov[3];
```

```
        iov[0].iov_base = buf0;
        iov[0].iov_len = strlen(buf0);
        iov[1].iov_base = buf1;
        iov[1].iov_len = strlen(buf1);
        iov[2].iov_base = buf2;
        iov[2].iov_len = strlen(buf2);
        ...
        iovcnt = sizeof(iov) / sizeof(struct iovec);
        bytes_written = writev(fd, iov, iovcnt);
        ...
```

APPLICATION USAGE

NAME

y0, y1, yn — Bessel functions of the second kind

SYNOPSIS

XSI
```
#include <math.h>

double y0(double x);
double y1(double x);
double yn(int n, double x);
```

DESCRIPTION

The *y0*( ), *y1*( ), and *yn*( ) functions shall compute Bessel functions of *x* of the second kind of orders 0, 1, and *n*, respectively.

An application wishing to check for error situations should set *errno* to zero and call *feclearexcept*(FE_ALL_EXCEPT) before calling these functions. On return, if *errno* is non-zero or *fetestexcept*(FE_INVALID | FE_DIVBYZERO | FE_OVERFLOW | FE_UNDERFLOW) is non-zero, an error has occurred.

RETURN VALUE

Upon successful completion, these functions shall return the relevant Bessel value of *x* of the second kind.

If *x* is NaN, NaN shall be returned.

If the *x* argument to these functions is negative, –HUGE_VAL or NaN shall be returned, and a domain error may occur.

If *x* is 0.0, –HUGE_VAL shall be returned and a pole error may occur.

If the correct result would cause underflow, 0.0 shall be returned and a range error may occur.

If the correct result would cause overflow, –HUGE_VAL or 0.0 shall be returned and a range error may occur.

ERRORS

These functions may fail if:

Domain Error — The value of *x* is negative.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [EDOM]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the invalid floating-point exception shall be raised.

Pole Error — The value of *x* is zero.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the divide-by-zero floating-point exception shall be raised.

Range Error — The correct result would cause overflow.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the overflow floating-point exception shall be raised.

Range Error — The value of *x* is too large in magnitude, or the correct result would cause underflow.

If the integer expression (*math_errhandling* & MATH_ERRNO) is non-zero, then *errno* shall be set to [ERANGE]. If the integer expression (*math_errhandling* & MATH_ERREXCEPT) is non-zero, then the underflow floating-point exception shall be raised.

EXAMPLES

None.

APPLICATION USAGE

On error, the expressions (*math_errhandling* & MATH_ERRNO) and (*math_errhandling* & MATH_ERREXCEPT) are independent of each other, but at least one of them must be non-zero.

RATIONALE

None.

FUTURE DIRECTIONS

None.

XBD Section 4.19 (on page 116), **<math.h>**

CHANGE HISTORY

First released in Issue 1. Derived from Issue 1 of the SVID.

Issue 5

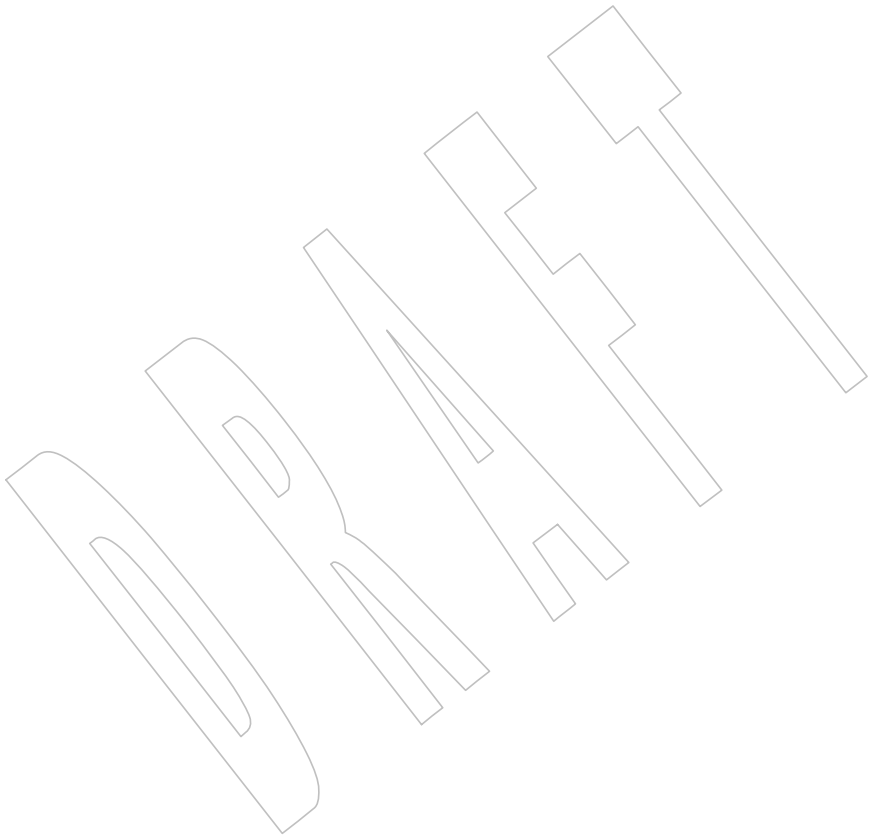
The DESCRIPTION is updated to indicate how an application should check for an error. This text was previously published in the APPLICATION USAGE section.

Issue 6

The normative text is updated to avoid use of the term "must" for application requirements.

The RETURN VALUE and ERRORS sections are reworked for alignment of the error handling with the ISO/IEC 9899: 1999 standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/148 is applied, updating the RETURN VALUE and ERRORS sections. The changes are made for consistency with the general rules stated in "Treatment of Error Conditions for Mathematical Functions" in the Base Definitions volume of POSIX.1-200x.



71586 *Technical Standard*

71587 **Volume 3:**

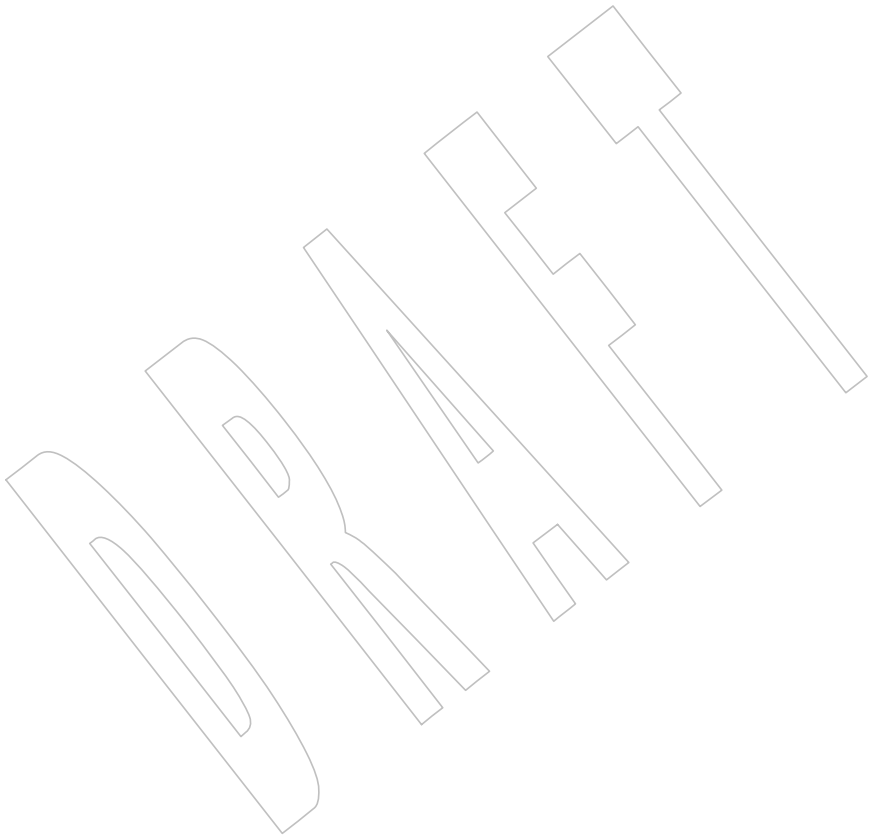
71590 *The Institute of Electrical and Electronics Engineers, Inc.*



71591 *Chapter 1*

71592 # *Introduction*

71593 The Shell and Utilities volume of POSIX.1-200x describes the commands and utilities offered to
71594 application programs by POSIX-conformant systems.

71595 ## 1.1 Relationship to Other Documents

71596 -

71597 ### 1.1.1 System Interfaces

71598 This subsection describes some of the features provided by the System Interfaces volume of
71599 POSIX.1-200x that are assumed to be globally available on all systems conforming to this volume
71600 of POSIX.1-200x. This subsection does not attempt to detail all of the features defined in the
71601 System Interfaces volume of POSIX.1-200x that are required by all of the utilities defined in this
71602 volume of POSIX.1-200x; the utility and function descriptions point out additional functionality
71603 required to provide the corresponding specific features needed by each.

71604 The following subsections describe frequently used concepts. Many of these concepts are
71605 described in the Base Definitions volume of POSIX.1-200x. Utility and function description
71606 statements override these defaults when appropriate.

71607 #### *1.1.1.1 Process Attributes*

71608 The following process attributes, as described in the System Interfaces volume of POSIX.1-200x,
71609 are assumed to be supported for all processes in this volume of POSIX.1-200x:

71610 Controlling Terminal
71611 Current Working Directory
71612 Effective Group ID
71613 Effective User ID
71614 File Descriptors
71615 File Mode Creation Mask
71616 Process Group ID
71617 Process ID
Real Group ID
Real User ID
Root Directory
Saved Set-Group-ID
Saved Set-User-ID
Session Membership
Supplementary Group IDs

71618 A conforming implementation may include additional process attributes.

71619 #### *1.1.1.2 Concurrent Execution of Processes*

71620 The following functionality of the *fork*() function defined in the System Interfaces volume of
71621 POSIX.1-200x shall be available on all systems conforming to this volume of POSIX.1-200x:

71622 1. Independent processes shall be capable of executing independently without either
71623 process terminating.

2. A process shall be able to create a new process with all of the attributes referenced in Section 1.1.1.1 (on page 2279), determined according to the semantics of a call to the *fork*( ) function defined in the System Interfaces volume of POSIX.1-200x followed by a call in the child process to one of the *exec* functions defined in the System Interfaces volume of POSIX.1-200x.

1.1.1.3 *File Access Permissions*

The file access control mechanism described by XBD Section 4.4 (on page 108) shall apply to all files on an implementation conforming to this volume of POSIX.1-200x.

1.1.1.4 *File Read, Write, and Creation*

If a file that does not exist is to be written, it shall be created as described below, unless the utility description states otherwise.

When a file that does not exist is created, the following features defined in the System Interfaces volume of POSIX.1-200x shall apply unless the utility or function description states otherwise:

1. The user ID of the file shall be set to the effective user ID of the calling process.
2. The group ID of the file shall be set to the effective group ID of the calling process or the group ID of the directory in which the file is being created.
3. If the file is a regular file, the permission bits of the file shall be set to:

   S_IROTH | S_IWOTH | S_IRGRP | S_IWGRP | S_IRUSR | S_IWUSR

   (see the description of *File Modes* in XBD Chapter 13 (on page 219), **<sys/stat.h>**) except that the bits specified by the file mode creation mask of the process shall be cleared. If the file is a directory, the permission bits shall be set to:

   S_IRWXU | S_IRWXG | S_IRWXO

   except that the bits specified by the file mode creation mask of the process shall be cleared.
4. The last data access, last data modification, and last file status change timestamps of the file shall be updated as specified in XBD Section 4.8 (on page 109).
5. If the file is a directory, it shall be an empty directory; otherwise, the file shall have length zero.
6. If the file is a symbolic link, the effect shall be undefined unless the {POSIX2_SYMLINKS} variable is in effect for the directory in which the symbolic link would be created.
7. Unless otherwise specified, the file created shall be a regular file.

When an attempt is made to create a file that already exists, the utility shall take the action indicated in Table 1-1 (on page 2281) corresponding to the type of the file the utility is trying to create and the type of the existing file, unless the utility description states otherwise.

Table 1-1 Actions when Creating a File that Already Exists

Existing Type	New Type B	C	D	F	L	M	P	Q	R	S	T	Function Creating New
A *fattach*()-ed STREAM	F	F	F	F	F	—	—	—	OF	—	U	N/A
B Block Special	F	F	F	F	F	U	U	U	OF	U	U	*mknod*()**
C Character Special	F	F	F	F	F	U	U	U	OF	U	U	*mknod*()**
D Directory	F	F	F	F	F	—	—	—	F	—	U	*mkdir*()
F FIFO Special File	F	F	F	F	F	—	—	—	O	—	U	*mkfifo*()
L Symbolic Link	F	F	F	F	F	—	—	—	FL	—	U	*symlink*()
M Shared Memory	F	F	F	F	F	—	—	—	—	—	U	*shm_open*()
P Semaphore	F	F	F	F	F	—	—	—	—	—	U	*sem_open*()
Q Message Queue	F	F	F	F	F	—	—	—	—	—	U	*mq_open*()
R Regular File	F	F	F	F	F	—	—	—	RF	—	U	*open*()
S Socket	F	F	F	F	F	—	—	—	—	—	U	*bind*()
T Typed Memory	F	F	F	F	F	U	U	U	U	U	U	*

The following codes are used in Table 1-1:

F Fail. The attempt to create the new file shall fail and the utility shall either continue with its operation or exit immediately with a non-zero exit status, depending on the description of the utility.

FL Follow link. Unless otherwise specified, the symbolic link shall be followed as specified for pathname resolution, and the operation performed shall be as if the target of the symbolic link (after all resolution) had been named. If the target of the symbolic link does not exist, it shall be as if that nonexistent target had been named directly.

O Open FIFO. When attempting to create a regular file, and the existing file is a FIFO special file:

1. If the FIFO is not already open for reading, the attempt shall block until the FIFO is opened for reading.
2. Once the FIFO is open for reading, the utility shall open the FIFO for writing and continue with its operation.

OF The named file shall be opened with the consequences defined for that file type.

RF Regular file. When attempting to create a regular file, and the existing file is a regular file:

1. The user ID, group ID, and permission bits of the file shall not be changed.
2. The file shall be truncated to zero length.
3. The last data modification and last file status change timestamps shall be marked for update.

— The effect is implementation-defined unless specified by the utility description.

U The effect is unspecified unless specified by the utility description.

* There is no portable way to create a file of this type.

** Not portable.

When a file is to be appended, the file shall be opened in a manner equivalent to using the O_APPEND flag, without the O_TRUNC flag, in the *open*() function defined in the System Interfaces volume of POSIX.1-200x.

When a file is to be read or written, the file shall be opened with an access mode corresponding to the operation to be performed. If file access permissions deny access, the requested operation shall fail.

1.1.1.5 File Removal

When a directory that is the root directory or current working directory of any process is removed, the effect is implementation-defined. If file access permissions deny access, the requested operation shall fail. Otherwise, when a file is removed:

1. Its directory entry shall be removed from the file system.
2. The link count of the file shall be decremented.
3. If the file is an empty directory (see XBD Section 3.144, on page 56):
   a. If no process has the directory open, the space occupied by the directory shall be freed and the directory shall no longer be accessible.
   b. If one or more processes have the directory open, the directory contents shall be preserved until all references to the file have been closed.
4. If the file is a directory that is not empty, the last file status change timestamp shall be marked for update.
5. If the file is not a directory:
   a. If the link count becomes zero:
      i. If no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible.
      ii. If one or more processes have the file open, the file contents shall be preserved until all references to the file have been closed.
   b. If the link count is not reduced to zero, the last file status change timestamp shall be marked for update.
6. The last data modification and last file status change timestamps of the containing directory shall be marked for update.

1.1.1.6 File Time Values

All files shall have the three time values described by XBD Section 4.8 (on page 109).

1.1.1.7 File Contents

When a reference is made to the contents of a file, *pathname*, this means the equivalent of all of the data placed in the space pointed to by *buf* when performing the *read*( ) function calls in the following operations defined in the System Interfaces volume of POSIX.1-200x:

```
while (read (fildes, buf, nbytes) > 0)
    ;
```

If the file is indicated by a pathname *pathname*, the file descriptor shall be determined by the equivalent of the following operation defined in the System Interfaces volume of POSIX.1-200x:

```
fildes = open (pathname, O_RDONLY);
```

The value of *nbytes* in the above sequence is unspecified; if the file is of a type where the data

returned by *read*() would vary with different values, the value shall be one that results in the most data being returned.

If the *read*() function calls would return an error, it is unspecified whether the contents of the file are considered to include any data from offsets in the file beyond where the error would be returned.

1.1.1.8 *Pathname Resolution*

The pathname resolution algorithm, described by XBD Section 4.12 (on page 111), shall be used by implementations conforming to this volume of POSIX.1-200x; see also XBD Section 4.5 (on page 108).

1.1.1.9 *Changing the Current Working Directory*

When the current working directory (see XBD Section 3.122, on page 53) is to be changed, unless the utility or function description states otherwise, the operation shall succeed unless a call to the *chdir*() function defined in the System Interfaces volume of POSIX.1-200x would fail when invoked with the new working directory pathname as its argument.

1.1.1.10 *Establish the Locale*

The functionality of the *setlocale*() function defined in the System Interfaces volume of POSIX.1-200x shall be available on all systems conforming to this volume of POSIX.1-200x; that is, utilities that require the capability of establishing an international operating environment shall be permitted to set the specified category of the international environment.

1.1.1.11 *Actions Equivalent to Functions*

Some utility descriptions specify that a utility performs actions equivalent to a function defined in the System Interfaces volume of POSIX.1-200x. Such specifications require only that the external effects be equivalent, not that any effect within the utility and visible only to the utility be equivalent.

1.1.2 Concepts Derived from the ISO C Standard

Some of the standard utilities perform complex data manipulation using their own procedure and arithmetic languages, as defined in their EXTENDED DESCRIPTION or OPERANDS sections. Unless otherwise noted, the arithmetic and semantic concepts (precision, type conversion, control flow, and so on) shall be equivalent to those defined in the ISO C standard, as described in the following sections. Note that there is no requirement that the standard utilities be implemented in any particular programming language.

1.1.2.1 *Arithmetic Precision and Operations*

Integer variables and constants, including the values of operands and option-arguments, used by the standard utilities listed in this volume of POSIX.1-200x shall be implemented as equivalent to the ISO C standard **signed long** data type; floating point shall be implemented as equivalent to the ISO C standard **double** type. Conversions between types shall be as described in the ISO C standard. All variables shall be initialized to zero if they are not otherwise assigned by the input to the application.

Arithmetic operators and control flow keywords shall be implemented as equivalent to those in the cited ISO C standard section, as listed in Table 1-2.

Table 1-2 Selected ISO C Standard Operators and Control Flow Keywords

Operation	ISO C Standard Equivalent Reference
( )	Section 6.5.1, Primary Expressions
postfix ++ postfix --	Section 6.5.2, Postfix Operators
unary + unary - prefix ++ prefix -- ~ ! *sizeof*( )	Section 6.5.3, Unary Operators
* / %	Section 6.5.5, Multiplicative Operators
+ -	Section 6.5.6, Additive Operators
<< >>	Section 6.5.7, Bitwise Shift Operators
<, <= >, >=	Section 6.5.8, Relational Operators
= = !=	Section 6.5.9, Equality Operators
&	Section 6.5.10, Bitwise AND Operator
^	Section 6.5.11, Bitwise Exclusive OR Operator
|	Section 6.5.12, Bitwise Inclusive OR Operator
&&	Section 6.5.13, Logical AND Operator
| |	Section 6.5.14, Logical OR Operator
expr?*expr*:*expr*	Section 6.5.15, Conditional Operator
=, *=, /=, %=, +=, -= <<=, >>=, &=, ^=, |=	Section 6.5.16, Assignment Operators
if ( ) **if** ( ) . . . **else** **switch** ( )	Section 6.8.4, Selection Statements
while ( ) **do** . . . **while** ( ) **for** ( )	Section 6.8.5, Iteration Statements
goto **continue** **break** **return**	Section 6.8.6, Jump Statements

The evaluation of arithmetic expressions shall be equivalent to that described in Section 6.5, Expressions, of the ISO C standard.

1.1.2.2 *Mathematical Functions*

Any mathematical functions with the same names as those in the following sections of the ISO C standard:

- Section 7.12, Mathematics, `<math.h>`
- Section 7.20.2, Pseudo-Random Sequence Generation Functions

shall be implemented to return the results equivalent to those returned from a call to the corresponding function described in the ISO C standard.

1.2 Utility Limits

This section lists magnitude limitations imposed by a specific implementation. The braces notation, {LIMIT}, is used in this volume of POSIX.1-200x to indicate these values, but the braces are not part of the name.

Table 1-3 Utility Limit Minimum Values

Name	Description	Value
{POSIX2_BC_BASE_MAX}	The maximum *obase* value allowed by the *bc* utility.	99
{POSIX2_BC_DIM_MAX}	The maximum number of elements permitted in an array by the *bc* utility.	2 048
{POSIX2_BC_SCALE_MAX}	The maximum *scale* value allowed by the *bc* utility.	99
{POSIX2_BC_STRING_MAX}	The maximum length of a string constant accepted by the *bc* utility.	1 000
{POSIX2_COLL_WEIGHTS_MAX}	The maximum number of weights that can be assigned to an entry of the *LC_COLLATE* **order** keyword in the locale definition file; see the **border_start** keyword in XBD Section 7.3.2 (on page 146).	2
{POSIX2_EXPR_NEST_MAX}	The maximum number of expressions that can be nested within parentheses by the *expr* utility.	32
{POSIX2_LINE_MAX}	Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>.	2 048
{POSIX2_RE_DUP_MAX}	The maximum number of repeated occurrences of a BRE permitted when using the interval notation \{*m*,*n*\}; see XBD Section 9.3.6 (on page 186).	255

The values specified in Table 1-3 represent the lowest values conforming implementations shall provide and, consequently, the largest values on which an application can rely without further

71860 enquiries, as described below. These values shall be accessible to applications via the *getconf*
71861 utility (see *getconf*, on page 2772).

71862 Implementations may provide more liberal, or less restrictive, values than shown in Table 1-3
71863 (on page 2285). These possibly more liberal values are accessible using the symbols in Table 1-4.

71864 The *sysconf*( ) function defined in the System Interfaces volume of POSIX.1-200x or the *getconf*
71865 utility return the value of each symbol on each specific implementation. The value so retrieved is
71866 the largest, or most liberal, value that is available throughout the session lifetime, as determined
71867 at session creation. The literal names shown in the table apply only to the *getconf* utility; the
71868 high-level language binding describes the exact form of each name to be used by the interfaces
71869 in that binding.

71870 All numeric limits defined by the System Interfaces volume of POSIX.1-200x, such as
71871 {PATH_MAX}, shall also apply to this volume of POSIX.1-200x. All the utilities defined by this
71872 volume of POSIX.1-200x are implicitly limited by these values, unless otherwise noted in the
71873 utility descriptions.

71874 It is not guaranteed that the application can actually reach the specified limit of an
71875 implementation in any given case, or at all, as a lack of virtual memory or other resources may
71876 prevent this. The limit value indicates only that the implementation does not specifically impose
71877 any arbitrary, more restrictive limit.

71878 **Table 1-4** Symbolic Utility Limits

71879

Name	Description	Minimum Value
71880 {BC_BASE_MAX}	The maximum *obase* value allowed by the *bc* utility.	{POSIX2_BC_BASE_MAX}
71882 {BC_DIM_MAX}	The maximum number of elements permitted in an array by the *bc* utility.	{POSIX2_BC_DIM_MAX}
71885 {BC_SCALE_MAX}	The maximum *scale* value allowed by the *bc* utility.	{POSIX2_BC_SCALE_MAX}
71887 {BC_STRING_MAX}	The maximum length of a string constant accepted by the *bc* utility.	{POSIX2_BC_STRING_MAX}
71890 {COLL_WEIGHTS_MAX}	The maximum number of weights that can be assigned to an entry of the *LC_COLLATE* **order** keyword in the locale definition file; see the **order_start** keyword in XBD Section 7.3.2 (on page 146).	{POSIX2_COLL_WEIGHTS_MAX}
71898 {EXPR_NEST_MAX}	The maximum number of expressions that can be nested within parentheses by the *expr* utility.	{POSIX2_EXPR_NEST_MAX}

Name	Description	Minimum Value
{LINE_MAX}	Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>.	{POSIX2_LINE_MAX}
{RE_DUP_MAX}	The maximum number of repeated occurrences of a BRE permitted when using the interval notation \{*m*,*n*\}; see XBD Section 9.3.6 (on page 186).	{POSIX2_RE_DUP_MAX}

The following value may be a constant within an implementation or may vary from one pathname to another.

{POSIX2_SYMLINKS}
When referring to a directory, the system supports the creation of symbolic links within that directory; for non-directory files, the meaning of {POSIX2_SYMLINKS} is undefined.

1.3 Grammar Conventions

Portions of this volume of POSIX.1-200x are expressed in terms of a special grammar notation. It is used to portray the complex syntax of certain program input. The grammar is based on the syntax used by the *yacc* utility. However, it does not represent fully functional *yacc* input, suitable for program use; the lexical processing and all semantic requirements are described only in textual form. The grammar is not based on source used in any traditional implementation and has not been tested with the semantic code that would normally be required to accompany it. Furthermore, there is no implication that the partial *yacc* code presented represents the most efficient, or only, means of supporting the complex syntax within the utility. Implementations may use other programming languages or algorithms, as long as the syntax supported is the same as that represented by the grammar.

The following typographical conventions are used in the grammar; they have no significance except to aid in reading.

- The identifiers for the reserved words of the language are shown with a leading capital letter. (These are terminals in the grammar; for example, **While**, **Case**.)
- The identifiers for terminals in the grammar are all named with uppercase letters and underscores; for example, **NEWLINE**, **ASSIGN_OP**, **NAME**.
- The identifiers for non-terminals are all lowercase.

1.4 Utility Description Defaults

This section describes all of the subsections used within the utility descriptions, including:

- Intended usage of the section
- Global defaults that affect all the standard utilities
- The meanings of notations used in this volume of POSIX.1-200x that are specific to individual utility sections

NAME

This section gives the name or names of the utility and briefly states its purpose.

SYNOPSIS

The SYNOPSIS section summarizes the syntax of the calling sequence for the utility, including options, option-arguments, and operands. Standards for utility naming are described in XBD Section 12.2 (on page 215); for describing the utility's arguments in XBD Section 12.1 (on page 213).

DESCRIPTION

The DESCRIPTION section describes the actions of the utility. If the utility has a very complex set of subcommands or its own procedural language, an EXTENDED DESCRIPTION section is also provided. Most explanations of optional functionality are omitted here, as they are usually explained in the OPTIONS section.

As stated in Section 1.1.1.11 (on page 2283), some functions are described in terms of equivalent functionality. When specific functions are cited, the implementation shall provide equivalent functionality including side-effects associated with successful execution of the function. The treatment of errors and intermediate results from the individual functions cited is generally not specified by this volume of POSIX.1-200x. See the utility's EXIT STATUS and CONSEQUENCES OF ERRORS sections for all actions associated with errors encountered by the utility.

OPTIONS

The OPTIONS section describes the utility options and option-arguments, and how they modify the actions of the utility. Standard utilities that have options either fully comply with XBD Section 12.2 (on page 215) or describe all deviations. Apparent disagreements between functionality descriptions in the OPTIONS and DESCRIPTION (or EXTENDED DESCRIPTION) sections are always resolved in favor of the OPTIONS section.

Each OPTIONS section that uses the phrase "The ... utility shall conform to the Utility Syntax Guidelines ..." refers only to the use of the utility as specified by this volume of POSIX.1-200x; implementation extensions should also conform to the guidelines, but may allow exceptions for historical practice.

Unless otherwise stated in the utility description, when given an option unrecognized by the implementation, or when a required option-argument is not provided, standard utilities shall issue a diagnostic message to standard error and exit with a non-zero exit status.

All utilities in this volume of POSIX.1-200x shall be capable of processing arguments using eight-bit transparency.

Default Behavior: When this section is listed as "None.", it means that the implementation need not support any options. Standard utilities that do not accept options, but that do accept operands, shall recognize "--" as a first argument to be discarded.

The requirement for recognizing "−−" is because conforming applications need a way to shield their operands from any arbitrary options that the implementation may provide as an extension. For example, if the standard utility *foo* is listed as taking no options, and the application needed to give it a pathname with a leading <hyphen>, it could safely do it as:

```
foo −− −myfile
```

and avoid any problems with −**m** used as an extension.

OPERANDS

The OPERANDS section describes the utility operands, and how they affect the actions of the utility. Apparent disagreements between functionality descriptions in the OPERANDS and DESCRIPTION (or EXTENDED DESCRIPTION) sections shall be resolved in favor of the OPERANDS section.

If an operand naming a file can be specified as '−', which means to use the standard input instead of a named file, this is explicitly stated in this section. Unless otherwise stated, the use of multiple instances of '−' to mean standard input in a single command produces unspecified results.

Unless otherwise stated, the standard utilities that accept operands shall process those operands in the order specified in the command line.

Default Behavior: When this section is listed as "None.", it means that the implementation need not support any operands.

STDIN

The STDIN section describes the standard input of the utility. This section is frequently merely a reference to the following section, as many utilities treat standard input and input files in the same manner. Unless otherwise stated, all restrictions described in the INPUT FILES section shall apply to this section as well.

Use of a terminal for standard input can cause any of the standard utilities that read standard input to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

The specified standard input format of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of POSIX.1-200x, except as provided by this volume of POSIX.1-200x.

Default Behavior: When this section is listed as "Not used.", it means that the standard input shall not be read when the utility is used as described by this volume of POSIX.1-200x.

INPUT FILES

The INPUT FILES section describes the files, other than the standard input, used as input by the utility. It includes files named as operands and option-arguments as well as other files that are referred to, such as start-up and initialization files, databases, and so on. Commonly-used files are generally described in one place and cross-referenced by other utilities.

All utilities in this volume of POSIX.1-200x shall be capable of processing input files using eight-bit transparency.

When a standard utility reads a seekable input file and terminates without an error before it reaches end-of-file, the utility shall ensure that the file offset in the open file description is properly positioned just past the last byte processed by the utility. For files that are not seekable, the state of the file offset in the open file description for that

72033 file is unspecified. A conforming application shall not assume that the following three
72034 commands are equivalent:

72035 ```
tail –n +2 file
72036 (sed –n 1q; cat) < file
72037 cat file | (sed –n 1q; cat)
```

72038 The second command is equivalent to the first only when the file is seekable. The third
72039 command leaves the file offset in the open file description in an unspecified state. Other
72040 utilities, such as *head*, *read*, and *sh*, have similar properties.

72041 Some of the standard utilities, such as filters, process input files a line or a block at a
72042 time and have no restrictions on the maximum input file size. Some utilities may have
72043 size limitations that are not as obvious as file space or memory limitations. Such
72044 limitations should reflect resource limitations of some sort, not arbitrary limits set by
72045 implementors. Implementations shall document those utilities that are limited by
72046 constraints other than file system space, available memory, and other limits specifically
72047 cited by this volume of POSIX.1-200x, and identify what the constraint is and indicate a
72048 way of estimating when the constraint would be reached. Similarly, some utilities
72049 descend the directory tree (recursively). Implementations shall also document any
72050 limits that they may have in descending the directory tree that are beyond limits cited
72051 by this volume of POSIX.1-200x.

72052 When an input file is described as a "text file", the utility produces undefined results if
72053 given input that is not from a text file, unless otherwise stated. Some utilities (for
72054 example, *make*, *read*, *sh*) allow for continued input lines using an escaped <newline>
72055 convention; unless otherwise stated, the utility need not be able to accumulate more
72056 than {LINE_MAX} bytes from a set of multiple, continued input lines. Thus, for a
72057 conforming application the total of all the continued lines in a set cannot exceed
72058 {LINE_MAX}. If a utility using the escaped <newline> convention detects an end-of-
72059 file condition immediately after an escaped <newline>, the results are unspecified.

72060 Record formats are described in a notation similar to that used by the C-language
72061 function, *printf*( ). See XBD Chapter 5 (on page 121) for a description of this notation.
72062 The format description is intended to be sufficiently rigorous to allow other
72063 applications to generate these input files. However, since <blank>s can legitimately be
72064 included in some of the fields described by the standard utilities, particularly in locales
72065 other than the POSIX locale, this intent is not always realized.

72066 **Default Behavior:** When this section is listed as "None.", it means that no input files
72067 are required to be supplied when the utility is used as described by this volume of
72068 POSIX.1-200x.

72069 **ENVIRONMENT VARIABLES**

72070 The ENVIRONMENT VARIABLES section lists what variables affect the utility's
72071 execution.

72072 The entire manner in which environment variables described in this volume of
72073 POSIX.1-200x affect the behavior of each utility is described in the ENVIRONMENT
72074 VARIABLES section for that utility, in conjunction with the global effects of the *LANG*,
72075 XSI *LC_ALL*, and *NLSPATH* environment variables described in XBD Chapter 8 (on page
72076 173). The existence or value of environment variables described in this volume of
72077 POSIX.1-200x shall not otherwise affect the specified behavior of the standard utilities.
72078 Any effects of the existence or value of environment variables not described by this
72079 volume of POSIX.1-200x upon the standard utilities are unspecified.

72080 For those standard utilities that use environment variables as a means for selecting a
```

utility to execute (such as *CC* in *make*), the string provided to the utility is subjected to the path search described for *PATH* in XBD Chapter 8 (on page 173).

All utilities in this volume of POSIX.1-200x shall be capable of processing environment variable names and values using eight-bit transparency.

Default Behavior: When this section is listed as "None.", it means that the behavior of the utility is not directly affected by environment variables described by this volume of POSIX.1-200x when the utility is used as described by this volume of POSIX.1-200x.

ASYNCHRONOUS EVENTS

The ASYNCHRONOUS EVENTS section lists how the utility reacts to such events as signals and what signals are caught.

Default Behavior: When this section is listed as "Default.", or it refers to "the standard action for all other signals; see Section 1.4 (on page 2288)" it means that the action taken as a result of the signal shall be one of the following:

1. The action shall be that inherited from the parent according to the rules of inheritance of signal actions defined in the System Interfaces volume of POSIX.1-200x.
2. When no action has been taken to change the default, the default action shall be that specified by the System Interfaces volume of POSIX.1-200x.
3. The result of the utility's execution is as if default actions had been taken.

A utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

STDOUT

The STDOUT section completely describes the standard output of the utility. This section is frequently merely a reference to the following section, OUTPUT FILES, because many utilities treat standard output and output files in the same manner.

Use of a terminal for standard output may cause any of the standard utilities that write standard output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ). See XBD Chapter 5 (on page 121) for a description of this notation.

The specified standard output of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of POSIX.1-200x, except as provided by this volume of POSIX.1-200x.

Some of the standard utilities describe their output using the verb *display*, defined in XBD Section 3.133 (on page 54). Output described in the STDOUT sections of such utilities may be produced using means other than standard output. When standard output is directed to a terminal, the output described shall be written directly to the terminal. Otherwise, the results are undefined.

Default Behavior: When this section is listed as "Not used.", it means that the standard output shall not be written when the utility is used as described by this volume of POSIX.1-200x.

STDERR

The STDERR section describes the standard error output of the utility. Only those messages that are purposely sent by the utility are described.

Use of a terminal for standard error may cause any of the standard utilities that write standard error output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

The format of diagnostic messages for most utilities is unspecified, but the language and cultural conventions of diagnostic and informative messages whose format is unspecified by this volume of POSIX.1-200x should be affected by the setting of *LC_MESSAGES* and *NLSPATH*.

XSI

The specified standard error output of standard utilities shall not depend on the existence or value of the environment variables defined in this volume of POSIX.1-200x, except as provided by this volume of POSIX.1-200x.

Default Behavior: When this section is listed as "The standard error shall be used only for diagnostic messages.", it means that, unless otherwise stated, the diagnostic messages shall be sent to the standard error only when the exit status indicates that an error occurred and the utility is used as described by this volume of POSIX.1-200x.

When this section is listed as "Not used.", it means that the standard error shall not be used when the utility is used as described in this volume of POSIX.1-200x.

OUTPUT FILES

The OUTPUT FILES section completely describes the files created or modified by the utility. Temporary or system files that are created for internal usage by this utility or other parts of the implementation (for example, spool, log, and audit files) are not described in this, or any, section. The utilities creating such files and the names of such files are unspecified. If applications are written to use temporary or intermediate files, they should use the *TMPDIR* environment variable, if it is set and represents an accessible directory, to select the location of temporary files.

Implementations shall ensure that temporary files, when used by the standard utilities, are named so that different utilities or multiple instances of the same utility can operate simultaneously without regard to their working directories, or any other process characteristic other than process ID. There are two exceptions to this rule:

1. Resources for temporary files other than the name space (for example, disk space, available directory entries, or number of processes allowed) are not guaranteed.
2. Certain standard utilities generate output files that are intended as input for other utilities (for example, *lex* generates **lex.yy.c**), and these cannot have unique names. These cases are explicitly identified in the descriptions of the respective utilities.

Any temporary file created by the implementation shall be removed by the implementation upon a utility's successful exit, exit because of errors, or before termination by any of the SIGHUP, SIGINT, or SIGTERM signals, unless specified otherwise by the utility description.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

Record formats are described in a notation similar to that used by the C-language function, *printf*( ); see XBD Chapter 5 (on page 121) for a description of this notation.

Default Behavior: When this section is listed as "None.", it means that no files are created or modified as a consequence of direct action on the part of the utility when the utility is used as described by this volume of POSIX.1-200x. However, the utility may

create or modify system files, such as log files, that are outside the utility's normal execution environment.

EXTENDED DESCRIPTION

The EXTENDED DESCRIPTION section provides a place for describing the actions of very complicated utilities, such as text editors or language processors, which typically have elaborate command languages.

Default Behavior: When this section is listed as "None.", no further description is necessary.

EXIT STATUS

The EXIT STATUS section describes the values the utility shall return to the calling program, or shell, and the conditions that cause these values to be returned. Usually, utilities return zero for successful completion and values greater than zero for various error conditions. If specific numeric values are listed in this section, the system shall use those values for the errors described. In some cases, status values are listed more loosely, such as >0. A strictly conforming application shall not rely on any specific value in the range shown and shall be prepared to receive any value in the range.

For example, a utility may list zero as a successful return, 1 as a failure for a specific reason, and >1 as "an error occurred". In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in this volume of POSIX.1-200x. In that way, it has maximum portability, even on implementations with extensions.

Unspecified error conditions may be represented by specific values not listed in this volume of POSIX.1-200x.

CONSEQUENCES OF ERRORS

The CONSEQUENCES OF ERRORS section describes the effects on the environment, file systems, process state, and so on, when error conditions occur. It does not describe error messages produced or exit status values used.

The many reasons for failure of a utility are generally not specified by the utility descriptions. Utilities may terminate prematurely if they encounter: invalid usage of options, arguments, or environment variables; invalid usage of the complex syntaxes expressed in EXTENDED DESCRIPTION sections; difficulties accessing, creating, reading, or writing files; or difficulties associated with the privileges of the process.

The following shall apply to each utility, unless otherwise stated:

- If the requested action cannot be performed on an operand representing a file, directory, user, process, and so on, the utility shall issue a diagnostic message to standard error and continue processing the next operand in sequence, but the final exit status shall be returned as non-zero.

  For a utility that recursively traverses a file hierarchy (such as *find* or *chown* **–R**), if the requested action cannot be performed on a file or directory encountered in the hierarchy, the utility shall issue a diagnostic message to standard error and continue processing the remaining files in the hierarchy, but the final exit status shall be returned as non-zero.

- If the requested action characterized by an option or option-argument cannot be performed, the utility shall issue a diagnostic message to standard error and the exit status returned shall be non-zero.

- When an unrecoverable error condition is encountered, the utility shall exit with a non-zero exit status.
- A diagnostic message shall be written to standard error whenever an error condition occurs.

When a utility encounters an error condition several actions are possible, depending on the severity of the error and the state of the utility. Included in the possible actions of various utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; validity checking of the file system or directory.

Default Behavior: When this section is listed as "Default.", it means that any changes to the environment are unspecified.

APPLICATION USAGE

This section is informative.

The APPLICATION USAGE section gives advice to the application programmer or user about the way the utility should be used.

EXAMPLES

This section is informative.

The EXAMPLES section gives one or more examples of usage, where appropriate. In the event of conflict between an example and a normative part of the specification, the normative material is to be taken as correct.

In all examples, quoting has been used, showing how sample commands (utility names combined with arguments) could be passed correctly to a shell (see *sh*) or as a string to the *system*( ) function defined in the System Interfaces volume of POSIX.1-200x. Such quoting would not be used if the utility is invoked using one of the *exec* functions defined in the System Interfaces volume of POSIX.1-200x.

RATIONALE

This section is informative.

This section contains historical information concerning the contents of this volume of POSIX.1-200x and why features were included or discarded by the standard developers.

FUTURE DIRECTIONS

This section is informative.

The FUTURE DIRECTIONS section should be used as a guide to current thinking; there is not necessarily a commitment to implement all of these future directions in their entirety.

SEE ALSO

This section is informative.

The SEE ALSO section lists related entries.

CHANGE HISTORY

This section is informative.

This section shows the derivation of the entry and any significant changes that have been made to it.

Certain of the standard utilities describe how they can invoke other utilities or applications, such as by passing a command string to the command interpreter. The external influences (STDIN, ENVIRONMENT VARIABLES, and so on) and external effects (STDOUT, CONSEQUENCES OF

ERRORS, and so on) of such invoked utilities are not described in the section concerning the standard utility that invokes them.

1.5 Considerations for Utilities in Support of Files of Arbitrary Size

The following utilities support files of any size up to the maximum that can be created by the implementation. This support includes correct writing of file size-related values (such as file sizes and offsets, line numbers, and block counts) and correct interpretation of command line arguments that contain such values.

basename Return non-directory portion of pathname.

cat Concatenate and print files.

cd Change working directory.

chgrp Change file group ownership.

chmod Change file modes.

chown Change file ownership.

cksum Write file checksums and sizes.

cmp Compare two files.

cp Copy files.

dd Convert and copy a file.

df Report free disk space.

dirname Return directory portion of pathname.

du Estimate file space usage.

find Find files.

ln Link files.

ls List directory contents.

mkdir Make directories.

mv Move files.

pathchk Check pathnames.

pwd Return working directory name.

rm Remove directory entries.

rmdir Remove directories.

sh Shell, the standard command language interpreter.

sum Print checksum and block or byte count of a file.

test Evaluate expression.

touch Change file access and modification times.

ulimit Set or report file size limit.

Exceptions to the requirement that utilities support files of any size up to the maximum are as follows:

1. Uses of files as command scripts, or for configuration or control, are exempt. For example, it is not required that *sh* be able to read an arbitrarily large **.profile**.
2. Shell input and output redirection are exempt. For example, it is not required that the redirections *sum* < *file* or *echo foo* > *file* succeed for an arbitrarily large existing file.

1.6 Built-In Utilities

Any of the standard utilities may be implemented as regular built-in utilities within the command language interpreter. This is usually done to increase the performance of frequently used utilities or to achieve functionality that would be more difficult in a separate environment. The utilities named in Table 1-5 are frequently provided in built-in form. All of the utilities named in the table have special properties in terms of command search order within the shell, as described in Section 2.9.1.1 (on page 2317).

Table 1-5 Regular Built-In Utilities

alias	*false*	*jobs*	*read*	*wait*
bg	*fc*	*kill*	*true*	
cd	*fg*	*newgrp*	*umask*	
command	*getopts*	*pwd*	*unalias*	

However, all of the standard utilities, including the regular built-ins in the table, but not the special built-ins described in Section 2.14 (on page 2334), shall be implemented in a manner so that they can be accessed via the *exec* family of functions as defined in the System Interfaces volume of POSIX.1-200x and can be invoked directly by those standard utilities that require it (*env*, *find*, *nice*, *nohup*, *time*, *xargs*).

72320 *Chapter 2*

72321 # *Shell Command Language*

72322 This chapter contains the definition of the Shell Command Language.

72323 ## 2.1 Shell Introduction

72324 The shell is a command language interpreter. This chapter describes the syntax of that command
72325 language as it is used by the *sh* utility and the *system*( ) and *popen*( ) functions defined in the
72326 System Interfaces volume of POSIX.1-200x.

72327 The shell operates according to the following general overview of operations. The specific
72328 details are included in the cited sections of this chapter.

72329 1. The shell reads its input from a file (see *sh*), from the **–c** option or from the *system*( ) and
72330 *popen*( ) functions defined in the System Interfaces volume of POSIX.1-200x. If the first
72331 line of a file of shell commands starts with the characters "#!", the results are
72332 unspecified.

72333 2. The shell breaks the input into tokens: words and operators; see Section 2.3 (on page
72334 2299).

72335 3. The shell parses the input into simple commands (see Section 2.9.1, on page 2316) and
72336 compound commands (see Section 2.9.4, on page 2321).

72337 4. The shell performs various expansions (separately) on different parts of each command,
72338 resulting in a list of pathnames and fields to be treated as a command and arguments; see
72339 Section 2.6 (on page 2305).

72340 5. The shell performs redirection (see Section 2.7, on page 2312) and removes redirection
72341 operators and their operands from the parameter list.

72342 6. The shell executes a function (see Section 2.9.5, on page 2324), built-in (see Section 2.14,
72343 on page 2334), executable file, or script, giving the names of the arguments as positional
72344 parameters numbered 1 to *n*, and the name of the command (or in the case of a function
72345 within a script, the name of the script) as the positional parameter numbered 0 (see
72346 Section 2.9.1.1, on page 2317).

72347 7. The shell optionally waits for the command to complete and collects the exit status (see
72348 Section 2.8.2, on page 2315).

2.2 Quoting

Quoting is used to remove the special meaning of certain characters or words to the shell. Quoting can be used to preserve the literal meaning of the special characters in the next paragraph, prevent reserved words from being recognized as such, and prevent parameter expansion and command substitution within here-document processing (see Section 2.7.4, on page 2313).

The application shall quote the following characters if they are to represent themselves:

```
|  &  ;  <  >  (  )  $  '  \  "  '  <space>  <tab>  <newline>
```

and the following may need to be quoted under certain circumstances. That is, these characters may be special depending on conditions described elsewhere in this volume of POSIX.1-200x:

```
*  ?  [  #  ~  =  %
```

The various quoting mechanisms are the escape character, single-quotes, and double-quotes. The here-document represents another form of quoting; see Section 2.7.4 (on page 2313).

2.2.1 Escape Character (Backslash)

A <backslash> that is not quoted shall preserve the literal value of the following character, with the exception of a <newline>. If a <newline> follows the <backslash>, the shell shall interpret this as line continuation. The <backslash> and <newline> shall be removed before splitting the input into tokens. Since the escaped <newline> is removed entirely from the input and is not replaced by any white space, it cannot serve as a token separator.

2.2.2 Single-Quotes

Enclosing characters in single-quotes (`''`) shall preserve the literal value of each character within the single-quotes. A single-quote cannot occur within single-quotes.

2.2.3 Double-Quotes

Enclosing characters in double-quotes (`""`) shall preserve the literal value of all characters within the double-quotes, with the exception of the characters backquote, <dollar-sign>, and <backslash>, as follows:

$ The <dollar-sign> shall retain its special meaning introducing parameter expansion (see Section 2.6.2, on page 2306), a form of command substitution (see Section 2.6.3, on page 2309), and arithmetic expansion (see Section 2.6.4, on page 2310).

The input characters within the quoted string that are also enclosed between `"$("` and the matching `')'` shall not be affected by the double-quotes, but rather shall define that command whose output replaces the `"$(...)"` when the word is expanded. The tokenizing rules in Section 2.3 (on page 2299), not including the alias substitutions in Section 2.3.1 (on page 2300), shall be applied recursively to find the matching `')'`.

Within the string of characters from an enclosed `"${"` to the matching `'}'`, an even number of unescaped double-quotes or single-quotes, if any, shall occur. A preceding <backslash> character shall be used to escape a literal `'{'` or `'}'`. The rule in Section 2.6.2 (on page 2306) shall be used to determine the matching `'}'`.

72387 ‘ The backquote shall retain its special meaning introducing the other form of command
72388 substitution (see Section 2.6.3, on page 2309). The portion of the quoted string from the
72389 initial backquote and the characters up to the next backquote that is not preceded by a
72390 <backslash>, having escape characters removed, defines that command whose output
72391 replaces "‘...‘" when the word is expanded. Either of the following cases produces
72392 undefined results:

72393 • A single-quoted or double-quoted string that begins, but does not end, within the
72394 "‘...‘" sequence

72395 • A "‘...‘" sequence that begins, but does not end, within the same double-quoted
72396 string

72397 \ The <backslash> shall retain its special meaning as an escape character (see Section 2.2.1, on
72398 page 2298) only when followed by one of the following characters when considered special:

72399 `$ ‘ " \ <newline>`

72400 The application shall ensure that a double-quote is preceded by a <backslash> to be included
72401 within double-quotes. The parameter '@' has special meaning inside double-quotes and is
72402 described in Section 2.5.2 (on page 2302).

72403 2.3 Token Recognition

72404 The shell shall read its input in terms of lines from a file, from a terminal in the case of an
72405 interactive shell, or from a string in the case of *sh* **−c** or *system*(). The input lines can be of
72406 unlimited length. These lines shall be parsed using two major modes: ordinary token recognition
72407 and processing of here-documents.

72408 When an **io_here** token has been recognized by the grammar (see Section 2.10, on page 2325),
72409 one or more of the subsequent lines immediately following the next **NEWLINE** token form the
72410 body of one or more here-documents and shall be parsed according to the rules of Section 2.7.4
72411 (on page 2313).

72412 When it is not processing an **io_here**, the shell shall break its input into tokens by applying the
72413 first applicable rule below to the next character in its input. The token shall be from the current
72414 position in the input until a token is delimited according to one of the rules below; the characters
72415 forming the token are exactly those in the input, including any quoting characters. If it is
72416 indicated that a token is delimited, and no characters have been included in a token, processing
72417 shall continue until an actual token is delimited.

72418 1. If the end of input is recognized, the current token shall be delimited. If there is no
72419 current token, the end-of-input indicator shall be returned as the token.

72420 2. If the previous character was used as part of an operator and the current character is not
72421 quoted and can be used with the current characters to form an operator, it shall be used as
72422 part of that (operator) token.

72423 3. If the previous character was used as part of an operator and the current character cannot
72424 be used with the current characters to form an operator, the operator containing the
72425 previous character shall be delimited.

72426 4. If the current character is <backslash>, single-quote, or double-quote and it is not quoted, |
72427 it shall affect quoting for subsequent characters up to the end of the quoted text. The rules |
72428 for quoting are as described in Section 2.2 (on page 2298). During token recognition no
72429 substitutions shall be actually performed, and the result token shall contain exactly the
72430 characters that appear in the input (except for <newline> joining), unmodified, including

any embedded or enclosing quotes or substitution operators, between the <quotation-mark> and the end of the quoted text. The token shall not be delimited by the end of the quoted field.

5. If the current character is an unquoted '$' or '`', the shell shall identify the start of any candidates for parameter expansion (Section 2.6.2, on page 2306), command substitution (Section 2.6.3, on page 2309), or arithmetic expansion (Section 2.6.4, on page 2310) from their introductory unquoted character sequences: '$' or "${", "$(" or '`', and "$((", respectively. The shell shall read sufficient input to determine the end of the unit to be expanded (as explained in the cited sections). While processing the characters, if instances of expansions or quoting are found nested within the substitution, the shell shall recursively process them in the manner specified for the construct that is found. The characters found from the beginning of the substitution to its end, allowing for any recursion necessary to recognize embedded constructs, shall be included unmodified in the result token, including any embedded or enclosing substitution operators or quotes. The token shall not be delimited by the end of the substitution.

6. If the current character is not quoted and can be used as the first character of a new operator, the current token (if any) shall be delimited. The current character shall be used as the beginning of the next (operator) token.

7. If the current character is an unquoted <newline>, the current token shall be delimited.

8. If the current character is an unquoted <blank>, any token containing the previous character is delimited and the current character shall be discarded.

9. If the previous character was part of a word, the current character shall be appended to that word.

10. If the current character is a '#', it and all subsequent characters up to, but excluding, the next <newline> shall be discarded as a comment. The <newline> that ends the line is not considered part of the comment.

11. The current character is used as the start of a new word.

Once a token is delimited, it is categorized as required by the grammar in Section 2.10 (on page 2325).

2.3.1 Alias Substitution

After a token has been delimited, but before applying the grammatical rules in Section 2.10 (on page 2325), a resulting word that is identified to be the command name word of a simple command shall be examined to determine whether it is an unquoted, valid alias name. However, reserved words in correct grammatical context shall not be candidates for alias substitution. A valid alias name (see XBD Section 3.10, on page 34) shall be one that has been defined by the *alias* utility and not subsequently undefined using *unalias*. Implementations also may provide predefined valid aliases that are in effect when the shell is invoked. To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word shall be replaced by the value of the alias; otherwise, it shall not be replaced.

If the value of the alias replacing the word ends in a <blank>, the shell shall check the next command word for alias substitution; this process shall continue until a word is found that is not a valid alias or an alias value does not end in a <blank>.

When used as specified by this volume of POSIX.1-200x, alias definitions shall not be inherited by separate invocations of the shell or by the utility execution environments invoked by the shell; see Section 2.12 (on page 2331).

2.4 Reserved Words

Reserved words are words that have special meaning to the shell; see Section 2.9 (on page 2316). The following words shall be recognized as reserved words:

!	**do**	**esac**	**in**
{	**done**	**fi**	**then**
}	**elif**	**for**	**until**
case	**else**	**if**	**while**

This recognition shall only occur when none of the characters is quoted and when the word is used as:

- The first word of a command
- The first word following one of the reserved words other than **case**, **for**, or **in**
- The third word in a **case** command (only **in** is valid in this case)
- The third word in a **for** command (only **in** and **do** are valid in this case)

See the grammar in Section 2.10 (on page 2325).

The following words may be recognized as reserved words on some implementations (when none of the characters are quoted), causing unspecified results:

[[	**]]**	**function**	**select**

Words that are the concatenation of a name and a <colon> (`':'`) are reserved; their use produces unspecified results.

2.5 Parameters and Variables

A parameter can be denoted by a name, a number, or one of the special characters listed in Section 2.5.2 (on page 2302). A variable is a parameter denoted by a name.

A parameter is set if it has an assigned value (null is a valid value). Once a variable is set, it can only be unset by using the *unset* special built-in command.

2.5.1 Positional Parameters

A positional parameter is a parameter denoted by the decimal value represented by one or more digits, other than the single digit 0. The digits denoting the positional parameters shall always be interpreted as a decimal value, even if there is a leading zero. When a positional parameter with more than one digit is specified, the application shall enclose the digits in braces (see Section 2.6.2, on page 2306). Positional parameters are initially assigned when the shell is invoked (see *sh*), temporarily replaced when a shell function is invoked (see Section 2.9.5, on page 2324), and can be reassigned with the *set* special built-in command.

2.5.2 Special Parameters

Listed below are the special parameters and the values to which they shall expand. Only the values of the special parameters are listed; see Section 2.6 (on page 2305) for a detailed summary of all the stages involved in expanding words.

@ Expands to the positional parameters, starting from one. When the expansion occurs within double-quotes, and where field splitting (see Section 2.6.5, on page 2311) is performed, each positional parameter shall expand as a separate field, with the provision that the expansion of the first parameter shall still be joined with the beginning part of the original word (assuming that the expanded parameter was embedded within a word), and the expansion of the last parameter shall still be joined with the last part of the original word. If there are no positional parameters, the expansion of `'@'` shall generate zero fields, even when `'@'` is double-quoted.

* Expands to the positional parameters, starting from one. When the expansion occurs within a double-quoted string (see Section 2.2.3, on page 2298), it shall expand to a single field with the value of each parameter separated by the first character of the *IFS* variable, or by a <space> if *IFS* is unset. If *IFS* is set to a null string, this is not equivalent to unsetting it; its first character does not exist, so the parameter values are concatenated.

Expands to the decimal number of positional parameters. The command name (parameter 0) shall not be counted in the number given by `'#'` because it is a special parameter, not a positional parameter.

? Expands to the decimal exit status of the most recent pipeline (see Section 2.9.2, on page 2318).

– (Hyphen.) Expands to the current option flags (the single-letter option names concatenated into a string) as specified on invocation, by the *set* special built-in command, or implicitly by the shell.

$ Expands to the decimal process ID of the invoked shell. In a subshell (see Section 2.12, on page 2331), `'$'` shall expand to the same value as that of the current shell.

! Expands to the decimal process ID of the most recent background command (see Section 2.9.3, on page 2319) executed from the current shell. (For example, background commands executed from subshells do not affect the value of `"$!"` in the current shell environment.) For a pipeline, the process ID is that of the last command in the pipeline.

0 (Zero.) Expands to the name of the shell or shell script. See *sh* (on page 3163) for a detailed description of how this name is derived.

See the description of the *IFS* variable in Section 2.5.3.

2.5.3 Shell Variables

Variables shall be initialized from the environment (as defined by XBD Chapter 8 (on page 173) and the *exec* function in the System Interfaces volume of POSIX.1-200x) and can be given new values with variable assignment commands. If a variable is initialized from the environment, it shall be marked for export immediately; see the *export* special built-in. New variables can be defined and initialized with variable assignments, with the *read* or *getopts* utilities, with the *name* parameter in a **for** loop, with the ${*name*=*word*} expansion, or with other mechanisms provided as implementation extensions.

The following variables shall affect the execution of the shell:

UP XSI *ENV* The processing of the *ENV* shell variable shall be supported on all XSI-conformant systems or if the system supports the User Portability Utilities option.

This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2, on page 2306) by the shell and the resulting value shall be used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of *ENV* is not an absolute pathname, the results are unspecified. *ENV* shall be ignored if the user's real and effective user IDs or real and effective group IDs are different.

HOME The pathname of the user's home directory. The contents of *HOME* are used in tilde expansion (see Section 2.6.1, on page 2305).

IFS A string treated as a list of characters that is used for field splitting and to split lines into fields with the *read* command.

If *IFS* is not set, it shall behave as normal for an unset variable, except that field splitting by the shell and line splitting by the *read* command shall be performed as if the value of *IFS* is <space><tab><newline>; see Section 2.6.5 (on page 2311).

Implementations may ignore the value of *IFS* in the environment, or the absence of *IFS* from the environment, at the time the shell is invoked, in which case the shell shall set *IFS* to <space><tab><newline> when it is invoked.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL The value of this variable overrides the *LC_** variables and *LANG*, as described in XBD Chapter 8 (on page 173).

LC_COLLATE Determine the behavior of range expressions, equivalence classes, and multi-character collating elements within pattern matching.

LC_CTYPE Determine the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters), which characters are defined as letters (character class **alpha**) and <blank> characters (character class **blank**), and the behavior of character classes within pattern matching. Changing the value of *LC_CTYPE* after the shell has started shall not affect the lexical processing of shell commands in the current shell execution environment or its subshells. Invoking a shell script or performing *exec sh* subjects the new shell to the changes in *LC_CTYPE*.

LC_MESSAGES Determine the language in which messages should be written.

LINENO Set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets *LINENO*, the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of *LINENO* is unspecified. This volume of POSIX.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH A string formatted as described in XBD Chapter 8 (on page 173), used to effect command interpretation; see Section 2.9.1.1 (on page 2317).

PPID Set by the shell to the decimal value of its parent process ID during initialization of the shell. In a subshell (see Section 2.12, on page 2331), *PPID* shall be set to the same value as that of the parent of the current shell. For example, *echo* $*PPID* and (*echo* $*PPID*) would produce the same value. This volume of POSIX.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PS1 Each time an interactive shell is ready to read a command, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value shall be `"$ "`. For users who have specific additional implementation-defined privileges, the default may be another, implementation-defined value. The shell shall replace each instance of the character `'!'` in *PS1* with the history file number of the next command to be typed. Escaping the `'!'` with another `'!'` (that is, `"!!"`) shall place the literal character `'!'` in the prompt. This volume of POSIX.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PS2 Each time the user enters a <newline> prior to completing a command line in an interactive shell, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is `"> "`. This volume of POSIX.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PS4 When an execution trace (*set* **–x**) is being performed in an interactive shell, before each line in the execution trace, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is `"+ "`. This volume of POSIX.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option.

PWD Set by the shell and by the *cd* utility. In the shell the value shall be initialized from the environment as follows. If a value for *PWD* is passed to the shell in the environment when it is executed, the value is an absolute pathname of the current working directory that is no longer than {PATH_MAX} bytes including the terminating null byte, and the value does not contain any components that are dot or dot-dot, then the shell shall set *PWD* to the value from the environment. Otherwise, if a value for *PWD* is passed to the shell in the environment when it is executed, the value is an absolute pathname of the current working directory, and the value does not contain any components that are dot or dot-dot, then it is unspecified whether the shell sets *PWD* to the value from the environment or sets *PWD* to the pathname that would be output by *pwd* **–P**. Otherwise, the *sh* utility sets *PWD* to the pathname that would be output by *pwd* **–P**. In cases where *PWD* is set to the value from the environment, the value can contain components that refer to files of type symbolic link. In cases where *PWD* is set to the pathname that would be output by *pwd* **–P**, if there is insufficient permission on the current working directory, or on any parent of that directory, to determine what that pathname would be, the value of *PWD* is unspecified. Assignments to this variable may be ignored. If an application sets or unsets the value of *PWD*, the behaviors of the *cd* and *pwd* utilities are unspecified.

2.6 Word Expansions

This section describes the various expansions that are performed on words. Not all expansions are performed on every word, as explained in the following sections.

Tilde expansions, parameter expansions, command substitutions, arithmetic expansions, and quote removals that occur within a single word expand to a single field. It is only field splitting or pathname expansion that can create multiple fields from a single word. The single exception to this rule is the expansion of the special parameter '@' within double-quotes, as described in Section 2.5.2 (on page 2302).

The order of word expansion shall be as follows:

1. Tilde expansion (see Section 2.6.1), parameter expansion (see Section 2.6.2, on page 2306), command substitution (see Section 2.6.3, on page 2309), and arithmetic expansion (see Section 2.6.4, on page 2310) shall be performed, beginning to end. See item 5 in Section 2.3 (on page 2299).
2. Field splitting (see Section 2.6.5, on page 2311) shall be performed on the portions of the fields generated by step 1, unless *IFS* is null.
3. Pathname expansion (see Section 2.6.6, on page 2311) shall be performed, unless *set* **−f** is in effect.
4. Quote removal (see Section 2.6.7, on page 2311) shall always be performed last.

The expansions described in this section shall occur in the same shell environment as that in which the command is executed.

If the complete expansion appropriate for a word results in an empty field, that empty field shall be deleted from the list of fields that form the completely expanded command, unless the original word contained single-quote or double-quote characters.

The '$' character is used to introduce parameter expansion, command substitution, or arithmetic evaluation. If an unquoted '$' is followed by a character that is either not numeric, the name of one of the special parameters (see Section 2.5.2, on page 2302), a valid first character of a variable name, a <left-curly-bracket> ('{') or a <left-parenthesis>, the result is unspecified.

2.6.1 Tilde Expansion

A "tilde-prefix" consists of an unquoted <tilde> character at the beginning of a word, followed by all of the characters preceding the first unquoted <slash> in the word, or all the characters in the word if there is no <slash>. In an assignment (see XBD Section 4.22, on page 118), multiple tilde-prefixes can be used: at the beginning of the word (that is, following the <equals-sign> of the assignment), following any unquoted <colon>, or both. A tilde-prefix in an assignment is terminated by the first unquoted <colon> or <slash>. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the <tilde> are treated as a possible login name from the user database. A portable login name cannot contain characters outside the set given in the description of the *LOGNAME* environment variable in XBD Section 8.3 (on page 177). If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix is replaced by the value of the variable *HOME*. If *HOME* is unset, the results are unspecified. Otherwise, the tilde-prefix shall be replaced by a pathname of the initial working directory associated with the login name obtained using the *getpwnam*() function as defined in the System Interfaces volume of POSIX.1-200x. If the system does not recognize the login name, the results are undefined.

The pathname resulting from tilde expansion shall be treated as if quoted to prevent it being

altered by field splitting and pathname expansion.

2.6.2 Parameter Expansion

The format for parameter expansion is as follows:

`${`*`expression`*`}`

where *expression* consists of all characters until the matching `'}'`. Any `'}'` escaped by a <backslash> or within a quoted string, and characters in embedded arithmetic expansions, command substitutions, and variable expansions, shall not be examined in determining the matching `'}'`.

The simplest form for parameter expansion is:

`${`*`parameter`*`}`

The value, if any, of *parameter* shall be substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when *parameter* is followed by a character that could be interpreted as part of the name. The matching closing brace shall be determined by counting brace levels, skipping over enclosed quoted strings, and command substitutions.

If the parameter name or symbol is not enclosed in braces, the expansion shall use the longest valid name (see XBD Section 3.230, on page 70), whether or not the symbol represented by that name exists.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion shall not be performed on the results of the expansion.
- Field splitting shall not be performed on the results of the expansion, with the exception of `'@'`; see Section 2.5.2 (on page 2302).

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*, as described below), *word* shall be subjected to tilde expansion, parameter expansion, command substitution, and arithmetic expansion. If *word* is not needed, it shall not be expanded. The `'}'` character that delimits the following parameter expansion modifications shall be determined as described previously in this section and in Section 2.2.3 (on page 2298). (For example, ${**foo-bar**}**xyz**} would result in the expansion of **foo** followed by the string **xyz**} if **foo** is set, else the string `"barxyz}"`).

${*parameter*:–*word*}
: **Use Default Values**. If *parameter* is unset or null, the expansion of *word* shall be substituted; otherwise, the value of *parameter* shall be substituted.

${*parameter*:=*word*}
: **Assign Default Values**. If *parameter* is unset or null, the expansion of *word* shall be assigned to *parameter*. In all cases, the final value of *parameter* shall be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.

${*parameter*:?[*word*]}
: **Indicate Error if Null or Unset**. If *parameter* is unset or null, the expansion of *word* (or a message indicating it is unset if *word* is omitted) shall be written to standard error and the shell exits with a non-zero exit status. Otherwise, the value of *parameter* shall be substituted. An interactive shell need not exit.

72731 ${*parameter*:+*word*} **Use Alternative Value**. If *parameter* is unset or null, null shall be
72732 substituted; otherwise, the expansion of *word* shall be substituted.

72733 In the parameter expansions shown previously, use of the <colon> in the format shall result in a
72734 test for a parameter that is unset or null; omission of the <colon> shall result in a test for a
72735 parameter that is only unset. The following table summarizes the effect of the <colon>:

72736 72737

	parameter **Set and Not Null**	*parameter* **Set But Null**	*parameter* **Unset**
72738 **${***parameter***:–***word***}**	substitute *parameter*	substitute *word*	substitute *word*
72739 **${***parameter***–***word***}**	substitute *parameter*	substitute null	substitute *word*
72740 **${***parameter***:=***word***}**	substitute *parameter*	assign *word*	assign *word*
72741 **${***parameter***=***word***}**	substitute *parameter*	substitute null	assign *word*
72742 **${***parameter***:?***word***}**	substitute *parameter*	error, exit	error, exit
72743 **${***parameter***?***word***}**	substitute *parameter*	substitute null	error, exit
72744 **${***parameter***:+***word***}**	substitute *word*	substitute null	substitute null
72745 **${***parameter***+***word***}**	substitute *word*	substitute *word*	substitute null

72746 In all cases shown with "substitute", the expression is replaced with the value shown. In all
72747 cases shown with "assign", *parameter* is assigned that value, which also replaces the expression.

72748 ${#*parameter*} **String Length**. The length in characters of the value of *parameter* shall be
72749 substituted. If *parameter* is `'*'` or `'@'`, the result of the expansion is
72750 unspecified.

72751 The following four varieties of parameter expansion provide for substring processing. In each
72752 case, pattern matching notation (see Section 2.13, on page 2332), rather than regular expression
72753 notation, shall be used to evaluate the patterns. If *parameter* is `'*'` or `'@'`, the result of the
72754 expansion is unspecified. Enclosing the full parameter expansion string in double-quotes shall
72755 not cause the following four varieties of pattern characters to be quoted, whereas quoting
72756 characters within the braces shall have this effect.

72757 ${*parameter*%*word*} **Remove Smallest Suffix Pattern**. The *word* shall be expanded to produce
72758 a pattern. The parameter expansion shall then result in *parameter*, with the
72759 smallest portion of the suffix matched by the *pattern* deleted.

72760 ${*parameter*%%*word*} **Remove Largest Suffix Pattern**. The *word* shall be expanded to produce a
72761 pattern. The parameter expansion shall then result in *parameter*, with the
72762 largest portion of the suffix matched by the *pattern* deleted.

72763 ${*parameter*#*word*} **Remove Smallest Prefix Pattern**. The *word* shall be expanded to produce
72764 a pattern. The parameter expansion shall then result in *parameter*, with the
72765 smallest portion of the prefix matched by the *pattern* deleted.

72766 ${*parameter*##*word*} **Remove Largest Prefix Pattern**. The *word* shall be expanded to produce a
72767 pattern. The parameter expansion shall then result in *parameter*, with the
72768 largest portion of the prefix matched by the *pattern* deleted.

Examples

${*parameter*:–*word*}

In this example, *ls* is executed only if *x* is null or unset. (The $(*ls*) command substitution notation is explained in Section 2.6.3 (on page 2309).)

```
${x:–$(ls)}
```

${*parameter*:=*word*}

```
unset X
echo ${X:=abc}
abc
```

${*parameter*:?*word*}

```
unset posix
echo ${posix:?}
sh: posix: parameter null or not set
```

${*parameter*:+*word*}

```
set a b c
echo ${3:+posix}
posix
```

${#*parameter*}

```
HOME=/usr/posix
echo ${#HOME}
10
```

${*parameter*%*word*}

```
x=file.c
echo ${x%.c}.o
file.o
```

${*parameter*%%*word*}

```
x=posix/src/std
echo ${x%%/*}
posix
```

${*parameter*#*word*}

```
x=$HOME/src/cmd
echo ${x#$HOME}
/src/cmd
```

${*parameter*##*word*}

```
x=/one/two/three
echo ${x##*/}
three
```

The double-quoting of patterns is different depending on where the double-quotes are placed:

`"${x#*}"` The <asterisk> is a pattern character.

`${x#"*"}` The literal <asterisk> is quoted and not special.

2.6.3 Command Substitution

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution shall occur when the command is enclosed as follows:

`$(`*command*`)`

or (backquoted version):

`‘`*command*`‘`

The shell shall expand the command substitution by executing *command* in a subshell environment (see Section 2.12, on page 2331) and replacing the command substitution (the text of *command* plus the enclosing `"$()"` or backquotes) with the standard output of the command, removing sequences of one or more <newline> characters at the end of the substitution. Embedded <newline> characters before the end of the output shall not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of *IFS* and quoting that is in effect. If the output contains any null bytes, the behavior is unspecified.

Within the backquoted style of command substitution, <backslash> shall retain its literal meaning, except when followed by: `‘$’`, `‘‘’`, or <backslash>. The search for the matching backquote shall be satisfied by the first unquoted non-escaped backquote; during this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the $(*command*) form, or a quoted string, undefined results occur. A single-quoted or double-quoted string that begins, but does not end, within the `"‘...’"` sequence produces undefined results.

With the $(*command*) form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except a script consisting solely of redirections which produces unspecified results.

The results of command substitution shall not be processed for further tilde expansion, parameter expansion, command substitution, or arithmetic expansion. If a command substitution occurs inside double-quotes, field splitting and pathname expansion shall not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application shall precede the inner backquotes with <backslash> characters; for example:

`\‘`*command*`\‘`

If the command substitution consists of a single subshell, such as:

`$( (`*command*`) )`

a conforming application shall separate the `"$("` and `’(’` into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.

2.6.4 Arithmetic Expansion

Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion shall be as follows:

```
$((expression))
```

The expression shall be treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell shall expand all tokens in the expression for parameter expansion, command substitution, and quote removal.

Next, the shell shall treat this as an arithmetic expression and substitute the value of the expression. The arithmetic expression shall be processed according to the rules given in Section 1.1.2.1 (on page 2283), with the following exceptions:

- Only signed long integer arithmetic is required.
- Only the decimal-constant, octal-constant, and hexadecimal-constant constants specified in the ISO C standard, Section 6.4.4.1 are required to be recognized as constants.
- The *sizeof*( ) operator and the prefix and postfix "++" and "--" operators are not required.
- Selection, iteration, and jump statements are not supported.

All changes to variables in an arithmetic expression shall be in effect after the arithmetic expansion, as in the parameter expansion "${x=value}".

If the shell variable *x* contains a value that forms a valid integer constant, then the arithmetic expansions "$((x))" and "$(($x))" shall return the same value.

As an extension, the shell may recognize arithmetic expressions beyond those listed. The shell may use a signed integer type with a rank larger than the rank of **signed long**. The shell may use a real-floating type instead of **signed long** as long as it does not affect the results in cases where there is no overflow. If the expression is invalid, the expansion fails and the shell shall write a message to standard error indicating the failure.

Examples

A simple example using arithmetic expansion:

```
# repeat a command 100 times
x=100
while [ $x -gt 0 ]
do
    command
    x=$(($x-1))
done
```

2.6.5 Field Splitting

After parameter expansion (Section 2.6.2, on page 2306), command substitution (Section 2.6.3, on page 2309), and arithmetic expansion (Section 2.6.4, on page 2310), the shell shall scan the results of expansions and substitutions that did not occur in double-quotes for field splitting and multiple fields can result.

The shell shall treat each character of the *IFS* as a delimiter and use the delimiters as field terminators to split the results of parameter expansion and command substitution into fields.

1. If the value of *IFS* is a <space>, <tab>, and <newline>, or if it is unset, any sequence of <space>, <tab>, or <newline> characters at the beginning or end of the input shall be ignored and any sequence of those characters within the input shall delimit a field. For example, the input:

   ```
   <newline><space><tab>foo<tab><tab>bar<space>
   ```

   yields two fields, **foo** and **bar**.

2. If the value of *IFS* is null, no field splitting shall be performed.

3. Otherwise, the following rules shall be applied in sequence. The term "*IFS* white space" is used to mean any sequence (zero or more instances) of white-space characters that are in the *IFS* value (for example, if *IFS* contains <space>/<comma>/<tab>, any sequence of <space> and <tab> characters is considered *IFS* white space).

   a. *IFS* white space shall be ignored at the beginning and end of the input.

   b. Each occurrence in the input of an *IFS* character that is not *IFS* white space, along with any adjacent *IFS* white space, shall delimit a field, as described previously.

   c. Non-zero-length *IFS* white space shall delimit a field.

2.6.6 Pathname Expansion

After field splitting, if *set* **–f** is not in effect, each field in the resulting command line shall be expanded using the algorithm described in Section 2.13 (on page 2332), qualified by the rules in Section 2.13.3 (on page 2333).

2.6.7 Quote Removal

The quote characters (<backslash>, single-quote, and double-quote) that were present in the original word shall be removed unless they have themselves been quoted.

2.7 Redirection

Redirection is used to open and close files for the current shell execution environment (see Section 2.12, on page 2331) or for any command. Redirection operators can be used with numbers representing file descriptors (see XBD Section 3.166, on page 60) as described below.

The overall format used for redirection is:

```
[n]redir-op word
```

The number *n* is an optional decimal number designating the file descriptor number; the application shall ensure it is delimited from any preceding text and immediately precede the redirection operator *redir-op*. If *n* is quoted, the number shall not be recognized as part of the redirection expression. For example:

```
echo \2>a
```

writes the character 2 into file **a**. If any part of *redir-op* is quoted, no redirection expression is recognized. For example:

```
echo 2\>a
```

writes the characters 2>*a* to standard output. The optional number, redirection operator, and *word* shall not appear in the arguments provided to the command to be executed (if any).

Open files are represented by decimal numbers starting with zero. The largest possible value is implementation-defined; however, all implementations shall support at least 0 to 9, inclusive, for use by the application. These numbers are called "file descriptors". The values 0, 1, and 2 have special meaning and conventional uses and are implied by certain redirection operations; they are referred to as *standard input*, *standard output*, and *standard error*, respectively. Programs usually take their input from standard input, and write output on standard output. Error messages are usually written on standard error. The redirection operators can be preceded by one or more digits (with no intervening <blank> characters allowed) to designate the file descriptor number.

If the redirection operator is "<<" or "<<–", the word that follows the redirection operator shall be subjected to quote removal; it is unspecified whether any of the other expansions occur. For the other redirection operators, the word that follows the redirection operator shall be subjected to tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal. Pathname expansion shall not be performed on the word by a non-interactive shell; an interactive shell may perform it, but shall do so only when the expansion would result in one word.

If more than one redirection operator is specified with a command, the order of evaluation is from beginning to end.

A failure to open or create a file shall cause a redirection to fail.

2.7.1 Redirecting Input

Input redirection shall cause the file whose name results from the expansion of *word* to be opened for reading on the designated file descriptor, or standard input if the file descriptor is not specified.

The general format for redirecting input is:

```
[n]<word
```

where the optional *n* represents the file descriptor number. If the number is omitted, the

72949 redirection shall refer to standard input (file descriptor 0).

72950 2.7.2 Redirecting Output

72951 The two general formats for redirecting output are:

72952 `[n]>word`
72953 `[n]>|word`

72954 where the optional *n* represents the file descriptor number. If the number is omitted, the
72955 redirection shall refer to standard output (file descriptor 1).

72956 Output redirection using the `'>'` format shall fail if the *noclobber* option is set (see the
72957 description of *set* –**C**) and the file named by the expansion of *word* exists and is a regular file.
72958 Otherwise, redirection using the `'>'` or `">|"` formats shall cause the file whose name results
72959 from the expansion of *word* to be created and opened for output on the designated file
72960 descriptor, or standard output if none is specified. If the file does not exist, it shall be created;
72961 otherwise, it shall be truncated to be an empty file after being opened.

72962 2.7.3 Appending Redirected Output

72963 Appended output redirection shall cause the file whose name results from the expansion of
72964 word to be opened for output on the designated file descriptor. The file is opened as if the *open*( )
72965 function as defined in the System Interfaces volume of POSIX.1-200x was called with the
72966 O_APPEND flag. If the file does not exist, it shall be created.

72967 The general format for appending redirected output is as follows:

72968 `[n]>>word`

72969 where the optional *n* represents the file descriptor number. If the number is omitted, the
72970 redirection refers to standard output (file descriptor 1).

72971 2.7.4 Here-Document

72972 The redirection operators `"<<"` and `"<<–"` both allow redirection of lines contained in a shell
72973 input file, known as a "here-document", to the input of a command.

72974 The here-document shall be treated as a single word that begins after the next <newline> and
72975 continues until there is a line containing only the delimiter and a <newline>, with no <blank>
72976 characters in between. Then the next here-document starts, if there is one. The format is as
72977 follows:

72978 `[n]<<word`
72979 `    here-document`
72980 `delimiter`

72981 where the optional *n* represents the file descriptor number. If the number is omitted, the here-
72982 document refers to standard input (file descriptor 0).

72983 If any character in *word* is quoted, the delimiter shall be formed by performing quote removal on
72984 *word*, and the here-document lines shall not be expanded. Otherwise, the delimiter shall be the
72985 *word* itself.

72986 If no characters in *word* are quoted, all lines of the here-document shall be expanded for
72987 parameter expansion, command substitution, and arithmetic expansion. In this case, the

72988 <backslash> in the input behaves as the <backslash> inside double-quotes (see Section 2.2.3, on
72989 page 2298). However, the double-quote character (`'"'`) shall not be treated specially within a
72990 here-document, except when the double-quote appears within `"$()"`, `"``"`, or `"${}"`.

72991 If the redirection symbol is `"<<-"`, all leading <tab> characters shall be stripped from input lines
72992 and the line containing the trailing delimiter. If more than one `"<<"` or `"<<-"` operator is
72993 specified on a line, the here-document associated with the first operator shall be supplied first
72994 by the application and shall be read first by the shell.

72995 When a here-document is read from a terminal device and the shell is interactive, it shall write
72996 the contents of the variable *PS2*, processed as described in Section 2.5.3 (on page 2302), to
72997 standard error before reading each line of input until the delimiter has been recognized.

72998 **Examples**

72999 An example of a here-document follows:

```
73000 cat <<eof1; cat <<eof2
73001 Hi,
73002 eof1
73003 Helene.
73004 eof2
```

73005 2.7.5 Duplicating an Input File Descriptor

73006 The redirection operator:

73007 **[***n***]<&***word*

73008 shall duplicate one input file descriptor from another, or shall close one. If *word* evaluates to one
73009 or more digits, the file descriptor denoted by *n*, or standard input if *n* is not specified, shall be
73010 made to be a copy of the file descriptor denoted by *word*; if the digits in *word* do not represent a
73011 file descriptor already open for input, a redirection error shall result; see Section 2.8.1 (on page
73012 2315). If *word* evaluates to `'-'`, file descriptor *n*, or standard input if *n* is not specified, shall be
73013 closed. Attempts to close a file descriptor that is not open shall not constitute an error. If *word*
73014 evaluates to something else, the behavior is unspecified.

73015 2.7.6 Duplicating an Output File Descriptor

73016 The redirection operator:

73017 **[***n***]>&***word*

73018 shall duplicate one output file descriptor from another, or shall close one. If *word* evaluates to
73019 one or more digits, the file descriptor denoted by *n*, or standard output if *n* is not specified, shall
73020 be made to be a copy of the file descriptor denoted by *word*; if the digits in *word* do not represent
73021 a file descriptor already open for output, a redirection error shall result; see Section 2.8.1 (on
73022 page 2315). If *word* evaluates to `'-'`, file descriptor *n*, or standard output if *n* is not specified, is
73023 closed. Attempts to close a file descriptor that is not open shall not constitute an error. If *word*
73024 evaluates to something else, the behavior is unspecified.

2.7.7 Open File Descriptors for Reading and Writing

The redirection operator:

`[n]<>word`

shall cause the file whose name is the expansion of *word* to be opened for both reading and writing on the file descriptor denoted by *n*, or standard input if *n* is not specified. If the file does not exist, it shall be created.

2.8 Exit Status and Errors

-

2.8.1 Consequences of Shell Errors

For a non-interactive shell, an error condition encountered by a special built-in (see Section 2.14, on page 2334) or other type of utility shall cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

Error	Special Built-In	Other Utilities
Shell language syntax error	Shall exit	Shall exit
Utility syntax error (option or operand error)	Shall exit	Shall not exit
Redirection error	Shall exit	Shall not exit
Variable assignment error	Shall exit	Shall not exit
Expansion error	Shall exit	Shall exit
Command not found	N/A	May exit
Dot script not found	Shall exit	N/A

An expansion error is one that occurs when the shell expansions defined in Section 2.6 (on page 2305) are carried out (for example, `"${x!y}"`, because `'!'` is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as "shall exit" or "(may) exit" occur in a subshell, the subshell shall (respectively may) exit with a non-zero status, but the script containing the subshell shall not exit because of the error.

In all of the cases shown in the table, an interactive shell shall write a diagnostic message to standard error without exiting.

2.8.2 Exit Status for Commands

Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status shall be 127. If the command name is found, but it is not an executable utility, the exit status shall be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status shall be greater than zero.

Internally, for purposes of deciding whether a command exits with a non-zero exit status, the shell shall recognize the entire status value retrieved for the command by the equivalent of the *wait*() function WEXITSTATUS macro (as defined in the System Interfaces volume of POSIX.1-200x). When reporting the exit status with the special parameter '?', the shell shall report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal shall be reported as greater than 128.

2.9 Shell Commands

This section describes the basic structure of shell commands. The following command descriptions each describe a format of the command that is only used to aid the reader in recognizing the command type, and does not formally represent the syntax. Each description discusses the semantics of the command; for a formal definition of the command language, consult Section 2.10 (on page 2325).

A *command* is one of the following:

- Simple command (see Section 2.9.1)
- Pipeline (see Section 2.9.2, on page 2318)
- List compound-list (see Section 2.9.3, on page 2319)
- Compound command (see Section 2.9.4, on page 2321)
- Function definition (see Section 2.9.5, on page 2324)

Unless otherwise stated, the exit status of a command shall be that of the last simple command executed by the command. There shall be no limit on the size of any shell command other than that imposed by the underlying system (memory constraints, {ARG_MAX}, and so on).

2.9.1 Simple Commands

A "simple command" is a sequence of optional variable assignments and redirections, in any sequence, optionally followed by words and redirections, terminated by a control operator.

When a given simple command is required to be executed (that is, when any conditional construct such as an AND-OR list or a **case** statement has not bypassed the simple command), the following expansions, assignments, and redirections shall all be performed from the beginning of the command text to the end:

1. The words that are recognized as variable assignments or redirections according to Section 2.10.2 (on page 2325) are saved for processing in steps 3 and 4.
2. The words that are not variable assignments or redirections shall be expanded. If any fields remain following their expansion, the first field shall be considered the command name and remaining fields are the arguments for the command.
3. Redirections shall be performed as described in Section 2.7 (on page 2312).
4. Each variable assignment shall be expanded for tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal prior to assigning the value.

In the preceding list, the order of steps 3 and 4 may be reversed if no command name results from step 2 or if the command name matches the name of a special built-in utility; see Section 2.14 (on page 2334).

If no command name results, variable assignments shall affect the current execution environment. Otherwise, the variable assignments shall be exported for the execution environment of the command and shall not affect the current execution environment (except for special built-ins). If any of the variable assignments attempt to assign a value to a read-only variable, a variable assignment error shall occur. See Section 2.8.1 (on page 2315) for the consequences of these errors.

If there is no command name, any redirections shall be performed in a subshell environment; it is unspecified whether this subshell environment is the same one as that used for a command substitution within the command. (To affect the current execution environment, see the *exec* special built-in.) If any of the redirections performed in the current shell execution environment fail, the command shall immediately fail with an exit status greater than zero, and the shell shall write an error message indicating the failure. See Section 2.8.1 (on page 2315) for the consequences of these failures on interactive and non-interactive shells.

If there is a command name, execution shall continue as described in Section 2.9.1.1. If there is no command name, but the command contained a command substitution, the command shall complete with the exit status of the last command substitution performed. Otherwise, the command shall complete with a zero exit status.

2.9.1.1 *Command Search and Execution*

If a simple command results in a command name and an optional list of arguments, the following actions shall be performed:

1. If the command name does not contain any <slash> characters, the first successful step in the following sequence shall occur:
   a. If the command name matches the name of a special built-in utility, that special built-in utility shall be invoked.
   b. If the command name matches the name of a function known to this shell, the function shall be invoked as described in Section 2.9.5 (on page 2324). If the implementation has provided a standard utility in the form of a function, it shall not be recognized at this point. It shall be invoked in conjunction with the path search in step 1d.
   c. If the command name matches the name of a utility listed in the following table, that utility shall be invoked.

alias	*false*	*jobs*	*read*	*wait*
bg	*fc*	*kill*	*true*	
cd	*fg*	*newgrp*	*umask*	
command	*getopts*	*pwd*	*unalias*	

   d. Otherwise, the command shall be searched for using the *PATH* environment variable as described in XBD Chapter 8 (on page 173):
      i. If the search is successful:
         a. If the system has implemented the utility as a regular built-in or as a shell function, it shall be invoked at this point in the path search.
         b. Otherwise, the shell executes the utility in a separate utility environment (see Section 2.12, on page 2331) with actions equivalent to calling the *execve*( ) function as defined in the System Interfaces volume of POSIX.1-200x with the *path* argument set to the pathname resulting from the search, *arg*0 set to the command name, and the

73148 remaining arguments set to the operands, if any.

73149 If the *execve*() function fails due to an error equivalent to the
73150 [ENOEXEC] error defined in the System Interfaces volume of
73151 POSIX.1-200x, the shell shall execute a command equivalent to
73152 having a shell invoked with the pathname resulting from the search
73153 as its first operand, with any remaining arguments passed to the new
73154 shell, except that the value of `"$0"` in the new shell may be set to the
73155 command name. If the executable file is not a text file, the shell may
73156 bypass this command execution. In this case, it shall write an error
73157 message, and shall return an exit status of 126.

73158 Once a utility has been searched for and found (either as a result of this
73159 specific search or as part of an unspecified shell start-up activity), an
73160 implementation may remember its location and need not search for the
73161 utility again unless the *PATH* variable has been the subject of an assignment.
73162 If the remembered location fails for a subsequent invocation, the shell shall
73163 repeat the search to find the new location for the utility, if any.

73164 ii. If the search is unsuccessful, the command shall fail with an exit status of
73165 127 and the shell shall write an error message.

73166 2. If the command name contains at least one <slash>, the shell shall execute the utility in a
73167 separate utility environment with actions equivalent to calling the *execve*() function
73168 defined in the System Interfaces volume of POSIX.1-200x with the *path* and *arg*0
73169 arguments set to the command name, and the remaining arguments set to the operands, if
73170 any.

73171 If the *execve*() function fails due to an error equivalent to the [ENOEXEC] error, the shell
73172 shall execute a command equivalent to having a shell invoked with the command name
73173 as its first operand, with any remaining arguments passed to the new shell. If the
73174 executable file is not a text file, the shell may bypass this command execution. In this case,
73175 it shall write an error message and shall return an exit status of 126.

73176 ### 2.9.2 Pipelines

73177 A *pipeline* is a sequence of one or more commands separated by the control operator `'|'`. The
73178 standard output of all but the last command shall be connected to the standard input of the next
73179 command.

73180 The format for a pipeline is:

73181 **[!]** *command1* **[** | *command2* **...]**

73182 The standard output of *command1* shall be connected to the standard input of *command2*. The
73183 standard input, standard output, or both of a command shall be considered to be assigned by
73184 the pipeline before any redirection specified by redirection operators that are part of the
73185 command (see Section 2.7, on page 2312).

73186 If the pipeline is not in the background (see Section 2.9.3.1, on page 2319), the shell shall wait for
73187 the last command specified in the pipeline to complete, and may also wait for all commands to
73188 complete.

73189 **Exit Status**

73190 If the reserved word **!** does not precede the pipeline, the exit status shall be the exit status of the
73191 last command specified in the pipeline. Otherwise, the exit status shall be the logical NOT of the
73192 exit status of the last command. That is, if the last command returns zero, the exit status shall be
73193 1; if the last command returns greater than zero, the exit status shall be zero.

73194 ## 2.9.3 Lists

73195 An *AND-OR list* is a sequence of one or more pipelines separated by the operators "&&" and
73196 "||".

73197 A *list* is a sequence of one or more AND-OR lists separated by the operators ';' and '&' and
73198 optionally terminated by ';', '&', or <newline>.

73199 The operators "&&" and "||" shall have equal precedence and shall be evaluated with left
73200 associativity. For example, both of the following commands write solely **bar** to standard output:

73201 ```
false && echo foo || echo bar
73202 true || echo foo && echo bar
```

73203 A ';' or <newline> terminator shall cause the preceding AND-OR list to be executed
73204 sequentially; an '&' shall cause asynchronous execution of the preceding AND-OR list.

73205 The term "compound-list" is derived from the grammar in Section 2.10 (on page 2325); it is
73206 equivalent to a sequence of *lists*, separated by <newline> characters, that can be preceded or
73207 followed by an arbitrary number of <newline> characters.

73208 **Examples**

73209 The following is an example that illustrates <newline> characters in compound-lists:

```
73210 while
73211     # a couple of <newline>s
73212     # a list
73213     date && who || ls; cat file
73214     # a couple of <newline>s
73215     # another list
73216     wc file > output & true
73217 do
73218     # 2 lists
73219     ls
73220     cat file
73221 done
```

73222 ### 2.9.3.1 *Asynchronous Lists*

73223 If a command is terminated by the control operator <ampersand> ('&'), the shell shall execute
73224 the command asynchronously in a subshell. This means that the shell shall not wait for the
73225 command to finish before executing the next command.

73226 The format for running a command in the background is:

73227 *command1* & [*command2* & ...]
```

The standard input for an asynchronous list, before any explicit redirections are performed, shall be considered to be assigned to a file that has the same properties as **/dev/null**. If it is an interactive shell, this need not happen. In all cases, explicit redirection of standard input shall override this activity.

When an element of an asynchronous list (the portion of the list ended by an <ampersand>, such as *command1*, above) is started by the shell, the process ID of the last command in the asynchronous list element shall become known in the current shell execution environment; see Section 2.12 (on page 2331). This process ID shall remain known until:

1. The command terminates and the application waits for the process ID.
2. Another asynchronous list is invoked before `"$!"` (corresponding to the previous asynchronous list) is expanded in the current execution environment.

The implementation need not retain more than the {CHILD_MAX} most recent entries in its list of known process IDs in the current shell execution environment.

Exit Status

The exit status of an asynchronous list shall be zero.

2.9.3.2 *Sequential Lists*

Commands that are separated by a <semicolon> (`';'`) shall be executed sequentially.

The format for executing commands sequentially shall be:

command1 **[;** ***command2*****]** **...**

Each command shall be expanded and executed in the order specified.

Exit Status

The exit status of a sequential list shall be the exit status of the last command in the list.

2.9.3.3 *AND Lists*

The control operator `"&&"` denotes an AND list. The format shall be:

command1 **[** **&&** ***command2*****]** **...**

First *command1* shall be executed. If its exit status is zero, *command2* shall be executed, and so on, until a command has a non-zero exit status or there are no more commands left to execute. The commands are expanded only if they are executed.

Exit Status

The exit status of an AND list shall be the exit status of the last command that is executed in the list.

2.9.3.4 *OR Lists*

The control operator `"||"` denotes an OR List. The format shall be:

command1 **[** **||** ***command2*****]** **...**

First, *command1* shall be executed. If its exit status is non-zero, *command2* shall be executed, and so on, until a command has a zero exit status or there are no more commands left to execute.

73264 **Exit Status**

73265 The exit status of an OR list shall be the exit status of the last command that is executed in the
73266 list.

73267 2.9.4 Compound Commands

73268 The shell has several programming constructs that are "compound commands", which provide
73269 control flow for commands. Each of these compound commands has a reserved word or control
73270 operator at the beginning, and a corresponding terminator reserved word or operator at the end.
73271 In addition, each can be followed by redirections on the same line as the terminator. Each
73272 redirection shall apply to all the commands within the compound command that do not
73273 explicitly override that redirection.

73274 2.9.4.1 *Grouping Commands*

73275 The format for grouping commands is as follows:

73276 (*compound-list*) Execute *compound-list* in a subshell environment; see Section 2.12 (on page
73277 2331). Variable assignments and built-in commands that affect the
73278 environment shall not remain in effect after the list finishes.

73279 { *compound-list*;} Execute *compound-list* in the current process environment. The semicolon
73280 shown here is an example of a control operator delimiting the } reserved
73281 word. Other delimiters are possible, as shown in Section 2.10 (on page
73282 2325); a <newline> is frequently used.

73283 **Exit Status**

73284 The exit status of a grouping command shall be the exit status of *compound-list*.

73285 2.9.4.2 *The for Loop*

73286 The **for** loop shall execute a sequence of commands for each member in a list of *items*. The **for**
73287 loop requires that the reserved words **do** and **done** be used to delimit the sequence of
73288 commands.

73289 The format for the **for** loop is as follows:

```
73290 for name [ in [word ... ]]
73291 do
73292     compound-list
73293 done
```

73294 First, the list of words following **in** shall be expanded to generate a list of items. Then, the
73295 variable *name* shall be set to each item, in turn, and the *compound-list* executed each time. If no
73296 items result from the expansion, the *compound-list* shall not be executed. Omitting:

73297 `in word ...`

73298 shall be equivalent to:

73299 `in "$@"`

73300 **Exit Status**

73301 The exit status of a **for** command shall be the exit status of the last command that executes. If
73302 there are no items, the exit status shall be zero.

73303 *2.9.4.3 Case Conditional Construct*

73304 The conditional construct **case** shall execute the *compound-list* corresponding to the first one of
73305 several *patterns* (see Section 2.13, on page 2332) that is matched by the string resulting from the
73306 tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote
73307 removal of the given word. The reserved word **in** shall denote the beginning of the patterns to
73308 be matched. Multiple patterns with the same *compound-list* shall be delimited by the '|'
73309 symbol. The control operator ')' terminates a list of patterns corresponding to a given action.
73310 The *compound-list* for each list of patterns, with the possible exception of the last, shall be
73311 terminated with ";;". The **case** construct terminates with the reserved word **esac** (**case**
73312 reversed).

73313 The format for the **case** construct is as follows:

```
73314 case word in
73315     [(]pattern1) compound-list;;
73316     [[(]pattern[ | pattern] ... ) compound-list;;] ...
73317     [[(]pattern[ | pattern] ... ) compound-list]
73318 esac
```

73319 The ";;" is optional for the last *compound-list*.

73320 In order from the beginning to the end of the **case** statement, each *pattern* that labels a *compound-*
73321 *list* shall be subjected to tilde expansion, parameter expansion, command substitution, and
73322 arithmetic expansion, and the result of these expansions shall be compared against the
73323 expansion of *word*, according to the rules described in Section 2.13 (on page 2332) (which also
73324 describes the effect of quoting parts of the pattern). After the first match, no more patterns shall
73325 be expanded, and the *compound-list* shall be executed. The order of expansion and comparison of
73326 multiple *patterns* that label a *compound-list* statement is unspecified.

73327 **Exit Status**

73328 The exit status of **case** shall be zero if no patterns are matched. Otherwise, the exit status shall be
73329 the exit status of the last command executed in the *compound-list*.

73330 *2.9.4.4 The if Conditional Construct*

73331 The **if** command shall execute a *compound-list* and use its exit status to determine whether to
73332 execute another *compound-list*.

73333 The format for the **if** construct is as follows:

```
73334 if compound-list
73335 then
73336     compound-list
73337 [elif compound-list
73338 then
73339     compound-list] ...
73340 [else
73341     compound-list]
73342 fi
```

The **if** *compound-list* shall be executed; if its exit status is zero, the **then** *compound-list* shall be executed and the command shall complete. Otherwise, each **elif** *compound-list* shall be executed, in turn, and if its exit status is zero, the **then** *compound-list* shall be executed and the command shall complete. Otherwise, the **else** *compound-list* shall be executed.

Exit Status

The exit status of the **if** command shall be the exit status of the **then** or **else** *compound-list* that was executed, or zero, if none was executed.

2.9.4.5 *The while Loop*

The **while** loop shall continuously execute one *compound-list* as long as another *compound-list* has a zero exit status.

The format of the **while** loop is as follows:

```
while compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a non-zero exit status, the **while** command shall complete. Otherwise, the *compound-list-2* shall be executed, and the process shall repeat.

Exit Status

The exit status of the **while** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.4.6 *The until Loop*

The **until** loop shall continuously execute one *compound-list* as long as another *compound-list* has a non-zero exit status.

The format of the **until** loop is as follows:

```
until compound-list-1
do
    compound-list-2
done
```

The *compound-list-1* shall be executed, and if it has a zero exit status, the **until** command completes. Otherwise, the *compound-list-2* shall be executed, and the process repeats.

Exit Status

The exit status of the **until** loop shall be the exit status of the last *compound-list-2* executed, or zero if none was executed.

2.9.5 Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a "function definition command".

The format of a function definition command is as follows:

```
fname() compound-command[io-redirect ...]
```

The function is named *fname*; the application shall ensure that it is a name (see XBD Section 3.230, on page 70). An implementation may allow other characters in a function name as an extension. The implementation shall maintain separate name spaces for functions and variables.

The argument *compound-command* represents a compound command, as described in Section 2.9.4 (on page 2321).

When the function is declared, none of the expansions in Section 2.6 (on page 2305) shall be performed on the text in *compound-command* or *io-redirect*; all expansions shall be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* shall be performed during the execution of the function itself, not the function definition. See Section 2.8.1 (on page 2315) for the consequences of failures of these operations on interactive and non-interactive shells.

When a function is executed, it shall have the syntax-error and variable-assignment properties described for special built-in utilities in the enumerated list at the beginning of Section 2.14 (on page 2334).

The *compound-command* shall be executed whenever the function name is specified as the name of a simple command (see Section 2.9.1.1, on page 2317). The operands to the command temporarily shall become the positional parameters during the execution of the *compound-command*; the special parameter `'#'` also shall be changed to reflect the number of operands. The special parameter 0 shall be unchanged. When the function completes, the values of the positional parameters and the special parameter `'#'` shall be restored to the values they had before the function was executed. If the special built-in *return* is executed in the *compound-command*, the function completes and execution shall resume with the next command after the function call.

Exit Status

The exit status of a function definition shall be zero if the function was declared successfully; otherwise, it shall be greater than zero. The exit status of a function invocation shall be the exit status of the last command executed by the function.

2.10 Shell Grammar

The following grammar defines the Shell Command Language. This formal syntax shall take precedence over the preceding text syntax description.

2.10.1 Shell Grammar Lexical Conventions

The input language to the shell must be first recognized at the character level. The resulting tokens shall be classified by their immediate context according to the following rules (applied in order). These rules shall be used to determine what a "token" is that is subject to parsing at the token level. The rules for token recognition in Section 2.3 (on page 2299) shall apply.

1. A <newline> shall be returned as the token identifier **NEWLINE**.
2. If the token is an operator, the token identifier for that operator shall result.
3. If the string consists solely of digits and the delimiter character is one of `'<'` or `'>'`, the token identifier **IO_NUMBER** shall be returned.
4. Otherwise, the token identifier **TOKEN** results.

Further distinction on **TOKEN** is context-dependent. It may be that the same **TOKEN** yields **WORD**, a **NAME**, an **ASSIGNMENT**, or one of the reserved words below, dependent upon the context. Some of the productions in the grammar below are annotated with a rule number from the following list. When a **TOKEN** is seen where one of those annotated productions could be used to reduce the symbol, the applicable rule shall be applied to convert the token identifier type of the **TOKEN** to a token identifier acceptable at that point in the grammar. The reduction shall then proceed based upon the token identifier type yielded by the rule applied. When more than one rule applies, the highest numbered rule shall apply (which in turn may refer to another rule). (Note that except in rule 7, the presence of an `'='` in the token has no effect.)

The **WORD** tokens shall have the word expansion rules applied to them immediately before the associated command is executed, not at the time the command is parsed.

2.10.2 Shell Grammar Rules

1. [Command Name]

   When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, the token **WORD** shall be returned. Also, if the parser is in any state where only a reserved word could be the next correct token, proceed as above.

   Note: Because at this point <quotation-mark> characters are retained in the token, quoted strings cannot be recognized as reserved words. This rule also implies that reserved words are not recognized except in certain positions in the input, such as after a <newline> or <semicolon>; the grammar presumes that if the reserved word is intended, it is properly delimited by the user, and does not attempt to reflect that requirement directly. Also note that line joining is done before tokenization, as described in Section 2.2.1 (on page 2298), so escaped <newline> characters are already removed at this point.

   Rule 1 is not directly referenced in the grammar, but is referred to by other rules, or applies globally.

2. [Redirection to or from filename]

   The expansions specified in Section 2.7 (on page 2312) shall occur. As specified there, exactly one field can result (or the result is unspecified), and there are additional

73451 requirements on pathname expansion.

73452 3. [Redirection from here-document]

73453 Quote removal shall be applied to the word to determine the delimiter that is used to find
73454 the end of the here-document that begins after the next <newline>.

73455 4. [Case statement termination]

73456 When the **TOKEN** is exactly the reserved word **esac**, the token identifier for **esac** shall
73457 result. Otherwise, the token **WORD** shall be returned.

73458 5. [**NAME** in **for**]

73459 When the **TOKEN** meets the requirements for a name (see XBD Section 3.230, on page
73460 70), the token identifier **NAME** shall result. Otherwise, the token **WORD** shall be
73461 returned.

73462 6. [Third word of **for** and **case**]

73463 a. [**case** only]

73464 When the **TOKEN** is exactly the reserved word **in**, the token identifier for **in** shall
73465 result. Otherwise, the token **WORD** shall be returned.

73466 b. [**for** only]

73467 When the **TOKEN** is exactly the reserved word **in** or **do**, the token identifier for **in**
73468 or **do** shall result, respectively. Otherwise, the token **WORD** shall be returned.

73469 (For a. and b.: As indicated in the grammar, a *linebreak* precedes the tokens **in** and **do**. If
73470 <newline> characters are present at the indicated location, it is the token after them that is
73471 treated in this fashion.)

73472 7. [Assignment preceding command name]

73473 a. [When the first word]

73474 If the **TOKEN** does not contain the character `'='`, rule 1 is applied. Otherwise, 7b
73475 shall be applied.

73476 b. [Not the first word]

73477 If the **TOKEN** contains the <equals-sign> character:

73478 — If it begins with `'='`, the token **WORD** shall be returned.

73479 — If all the characters preceding `'='` form a valid name (see XBD Section 3.230,
73480 on page 70), the token **ASSIGNMENT_WORD** shall be returned. (Quoted
73481 characters cannot participate in forming a valid name.)

73482 — Otherwise, it is unspecified whether it is **ASSIGNMENT_WORD** or **WORD**
73483 that is returned.

73484 Assignment to the **NAME** shall occur as specified in Section 2.9.1 (on page 2316).

73485 8. [**NAME** in function]

73486 When the **TOKEN** is exactly a reserved word, the token identifier for that reserved word
73487 shall result. Otherwise, when the **TOKEN** meets the requirements for a name, the token
73488 identifier **NAME** shall result. Otherwise, rule 7 applies.

73489 9. [Body of function]

73490 Word expansion and assignment shall never occur, even when required by the rules

above, when this rule is being parsed. Each **TOKEN** that might either be expanded or have assignment applied to it shall instead be returned as a single **WORD** consisting only of characters that are exactly the token described in Section 2.3 (on page 2299).

2.11 Signals and Error Handling

When a command is in an asynchronous list, it shall inherit from the shell a signal action of ignored (SIG_IGN) for the SIGQUIT and SIGINT signals, and may inherit a signal mask in which SIGQUIT and SIGINT are blocked. Otherwise, the signal actions and signal mask inherited by the command shall be the same as those inherited by the shell from its parent unless a signal action is modified by the *trap* special built-in (see *trap*)

When a signal for which a trap has been set is received while the shell is waiting for the completion of a utility executing a foreground command, the trap associated with that signal shall not be executed until after the foreground command has completed. When the shell is waiting, by means of the *wait* utility, for asynchronous commands to complete, the reception of a signal for which a trap has been set shall cause the *wait* utility to return immediately with an exit status >128, immediately after which the trap associated with that signal shall be taken.

If multiple signals are pending for the shell for which there are associated trap actions, the order of execution of trap actions is unspecified.

2.12 Shell Execution Environment

A shell execution environment consists of the following:

- Open files inherited upon invocation of the shell, plus open files controlled by *exec*
- Working directory as set by *cd*
- File creation mask set by *umask*
- Current traps set by *trap*
- Shell parameters that are set by variable assignment (see the *set* special built-in) or from the System Interfaces volume of POSIX.1-200x environment inherited by the shell when it begins (see the *export* special built-in)
- Shell functions; see Section 2.9.5 (on page 2324)
- Options turned on at invocation or by *set*
- Process IDs of the last commands in asynchronous lists known to this shell environment; see Section 2.9.3.1 (on page 2319)
- Shell aliases; see Section 2.3.1 (on page 2300)

Utilities other than the special built-ins (see Section 2.14, on page 2334) shall be invoked in a separate environment that consists of the following. The initial value of these objects shall be the same as that for the parent shell, except as noted below.

- Open files inherited on invocation of the shell, open files controlled by the *exec* special built-in plus any modifications, and additions specified by any redirections to the utility
- Current working directory
- File creation mask
- If the utility is a shell script, traps caught by the shell shall be set to the default values and traps ignored by the shell shall be set to be ignored by the utility; if the utility is not a shell script, the trap actions (default or ignore) shall be mapped into the appropriate signal handling actions for the utility
- Variables with the *export* attribute, along with those explicitly exported for the duration of the command, shall be passed to the utility environment variables

The environment of the shell process shall not be changed by the utility unless explicitly specified by the utility description (for example, *cd* and *umask*).

A subshell environment shall be created as a duplicate of the shell environment, except that signal traps set by that shell environment shall be set to the default values. Changes made to the subshell environment shall not affect the shell environment. Command substitution, commands that are grouped with parentheses, and asynchronous lists shall be executed in a subshell environment. Additionally, each command of a multi-command pipeline is in a subshell environment; as an extension, however, any or all commands in a pipeline may be executed in the current environment. All other commands shall be executed in the current shell environment.

2.13 Pattern Matching Notation

The pattern matching notation described in this section is used to specify patterns for matching strings in the shell. Historically, pattern matching notation is related to, but slightly different from, the regular expression notation described in XBD Chapter 9 (on page 181). For this reason, the description of the rules for this pattern matching notation are based on the description of regular expression notation, modified to account for the differences.

2.13.1 Patterns Matching a Single Character

The following patterns matching a single character shall match a single character: ordinary characters, special pattern characters, and pattern bracket expressions. The pattern bracket expression also shall match a single collating element. A <backslash> character shall escape the following character. The escaping <backslash> shall be discarded.

An ordinary character is a pattern that shall match itself. It can be any character in the supported character set except for NUL, those special shell characters in Section 2.2 (on page 2298) that require quoting, and the following three special pattern characters. Matching shall be based on the bit pattern used for encoding the character, not on the graphic representation of the character. If any character (ordinary, shell special, or pattern special) is quoted, that pattern shall match the character itself. The shell special characters always require quoting.

When unquoted and outside a bracket expression, the following three characters shall have special meaning in the specification of patterns:

? A <question-mark> is a pattern that shall match any character.

* An <asterisk> is a pattern that shall match multiple characters, as described in Section 2.13.2.

[If an open bracket introduces a bracket expression as in XBD Section 9.3.5 (on page 184), except that the <exclamation-mark> character (`'!'`) shall replace the <circumflex> character (`'^'`) in its role in a non-matching list in the regular expression notation, it shall introduce a pattern bracket expression. A bracket expression starting with an unquoted <circumflex> character produces unspecified results. Otherwise, `'['` shall match the character itself.

When pattern matching is used where shell quote removal is not performed (such as in the argument to the *find* –*name* primary when *find* is being called using one of the *exec* functions as defined in the System Interfaces volume of POSIX.1-200x, or in the *pattern* argument to the *fnmatch*() function), special characters can be escaped to remove their special meaning by preceding them with a <backslash> character. This escaping <backslash> is discarded. The sequence `"\\"` represents one literal <backslash>. All of the requirements and effects of quoting on ordinary, shell special, and special pattern characters shall apply to escaping in this context.

2.13.2 Patterns Matching Multiple Characters

The following rules are used to construct patterns matching multiple characters from patterns matching a single character:

1. The <asterisk> (`'*'`) is a pattern that shall match any string, including the null string.
2. The concatenation of patterns matching a single character is a valid pattern that shall match the concatenation of the single characters or collating elements matched by each of the concatenated patterns.

3. The concatenation of one or more patterns matching a single character with one or more <asterisk> characters is a valid pattern. In such patterns, each <asterisk> shall match a string of zero or more characters, matching the greatest possible number of characters that still allows the remainder of the pattern to match the string.

2.13.3 Patterns Used for Filename Expansion

The rules described so far in Section 2.13.1 (on page 2332) and Section 2.13.2 (on page 2332) are qualified by the following rules that apply when pattern matching notation is used for filename expansion:

1. The <slash> character in a pathname shall be explicitly matched by using one or more <slash> characters in the pattern; it shall neither be matched by the <asterisk> or <question-mark> special characters nor by a bracket expression. <slash> characters in the pattern shall be identified before bracket expressions; thus, a <slash> cannot be included in a pattern bracket expression used for filename expansion. If a <slash> character is found following an unescaped <left-square-bracket> character before a corresponding <right-square-bracket> is found, the open bracket shall be treated as an ordinary character. For example, the pattern `"a[b/c]d"` does not match such pathnames as **abd** or **a/d**. It only matches a pathname of literally **a[b/c]d**.

2. If a filename begins with a <period> (`'.'`), the <period> shall be explicitly matched by using a <period> as the first character of the pattern or immediately following a <slash> character. The leading <period> shall not be matched by:

   - The <asterisk> or <question-mark> special characters
   - A bracket expression containing a non-matching list, such as `"[!a]"`, a range expression, such as `"[%–0]"`, or a character class expression, such as `"[[:punct:]]"`

   It is unspecified whether an explicit <period> in a bracket expression matching list, such as `"[.abc]"`, can match a leading <period> in a filename.

3. Specified patterns shall be matched against existing filenames and pathnames, as appropriate. Each component that contains a pattern character shall require read permission in the directory containing that component. Any component, except the last, that does not contain a pattern character shall require search permission. For example, given the pattern:

   ```
   /foo/bar/x*/bam
   ```

   search permission is needed for directories **/** and **foo**, search and read permissions are needed for directory **bar**, and search permission is needed for each **x*** directory. If the pattern matches any existing filenames or pathnames, the pattern shall be replaced with those filenames and pathnames, sorted according to the collating sequence in effect in the current locale.

   If the pattern contains an open bracket (`'['`) that does not introduce a bracket expression as in XBD Section 9.3.5 (on page 184), it is unspecified whether other unquoted pattern matching characters within the same slash-delimited component of the pattern retain their special meanings or are treated as ordinary characters. For example, the pattern `"a*[/b*"` may match all filenames beginning with `'b'` in the directory `"a*["` or it may match all filenames beginning with `'b'` in all directories with names beginning with `'a'` and ending with `'['`.

   If the pattern does not match any existing filenames or pathnames, the pattern string shall

be left unchanged.

2.14 Special Built-In Utilities

The following "special built-in" utilities shall be supported in the shell command language. The output of each command, if any, shall be written to standard output, subject to the normal redirection and piping possible with all commands.

The term "built-in" implies that the shell can execute the utility directly and does not need to search for it. An implementation may choose to make any utility a built-in; however, the special built-in utilities described here differ from regular built-in utilities in two respects:

1. A syntax error in a special built-in utility may cause a shell executing that utility to abort, while a syntax error in a regular built-in utility shall not cause a shell executing that utility to abort. (See Section 2.8.1 (on page 2315) for the consequences of errors on interactive and non-interactive shells.) If a special built-in utility encountering a syntax error does not abort the shell, its exit value shall be non-zero.
2. Variable assignments specified with special built-in utilities remain in effect after the built-in completes; this shall not be the case with a regular built-in or other utility.

The special built-in utilities in this section need not be provided in a manner accessible via the *exec* family of functions defined in the System Interfaces volume of POSIX.1-200x.

Some of the special built-ins are described as conforming to XBD Section 12.2 (on page 215). For those that are not, the requirement in Section 1.4 (on page 2288) that "−−" be recognized as a first argument to be discarded does not apply and a conforming application shall not use that argument.

NAME

break — exit from for, while, or until loop

SYNOPSIS

```
break [n]
```

DESCRIPTION

The *break* utility shall exit from the smallest enclosing **for**, **while**, or **until** loop, if any; or from the *n*th enclosing loop if *n* is specified. The value of *n* is an unsigned decimal integer greater than or equal to 1. The default shall be equivalent to *n*=1. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be exited. Execution shall continue with the command immediately following the loop.

OPTIONS

None.

OPERANDS

See the DESCRIPTION.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

None.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

0 Successful completion.

>0 The *n* value was not an unsigned decimal integer greater than or equal to 1.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

```
for i in *
do
    if test –d "$i"
    then break
    fi
done
```

RATIONALE

In early proposals, consideration was given to expanding the syntax of *break* and *continue* to refer to a label associated with the appropriate loop as a preferable alternative to the *n* method. However, this volume of POSIX.1-200x does reserve the name space of command names ending with a <colon>. It is anticipated that a future implementation could take advantage of this and provide something like:

```
outofloop: for i in a b c d e
do
    for j in 0 1 2 3 4 5 6 7 8 9
    do
        if test –r "${i}${j}"
        then break outofloop
        fi
    done
done
```

and that this might be standardized after implementation experience is achieved.

FUTURE DIRECTIONS

None.

Section 2.14 (on page 2334)

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

73905 **NAME**

73906 colon — null utility

73907 **SYNOPSIS**

73908 `: [`*`argument`*`...]`

73909 **DESCRIPTION**

73910 This utility shall only expand command *argument*s. It is used when a command is needed, as in
73911 the **then** condition of an **if** command, but nothing is to be done by the command.

73912 **OPTIONS**

73913 None.

73914 **OPERANDS**

73915 See the DESCRIPTION.

73916 **STDIN**

73917 Not used.

73918 **INPUT FILES**

73919 None.

73920 **ENVIRONMENT VARIABLES**

73921 None.

73922 **ASYNCHRONOUS EVENTS**

73923 Default.

73924 **STDOUT**

73925 Not used.

73926 **STDERR**

73927 The standard error shall be used only for diagnostic messages.

73928 **OUTPUT FILES**

73929 None.

73930 **EXTENDED DESCRIPTION**

73931 None.

73932 **EXIT STATUS**

73933 Zero.

73934 **CONSEQUENCES OF ERRORS**

73935 Default.

73936 **APPLICATION USAGE**

73937 None.

73938 **EXAMPLES**

```
73939       : ${X=abc}
73940       if     false
73941       then   :
73942       else   echo $X
73943       fi
73944       abc
```

73945 As with any of the special built-ins, the null utility can also have variable assignments and
73946 redirections associated with it, such as:

```
73947       x=y : > z
```

which sets variable *x* to the value *y* (so that it persists after the null utility completes) and creates or truncates file **z**.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

73963 **NAME**

73964 continue — continue for, while, or until loop

73965 **SYNOPSIS**

73966 `continue [n]`

73967 **DESCRIPTION**

73968 The *continue* utility shall return to the top of the smallest enclosing **for**, **while**, or **until** loop, or to
73969 the top of the *n*th enclosing loop, if *n* is specified. This involves repeating the condition list of a
73970 **while** or **until** loop or performing the next assignment of a **for** loop, and re-executing the loop if
73971 appropriate.

73972 The value of *n* is a decimal integer greater than or equal to 1. The default shall be equivalent to
73973 *n*=1. If *n* is greater than the number of enclosing loops, the outermost enclosing loop shall be
73974 used.

73975 **OPTIONS**

73976 None.

73977 **OPERANDS**

73978 See the DESCRIPTION.

73979 **STDIN**

73980 Not used.

73981 **INPUT FILES**

73982 None.

73983 **ENVIRONMENT VARIABLES**

73984 None.

73985 **ASYNCHRONOUS EVENTS**

73986 Default.

73987 **STDOUT**

73988 Not used.

73989 **STDERR**

73990 The standard error shall be used only for diagnostic messages.

73991 **OUTPUT FILES**

73992 None.

73993 **EXTENDED DESCRIPTION**

73994 None.

73995 **EXIT STATUS**

73996 0 Successful completion.

73997 >0 The *n* value was not an unsigned decimal integer greater than or equal to 1.

73998 **CONSEQUENCES OF ERRORS**

73999 Default.

APPLICATION USAGE

None.

EXAMPLES

```
for i in *
do
    if test –d "$i"
    then continue
    fi
    printf '"%s" is not a directory.\n' "$i"
done
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

Section 2.14 (on page 2334)

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

The example is changed to use the *printf* utility rather than *echo*.

74023 **NAME**

74024 dot — execute commands in the current environment

74025 **SYNOPSIS**

74026 `. file`

74027 **DESCRIPTION**

74028 The shell shall execute commands from the *file* in the current environment.

74029 If *file* does not contain a <slash>, the shell shall use the search path specified by *PATH* to find the
74030 directory containing *file*. Unlike normal command search, however, the file searched for by the
74031 *dot* utility need not be executable. If no readable file is found, a non-interactive shell shall abort;
74032 an interactive shell shall write a diagnostic message to standard error, but this condition shall
74033 not be considered a syntax error.

74034 **OPTIONS**

74035 None.

74036 **OPERANDS**

74037 See the DESCRIPTION.

74038 **STDIN**

74039 Not used.

74040 **INPUT FILES**

74041 See the DESCRIPTION.

74042 **ENVIRONMENT VARIABLES**

74043 See the DESCRIPTION.

74044 **ASYNCHRONOUS EVENTS**

74045 Default.

74046 **STDOUT**

74047 Not used.

74048 **STDERR**

74049 The standard error shall be used only for diagnostic messages.

74050 **OUTPUT FILES**

74051 None.

74052 **EXTENDED DESCRIPTION**

74053 None.

74054 **EXIT STATUS**

74055 Returns the value of the last command executed, or a zero exit status if no command is executed.

74056 **CONSEQUENCES OF ERRORS**

74057 Default.

APPLICATION USAGE

None.

EXAMPLES

```
cat foobar
foo=hello bar=world
. ./foobar
echo $foo $bar
hello world
```

RATIONALE

Some older implementations searched the current directory for the *file*, even if the value of *PATH* disallowed it. This behavior was omitted from this volume of POSIX.1-200x due to concerns about introducing the susceptibility to trojan horses that the user might be trying to avoid by leaving **dot** out of *PATH*.

The KornShell version of *dot* takes optional arguments that are set to the positional parameters. This is a valid extension that allows a *dot* script to behave identically to a function.

FUTURE DIRECTIONS

None.

Section 2.14 (on page 2334)

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-164 is applied.

74084 **NAME**

74085 eval — construct command by concatenating arguments

74086 **SYNOPSIS**

74087 `eval [`*`argument`*`...]`

74088 **DESCRIPTION**

74089 The *eval* utility shall construct a command by concatenating *argument*s together, separating each
74090 with a <space> character. The constructed command shall be read and executed by the shell.

74091 **OPTIONS**

74092 None.

74093 **OPERANDS**

74094 See the DESCRIPTION.

74095 **STDIN**

74096 Not used.

74097 **INPUT FILES**

74098 None.

74099 **ENVIRONMENT VARIABLES**

74100 None.

74101 **ASYNCHRONOUS EVENTS**

74102 Default.

74103 **STDOUT**

74104 Not used.

74105 **STDERR**

74106 The standard error shall be used only for diagnostic messages.

74107 **OUTPUT FILES**

74108 None.

74109 **EXTENDED DESCRIPTION**

74110 None.

74111 **EXIT STATUS**

74112 If there are no *argument*s, or only null arguments, *eval* shall return a zero exit status; otherwise, it
74113 shall return the exit status of the command defined by the string of concatenated *argument*s
74114 separated by <space> characters.

74115 **CONSEQUENCES OF ERRORS**

74116 Default.

74117 **APPLICATION USAGE**

74118 None.

74119 **EXAMPLES**

```
74120       foo=10 x=foo
74121       y='$'$x
74122       echo $y
74123       $foo
74124       eval y='$'$x
74125       echo $y
74126       10
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

Section 2.14 (on page 2334)

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

74140 **NAME**

74141 exec — execute commands and open, close, or copy file descriptors

74142 **SYNOPSIS**

74143 `exec [`*`command`* `[`*`argument`*`...]]`

74144 **DESCRIPTION**

74145 The *exec* utility shall open, close, and/or copy file descriptors as specified by any redirections as
74146 part of the command.

74147 If *exec* is specified without *command* or *argument*s, and any file descriptors with numbers greater
74148 than 2 are opened with associated redirection statements, it is unspecified whether those file
74149 descriptors remain open when the shell invokes another utility. Scripts concerned that child
74150 shells could misuse open file descriptors can always close them explicitly, as shown in one of the
74151 following examples.

74152 If *exec* is specified with *command*, it shall replace the shell with *command* without creating a new
74153 process. If *argument*s are specified, they shall be arguments to *command*. Redirection affects the
74154 current shell execution environment.

74155 **OPTIONS**

74156 None.

74157 **OPERANDS**

74158 See the DESCRIPTION.

74159 **STDIN**

74160 Not used.

74161 **INPUT FILES**

74162 None.

74163 **ENVIRONMENT VARIABLES**

74164 None.

74165 **ASYNCHRONOUS EVENTS**

74166 Default.

74167 **STDOUT**

74168 Not used.

74169 **STDERR**

74170 The standard error shall be used only for diagnostic messages.

74171 **OUTPUT FILES**

74172 None.

74173 **EXTENDED DESCRIPTION**

74174 None.

74175 **EXIT STATUS**

74176 If *command* is specified, *exec* shall not return to the shell; rather, the exit status of the process shall
74177 be the exit status of the program implementing *command*, which overlaid the shell. If *command* is
74178 not found, the exit status shall be 127. If *command* is found, but it is not an executable utility, the
74179 exit status shall be 126. If a redirection error occurs (see Section 2.8.1, on page 2315), the shell
74180 shall exit with a value in the range 1–125. Otherwise, *exec* shall return a zero exit status.

74181 **CONSEQUENCES OF ERRORS**

74182 Default.

74183 **APPLICATION USAGE**

74184 None.

74185 **EXAMPLES**

74186 Open *readfile* as file descriptor 3 for reading:

74187
```
exec 3< readfile
```

74188 Open *writefile* as file descriptor 4 for writing:

74189
```
exec 4> writefile
```

74190 Make file descriptor 5 a copy of file descriptor 0:

74191
```
exec 5<&0
```

74192 Close file descriptor 3:

74193
```
exec 3<&–
```

74194 Cat the file **maggie** by replacing the current shell with the *cat* utility:

74195
```
exec cat maggie
```

74196 **RATIONALE**

74197 Most historical implementations were not conformant in that:

74198
```
foo=bar exec cmd
```

74199 did not pass **foo** to **cmd**.

74200 **FUTURE DIRECTIONS**

74201 None.

74202 **SEE ALSO**

74203 Section 2.14 (on page 2334)

74204 **CHANGE HISTORY**

74205 **Issue 6**

74206 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
74207 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
74208 behavior is intended.

74209 **Issue 7**

74210 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

74211 **NAME**

74212 exit — cause the shell to exit

74213 **SYNOPSIS**

74214 `exit [`*n*`]`

74215 **DESCRIPTION**

74216 The *exit* utility shall cause the shell to exit with the exit status specified by the unsigned decimal
74217 integer *n*. If *n* is specified, but its value is not between 0 and 255 inclusively, the exit status is
74218 undefined.

74219 A *trap* on **EXIT** shall be executed before the shell terminates, except when the *exit* utility is
74220 invoked in that *trap* itself, in which case the shell shall exit immediately.

74221 **OPTIONS**

74222 None.

74223 **OPERANDS**

74224 See the DESCRIPTION.

74225 **STDIN**

74226 Not used.

74227 **INPUT FILES**

74228 None.

74229 **ENVIRONMENT VARIABLES**

74230 None.

74231 **ASYNCHRONOUS EVENTS**

74232 Default.

74233 **STDOUT**

74234 Not used.

74235 **STDERR**

74236 The standard error shall be used only for diagnostic messages.

74237 **OUTPUT FILES**

74238 None.

74239 **EXTENDED DESCRIPTION**

74240 None.

74241 **EXIT STATUS**

74242 The exit status shall be *n*, if specified. Otherwise, the value shall be the exit value of the last
74243 command executed, or zero if no command was executed. When *exit* is executed in a *trap* action,
74244 the last command is considered to be the command that executed immediately preceding the
74245 *trap* action.

74246 **CONSEQUENCES OF ERRORS**

74247 Default.

APPLICATION USAGE

None.

EXAMPLES

Exit with a *true* value:

```
exit 0
```

Exit with a *false* value:

```
exit 1
```

RATIONALE

As explained in other sections, certain exit status values have been reserved for special uses and should be used by applications only for those purposes:

126 A file to be executed was found, but it was not an executable utility.

127 A utility to be executed was not found.

>128 A command was interrupted by a signal.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 2.14 (on page 2334)

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

74270 **NAME**

74271 export — set the export attribute for variables

74272 **SYNOPSIS**

74273 `export name[=word]...`

74274 `export –p`

74275 **DESCRIPTION**

74276 The shell shall give the *export* attribute to the variables corresponding to the specified *name*s,
74277 which shall cause them to be in the environment of subsequently executed commands. If the
74278 name of a variable is followed by =*word*, then the value of that variable shall be set to *word*.

74279 The *export* special built-in shall support XBD Section 12.2 (on page 215).

74280 When **–p** is specified, *export* shall write to the standard output the names and values of all
74281 exported variables, in the following format:

74282 `"export %s=%s\n", <name>, <value>`

74283 if *name* is set, and:

74284 `"export %s\n", <name>`

74285 if *name* is unset.

74286 The shell shall format the output, including the proper use of quoting, so that it is suitable for
74287 reinput to the shell as commands that achieve the same exporting results, except:

74288 1. Read-only variables with values cannot be reset.

74289 2. Variables that were unset at the time they were output need not be reset to the unset state
74290 if a value is assigned to the variable between the time the state was saved and the time at
74291 which the saved output is reinput to the shell.

74292 When no arguments are given, the results are unspecified.

74293 **OPTIONS**

74294 See the DESCRIPTION.

74295 **OPERANDS**

74296 See the DESCRIPTION.

74297 **STDIN**

74298 Not used.

74299 **INPUT FILES**

74300 None.

74301 **ENVIRONMENT VARIABLES**

74302 None.

74303 **ASYNCHRONOUS EVENTS**

74304 Default.

74305 **STDOUT**

74306 See the DESCRIPTION.

74307 **STDERR**

74308 The standard error shall be used only for diagnostic messages.

74309 **OUTPUT FILES**

74310 None.

74311 **EXTENDED DESCRIPTION**

74312 None.

74313 **EXIT STATUS**

74314 Zero.

74315 **CONSEQUENCES OF ERRORS**

74316 Default.

74317 **APPLICATION USAGE**

74318 None.

74319 **EXAMPLES**

74320 Export *PWD* and *HOME* variables:

74321
```
export PWD HOME
```

74322 Set and export the *PATH* variable:

74323
```
export PATH=/local/bin:$PATH
```

74324 Save and restore all exported variables:

74325
```
export -p > temp-file
unset a lot of variables
... processing
. temp-file
```

74329 **RATIONALE**

74330 Some historical shells use the no-argument case as the functional equivalent of what is required
74331 here with **-p**. This feature was left unspecified because it is not historical practice in all shells,
74332 and some scripts may rely on the now-unspecified results on their implementations. Attempts to
74333 specify the **-p** output as the default case were unsuccessful in achieving consensus. The **-p**
74334 option was added to allow portable access to the values that can be saved and then later restored
74335 using; for example, a *dot* script.

74336 **FUTURE DIRECTIONS**

74337 None.

74338 **SEE ALSO**

74339 Section 2.14 (on page 2334)

74340 XBD Section 12.2 (on page 215)

74341 **CHANGE HISTORY**

74342 **Issue 6**

74343 IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the format when a variable is unset.

74344 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
74345 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
74346 behavior is intended.

74347 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/6 is applied, adding the following text to
74348 the end of the first paragraph of the DESCRIPTION: "If the name of a variable is followed by
74349 *=word*, then the value of that variable shall be set to *word*.". The reason for this change is that the
74350 SYNOPSIS for *export* includes:

74351 `export name[=word]...`

74352 but the meaning of the optional "*=word*" is never explained in the text.

74353 **NAME**

74354 readonly — set the readonly attribute for variables

74355 **SYNOPSIS**

74356 `readonly name[=word]...`

74357 `readonly −p`

74358 **DESCRIPTION**

74359 The variables whose *name*s are specified shall be given the *readonly* attribute. The values of
74360 variables with the *readonly* attribute cannot be changed by subsequent assignment, nor can those
74361 variables be unset by the *unset* utility. If the name of a variable is followed by *=word*, then the
74362 value of that variable shall be set to *word*.

74363 The *readonly* special built-in shall support XBD Section 12.2 (on page 215).

74364 When **−p** is specified, *readonly* writes to the standard output the names and values of all read-
74365 only variables, in the following format:

74366 `"readonly %s=%s\n", <name>, <value>`

74367 if *name* is set, and

74368 `"readonly %s\n", <name>`

74369 if *name* is unset.

74370 The shell shall format the output, including the proper use of quoting, so that it is suitable for
74371 reinput to the shell as commands that achieve the same value and *readonly* attribute-setting
74372 results in a shell execution environment in which:

74373 1. Variables with values at the time they were output do not have the *readonly* attribute set.

74374 2. Variables that were unset at the time they were output do not have a value at the time at
74375 which the saved output is reinput to the shell.

74376 When no arguments are given, the results are unspecified.

74377 **OPTIONS**

74378 See the DESCRIPTION.

74379 **OPERANDS**

74380 See the DESCRIPTION.

74381 **STDIN**

74382 Not used.

74383 **INPUT FILES**

74384 None.

74385 **ENVIRONMENT VARIABLES**

74386 None.

74387 **ASYNCHRONOUS EVENTS**

74388 Default.

74389 **STDOUT**

74390 See the DESCRIPTION.

74391 **STDERR**
74392 The standard error shall be used only for diagnostic messages.

74393 **OUTPUT FILES**
74394 None.

74395 **EXTENDED DESCRIPTION**
74396 None.

74397 **EXIT STATUS**
74398 Zero.

74399 **CONSEQUENCES OF ERRORS**
74400 Default.

74401 **APPLICATION USAGE**
74402 None.

74403 **EXAMPLES**
74404
```
readonly HOME PWD
```

74405 **RATIONALE**
74406 Some historical shells preserve the *readonly* attribute across separate invocations. This volume of
74407 POSIX.1-200x allows this behavior, but does not require it.

74408 The **–p** option allows portable access to the values that can be saved and then later restored
74409 using, for example, a *dot* script. Also see the RATIONALE for *export* (on page 2349) for a
74410 description of the no-argument and **–p** output cases and a related example.

74411 Read-only functions were considered, but they were omitted as not being historical practice or
74412 particularly useful. Furthermore, functions must not be read-only across invocations to preclude
74413 "spoofing" (spoofing is the term for the practice of creating a program that acts like a well-
74414 known utility with the intent of subverting the real intent of the user) of administrative or
74415 security-relevant (or security-conscious) shell scripts.

74416 **FUTURE DIRECTIONS**
74417 None.

74418 **SEE ALSO**
74419 Section 2.14 (on page 2334)

74420 XBD Section 12.2 (on page 215)

74421 **CHANGE HISTORY**

74422 **Issue 6**
74423 IEEE PASC Interpretation 1003.2 #203 is applied, clarifying the format when a variable is unset.

74424 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
74425 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
74426 behavior is intended.

74427 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/7 is applied, adding the following text to
74428 the end of the first paragraph of the DESCRIPTION: "If the name of a variable is followed by
74429 *=word*, then the value of that variable shall be set to *word*.". The reason for this change is that the
74430 SYNOPSIS for *readonly* includes:

74431 `readonly name[=word]...`

74432 but the meaning of the optional "*=word*" is never explained in the text.

74433 **NAME**

74434 return — return from a function

74435 **SYNOPSIS**

74436 `return [`*n*`]`

74437 **DESCRIPTION**

74438 The *return* utility shall cause the shell to stop executing the current function or *dot* script. If the
74439 shell is not currently executing a function or *dot* script, the results are unspecified.

74440 **OPTIONS**

74441 None.

74442 **OPERANDS**

74443 See the DESCRIPTION.

74444 **STDIN**

74445 Not used.

74446 **INPUT FILES**

74447 None.

74448 **ENVIRONMENT VARIABLES**

74449 None.

74450 **ASYNCHRONOUS EVENTS**

74451 Default.

74452 **STDOUT**

74453 Not used.

74454 **STDERR**

74455 The standard error shall be used only for diagnostic messages.

74456 **OUTPUT FILES**

74457 None.

74458 **EXTENDED DESCRIPTION**

74459 None.

74460 **EXIT STATUS**

74461 The value of the special parameter `'?'` shall be set to *n*, an unsigned decimal integer, or to the
74462 exit status of the last command executed if *n* is not specified. If the value of *n* is greater than 255,
74463 the results are undefined. When *return* is executed in a *trap* action, the last command is
74464 considered to be the command that executed immediately preceding the *trap* action.

74465 **CONSEQUENCES OF ERRORS**

74466 Default.

74467 **APPLICATION USAGE**

74468 None.

74469 **EXAMPLES**

74470 None.

74471 **RATIONALE**

74472 The behavior of *return* when not in a function or *dot* script differs between the System V shell
74473 and the KornShell. In the System V shell this is an error, whereas in the KornShell, the effect is
74474 the same as *exit*.

74475 The results of returning a number greater than 255 are undefined because of differing practices

in the various historical implementations. Some shells AND out all but the low-order 8 bits; others allow larger values, but not of unlimited size.

See the discussion of appropriate exit status values under *exit* (on page 2347).

FUTURE DIRECTIONS

None.

Section 2.14 (on page 2334)

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

NAME

set — set or unset options and positional parameters

SYNOPSIS

```
set [–abCefhmnuvx] [–o option] [argument...]
set [+abCefhmnuvx] [+o option] [argument...]
set –– [argument...]
set –o
set +o
```

DESCRIPTION

If no *option*s or *argument*s are specified, *set* shall write the names and values of all shell variables in the collation sequence of the current locale. Each *name* shall start on a separate line, using the format:

```
"%s=%s\n", <name>, <value>
```

The *value* string shall be written with appropriate quoting; see the description of shell quoting in Section 2.2 (on page 2298). The output shall be suitable for reinput to the shell, setting or resetting, as far as possible, the variables that are currently set; read-only variables cannot be reset.

When options are specified, they shall set or unset attributes of the shell, as described below. When *argument*s are specified, they cause positional parameters to be set or unset, as described below. Setting or unsetting attributes and positional parameters are not necessarily related actions, but they can be combined in a single invocation of *set*.

The *set* special built-in shall support XBD Section 12.2 (on page 215) except that options can be specified with either a leading <hyphen> (meaning enable the option) or <plus-sign> (meaning disable it) unless otherwise specified.

Implementations shall support the options in the following list in both their <hyphen> and <plus-sign> forms. These options can also be specified as options to *sh*.

–a When this option is on, the *export* attribute shall be set for each variable to which an assignment is performed; see XBD Section 4.22 (on page 118). If the assignment precedes a utility name in a command, the *export* attribute shall not persist in the current execution environment after the utility completes, with the exception that preceding one of the special built-in utilities causes the *export* attribute to persist after the built-in has completed. If the assignment does not precede a utility name in the command, or if the assignment is a result of the operation of the *getopts* or *read* utilities, the *export* attribute shall persist until the variable is unset.

–b This option shall be supported if the implementation supports the User Portability Utilities option. It shall cause the shell to notify the user asynchronously of background job completions. The following message is written to standard error:

```
"[%d]%c %s%s\n", <job-number>, <current>, <status>, <job-name>
```

where the fields shall be as follows:

<*current*> The character `'+'` identifies the job that would be used as a default for the *fg* or *bg* utilities; this job can also be specified using the *job_id* "%+" or "%%". The character `'–'` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* "%–". For other jobs, this field is a <space>. At most one job

74532 can be identified with '+' and at most one job can be identified with '−'.
74533 If there is any suspended job, then the current job shall be a suspended
74534 job. If there are at least two suspended jobs, then the previous job also
74535 shall be a suspended job.

74536 <*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*,
74537 and *kill* utilities. Using these utilities, the job can be identified by prefixing
74538 the job number with '%'.

74539 <*status*> Unspecified.

74540 <*job-name*> Unspecified.

74541 When the shell notifies the user a job has been completed, it may remove the job's process
74542 ID from the list of those known in the current shell execution environment; see Section
74543 2.9.3.1 (on page 2319). Asynchronous notification shall not be enabled by default.

74544 **−C** (Uppercase C.) Prevent existing files from being overwritten by the shell's '>' redirection
74545 operator (see Section 2.7.2, on page 2313); the ">|" redirection operator shall override this
74546 *noclobber* option for an individual file.

74547 **−e** When this option is on, if a simple command fails for any of the reasons listed in Section
74548 2.8.1 (on page 2315) or returns an exit status value >0, and is not part of the compound list
74549 following a **while**, **until**, or **if** keyword, and is not a part of an AND or OR list, and is not a
74550 pipeline preceded by the **!** reserved word, then the shell shall immediately exit.

74551 **−f** The shell shall disable pathname expansion.

74552 **−h** Locate and remember utilities invoked by functions as those functions are defined (the
74553 utilities are normally located when the function is executed).

74554 **−m** This option shall be supported if the implementation supports the User Portability Utilities
74555 option. All jobs shall be run in their own process groups. Immediately before the shell issues
74556 a prompt after completion of the background job, a message reporting the exit status of the
74557 background job shall be written to standard error. If a foreground job stops, the shell shall
74558 write a message to standard error to that effect, formatted as described by the *jobs* utility. In
74559 addition, if a job changes status other than exiting (for example, if it stops for input or
74560 output or is stopped by a SIGSTOP signal), the shell shall write a similar message
74561 immediately prior to writing the next prompt. This option is enabled by default for
74562 interactive shells.

74563 **−n** The shell shall read commands but does not execute them; this can be used to check for
74564 shell script syntax errors. An interactive shell may ignore this option.

74565 **−o** Write the current settings of the options to standard output in an unspecified format.

74566 **+o** Write the current option settings to standard output in a format that is suitable for reinput
74567 to the shell as commands that achieve the same options settings.

74568 **−o** *option*
74569 This option is supported if the system supports the User Portability Utilities option. It shall
74570 set various options, many of which shall be equivalent to the single option letters. The
74571 following values of *option* shall be supported:

74572 *allexport* Equivalent to **−a**.

74573 *errexit* Equivalent to **−e**.

74574 *ignoreeof* Prevent an interactive shell from exiting on end-of-file. This setting prevents
74575 accidental logouts when <control>-D is entered. A user shall explicitly *exit* to
74576 leave the interactive shell.

74577 *monitor* Equivalent to **–m**. This option is supported if the system supports the User
74578 Portability Utilities option.

74579 *noclobber* Equivalent to **–C** (uppercase C).

74580 *noglob* Equivalent to **–f**.

74581 *noexec* Equivalent to **–n**.

74582 *nolog* Prevent the entry of function definitions into the command history; see
74583 Command History List (on page 3167).

74584 *notify* Equivalent to **–b**.

74585 *nounset* Equivalent to **–u**.

74586 *verbose* Equivalent to **–v**.

74587 *vi* Allow shell command line editing using the built-in *vi* editor. Enabling *vi*
74588 mode shall disable any other command line editing mode provided as an
74589 implementation extension.

74590 It need not be possible to set *vi* mode on for certain block-mode terminals.

74591 *xtrace* Equivalent to **–x**.

74592 **–u** The shell shall write a message to standard error when it tries to expand a variable that is
74593 not set and immediately exit. An interactive shell shall not exit.

74594 **–v** The shell shall write its input to standard error as it is read.

74595 **–x** The shell shall write to standard error a trace for each command after it expands the
74596 command and before it executes it. It is unspecified whether the command that turns
74597 tracing off is traced.

74598 The default for all these options shall be off (unset) unless stated otherwise in the description of
74599 the option or unless the shell was invoked with them on; see *sh*.

74600 The remaining arguments shall be assigned in order to the positional parameters. The special
74601 parameter `'#'` shall be set to reflect the number of positional parameters. All positional
74602 parameters shall be unset before any new values are assigned.

74603 If the first argument is `'–'`, the results are unspecified.

74604 The special argument `"––"` immediately following the *set* command name can be used to
74605 delimit the arguments if the first argument begins with `'+'` or `'–'`, or to prevent inadvertent
74606 listing of all shell variables when there are no arguments. The command *set* –– without *argument*
74607 shall unset all positional parameters and set the special parameter `'#'` to zero.

74608 **OPTIONS**

74609 See the DESCRIPTION.

74610 **OPERANDS**

74611 See the DESCRIPTION.

74612 **STDIN**

74613 Not used.

74614 **INPUT FILES**

74615 None.

74616 **ENVIRONMENT VARIABLES**

74617 None.

74618 **ASYNCHRONOUS EVENTS**

74619 Default.

74620 **STDOUT**

74621 See the DESCRIPTION.

74622 **STDERR**

74623 The standard error shall be used only for diagnostic messages.

74624 **OUTPUT FILES**

74625 None.

74626 **EXTENDED DESCRIPTION**

74627 None.

74628 **EXIT STATUS**

74629 Zero.

74630 **CONSEQUENCES OF ERRORS**

74631 Default.

74632 **APPLICATION USAGE**

74633 None.

74634 **EXAMPLES**

74635 Write out all variables and their values:

74636 `set`

74637 Set $1, $2, and $3 and set `"$#"` to 3:

74638 `set c a b`

74639 Turn on the **–x** and **–v** options:

74640 `set –xv`

74641 Unset all positional parameters:

74642 `set ––`

74643 Set $1 to the value of *x*, even if it begins with `'–'` or `'+'`:

74644 `set –– "$x"`

74645 Set the positional parameters to the expansion of *x*, even if *x* expands with a leading `'–'` or `'+'`:

74646 `set –– $x`

74647 **RATIONALE**

74648 The *set* –– form is listed specifically in the SYNOPSIS even though this usage is implied by the
74649 Utility Syntax Guidelines. The explanation of this feature removes any ambiguity about whether
74650 the *set* –– form might be misinterpreted as being equivalent to *set* without any options or
74651 arguments. The functionality of this form has been adopted from the KornShell. In System V, *set*

74652 74653 74654 −− only unsets parameters if there is at least one argument; the only way to unset all parameters is to use *shift*. Using the KornShell version should not affect System V scripts because there should be no reason to issue it without arguments deliberately; if it were issued as, for example:

74655
```
set −− "$@"
```

74656 74657 and there were in fact no arguments resulting from "$@", unsetting the parameters would have no result.

74658 74659 The *set* + form in early proposals was omitted as being an unnecessary duplication of *set* alone and not widespread historical practice.

74660 74661 74662 The *noclobber* option was changed to allow *set* −**C** as well as the *set* −**o** *noclobber* option. The single-letter version was added so that the historical "$−" paradigm would not be broken; see Section 2.5.2 (on page 2302).

74663 The −**h** flag is related to command name hashing. See *hash* (on page 2788).

74664 The following *set* flags were omitted intentionally with the following rationale:

74665 74666 74667 74668 74669 74670 −**k** The −**k** flag was originally added by the author of the Bourne shell to make it easier for users of pre-release versions of the shell. In early versions of the Bourne shell the construct *set name=value* had to be used to assign values to shell variables. The problem with −**k** is that the behavior affects parsing, virtually precluding writing any compilers. To explain the behavior of −**k**, it is necessary to describe the parsing algorithm, which is implementation-defined. For example:

74671
```
set −k; echo name=value
```

74672 and:

74673 74674
```
set −k
echo name=value
```

74675 74676 behave differently. The interaction with functions is even more complex. What is more, the −**k** flag is never needed, since the command line could have been reordered.

74677 74678 74679 74680 −**t** The −**t** flag is hard to specify and almost never used. The only known use could be done with here-documents. Moreover, the behavior with *ksh* and *sh* differs. The reference page says that it exits after reading and executing one command. What is one command? If the input is *date;date*, *sh* executes both *date* commands while *ksh* does only the first.

74681 74682 74683 74684 74685 Consideration was given to rewriting *set* to simplify its confusing syntax. A specific suggestion was that the *unset* utility should be used to unset options instead of using the non-*getopt*( )-able +*option* syntax. However, the conclusion was reached that the historical practice of using +*option* was satisfactory and that there was no compelling reason to modify such widespread historical practice.

74686 74687 74688 74689 74690 The −**o** option was adopted from the KornShell to address user needs. In addition to its generally friendly interface, −**o** is needed to provide the *vi* command line editing mode, for which historical practice yields no single-letter option name. (Although it might have been possible to invent such a letter, it was recognized that other editing modes would be developed and −**o** provides ample name space for describing such extensions.)

74691 74692 74693 Historical implementations are inconsistent in the format used for −**o** option status reporting. The **+o** format without an option-argument was added to allow portable access to the options that can be saved and then later restored using, for instance, a dot script.

74694 Historically, *sh* did trace the command *set* **+x**, but *ksh* did not.

The *ignoreeof* setting prevents accidental logouts when the end-of-file character (typically <control>-D) is entered. A user shall explicitly *exit* to leave the interactive shell.

The *set* **−m** option was added to apply only to the UPE because it applies primarily to interactive use, not shell script applications.

The ability to do asynchronous notification became available in the 1988 version of the KornShell. To have it occur, the user had to issue the command:

```
trap "jobs −n" CLD
```

The C shell provides two different levels of an asynchronous notification capability. The environment variable *notify* is analogous to what is done in *set* **−b** or *set* **−o** *notify*. When set, it notifies the user immediately of background job completions. When unset, this capability is turned off.

The other notification ability comes through the built-in utility *notify*. The syntax is:

```
notify [%job ... ]
```

By issuing *notify* with no operands, it causes the C shell to notify the user asynchronously when the state of the current job changes. If given operands, *notify* asynchronously informs the user of changes in the states of the specified jobs.

To add asynchronous notification to the POSIX shell, neither the KornShell extensions to *trap*, nor the C shell *notify* environment variable seemed appropriate (*notify* is not a proper POSIX environment variable name).

The *set* **−b** option was selected as a compromise.

The *notify* built-in was considered to have more functionality than was required for simple asynchronous notification.

FUTURE DIRECTIONS

None.

XBD Section 4.22 (on page 118), Section 12.2 (on page 215)

CHANGE HISTORY

Issue 6

The obsolescent *set* command name followed by '−' has been removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The *nolog* option is added to *set* **−o**.

IEEE PASC Interpretation 1003.2 #167 is applied, clarifying that the options default also takes into account the description of the option.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/8 is applied, changing the square brackets in the example in RATIONALE to be in bold, which is the typeface used for optional items.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first argument is '–'.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

XSI shading is removed from the **–h** functionality. +

74741 **NAME**

74742 shift — shift positional parameters

74743 **SYNOPSIS**

74744 `shift [`*n*`]`

74745 **DESCRIPTION**

74746 The positional parameters shall be shifted. Positional parameter 1 shall be assigned the value of
74747 parameter (1+*n*), parameter 2 shall be assigned the value of parameter (2+*n*), and so on. The
74748 parameters represented by the numbers `"$#"` down to `"$#–n+1"` shall be unset, and the
74749 parameter `'#'` is updated to reflect the new number of positional parameters.

74750 The value *n* shall be an unsigned decimal integer less than or equal to the value of the special
74751 parameter `'#'`. If *n* is not given, it shall be assumed to be 1. If *n* is 0, the positional and special
74752 parameters are not changed.

74753 **OPTIONS**

74754 None.

74755 **OPERANDS**

74756 See the DESCRIPTION.

74757 **STDIN**

74758 Not used.

74759 **INPUT FILES**

74760 None.

74761 **ENVIRONMENT VARIABLES**

74762 None.

74763 **ASYNCHRONOUS EVENTS**

74764 Default.

74765 **STDOUT**

74766 Not used.

74767 **STDERR**

74768 The standard error shall be used only for diagnostic messages.

74769 **OUTPUT FILES**

74770 None.

74771 **EXTENDED DESCRIPTION**

74772 None.

74773 **EXIT STATUS**

74774 The exit status is >0 if *n*>$#; otherwise, it is zero.

74775 **CONSEQUENCES OF ERRORS**

74776 Default.

74777 **APPLICATION USAGE**

74778 None.

74779 **EXAMPLES**

74780
```
$ set a b c d e
```
74781
```
$ shift 2
```
74782
```
$ echo $*
```
74783
```
c d e
```

74784 **RATIONALE**

74785 None.

74786 **FUTURE DIRECTIONS**

74787 None.

74788 **SEE ALSO**

74789 Section 2.14 (on page 2334)

74790 **CHANGE HISTORY**

74791 **Issue 6**

74792 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
74793 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
74794 behavior is intended.

74795 **NAME**

74796 times — write process times

74797 **SYNOPSIS**

74798
```
times
```

74799 **DESCRIPTION**

74800 The *times* utility shall write the accumulated user and system times for the shell and for all of its
74801 child processes, in the following POSIX locale format:

74802
```
"%dm%fs %dm%fs\n%dm%fs %dm%fs\n", <shell user minutes>,
    <shell user seconds>, <shell system minutes>,
    <shell system seconds>, <children user minutes>,
    <children user seconds>, <children system minutes>,
    <children system seconds>
```

74807 The four pairs of times shall correspond to the members of the **<sys/times.h> tms** structure
74808 (defined in XBD Chapter 13, on page 219) as returned by *times*(): *tms_utime*, *tms_stime*,
74809 *tms_cutime*, and *tms_cstime*, respectively.

74810 **OPTIONS**

74811 None.

74812 **OPERANDS**

74813 None.

74814 **STDIN**

74815 Not used.

74816 **INPUT FILES**

74817 None.

74818 **ENVIRONMENT VARIABLES**

74819 None.

74820 **ASYNCHRONOUS EVENTS**

74821 Default.

74822 **STDOUT**

74823 See the DESCRIPTION.

74824 **STDERR**

74825 The standard error shall be used only for diagnostic messages.

74826 **OUTPUT FILES**

74827 None.

74828 **EXTENDED DESCRIPTION**

74829 None.

74830 **EXIT STATUS**

74831 Zero.

74832 **CONSEQUENCES OF ERRORS**

74833 Default.

APPLICATION USAGE

None.

EXAMPLES

```
$ times
0m0.43s 0m1.11s
8m44.18s 1m43.23s
```

RATIONALE

The *times* special built-in from the Single UNIX Specification is now required for all conforming shells.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/9 is applied, changing text in the DESCRIPTION from: "Write the accumulated user and system times for the shell and for all of its child processes ..." to: "The *times* utility shall write the accumulated user and system times for the shell and for all of its child processes ...".

74854 **NAME**

74855 trap — trap signals

74856 **SYNOPSIS**

74857 `trap` *n* `[`*condition*`...]`

74858 `trap [`*action condition*`...]`

74859 **DESCRIPTION**

74860 If the first operand is an unsigned decimal integer, the shell shall treat all operands as
74861 conditions, and shall reset each condition to the default value. Otherwise, if there are operands,
74862 the first is treated as an action and the remaining as conditions.

74863 If *action* is `'-'`, the shell shall reset each *condition* to the default value. If *action* is null (`""`), the
74864 shell shall ignore each specified *condition* if it arises. Otherwise, the argument *action* shall be read
74865 and executed by the shell when one of the corresponding conditions arises. The action of *trap*
74866 shall override a previous action (either default action or one explicitly set). The value of `"$?"`
74867 after the *trap* action completes shall be the value it had before *trap* was invoked.

74868 The condition can be EXIT, 0 (equivalent to EXIT), or a signal specified using a symbolic name,
74869 without the SIG prefix, as listed in the tables of signal names in the **<signal.h>** header defined in
74870 XBD Chapter 13 (on page 219); for example, HUP, INT, QUIT, TERM. Implementations may
74871 permit names with the SIG prefix or ignore case in signal names as an extension. Setting a trap
74872 for SIGKILL or SIGSTOP produces undefined results.

74873 The environment in which the shell executes a *trap* on EXIT shall be identical to the environment
74874 immediately after the last command executed before the *trap* on EXIT was taken.

74875 Each time *trap* is invoked, the *action* argument shall be processed in a manner equivalent to:

74876 `eval` *action*

74877 Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although
74878 no error need be reported when attempting to do so. An interactive shell may reset or catch
74879 signals ignored on entry. Traps shall remain in place for a given shell until explicitly changed
74880 with another *trap* command.

74881 When a subshell is entered, traps that are not being ignored are set to the default actions. This
74882 does not imply that the *trap* command cannot be used within the subshell to set new traps.

74883 The *trap* command with no arguments shall write to standard output a list of commands
74884 associated with each condition. The format shall be:

74885 `"trap -- %s %s ...\n", <`*action*`>, <`*condition*`> ...`

74886 The shell shall format the output, including the proper use of quoting, so that it is suitable for
74887 reinput to the shell as commands that achieve the same trapping results. For example:

74888 `save_traps=$(trap)`
74889 `...`
74890 `eval "$save_traps"`

74891 XSI XSI-conformant systems also allow numeric signal numbers for the conditions corresponding to
74892 the following signal names:

74893 1 SIGHUP

74894 2 SIGINT

74895 3 SIGQUIT

74896	6	SIGABRT
74897	9	SIGKILL
74898	14	SIGALRM
74899	15	SIGTERM

74900 The *trap* special built-in shall conform to XBD Section 12.2 (on page 215).

74901 **OPTIONS**

74902 None.

74903 **OPERANDS**

74904 See the DESCRIPTION.

74905 **STDIN**

74906 Not used.

74907 **INPUT FILES**

74908 None.

74909 **ENVIRONMENT VARIABLES**

74910 None.

74911 **ASYNCHRONOUS EVENTS**

74912 Default.

74913 **STDOUT**

74914 See the DESCRIPTION.

74915 **STDERR**

74916 The standard error shall be used only for diagnostic messages.

74917 **OUTPUT FILES**

74918 None.

74919 **EXTENDED DESCRIPTION**

74920 None.

74921 **EXIT STATUS**

74922 XSI If the trap name or number is invalid, a non-zero exit status shall be returned; otherwise, zero
74923 XSI shall be returned. For both interactive and non-interactive shells, invalid signal names or
74924 numbers shall not be considered a syntax error and do not cause the shell to abort.

74925 **CONSEQUENCES OF ERRORS**

74926 Default.

74927 **APPLICATION USAGE**

74928 None.

74929 **EXAMPLES**

74930 Write out a list of all traps and actions:

74931 ```
trap
```

74932 Set a trap so the *logout* utility in the directory referred to by the *HOME* environment variable
74933 executes when the shell terminates:

74934 ```
trap '$HOME/logout' EXIT
```

74935 or:

```
trap '$HOME/logout' 0
```

Unset traps on INT, QUIT, TERM, and EXIT:

```
trap - INT QUIT TERM EXIT
```

RATIONALE

Implementations may permit lowercase signal names as an extension. Implementations may also accept the names with the SIG prefix; no known historical shell does so. The *trap* and *kill* utilities in this volume of POSIX.1-200x are now consistent in their omission of the SIG prefix for signal names. Some *kill* implementations do not allow the prefix, and *kill* **–l** lists the signals without prefixes.

Trapping SIGKILL or SIGSTOP is syntactically accepted by some historical implementations, but it has no effect. Portable POSIX applications cannot attempt to trap these signals.

The output format is not historical practice. Since the output of historical *trap* commands is not portable (because numeric signal values are not portable) and had to change to become so, an opportunity was taken to format the output in a way that a shell script could use to save and then later reuse a trap if it wanted.

The KornShell uses an **ERR** trap that is triggered whenever *set* **–e** would cause an exit. This is allowable as an extension, but was not mandated, as other shells have not used it.

The text about the environment for the EXIT trap invalidates the behavior of some historical versions of interactive shells which, for example, close the standard input before executing a trap on 0. For example, in some historical interactive shell sessions the following trap on 0 would always print `"--"`:

```
trap 'read foo; echo "-$foo-"' 0
```

The command:

```
trap '$cmd' 0
```

causes the contents of the shell variable *cmd* to be executed as a command when the shell exits. Using double-quotes instead of single-quotes might have unexpected behavior, since in theory the value of *cmd* might be a decimal integer which would be treated as a condition, not an action; or *cmd* might begin with `'-'`. Also, using double-quotes will cause the value of *cmd* to be expanded twice, once when *trap* is executed, and once when the condition arises.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

Issue 6

XSI-conforming implementations provide the mapping of signal names to numbers given above (previously this had been marked obsolescent). Other implementations need not provide this optional mapping.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.4). No change in behavior is intended.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #116 is applied.

74981 **NAME**

74982 unset — unset values and attributes of variables and functions

74983 **SYNOPSIS**

74984 `unset [-fv] name...`

74985 **DESCRIPTION**

74986 Each variable or function specified by *name* shall be unset.

74987 If **-v** is specified, *name* refers to a variable name and the shell shall unset it and remove it from
74988 the environment. Read-only variables cannot be unset.

74989 If **-f** is specified, *name* refers to a function and the shell shall unset the function definition.

74990 If neither **-f** nor **-v** is specified, *name* refers to a variable; if a variable by that name does not
74991 exist, it is unspecified whether a function by that name, if any, shall be unset.

74992 Unsetting a variable or function that was not previously set shall not be considered an error and
74993 does not cause the shell to abort.

74994 The *unset* special built-in shall support XBD Section 12.2 (on page 215).

74995 Note that:

74996 `VARIABLE=`

74997 is not equivalent to an *unset* of **VARIABLE**; in the example, **VARIABLE** is set to `""`. Also, the
74998 variables that can be *unset* should not be misinterpreted to include the special parameters (see
74999 Section 2.5.2, on page 2302).

75000 **OPTIONS**

75001 See the DESCRIPTION.

75002 **OPERANDS**

75003 See the DESCRIPTION.

75004 **STDIN**

75005 Not used.

75006 **INPUT FILES**

75007 None.

75008 **ENVIRONMENT VARIABLES**

75009 None.

75010 **ASYNCHRONOUS EVENTS**

75011 Default.

75012 **STDOUT**

75013 Not used.

75014 **STDERR**

75015 The standard error shall be used only for diagnostic messages.

75016 **OUTPUT FILES**

75017 None.

75018 **EXTENDED DESCRIPTION**

75019 None.

75020 **EXIT STATUS**

75021 0 All *name* operands were successfully unset.

75022 >0 At least one *name* could not be unset.

75023 **CONSEQUENCES OF ERRORS**

75024 Default.

75025 **APPLICATION USAGE**

75026 None.

75027 **EXAMPLES**

75028 Unset *VISUAL* variable:

75029 `unset –v VISUAL`

75030 Unset the functions **foo** and **bar**:

75031 `unset –f foo bar`

75032 **RATIONALE**

75033 Consideration was given to omitting the **–f** option in favor of an *unfunction* utility, but the
75034 standard developers decided to retain historical practice.

75035 The **–v** option was introduced because System V historically used one name space for both
75036 variables and functions. When *unset* is used without options, System V historically unset either a
75037 function or a variable, and there was no confusion about which one was intended. A portable
75038 POSIX application can use *unset* without an option to unset a variable, but not a function; the **–f**
75039 option must be used.

75040 **FUTURE DIRECTIONS**

75041 None.

75042 **SEE ALSO**

75043 Section 2.14 (on page 2334)

75044 XBD Section 12.2 (on page 215)

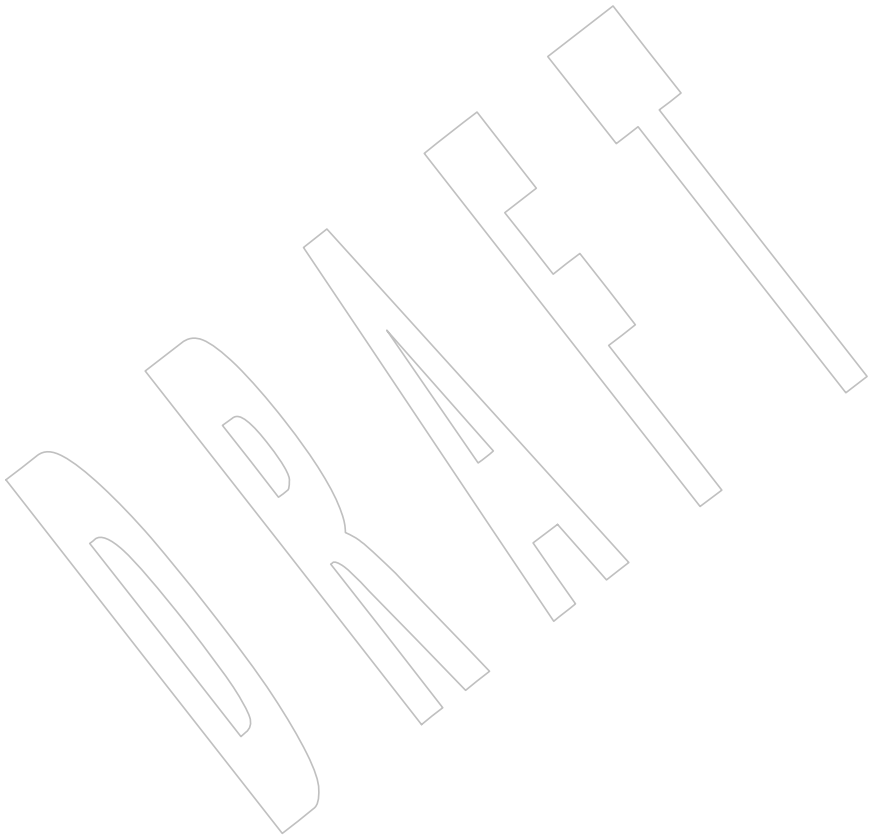
75045 **CHANGE HISTORY**

75046 **Issue 6**

75047 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page
75048 sections use terms as described in the Utility Description Defaults (Section 1.4). No change in
75049 behavior is intended.

75050 **Issue 7**

75051 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.



75052 *Chapter 3*

75053 # *Batch Environment Services*

75054 OB BE This chapter describes the services and utilities that shall be implemented on all systems that
75055 claim conformance to the Batch Environment Services and Utilities option. The functionality
75056 described in this section shall be provided on implementations that support the Batch
75057 Environment Services and Utilities option (and the rest of this section is not further shaded for
75058 this option).

75059 Note that the Batch Environment Services and Utilities option is marked obsolescent in Issue 7.

75060 ## 3.1 General Concepts

75061 -

75062 ### 3.1.1 Batch Client-Server Interaction

75063 Batch jobs are created and managed by batch servers. A batch client interacts with a batch server
75064 to access batch services on behalf of the user. In order to use batch services, a user must have
75065 access to a batch client.

75066 A batch server is a computational entity, such as a daemon process, that provides batch services.
75067 Batch servers route, queue, modify, and execute batch jobs on behalf of batch clients.

75068 The batch utilities described in this volume of POSIX.1-200x (and listed in Table 3-1) are clients
75069 of batch services; they allow users to perform actions on the job such as creating, modifying, and
75070 deleting batch jobs from a shell command line. Although these batch utilities may be said to
75071 accomplish certain services, they actually obtain services on behalf of a user by means of
75072 requests to batch servers.

75073 **Table 3-1** Batch Utilities

75074	*qalter*	*qmove*	*qrls*	*qstat*
75075	*qdel*	*qmsg*	*qselect*	*qsub*
75076	*qhold*	*qrerun*	*qsig*	

75077 Client-server interaction takes place by means of the batch requests defined in this chapter.
75078 Because direct access to batch jobs and queues is limited to batch servers, clients and servers of
75079 different implementations can interoperate, since dependencies on private structures for batch
75080 jobs and queues are limited to batch servers. Also, batch servers may be clients of other batch
75081 servers.

3.1.2 Batch Queues

Two types of batch queue are described: routing queues and execution queues. When a batch job is placed in a routing queue, it is a candidate for routing. A batch job is removed from routing queues under the following conditions:

- The batch job has been routed to another queue.
- The batch job has been deleted from the batch queue.
- The batch job has been aborted.

When a batch job is placed in an execution queue, it is a candidate for execution.

A batch job is removed from an execution queue under the following conditions:

- The batch job has been executed and exited.
- The batch job has been aborted.
- The batch job has been deleted from the batch queue.
- The batch job has been moved to another queue.

Access to a batch queue is limited to the batch server that manages the batch queue. Clients never access a batch queue or a batch job directly, either to read or write information; all client access to batch queues or jobs takes place through batch servers.

3.1.3 Batch Job Creation

When a batch server creates a batch job on behalf of a client, it shall assign a batch job identifier to the job. A batch job identifier consists of both a sequence number that is unique among the sequence numbers issued by that server and the name of the server. Since the batch server name is unique within a name space, the job identifier is likewise unique within the name space.

The batch server that creates a batch job shall return the batch server-assigned job identifier to the client that requested the job creation. If the batch server routes or moves the job to another server, it sends the job identifier with the job. Once assigned, the job identifier of a batch job shall never change.

3.1.4 Batch Job Tracking

Since a batch job may be moved after creation, the batch server name component of the job identifier need not indicate the location of the job. An implementation may provide a batch job tracking mechanism, in which case the user generally does not need to know the location of the job. However, an implementation need not provide a batch job tracking mechanism, in which case the user must find routed jobs by probing the possible destinations.

3.1.5 Batch Job Routing

To route a batch job, a batch server either moves the job to some other queue that is managed by the batch server, or requests that some other batch server accept the job.

Each routing queue has one or more queues to which it can route batch jobs. The batch server administrator creates routing queues.

A batch server may route a batch job from a routing queue to another routing queue. Batch servers shall prevent or otherwise handle cases of circular routing paths. As a deferred service, a batch server routes jobs from the routing queues that it manages. The algorithm by which a batch server selects a batch queue to which to route a batch job is implementation-defined.

A batch job need not be eligible for routing to all the batch queues fed by the routing queue from which it is routed. A batch server that has been asked to accept the job may reject the request if the job requires resources that are unavailable to that batch server, or if the client is not authorized to access the batch server.

Batch servers may route high-priority jobs before low-priority jobs, but, on other than overloaded systems, the effect may be imperceptible to the user. If all the batch servers fed by a routing queue reject requests to accept the job for reasons that are permanent, the batch server that manages the job shall abort the job. If all or some rejections are temporary, the batch server should try to route the job again at some later point.

The reasons for rejecting a batch job are implementation-defined.

The reasons for which the routing should be retried later and the reasons for which the job should be aborted are also implementation-defined.

3.1.6 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path* attribute of the job. The script shall be passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state. The primary program that is executed by a batch job is typically, though not necessarily, a shell program.

A batch server shall execute eligible jobs as a deferred service—no client request is necessary once the batch job is created and eligible. However, the attributes of a batch job, such as the job hold type, may render the job ineligible. A batch server shall scan the execution queues that it manages for jobs that are eligible for execution. The algorithm by which the batch server selects eligible jobs for execution is implementation-defined.

As part of creating the process for the batch job, the batch server shall open the standard output and standard error streams of the session.

The attributes of a batch job may indicate that the batch server executing the job shall send mail to a list of users at the time it begins execution of the job.

3.1.7 Batch Job Exit

When the session leader of an executing job terminates, the job exits. As part of exiting a batch job, the batch server that manages the job shall remove the job from the batch queue in which it resides. The server shall transfer output files of the job to a location described by the attributes of the job.

The attributes of a batch job may indicate that the batch server managing the job shall send mail to a list of users at the time the job exits.

3.1.8 Batch Job Abort

A batch server shall abort jobs for which a required deferred service cannot be performed. The attributes of a batch job may indicate that the batch server that aborts the job shall send mail to a list of users at the time it aborts the job.

3.1.9 Batch Authorization

Clients, such as the batch environment utilities (marked BE), access batch services by means of requests to one or more batch servers. To acquire the services of any given batch server, the user identifier under which the client runs must be authorized to use that batch server.

The user with an associated user name that creates a batch job shall own the job and can perform actions such as read, modify, delete, and move.

A user identifier of the same value at a different host need not be the same user. For example, user name *smith* at host **alpha** may or may not represent the same person as user name *smith* at host **beta**. Likewise, the same person may have access to different user names on different hosts.

An implementation may optionally provide an authorization mechanism that permits one user name to access jobs under another user name.

A process on a client host may be authorized to run processes under multiple user names at a batch server host. Where appropriate, the utilities defined in this volume of POSIX.1-200x provide a means for a user to choose from among such user names when creating or modifying a batch job.

3.1.10 Batch Administration

The processing of a batch job by a batch server is affected by the attributes of the job. The processing of a batch job may also be affected by the attributes of the batch queue in which the job resides and by the status of the batch server that manages the job. See also XBD Chapter 3 (on page 33) for batch definitions.

3.1.11 Batch Notification

Whereas batch servers are persistent entities, clients are often transient. For example, the *qsub* utility creates a batch job and exits. For this reason, batch servers notify users of batch job events by sending mail to the user that owns the job, or to other designated users.

3.2 Batch Services

The presence of Batch Environment Services and Utilities option services is indicated by the configuration variable POSIX2_PBS. A conforming batch server provides services as defined in this section.

A batch server shall provide batch services in two ways:

1. The batch server provides a service at the request of a client.
2. The batch server provides a deferred service as a result of a change in conditions monitored by the batch server.

If a batch server cannot complete a request, it shall reject the request. If a batch server cannot complete a deferred service for a batch job, the batch server shall abort the batch job. Table 3-2 is a summary of environment variables that shall be supported by an implementation of the batch server and utilities.

Table 3-2 Environment Variable Summary

Variable	Description
PBS_DPREFIX	Defines the directive prefix (see *qsub*)
PBS_ENVIRONMENT	Batch Job is batch or interactive (see Section 3.2.2.1)
PBS_JOBID	The *job_identifier* attribute of job (see Section 3.2.3.8)
PBS_JOBNAME	The *job_name* attribute of job (see Section 3.2.3.8)
PBS_O_HOME	Defines the *HOME* of the batch client (see *qsub*)
PBS_O_HOST	Defines the host name of the batch client (see *qsub*)
PBS_O_LANG	Defines the *LANG* of the batch client (see *qsub*)
PBS_O_LOGNAME	Defines the *LOGNAME* of the batch client (see *qsub*)
PBS_O_MAIL	Defines the *MAIL* of the batch client (see *qsub*)
PBS_O_PATH	Defines the *PATH* of the batch client (see *qsub*)
PBS_O_QUEUE	Defines the submit queue of the batch client (see *qsub*)
PBS_O_SHELL	Defines the *SHELL* of the batch client (see *qsub*)
PBS_O_TZ	Defines the *TZ* of the batch client (see *qsub*)
PBS_O_WORKDIR	Defines the working directory of the batch client (see *qsub*)
PBS_QUEUE	Defines the initial execution queue (see Section 3.2.2.1)

3.2.1 Batch Job States

A batch job shall always be in one of the following states: QUEUED, RUNNING, HELD, WAITING, EXITING, or TRANSITING. The state of a batch job determines the types of requests that the batch server that manages the batch job can accept for the batch job. A batch server shall change the state of a batch job either in response to service requests from clients or as a result of deferred services, such as job execution or job routing.

A batch job that is in the QUEUED state resides in a queue but is still pending either execution or routing, depending on the queue type.

A batch server that queues a batch job in a routing queue shall put the batch job in the QUEUED state. A batch server that puts a batch job in an execution queue, but has not yet executed the batch job, shall put the batch job in the QUEUED state. A batch job that resides in an execution queue and is executing is defined to be in the RUNNING state. While a batch job is in the RUNNING state, a session leader is associated with the batch job.

A batch job that resides in an execution queue, but is ineligible to run because of a hold attribute, is defined to be in the HELD state.

A batch job that is not held, but must wait until a future date and time before executing, is defined to be in the WAITING state.

When the session leader associated with a running job exits, the batch job shall be placed in the EXITING state.

A batch job for which the session leader has terminated is defined to be in the EXITING state, and the batch server that manages such a batch job cannot accept job modification requests that affect the batch job. While a batch job is in the EXITING state, the batch server that manages the batch job is staging output files and notifying clients of job completion. Once a batch job has exited, it no longer exists as an object managed by a batch server.

A batch job that is being moved from a routing queue to another queue is defined to be in the TRANSITING state.

When a batch job in a routing queue has been selected to be moved to a new destination, then the batch job shall be in either the QUEUED state or the TRANSITING state, depending on the batch server implementation.

Batch jobs with either an *Execution_Time* attribute value set in the future or a *Hold_Types* attribute of value not equal to NO_HOLD, or both, may be routed or held in the routing queue. The treatment of jobs with the *Execution_Time* or *Hold_Types* attributes in a routing queue is implementation-defined.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has a *Hold_Types* attribute value of other than NO_HOLD, then the job should be in the HELD state.

Note: The effect of a hold upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A *Hold_Types* attribute value of NO_HOLD
- An *Execution_Time* attribute in the past

then the batch job shall be in the QUEUED state.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A *Hold_Types* attribute value of NO_HOLD
- An *Execution_Time* attribute in the future

then the batch job may be in the WAITING state.

Note: The effect of a future execution time upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.

Table 3-3 describes the next state of a batch job, given the current state of the batch job and the type of request. Table 3-4 (on page 2383) describes the response of a batch server to a request, given the current state of the batch job and the type of request.

3.2.2 Deferred Batch Services

This section describes the deferred services performed by batch servers: job execution, job routing, job exit, job abort, and the rerunning of jobs after a restart.

3.2.2.1 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the *Shell_Path_List* attribute of the batch job. The script is passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state.

Table 3-3 Next State Table

Request Type	Current State						
	X	**Q**	**R**	**H**	**W**	**E**	**T**
Queue Batch Job Request	Q	e	e	e	e	e	e

e Error

A batch server that has an execution queue containing jobs is said to own the queue and manage the batch jobs in that queue. A batch server that has been started shall execute the batch jobs in the execution queues owned by the batch server. The batch server shall schedule for execution those jobs in the execution queues that are in the QUEUED state. The algorithm for scheduling jobs is implementation-defined.

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, an environment variable named *PBS_ENVIRONMENT*, the value of which is the string PBS_BATCH encoded in the portable character set.

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, an environment variable named *PBS_QUEUE*, the value of which is the name of the execution queue of the batch job encoded in the portable character set.

To rerun a batch job is to requeue a batch job that is currently executing and then kill the session leader of the executing job by sending a SIGKILL prior to completion; see Section 3.2.3.11 (on page 2395). A batch server that reruns a batch job shall append the standard output and standard error files of the batch job to the corresponding files of the previous execution, if they exist, with appropriate annotation. If either file does not exist, that file shall be created as in normal execution.

Table 3-4 Results/Output Table

Request Type	Current State

Legend

O OK

e Error message

The execution of a batch job by a batch server shall be controlled by job, queue, and server attributes, as defined in this section.

Account_Name Attribute

Batch accounting is an optional feature of batch servers. If a batch server implements accounting, the statements in this section apply and the configuration variable POSIX2_PBS_ACCOUNTING shall be set to 1.

A batch server that executes a batch job shall charge the account named in the *Account_Name* attribute of the batch job for resources consumed by the batch job.

If the *Account_Name* attribute of the batch job is absent from the batch job attribute list or is altered while the batch job is in execution, the batch server action is implementation-defined.

Checkpoint Attribute

Batch checkpointing is an optional feature of batch servers. If a batch server implements checkpointing, the statements in this section apply and the configuration variable POSIX2_PBS_CHECKPOINT shall be set to 1.

There are two attributes associated with the checkpointing feature: *Checkpoint* and *Minimum_Cpu_Interval*. *Checkpoint* is a batch job attribute, while *Minimum_Cpu_Interval* is a queue attribute. An implementation that does not support checkpointing shall support the *Checkpoint* job attribute to the extent that the batch server shall maintain and pass this attribute to other servers.

The behavior of a batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_UNSPECIFIED is implementation-defined. A batch server that executes a batch job for which the value of the *Checkpoint* attribute is NO_CHECKPOINT shall

not checkpoint the batch job.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_SHUTDOWN shall checkpoint the batch job only when the batch server accepts a request to shut down during the time when the batch job is in the RUNNING state.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is CHECKPOINT_AT_MIN_CPU_INTERVAL shall checkpoint the batch job at the interval specified by the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected. The *Minimum_Cpu_Interval* attribute shall be specified in units of CPU minutes.

A batch server that executes a batch job for which the value of the *Checkpoint* attribute is an unsigned integer shall checkpoint the batch job at an interval that is the value of either the *Checkpoint* attribute, or the *Minimum_Cpu_Interval* attribute of the queue for which the batch job has been selected, whichever is greater. Both intervals shall be in units of CPU minutes. When the *Minimum_Cpu_Interval* attribute is greater than the *Checkpoint* attribute, the batch job shall write a warning message to the standard error stream of the batch job.

Error_Path Attribute

The *Error_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*. When the *Join_Path* attribute of the batch job is set to the value FALSE and the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_ERROR, a batch server that executes a batch job shall perform one of the following actions:

- Set the standard error stream of the session leader of the batch job to the path described by the value of the *Error_Path* attribute of the batch job.
- Buffer the standard error of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the *Error_Path* attribute of the batch job.

Applications shall not rely on having access to the standard error of a batch job prior to the completion of the batch job.

When the *Error_Path* attribute does not specify a host name, then the batch server shall retain the standard error of the batch job on the host of execution.

When the *Error_Path* attribute does specify a host name and the *Keep_Files* attribute does not contain the value KEEP_STD_ERROR, then the final destination of the standard error of the batch job shall be on the host whose host name is specified.

If the path indicated by the value of the *Error_Path* attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.

When the batch server buffers the standard error of the batch job and the file cannot be opened for write upon completion of the batch job, then the server shall place the standard error in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the *mailx* utility.

If a batch server that does not buffer the standard error cannot open the standard error path of the batch job for write access, then the batch server shall abort the batch job.

75405 **Execution_Time Attribute**

75406 A batch server shall not execute a batch job before the time represented by the value of the
75407 *Execution_Time* attribute of the batch job. The *Execution_Time* attribute is defined in seconds since
75408 the Epoch.

75409 **Hold_Types Attribute**

75410 A batch server shall support the following hold types:

75411 s Can be set or released by a user with at least a privilege level of batch administrator
75412 (SYSTEM).

75413 o Can be set or released by a user with at least a privilege level of batch operator
75414 (OPERATOR).

75415 u Can be set or released by the user with at least a privilege level of user, where the user is
75416 defined in the *Job_Owner* attribute (USER).

75417 n Indicates that none of the *Hold_Types* attributes are set (NO_HOLD).

75418 An implementation may define other hold types. Any additional hold types, how they are
75419 specified, their internal representation, their behavior, and how they affect the behavior of other
75420 utilities are implementation-defined.

75421 The value of the *Hold_Types* attribute shall be the union of the valid hold types (`'s'`, `'o'`, `'u'`,
75422 and any implementation-defined hold types), or `'n'`.

75423 A batch server shall not execute a batch job if the *Hold_Types* attribute of the batch job has a
75424 value other than NO_HOLD. If the *Hold_Types* attribute of the batch job has a value other than
75425 NO_HOLD, the batch job shall be in the HELD state.

75426 **Job_Owner Attribute**

75427 The *Job_Owner* attribute consists of a pair of user name and host name values of the form:

75428 `username@hostname`

75429 A batch server that accepts a *Queue Batch Job Request* shall set the *Job_Owner* attribute to a string
75430 that is the *username@hostname* of the user who submitted the job.

75431 **Join_Path Attribute**

75432 A batch server that executes a batch job for which the value of the *Join_Path* attribute is TRUE
75433 shall ignore the value of the *Error_Path* attribute and merge the standard error of the batch job
75434 with the standard output of the batch job.

75435 **Keep_Files Attribute**

75436 A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes
75437 the value KEEP_STD_OUTPUT shall retain the standard output of the batch job on the host
75438 where execution occurs. The standard output shall be retained in the home directory of the user
75439 under whose user ID the batch job is executed and the filename shall be the default filename for
75440 the standard output as defined under the **–o** option of the *qsub* utility. The *Output_Path* attribute
75441 is not modified.

75442 A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes
75443 the value KEEP_STD_ERROR shall retain the standard error of the batch job on the host where
75444 execution occurs. The standard error shall be retained in the home directory of the user under
75445 whose user ID the batch job is executed and the filename shall be the default filename for

75446 standard error as defined under the **–e** option of the *qsub* utility. The *Error_Path* attribute is not
75447 modified.

75448 A batch server that executes a batch job for which the value of the *Keep_Files* attribute includes
75449 values other than KEEP_STD_OUTPUT and KEEP_STD_ERROR shall retain these other files on
75450 the host where execution occurs. These files (with implementation-defined names) shall be
75451 retained in the home directory of the user under whose user identifier the batch job is executed.

75452 **Mail_Points and Mail_Users Attributes**

75453 A batch server that executes a batch job for which one of the values of the *Mail_Points* attribute is
75454 the value MAIL_AT_BEGINNING shall send a mail message to each user account listed in the
75455 *Mail_Users* attribute of the batch job.

75456 The mail message shall contain at least the batch job identifier, queue, and server at which the
75457 batch job currently resides, and the *Job_Owner* attribute.

75458 **Output_Path Attribute**

75459 The *Output_Path* attribute of a running job cannot be changed by a *Modify Batch Job Request*.
75460 When the *Keep_Files* attribute of the batch job does not contain the value KEEP_STD_OUTPUT, a
75461 batch server that executes a batch job shall either:

75462 • Set the standard output stream of the session leader of the batch job to the destination
75463 described by the value of the *Output_Path* attribute of the batch job.

75464 or:

75465 • Buffer the standard output of the session leader of the batch job until completion of the
75466 batch job, and when the batch job exits return the contents to the destination described by
75467 the value of the *Output_Path* attribute of the batch job.

75468 When the *Output_Path* attribute does not specify a host name, then the batch server shall retain
75469 the standard output of the batch job on the host of execution.

75470 When the *Keep_Files* attribute does not contain the value KEEP_STD_OUTPUT and the
75471 *Output_Path* attribute does specify a host name, then the final destination of the standard output
75472 of the batch job shall be on the host specified.

75473 If the path specified in the *Output_Path* attribute of the batch job is a relative path, the batch
75474 server shall expand the path relative to the home directory of the user on the host to which the
75475 file is being returned.

75476 Whether or not the batch server buffers the standard output of the batch job until completion of
75477 the batch job is implementation-defined. Applications shall not rely on having access to the
75478 standard output of a batch job prior to the completion of the batch job.

75479 When the batch server does buffer the standard output of the batch job and the file cannot be
75480 opened for write upon completion of the batch job, then the batch server shall place the standard
75481 output in an implementation-defined location and notify the user of the location via mail. It shall
75482 be possible for the user to process this mail using the *mailx* utility.

75483 If a batch server that does not buffer the standard output cannot open the standard output path
75484 of the batch job for write access, then the batch server shall abort the batch job.

75485 **Priority Attribute**

75486 A batch server implementation may choose to preferentially execute a batch job based on the
75487 *Priority* attribute. The interpretation of the batch job *Priority* attribute by a batch server is
75488 implementation-defined. If an implementation uses the *Priority* attribute, it shall interpret larger
75489 values of the *Priority* attribute to mean the batch job shall be preferentially selected for execution.

75490 **Rerunable Attribute**

75491 A batch job that began execution but did not complete, because the batch server either shut
75492 down or terminated abnormally, shall be requeued if the *Rerunable* attribute of the batch job has
75493 the value TRUE.

75494 If a batch job, which was requeued after beginning execution but prior to completion, has a valid
75495 checkpoint file and the batch server supports checkpointing, then the batch job shall be restarted
75496 from the last valid checkpoint.

75497 If the batch job cannot be restarted from a checkpoint, then when a batch job has a *Rerunable*
75498 attribute value of TRUE and was requeued after beginning execution but prior to completion,
75499 the batch server shall place the batch job into execution at the beginning of the job.

75500 When a batch job has a *Rerunable* attribute value other than TRUE and was requeued after
75501 beginning execution but prior to completion, and the batch job cannot be restarted from a
75502 checkpoint, then the batch server shall abort the batch job.

75503 **Resource_List Attribute**

75504 A batch server that executes a batch job shall establish the resource limits of the session leader of
75505 the batch job according to the values of the *Resource_List* attribute of the batch job. Resource
75506 limits shall be enforced by an implementation-defined method.

75507 **Shell_Path_List Attribute**

75508 The *Shell_Path_List* job attribute consists of a list of pairs of pathname and host name values. The
75509 host name component can be omitted, in which case the pathname serves as the default
75510 pathname when a batch server cannot find the name of the host on which it is running in the list.

75511 A batch server that executes a batch job shall select, from the value of the *Shell_Path_List*
75512 attribute of the batch job, a pathname where the shell to execute the batch job shall be found.
75513 The batch server shall select the pathname, in order of preference, according to the following
75514 methods:

75515 • Select the pathname that contains the name of the host on which the batch server is
75516 running.

75517 • Select the pathname for which the host name has been omitted.

75518 • Select the pathname for the login shell of the user under which the batch job is to execute.

75519 If the shell path value selected is an invalid pathname, the batch server shall abort the batch job.

75520 If the value of the selected pathname from the *Shell_Path_List* attribute of the batch job
75521 represents a partial path, the batch server shall expand the path relative to a path that is
75522 implementation-defined.

75523 The batch server that executes the batch job shall execute the program that was selected from the
75524 *Shell_Path_List* attribute of the batch job. The batch server shall pass the path to the script of the
75525 batch job as the first argument to the shell program.

75526 **User_List Attribute**

75527 The *User_List* job attribute consists of a list of pairs of user name and host name values. The host
75528 name component can be omitted, in which case the user name serves as a default when a batch
75529 server cannot find the name of the host on which it is running in the list.

75530 A batch server that executes a batch job shall select, from the value of the *User_List* attribute of
75531 the batch job, a user name under which to create the session leader. The server shall select the
75532 user name, in order of preference, according to the following methods:

75533 • Select the user name of a value that contains the name of the host on which the batch
75534 server executes.

75535 • Select the user name of a value for which the host name has been omitted.

75536 • Select the user name from the *Job_Owner* attribute of the batch job.

75537 **Variable_List Attribute**

75538 A batch server that executes a batch job shall create, in the environment of the session leader of
75539 the batch job, each environment variable listed in the *Variable_List* attribute of the batch job, and
75540 set the value of each such environment variable to that of the corresponding variable in the
75541 variable list.

75542 *3.2.2.2 Batch Job Routing*

75543 To route a batch job is to select a queue from a list and move the batch job to that queue.

75544 A batch server that has routing queues, which have been started, shall route the jobs in the
75545 routing queues owned by the batch server. A batch server may delay the routing of a batch job.
75546 The algorithm for selecting a batch job and the queue to which it will be routed is
75547 implementation-defined.

75548 When a routing queue has multiple possible destinations specified, then the precedence of the
75549 destinations is implementation-defined.

75550 A batch server that routes a batch job to a queue at another server shall move the batch job into
75551 the target queue with a *Queue Batch Job Request*.

75552 If the target server rejects the *Queue Batch Job Request*, the routing server shall retry routing the
75553 batch job or abort the batch job. A batch server that retries failed routings shall provide a means
75554 for the batch administrator to specify the number of retries and the minimum period of time
75555 between retries. The means by which an administrator specifies the number of retries and the
75556 delay between retries is implementation-defined. When the number of retries specified by the
75557 batch administrator has been exhausted, the batch server shall abort the batch job and perform
75558 the functions of *Batch Job Exit*; see Section 3.2.2.3.

75559 *3.2.2.3 Batch Job Exit*

75560 For each job in the EXITING state, the batch server that exited the batch job shall perform the
75561 following deferred services in the order specified:

75562 1. If buffering standard error, move that file into the location specified by the *Error_Path*
75563 attribute of the batch job.

75564 2. If buffering standard output, move that file into the location specified by the *Output_Path*
75565 attribute of the batch job.

3. If the *Mail_Points* attribute of the batch job includes MAIL_AT_EXIT, send mail to the users listed in the *Mail_Users* attribute of the batch job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, and the *Job_Owner* attribute.
4. Remove the batch job from the queue.

If a batch server that buffers the standard error output cannot return the standard error file to the standard error path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard error file to the batch job owner.
- Save the standard error file and mail the location and name of the file where the standard error is stored to the batch job owner.
- Save the standard error file and notify the user by other implementation-defined means.

If a batch server that buffers the standard output cannot return the standard output file to the standard output path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard output file to the batch job owner.
- Save the standard output file and mail the location and name of the file where the standard output is stored to the batch job owner.
- Save the standard output file and notify the user by other implementation-defined means.

At the conclusion of job exit processing, the batch job is no longer managed by a batch server.

3.2.2.4 *Batch Server Restart*

A batch server that has been either shutdown or terminated abnormally, and has returned to operation, is said to have "restarted".

Upon restarting, a batch server shall requeue those jobs managed by the batch server that were in the RUNNING state at the time the batch server shut down and for which the *Rerunable* attribute of the batch job has the value TRUE.

Queues are defined to be non-volatile. A batch server shall store the content of queues that it controls in such a way that server and system shutdowns do not erase the content of the queues.

3.2.2.5 *Batch Job Abort*

A batch server that cannot perform a deferred service for a batch job shall abort the batch job.

A batch server that aborts a batch job shall perform the following services:

- Delete the batch job from the queue in which it resides.
- If the *Mail_Points* attribute of the batch job includes the value MAIL_AT_ABORT, send mail to the users listed in the value of the *Mail_Users* attribute of the job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, the *Job_Owner* attribute, and the reason for the abort.
- If the batch job was in the RUNNING state, terminate the session leader of the executing job by sending the session leader a SIGKILL, place the batch job in the EXITING state, and perform the actions of *Batch Job Exit*.

3.2.3 Requested Batch Services

This section describes the services provided by batch servers in response to requests from clients. Table 3-5 summarizes the current set of batch service requests and for each gives its type (deferred or not) and whether it is an optional function.

Table 3-5 Batch Services Summary

Batch Service	Deferred	Optional
Batch Job Execution	Yes	No
Batch Job Routing	Yes	No
Batch Job Exit	Yes	No
Batch Server Restart	Yes	No
Batch Job Abort	Yes	No
Delete Batch Job Request	No	No
Hold Batch Job Request	No	No
Batch Job Message Request	No	Yes
Batch Job Status Request	No	No
Locate Batch Job Request	No	Yes
Modify Batch Job Request	No	No
Move Batch Job Request	No	No
Queue Batch Job Request	No	No
Batch Queue Status Request	No	No
Release Batch Job Request	No	No
Rerun Batch Job Request	No	No
Select Batch Jobs Request	No	No
Server Shutdown Request	No	No
Server Status Request	No	No
Signal Batch Job Request	No	No
Track Batch Job Request	No	Yes

If a request is rejected because the batch client is not authorized to perform the action, the batch server shall return the same status as when the batch job does not exist.

3.2.3.1 *Delete Batch Job Request*

A batch job is defined to have been deleted when it has been removed from the queue in which it resides and not instantiated in another queue. A client requests that the server that manages a batch job delete the batch job. Such a request is called a *Delete Batch Job Request*.

A batch server shall reject a *Delete Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to delete the designated job.
- The designated job is not managed by the batch server.
- The designated job is in a state inconsistent with the delete request.

A batch server may reject a *Delete Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server requested to delete a batch job shall delete the batch job if the batch job exists and is not in the EXITING state.

A batch server that deletes a batch job in the RUNNING state shall send a SIGKILL signal to the

session leader of the batch job. It is implementation-defined whether additional signals are sent to the session leader of the job prior to sending the SIGKILL signal.

A batch server that deletes a batch job in the RUNNING state shall place the batch job in the EXITING state after it has killed the session leader of the batch job and shall perform the actions of *Batch Job Exit*.

3.2.3.2 *Hold Batch Job Request*

A batch client can request that the batch server add one or more holds to a batch job. Such a request is called a *Hold Batch Job Request*.

A batch server shall reject a *Hold Batch Job Request* if any of the following statements are true:

- The batch server does not support one or more of the requested holds to be added to the batch job.
- The user of the batch client is not authorized to add one or more of the requested holds to the batch job.
- The batch server does not manage the specified job.
- The designated job is in the EXITING state.

A batch server may reject a *Hold Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Hold Batch Job Request* for a batch job in the RUNNING state shall place a hold on the batch job. The effects, if any, the hold will have on a batch job in the RUNNING state are implementation-defined.

A batch server that accepts a *Hold Batch Job Request* shall add each type of hold listed in the *Hold Batch Job Request*, that is not already present, to the value of the *Hold_Types* attribute of the batch job.

3.2.3.3 *Batch Job Message Request*

Batch Job Message Request is an optional feature of batch servers. If an implementation supports *Batch Job Message Request*, the statements in this section apply and the configuration variable POSIX2_PBS_MESSAGE shall be set to 1.

A batch client can request that a batch server write a message into certain output files of a batch job. Such a request is called a *Batch Job Message Request*.

A batch server shall reject a *Batch Job Message Request* if any of the following statements are true:

- The batch server does not support sending messages to jobs.
- The user of the batch client is not authorized to post a message to the designated job.
- The designated job does not exist on the batch server.
- The designated job is not in the RUNNING state.

A batch server may reject a *Batch Job Message Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Batch Job Message Request* shall write the message sent by the batch client into the files indicated by the batch client.

75688 ### 3.2.3.4 *Batch Job Status Request*

75689 A batch client can request that a batch server respond with the status and attributes of a batch
75690 job. Such a request is called a *Batch Job Status Request*.

75691 A batch server shall reject a *Batch Job Status Request* if any of the following statements are true:

75692 - The user of the batch client is not authorized to query the status of the designated job.
75693 - The designated job is not managed by the batch server.

75694 A batch server may reject a *Batch Job Status Request* for other implementation-defined reasons.
75695 The method used to determine whether the user of a client is authorized to perform the
75696 requested action is implementation-defined.

75697 A batch server that accepts a *Batch Job Status Request* shall return a *Batch Job Status Message* to the
75698 batch client.

75699 A batch server may return other information in response to a *Batch Job Status Request*.

75700 ### 3.2.3.5 *Locate Batch Job Request*

75701 *Locate Batch Job Request* is an optional feature of batch servers. If an implementation supports
75702 *Locate Batch Job Request*, the statements in this section apply and the configuration variable
75703 POSIX2_PBS_LOCATE shall be set to 1.

75704 A batch client can ask a batch server to respond with the location of a batch job that was created
75705 by the batch server. Such a request is called a *Locate Batch Job Request*.

75706 A batch server that accepts a *Locate Batch Job Request* shall return a *Batch Job Location Message* to
75707 the batch client.

75708 A batch server may reject a *Locate Batch Job Request* for a batch job that was not created by that
75709 server.

75710 A batch server may reject a *Locate Batch Job Request* for a batch job that is no longer managed by
75711 that server; that is, for a batch job that is not in a queue owned by that server.

75712 A batch server may reject a *Locate Batch Job Request* for other implementation-defined reasons.

75713 ### 3.2.3.6 *Modify Batch Job Request*

75714 Batch clients modify (alter) the attributes of a batch job by making a request to the server that
75715 manages the batch job. Such a request is called a *Modify Batch Job Request*.

75716 A batch server shall reject a *Modify Batch Job Request* if any of the following statements are true:

75717 - The user of the batch client is not authorized to make the requested modification to the
75718 batch job.
75719 - The designated job is not managed by the batch server.
75720 - The requested modification is inconsistent with the state of the batch job.
75721 - An unrecognized resource is requested for a batch job in an execution queue.

75722 A batch server may reject a *Modify Batch Job Request* for other implementation-defined reasons.
75723 The method used to determine whether the user of a client is authorized to perform the
75724 requested action is implementation-defined.

75725 A batch server that accepts a *Modify Batch Job Request* shall modify all the specified attributes of
75726 the batch job. A batch server that rejects a *Modify Batch Job Request* shall modify none of the

attributes of the batch job.

If the servicing by a batch server of an otherwise valid request would result in no change, then the batch server shall indicate successful completion of the request.

3.2.3.7 *Move Batch Job Request*

A batch client can request that a batch server move a batch job to another destination. Such a request is called a *Move Batch Job Request*.

A batch server shall reject a *Move Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to remove the designated job from the queue in which the batch job resides.
- The user of the batch client is not authorized to move the designated job to the destination.
- The designated job is not managed by the batch server.
- The designated job is in the EXITING state.
- The destination is inaccessible.

A batch server can reject a *Move Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Move Batch Job Request* shall perform the following services:

- Queue the designated job at the destination.
- Remove the designated job from the queue in which the batch job resides.

If the destination resides on another batch server, the batch server shall queue the batch job at the destination by sending a *Queue Batch Job Request* to the other server. If the *Queue Batch Job Request* fails, the batch server shall reject the *Move Batch Job Request*. If the *Queue Batch Job Request* succeeds, the batch server shall remove the batch job from its queue.

The batch server shall not modify any attributes of the batch job.

3.2.3.8 *Queue Batch Job Request*

A batch queue is controlled by one and only one batch server. A batch server is said to own the queues that it controls. Batch clients make requests of batch servers to have jobs queued. Such a request is called a *Queue Batch Job Request*.

A batch server requested to queue a batch job for which the queue is not specified shall select an implementation-defined queue for the batch job. Such a queue is called the "default queue" of the batch server. The implementation shall provide the means for a batch administrator to specify the default queue. The queue, whether specified or defaulted, is called the "target queue".

A batch server shall reject a *Queue Batch Job Request* if any of the following statements are true:

- The client is not authorized to create a batch job in the target queue.
- The request specifies a queue that does not exist on the batch server.
- The target queue is an execution queue and the batch server cannot satisfy a resource requirement of the batch job.

- The target queue is an execution queue and an unrecognized resource is requested.
- The target queue is an execution queue, the batch server does not support checkpointing, and the value of the *Checkpoint* attribute of the batch job is not NO_CHECKPOINT.
- The job requires access to a user identifier that the batch client is not authorized to access.

A batch server may reject a *Queue Batch Job Request* for other implementation-defined reasons.

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_O_QUEUE value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the name of the target queue. Once set, no server shall change the value of PBS_O_QUEUE, even if the batch job is moved to another queue.

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBID value is missing from the value of the *Variable_List* attribute shall add that variable to the list and set the value to the batch job identifier assigned by the server in the format:

```
sequence_number.server
```

A batch server that accepts a *Queue Batch Job Request* for a batch job for which the PBS_JOBNAME value is missing from the value of the *Variable_List* attribute of the batch job shall add that variable to the list and set the value to the *Job_Name* attribute of the batch job.

3.2.3.9 *Batch Queue Status Request*

A batch client can request that a batch server respond with the status and attributes of a queue. Such a request is called a *Batch Queue Status Request*.

A batch server shall reject a *Batch Queue Status Request* if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated queue.
- The designated queue does not exist on the batch server.

A batch server may reject a *Batch Queue Status Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Batch Queue Status Request* shall return a *Batch Queue Status Reply* to the batch client.

3.2.3.10 *Release Batch Job Request*

A batch client can request that the server remove one or more holds from a batch job. Such a request is called a *Release Batch Job Request*.

A batch server shall reject a *Release Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to remove one or more of the requested holds from the batch job.
- The batch server does not manage the specified job.

A batch server may reject a *Release Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a *Release Batch Job Request* shall remove each type of hold listed in the

Release Batch Job Request, that is present, from the value of the *Hold_Types* attribute of the batch job.

3.2.3.11 *Rerun Batch Job Request*

To rerun a batch job is to kill the session leader of the batch job and leave the batch job eligible for re-execution. A batch client can request that a batch server rerun a batch job. Such a request is called *Rerun Batch Job Request*.

A batch server shall reject a *Rerun Batch Job Request* if any of the following statements are true:

- The user of the batch client is not authorized to rerun the designated job.
- The *Rerunable* attribute of the designated job has the value FALSE.
- The designated job is not in the RUNNING state.
- The batch server does not manage the designated job.

A batch server may reject a *Rerun Batch Job Request* for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that rejects a *Rerun Batch Job Request* shall in no way modify the execution of the batch job.

A batch server that accepts a request to rerun a batch job shall perform the following services:

- Requeue the batch job in the execution queue in which it was executing.
- Send a SIGKILL signal to the process group of the session leader of the batch job.

An implementation may indicate to the batch job owner that the batch job has been rerun. Whether and how the batch job owner is notified that a batch job is rerun is implementation-defined.

A batch server that reruns a batch job may send other implementation-defined signals to the session leader of the batch job prior to sending the SIGKILL signal.

A batch server may preferentially select a rerun job for execution. Whether rerun jobs shall be selected for execution before other jobs is implementation-defined.

3.2.3.12 *Select Batch Jobs Request*

A batch client can request from a batch server a list of jobs managed by that server that match a list of selection criteria. Such a request is called a *Select Batch Jobs Request*. All the batch jobs managed by the batch server that receives the request are candidates for selection.

A batch server that accepts a *Select Batch Jobs Request* shall return a list of zero or more job identifiers that correspond to jobs that meet the selection criteria.

If the batch client is not authorized to query the status of a batch job, the batch server shall not select the batch job.

75839 ### 3.2.3.13 *Server Shutdown Request*

75840 A batch server is defined to have shut down when it does not respond to requests from clients
75841 and does not perform deferred services for jobs. A batch client can request that a batch server
75842 shut down. Such a request is called a *Server Shutdown Request*.

75843 A batch server shall reject a *Server Shutdown Request* from a client that is not authorized to shut
75844 down the batch server. The method used to determine whether the user of a client is authorized
75845 to perform the requested action is implementation-defined.

75846 A batch server may reject a *Server Shutdown Request* for other implementation-defined reasons.
75847 The reasons for which a *Server Shutdown Request* may be rejected are implementation-defined.

75848 At server shutdown, a batch server shall do, in order of preference, one of the following:

75849 • If checkpointing is implemented and the batch job is checkpointable, then checkpoint the
75850 batch job and requeue it.

75851 • If the batch job is rerunnable, then requeue the batch job to be rerun (restarted from the
75852 beginning).

75853 • Abort the batch job.

75854 ### 3.2.3.14 *Server Status Request*

75855 A batch client can request that a batch server respond with the status and attributes of the batch
75856 server. Such a request is called a *Server Status Request*.

75857 A batch server shall reject a *Server Status Request* if the following statement is true:

75858 • The user of the batch client is not authorized to query the status of the designated server.

75859 A batch server may reject a *Server Status Request* for other implementation-defined reasons. The
75860 method used to determine whether the user of a client is authorized to perform the requested
75861 action is implementation-defined.

75862 A batch server that accepts a *Server Status Request* shall return a *Server Status Reply* to the batch
75863 client.

75864 ### 3.2.3.15 *Signal Batch Job Request*

75865 A batch client can request that a batch server signal the session leader of a batch job. Such a
75866 request is called a *Signal Batch Job Request*.

75867 A batch server shall reject a *Signal Batch Job Request* if any of the following statements are true:

75868 • The user of the batch client is not authorized to signal the batch job.

75869 • The job is not in the RUNNING state.

75870 • The batch server does not manage the designated job.

75871 • The requested signal is not supported by the implementation.

75872 A batch server may reject a *Signal Batch Job Request* for other implementation-defined reasons.
75873 The method used to determine whether the user of a client is authorized to perform the
75874 requested action is implementation-defined.

75875 A batch server that accepts a request to signal a batch job shall send the signal requested by the
75876 batch client to the process group of the session leader of the batch job.

75877 *3.2.3.16 Track Batch Job Request*

75878 *Track Batch Job Request* is an optional feature of batch servers. If an implementation supports
75879 *Track Batch Job Request*, the statements in this section apply and the configuration variable
75880 POSIX2_PBS_TRACK shall be set to 1.

75881 *Track Batch Job Request* provides a method for tracking the current location of a batch job. Clients
75882 may use the tracking information to determine the batch server that should receive a batch
75883 server request.

75884 If *Track Batch Job Request* is supported by a batch server, then when the batch server queues a
75885 batch job as a result of a *Queue Batch Job Request*, and the batch server is not the batch server that
75886 created the batch job, the batch server shall send a *Track Batch Job Request* to the batch server that
75887 created the job.

75888 If *Track Batch Job Request* is supported by a batch server, then the *Track Batch Job Request* may also
75889 be sent to other servers as a backup to the primary server. The method by which backup servers
75890 are specified is implementation-defined.

75891 If *Track Batch Job Request* is supported by a batch server that receives a *Track Batch Job Request*,
75892 then the batch server shall record the current location of the batch job as contained in the
75893 request.

75894 3.3 Common Behavior for Batch Environment Utilities

75895

75896 3.3.1 Batch Job Identifier

75897 A utility shall recognize *job_identifier*s of the format:

75898 `[sequence_number][.server_name][@server]`

75899 where:

75900 *sequence_number* An integer that, when combined with *server_name*, provides a batch job
75901 identifier that is unique within the batch system.

75902 *server_name* The name of the batch server to which the batch job was originally submitted.

75903 *server* The name of the batch server that is currently managing the batch job.

75904 If the application omits the batch *server_name* portion of a batch job identifier, a utility shall use
75905 the name of a default batch server.

75906 If the application omits the batch *server* portion of a batch job identifier, a utility shall use:

75907 • The batch server indicated by *server_name*, if present

75908 • The name of the default batch server

75909 • The name of the batch server that is currently managing the batch job

75910 If only @*server* is specified, then the status of all jobs owned by the user on the requested server
75911 is listed.

75912 The means by which a utility determines the default batch server is implementation-defined.

75913 If the application presents the batch *server* portion of a batch job identifier to a utility, the utility
75914 shall send the request to the specified server.

A strictly conforming application shall use the syntax described for the job identifier. Whenever a batch job identifier is specified whose syntax is not recognized by an implementation, then a message for each error that occurs shall be written to standard error and the utility shall exit with an exit status greater than zero.

When a batch job identifier is supplied as an argument to a batch utility and the *server_name* portion of the batch job identifier is omitted, then the utility shall use the name of the default batch server.

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is omitted, then the utility shall use either:

- The name of the default batch server

  or:

- The name of the batch server that is currently managing the batch job

When a batch job identifier is supplied as an argument to a batch utility and the batch *server* portion of the batch job identifier is specified, then the utility shall send the required *Batch Server Request* to the specified server.

3.3.2 Destination

The utility shall recognize a *destination* of the format:

```
[queue][@server]
```

where:

queue The name of a valid execution or routing queue at the batch server denoted by *@server*, defined as a string of up to 15 alphanumeric characters in the portable character set (see XBD Section 6.1, on page 125) where the first character is alphabetic.

server The name of a batch server, defined as a string of alphanumeric characters in the portable character set.

If the application omits the batch *server* portion of a destination, then the utility shall use either:

- The name of the default batch server

  or:

- The name of the batch server that is currently managing the batch job

The means by which a utility determines the default batch server is implementation-defined.

If the application omits the *queue* portion of a destination, then the utility shall use the name of the default queue at the batch server chosen. The means by which a batch server determines its default queue is implementation-defined. If a destination is specified in the *queue@server* form, then the utility shall use the specified queue at the specified server.

A strictly conforming application shall use the syntax described for a destination. Whenever a destination is specified whose syntax is not recognized by an implementation, then a message shall be written to standard error and the utility shall exit with an exit status greater than zero.

3.3.3 Multiple Keyword-Value Pairs

For each option that can have multiple keyword-value pair arguments, the following rules shall apply. Examples of options that can have list-oriented option-arguments are **–u** *value@keyword* and **–l** *keyword=value*.

1. If a batch utility is presented with a list-oriented option-argument for which a keyword has a corresponding value that begins with a single or double-quote, then the utility shall stop interpreting the input stream for delimiters until a second single or double-quote, respectively, is encountered. This feature allows some flexibility for a <comma> (`','`) or <equals-sign> (`'='`) to be part of the value string for a particular keyword; for example:

   ```
   keywd1='val1,val2',keywd2="val3,val4"
   ```

   Note: This may require the user to escape the quotes as in the following command:

   ```
   foo –xkeywd1=\'val1,val2\',keywd2=\"val3,val4\"
   ```

2. If a batch server is presented with a list-oriented attribute that has a keyword that was encountered earlier in the list, then the later entry for that keyword shall replace the earlier entry.

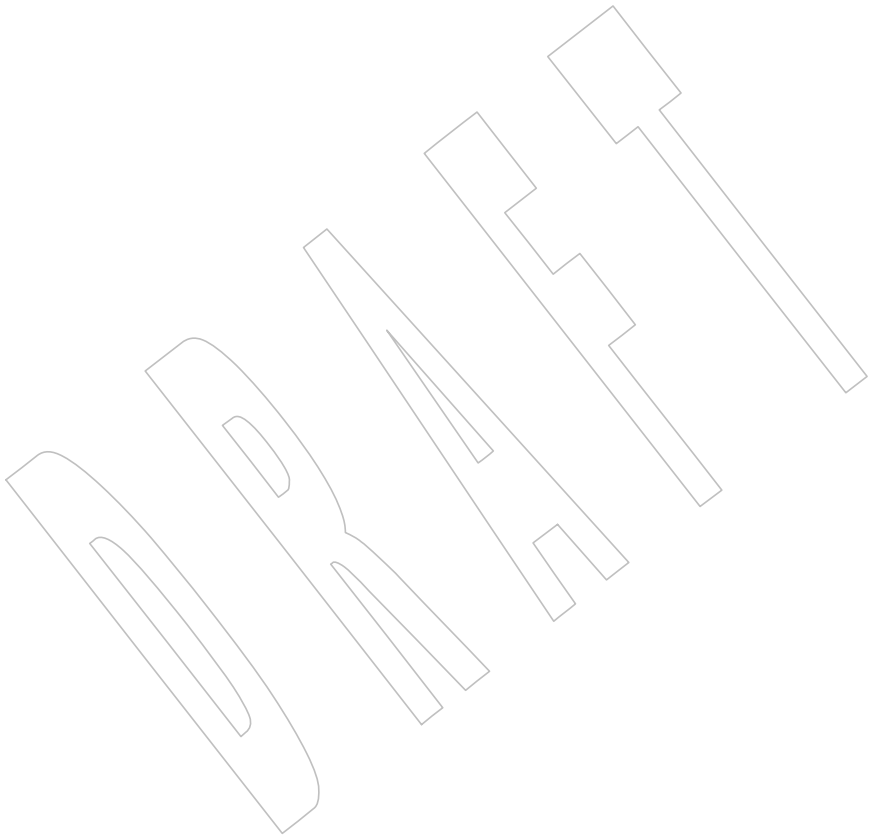
3. If a batch server is presented with a list-oriented attribute that has a keyword without any corresponding value of the form *keyword=* or *@keyword* and the same keyword was encountered earlier in the list, then the prior entry for that keyword shall be ignored by the batch server.

4. If a batch utility is expecting a list-oriented option-argument entry of the form *keyword=value*, but is presented with an entry of the form *keyword* without any corresponding *value*, then the entry shall be treated as though a default value of NULL was assigned (that is, *keyword*=NULL) for entry parsing purposes. The utility shall include only the keyword, not the NULL value, in the associated job attribute.

5. If a batch utility is expecting a list-oriented option-argument entry of the form *value@keyword*, but is presented with an entry of the form *value* without any corresponding *keyword*, then the entry shall be treated as though a keyword of NULL was assigned (that is, *value*@NULL) for entry parsing purposes. The utility shall include only the value, not the NULL keyword, in the associated job attribute.

6. A batch server shall accept a list-oriented attribute that has multiple occurrences of the same keyword, interpreting the keywords, in order, with the last value encountered taking precedence over prior instances of the same keyword. This rule allows, but does not require, a batch utility to preprocess the attribute to remove duplicate keywords.

7. If a batch utility is presented with multiple list-oriented option-arguments on the command line or in script directives, or both, for a single option, then the utility shall concatenate, in order, any command line keyword and value pairs to the end of any directive keyword and value pairs separated by a single <comma> to produce a single string that is an equivalent, valid option-argument. The resulting string shall be assigned to the associated attribute of the batch job (after optionally removing duplicate entries as described in item 6).



75992 *Chapter 4*

75993 # *Utilities*

75994 This chapter contains the definitions of the utilities, as follows:

75995 • Mandatory utilities that are present on every conformant system

75996 • Optional utilities that are present only on systems supporting the associated option; see
75997 Section 1.7.1 (on page 7) for information on the options in this volume of POSIX.1-200x

NAME

admin — create and administer SCCS files (**DEVELOPMENT**)

SYNOPSIS

XSI

```
admin –i[name] [–n] [–a login] [–d flag] [–e login] [–f flag]
    [–m mrlist] [–r rel] [–t[name] [–y[comment]] newfile

admin –n [–a login] [–d flag] [–e login] [–f flag] [–m mrlist]
    [–t[name]] [–y[comment]] newfile...

admin [–a login] [–d flag] [–m mrlist] [–r rel] [–t[name]] file...

admin –h file...

admin –z file...
```

DESCRIPTION

The *admin* utility shall create new SCCS files or change parameters of existing ones. If a named file does not exist, it shall be created, and its parameters shall be initialized according to the specified options. Parameters not initialized by an option shall be assigned a default value. If a named file does exist, parameters corresponding to specified options shall be changed, and other parameters shall be left as is.

All SCCS filenames supplied by the application shall be of the form s.*filename*. New SCCS files shall be given read-only permission mode. Write permission in the parent directory is required to create a file. All writing done by *admin* shall be to a temporary *x-file*, named x.*filename* (see *get*) created with read-only mode if *admin* is creating a new SCCS file, or created with the same mode as that of the SCCS file if the file already exists. After successful execution of *admin*, the SCCS file shall be removed (if it exists), and the *x-file* shall be renamed with the name of the SCCS file. This ensures that changes are made to the SCCS file only if no errors occur.

The *admin* utility shall also use a transient lock file (named z.*filename*), which is used to prevent simultaneous updates to the SCCS file; see *get*.

OPTIONS

The *admin* utility shall conform to XBD Section 12.2 (on page 215), except that the **–i**, **–t**, and **–y** options have optional option-arguments. These optional option-arguments shall not be presented as separate arguments. The following options are supported:

–n Create a new SCCS file. When **–n** is used without **–i**, the SCCS file shall be created with control information but without any file data.

–i[*name***]** Specify the *name* of a file from which the text for a new SCCS file shall be taken. The text constitutes the first delta of the file (see the **–r** option for the delta numbering scheme). If the **–i** option is used, but the *name* option-argument is omitted, the text shall be obtained by reading the standard input. If this option is omitted, the SCCS file shall be created with control information but without any file data. The **–i** option implies the **–n** option.

–r *SID* Specify the SID of the initial delta to be inserted. This SID shall be a trunk SID; that is, the branch and sequence numbers shall be zero or missing. The level number is optional, and defaults to 1.

–t[*name***]** Specify the *name* of a file from which descriptive text for the SCCS file shall be taken. In the case of existing SCCS files (neither **–i** nor **–n** is specified):

- A **–t** option without a *name* option-argument shall cause the removal of descriptive text (if any) currently in the SCCS file.
- A **–t** option with a *name* option-argument shall cause the text (if any) in the named file to replace the descriptive text (if any) currently in the SCCS file.

–f *flag* Specify a *flag*, and, possibly, a value for the *flag*, to be placed in the SCCS file. Several **–f** options may be supplied on a single *admin* command line. Implementations shall recognize the following flags and associated values:

b Allow use of the **–b** option on a *get* command to create branch deltas.

c*ceil* Specify the highest release (that is, ceiling), a number less than or equal to 9 999, which may be retrieved by a *get* command for editing. The default value for an unspecified **c** flag shall be 9 999.

f*floor* Specify the lowest release (that is, floor), a number greater than 0 but less than 9 999, which may be retrieved by a *get* command for editing. The default value for an unspecified **f** flag shall be 1.

d*SID* Specify the default delta number (SID) to be used by a *get* command.

i*str* Treat the "No ID keywords" message issued by *get* or *delta* as a fatal error. In the absence of this flag, the message is only a warning. The message is issued if no SCCS identification keywords (see *get*) are found in the text retrieved or stored in the SCCS file. If a value is supplied, the application shall ensure that the keywords exactly match the given string; however, the string shall contain a keyword, and no embedded <newline> characters.

j Allow concurrent *get* commands for editing on the same SID of an SCCS file. This allows multiple concurrent updates to the same version of the SCCS file.

l*list* Specify a *list* of releases to which deltas can no longer be made (that is, *get* **–e** against one of these locked releases fails). Conforming applications shall use the following syntax to specify a *list*. Implementations may accept additional forms as an extension:

```
<list> ::= a | <range-list>
<range-list> ::= <range> | <range-list>, <range>
<range> ::= <SID>
```

The character *a* in the *list* shall be equivalent to specifying all releases for the named SCCS file. The non-terminal <*SID*> in range shall be the delta number of an existing delta associated with the SCCS file.

n Cause *delta* to create a null delta in each of those releases (if any) being skipped when a delta is made in a new release (for example, in making delta 5.1 after delta 2.7, releases 3 and 4 are skipped). These null deltas shall serve as anchor points so that branch deltas may later be created from them. The absence of this flag shall cause skipped releases to be nonexistent in the SCCS file, preventing branch deltas from being created from them in the future. During the initial creation of an SCCS file, the **n** flag may be ignored; that is, if the **–r** option is used to set the release number of the initial SID to a value greater than 1, null deltas need not be created for the "skipped" releases.

q*text* Substitute user-definable *text* for all occurrences of the %**Q**% keyword in the SCCS file text retrieved by *get*.

m*mod* Specify the module name of the SCCS file substituted for all occurrences of the %**M**% keyword in the SCCS file text retrieved by *get*. If the **m** flag is not specified, the value assigned shall be the name of the SCCS file with the leading `'.'` removed.

t*type* Specify the *type* of module in the SCCS file substituted for all occurrences of the %**Y**% keyword in the SCCS file text retrieved by *get*.

v*pgm* Cause *delta* to prompt for modification request (MR) numbers as the reason for creating a delta. The optional value specifies the name of an MR number validation program. (If this flag is set when creating an SCCS file, the application shall ensure that the **m** option is also used even if its value is null.)

–d *flag* Remove (delete) the specified *flag* from an SCCS file. Several **–d** options may be supplied on a single *admin* command. See the **–f** option for allowable *flag* names. (The **l***list* flag gives a *list* of releases to be unlocked. See the **–f** option for further description of the **l** flag and the syntax of a *list*.)

–a *login* Specify a *login* name, or numerical group ID, to be added to the list of users who may make deltas (changes) to the SCCS file. A group ID shall be equivalent to specifying all *login* names common to that group ID. Several **–a** options may be used on a single *admin* command line. As many *login*s, or numerical group IDs, as desired may be on the list simultaneously. If the list of users is empty, then anyone may add deltas. If *login* or group ID is preceded by a `'!'`, the users so specified shall be denied permission to make deltas.

–e *login* Specify a *login* name, or numerical group ID, to be erased from the list of users allowed to make deltas (changes) to the SCCS file. Specifying a group ID is equivalent to specifying all *login* names common to that group ID. Several **–e** options may be used on a single *admin* command line.

–y[*comment*] Insert the *comment* text into the SCCS file as a comment for the initial delta in a manner identical to that of *delta*. In the POSIX locale, omission of the **–y** option shall result in a default comment line being inserted in the form:

`"date and time created %s %s by %s", <date>, <time>, <login>`

where <*date*> is expressed in the format of the *date* utility's `%y/%m/%d` conversion specification, <*time*> in the format of the *date* utility's `%T` conversion specification format, and <*login*> is the login name of the user creating the file.

–m *mrlist* Insert the list of modification request (MR) numbers into the SCCS file as the reason for creating the initial delta in a manner identical to *delta*. The application shall ensure that the **v** flag is set and the MR numbers are validated if the **v** flag has a value (the name of an MR number validation program). A diagnostic message shall be written if the **v** flag is not set or MR validation fails.

–h Check the structure of the SCCS file and compare the newly computed checksum with the checksum that is stored in the SCCS file. If the newly computed checksum does not match the checksum in the SCCS file, a diagnostic message shall be written.

76129 **–z** Recompute the SCCS file checksum and store it in the first line of the SCCS file (see
76130 the **–h** option above). Note that use of this option on a truly corrupted file may
76131 prevent future detection of the corruption.

76132 **OPERANDS**

76133 The following operands shall be supported:

76134 *file* A pathname of an existing SCCS file or a directory. If *file* is a directory, the *admin*
76135 utility shall behave as though each file in the directory were specified as a named
76136 file, except that non-SCCS files (last component of the pathname does not begin
76137 with **s.**) and unreadable files shall be silently ignored.

76138 *newfile* A pathname of an SCCS file to be created.

76139 If exactly one *file* or *newfile* operand appears, and it is '–', the standard input shall be read; each
76140 line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-
76141 SCCS files and unreadable files shall be silently ignored.

76142 **STDIN**

76143 The standard input shall be a text file used only if **–i** is specified without an option-argument or
76144 if a *file* or *newfile* operand is specified as '–'. If the first character of any standard input line is
76145 <SOH> in the POSIX locale, the results are unspecified.

76146 **INPUT FILES**

76147 The existing SCCS files shall be text files of an unspecified format.

76148 The application shall ensure that the file named by the **–i** option's *name* option-argument shall
76149 be a text file; if the first character of any line in this file is <SOH> in the POSIX locale, the results
76150 are unspecified. If this file contains more than 99 999 lines, the number of lines recorded in the
76151 header for this file shall be 99 999 for this delta.

76152 **ENVIRONMENT VARIABLES**

76153 The following environment variables shall affect the execution of *admin*:

76154 *LANG* Provide a default value for the internationalization variables that are unset or null.
76155 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
76156 variables used to determine the values of locale categories.)

76157 *LC_ALL* If set to a non-empty string value, override the values of all the other
76158 internationalization variables.

76159 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
76160 characters (for example, single-byte as opposed to multi-byte characters in
76161 arguments and input files).

76162 *LC_MESSAGES*
76163 Determine the locale that should be used to affect the format and contents of
76164 diagnostic messages written to standard error and the contents of the default **–y**
76165 comment.

76166 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

76167 **ASYNCHRONOUS EVENTS**

76168 Default.

76169 **STDOUT**

76170 Not used.

76171 **STDERR**

76172 The standard error shall be used only for diagnostic messages.

76173 **OUTPUT FILES**

76174 Any SCCS files created shall be text files of an unspecified format. During processing of a *file*, a
76175 locking *z-file*, as described in *get* (on page 2764), may be created and deleted.

76176 **EXTENDED DESCRIPTION**

76177 None.

76178 **EXIT STATUS**

76179 The following exit values shall be returned:

76180 0 Successful completion.

76181 >0 An error occurred.

76182 **CONSEQUENCES OF ERRORS**

76183 Default.

76184 **APPLICATION USAGE**

76185 It is recommended that directories containing SCCS files be writable by the owner only, and that
76186 SCCS files themselves be read-only. The mode of the directories should allow only the owner to
76187 modify SCCS files contained in the directories. The mode of the SCCS files prevents any
76188 modification at all except by SCCS commands.

76189 **EXAMPLES**

76190 None.

76191 **RATIONALE**

76192 None.

76193 **FUTURE DIRECTIONS**

76194 None.

76195 **SEE ALSO**

76196 *delta*, *get*, *prs*, *what*

76197 XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

76198 **CHANGE HISTORY**

76199 First released in Issue 2.

76200 **Issue 6**

76201 The normative text is reworded to avoid use of the term "must" for application requirements,
76202 and to emphasize the term "shall" for implementation requirements.

76203 The grammar is updated.

76204 The Open Group Base Resolution bwg2001-007 is applied, adding new text to the INPUT FILES
76205 section warning that the maximum lines recorded in the file is 99 999.

76206 The Open Group Base Resolution bwg2001-009 is applied, amending the description of the **–h**
76207 option.

NAME

alias — define or display aliases

SYNOPSIS

```
alias [alias-name[=string]...]
```

DESCRIPTION

The *alias* utility shall create or redefine alias definitions or write the values of existing alias definitions to standard output. An alias definition provides a string value that shall replace a command name when it is encountered; see Section 2.3.1 (on page 2300).

An alias definition shall affect the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this volume of POSIX.1-200x, the alias definition shall not affect the parent process of the current shell nor any utility environment invoked by the shell; see Section 2.12 (on page 2331).

OPTIONS

None.

OPERANDS

The following operands shall be supported:

alias-name Write the alias definition to standard output.

alias-name=string
Assign the value of *string* to the alias *alias-name*.

If no operands are given, all alias definitions shall be written to standard output.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *alias*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

76248 **STDOUT**

76249 The format for displaying aliases (when no operands or only *name* operands are specified) shall
76250 be:

76251 `"%s=%s\n", name, value`

76252 The *value* string shall be written with appropriate quoting so that it is suitable for reinput to the
76253 shell. See the description of shell quoting in Section 2.2 (on page 2298).

76254 **STDERR**

76255 The standard error shall be used only for diagnostic messages.

76256 **OUTPUT FILES**

76257 None.

76258 **EXTENDED DESCRIPTION**

76259 None.

76260 **EXIT STATUS**

76261 The following exit values shall be returned:

76262 0 Successful completion.

76263 >0 One of the *name* operands specified did not have an alias definition, or an error occurred.

76264 **CONSEQUENCES OF ERRORS**

76265 Default.

76266 **APPLICATION USAGE**

76267 None.

76268 **EXAMPLES**

76269 1. Create a short alias for a commonly used *ls* command:

76270 ```
alias lf="ls -CF"
```

76271 2. Create a simple "redo" command to repeat previous entries in the command history file:

76272 ```
alias r='fc -s'
```

76273 3. Use 1K units for *du*:

76274 ```
alias du=du\ -k
```

76275 4. Set up *nohup* so that it can deal with an argument that is itself an alias name:

76276 ```
alias nohup="nohup "
```

76277 **RATIONALE**

76278 The *alias* description is based on historical KornShell implementations. Known differences exist
76279 between that and the C shell. The KornShell version was adopted to be consistent with all the
76280 other KornShell features in this volume of POSIX.1-200x, such as command line editing.

76281 Since *alias* affects the current shell execution environment, it is generally provided as a shell
76282 regular built-in.

76283 Historical versions of the KornShell have allowed aliases to be exported to scripts that are
76284 invoked by the same shell. This is triggered by the *alias* **-x** flag; it is allowed by this volume of
76285 POSIX.1-200x only when an explicit extension such as **-x** is used. The standard developers
76286 considered that aliases were of use primarily to interactive users and that they should normally
76287 not affect shell scripts called by those users; functions are available to such scripts.

Historical versions of the KornShell had not written aliases in a quoted manner suitable for reentry to the shell, but this volume of POSIX.1-200x has made this a requirement for all similar output. Therefore, consistency was chosen over this detail of historical practice.

FUTURE DIRECTIONS

None.

SEE ALSO

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

Issue 7

The *alias* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The first example is changed to remove the creation of an alias for a standard utility that alters its behavior to be non-conforming.

NAME

ar — create and maintain library archives

SYNOPSIS

```

XSI
```
ar –x [–v] [–sCT] archive [file...]
```

DESCRIPTION

The *ar* utility is part of the Software Development Utilities option.

The *ar* utility can be used to create and maintain groups of files combined into an archive. Once an archive has been created, new files can be added, and existing files in an archive can be extracted, deleted, or replaced. When an archive consists entirely of valid object files, the implementation shall format the archive so that it is usable as a library for link editing (see *c99* and *fort77*). When some of the archived files are not valid object files, the suitability of the archive for library use is undefined. XSI If an archive consists entirely of printable files, the entire archive shall be printable.

When *ar* creates an archive, it creates administrative information indicating whether a symbol table is present in the archive. When there is at least one object file that *ar* recognizes as such in the archive, an archive symbol table shall be created in the archive and maintained by *ar*; it is used by the link editor to search the archive. Whenever the *ar* utility is used to create or update the contents of such an archive, the symbol table shall be rebuilt. The **–s** option shall force the symbol table to be rebuilt.

All *file* operands can be pathnames. However, files within archives shall be named by a filename, which is the last component of the pathname used when the file was entered into the archive. The comparison of *file* operands to the names of files in archives shall be performed by comparing the last component of the operand to the name of the file in the archive.

It is unspecified whether multiple files in the archive may be identically named. In the case of such files, however, each *file* XSI and *posname* operand shall match only the first file in the archive having a name that is the same as the last component of the operand.

OPTIONS

The *ar* utility shall conform to XBD Section 12.2 (on page 215), except for Guideline 9.

The following options shall be supported:

XSI **–a** Position new files in the archive after the file named by the *posname* operand.

XSI **–b** Position new files in the archive before the file named by the *posname* operand.

–c Suppress the diagnostic message that is written to standard error by default when the archive *archive* is created.

XSI **–C** Prevent extracted files from replacing like-named files in the file system. This option is useful when **–T** is also used, to prevent truncated filenames from replacing files with the same prefix.

–d Delete one or more *file*s from *archive*.

XSI **–i** Position new files in the archive before the file in the archive named by the *posname* operand (equivalent to **–b**).

XSI **–m** Move the named files in the archive. The **–a**, **–b**, or **–i** options with the *posname* operand indicate the position; otherwise, move the names files in the archive to the end of the archive.

–p Write the contents of the *file*s in the archive named by *file* operands from *archive* to the standard output. If no *file* operands are specified, the contents of all files in the archive shall be written in the order of the archive.

XSI **–q** Append the named files to the end of the archive. In this case *ar* does not check whether the added files are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece by piece.

–r Replace or add *file*s to *archive*. If the archive named by *archive* does not exist, a new archive shall be created and a diagnostic message shall be written to standard error (unless the **–c** option is specified). If no *file*s are specified and the *archive* exists, the results are undefined. Files that replace existing files in the archive shall not change the order of the archive. Files that do not replace existing files in the archive shall be appended to the archive XSI unless a **–a**, **–b**, or **–i** option specifies another position.

XSI **–s** Force the regeneration of the archive symbol table even if *ar* is not invoked with an option that modifies the archive contents. This option is useful to restore the archive symbol table after it has been stripped; see *strip*.

–t Write a table of contents of *archive* to the standard output. Only the files specified by the *file* operands shall be included in the written list. If no *file* operands are specified, all files in *archive* shall be included in the order of the archive.

XSI **–T** Allow filename truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long shall be an error; a diagnostic message shall be written and the file shall not be extracted.

–u Update older files in the archive. When used with the **–r** option, files in the archive shall be replaced only if the corresponding *file* has a modification time that is at least as new as the modification time of the file in the archive.

76386 **–v** Give verbose output. When used with the option characters **–d**, **–r**, or **–x**, write a
76387 detailed file-by-file description of the archive creation and maintenance activity, as
76388 described in the STDOUT section.

76389 When used with **–p**, write the name of the file in the archive to the standard output
76390 before writing the file in the archive itself to the standard output, as described in
76391 the STDOUT section.

76392 When used with **–t**, include a long listing of information about the files in the
76393 archive, as described in the STDOUT section.

76394 **–x** Extract the files in the archive named by the *file* operands from *archive*. The
76395 contents of the archive shall not be changed. If no *file* operands are given, all files
76396 in the archive shall be extracted. The modification time of each file extracted shall
76397 be set to the time the file is extracted from the archive.

76398 **OPERANDS**

76399 The following operands shall be supported:

76400 *archive* A pathname of the archive.

76401 *file* A pathname. Only the last component shall be used when comparing against the
76402 names of files in the archive. If two or more *file* operands have the same last
76403 pathname component (basename), the results are unspecified. The
76404 implementation's archive format shall not truncate valid filenames of files added
76405 to or replaced in the archive.

76406 XSI *posname* The name of a file in the archive, used for relative positioning; see options **–m** and
76407 **–r**.

76408 **STDIN**

76409 Not used.

76410 **INPUT FILES**

76411 The archive named by *archive* shall be a file in the format created by *ar* **–r**.

76412 **ENVIRONMENT VARIABLES**

76413 The following environment variables shall affect the execution of *ar*:

76414 *LANG* Provide a default value for the internationalization variables that are unset or null.
76415 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
76416 variables used to determine the values of locale categories.)

76417 *LC_ALL* If set to a non-empty string value, override the values of all the other
76418 internationalization variables.

76419 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
76420 characters (for example, single-byte as opposed to multi-byte characters in
76421 arguments and input files).

76422 *LC_MESSAGES*
76423 Determine the locale that should be used to affect the format and contents of
76424 diagnostic messages written to standard error.

76425 *LC_TIME* Determine the format and content for date and time strings written by *ar* **–tv**.

76426 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Determine the pathname that overrides the default directory for temporary files, if any.

TZ Determine the timezone used to calculate date and time strings written by *ar* –**tv**. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the –**d** option is used with the –**v** option, the standard output format shall be:

```
"d – %s\n", <file>
```

where *file* is the operand specified on the command line.

If the –**p** option is used with the –**v** option, *ar* shall precede the contents of each file with:

```
"\n<%s>\n\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, and the name of the file in the archive if they were not.

If the –**r** option is used with the –**v** option:

- If *file* is already in the archive, the standard output format shall be:

  ```
  "r – %s\n", <file>
  ```

  where <*file*> is the operand specified on the command line.

- If *file* is not already in the archive, the standard output format shall be:

  ```
  "a – %s\n", <file>
  ```

  where <*file*> is the operand specified on the command line.

If the –**t** option is used, *ar* shall write the names of the files in the archive to the standard output in the format:

```
"%s\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

If the –**t** option is used with the –**v** option, the standard output format shall be:

```
"%s %u/%u %u %s %d %d:%d %d %s\n", <member mode>, <user ID>,
    <group ID>, <number of bytes in member>,
    <abbreviated month>, <day-of-month>, <hour>,
    <minute>, <year>, <file>
```

where:

<*file*> Shall be the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

<*member mode*>
Shall be formatted the same as the <*file mode*> string defined in the STDOUT section of *ls*, except that the first character, the <*entry type*>, is not used; the string represents the file mode of the file in the archive at the time it was added to or replaced in the archive.

The following represent the last-modification time of a file when it was most recently added to or replaced in the archive:

<abbreviated month>
: Equivalent to the format of the `%b` conversion specification format in *date*.

<day-of-month>
: Equivalent to the format of the `%e` conversion specification format in *date*.

<hour>
: Equivalent to the format of the `%H` conversion specification format in *date*.

<minute>
: Equivalent to the format of the `%M` conversion specification format in *date*.

<year>
: Equivalent to the format of the `%Y` conversion specification format in *date*.

When *LC_TIME* does not specify the POSIX locale, a different format and order of presentation of these fields relative to each other may be used in a format appropriate in the specified locale.

If the **–x** option is used with the **–v** option, the standard output format shall be:

```
"x – %s\n", <file>
```

where *file* is the operand specified on the command line, if *file* operands were specified, or the name of the file in the archive if they were not.

STDERR

The standard error shall be used only for diagnostic messages. The diagnostic message about creating a new archive when **–c** is not specified shall not modify the exit status.

OUTPUT FILES

Archives are files with unspecified formats.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The archive format is not described. It is recognized that there are several known *ar* formats, which are not compatible. The *ar* utility is included, however, to allow creation of archives that are intended for use only on one machine. The archive is specified as a file, and it can be moved as a file. This does allow an archive to be moved from one machine to another machine that uses the same implementation of *ar*.

Utilities such as *pax* (and its forebears *tar* and *cpio*) also provide portable "archives". This is a not a duplication; the *ar* utility is included to provide an interface primarily for *make* and the compilers, based on a historical model.

In historical implementations, the **–q** option (available on XSI-conforming systems) is known to execute quickly because *ar* does not check on whether the added members are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece-by-piece. These remarks may but need not remain true for a brand new implementation of this utility; hence, these remarks have been moved into the RATIONALE.

BSD implementations historically required applications to provide the **–s** option whenever the archive was supposed to contain a symbol table. As in this volume of POSIX.1-200x, System V historically creates or updates an archive symbol table whenever an object file is removed from, added to, or updated in the archive.

The OPERANDS section requires what might seem to be true without specifying it: the archive cannot truncate the filenames below {NAME_MAX}. Some historical implementations do so, however, causing unexpected results for the application. Therefore, this volume of POSIX.1-200x makes the requirement explicit to avoid misunderstandings.

According to the System V documentation, the options **–dmpqrtx** are not required to begin with a <hyphen> (`'–'`). This volume of POSIX.1-200x requires that a conforming application use the leading <hyphen>.

The archive format used by the 4.4 BSD implementation is documented in this RATIONALE as an example:

> A file created by *ar* begins with the "magic" string `"!<arch>\n"`. The rest of the archive is made up of objects, each of which is composed of a header for a file, a possible filename, and the file contents. The header is portable between machine architectures, and, if the file contents are printable, the archive is itself printable.
>
> The header is made up of six ASCII fields, followed by a two-character trailer. The fields are the object name (16 characters), the file last modification time (12 characters), the user and group IDs (each 6 characters), the file mode (8 characters), and the file size (10 characters). All numeric fields are in decimal, except for the file mode, which is in octal.
>
> The modification time is the file *st_mtime* field. The user and group IDs are the file *st_uid* and *st_gid* fields. The file mode is the file *st_mode* field. The file size is the file *st_size* field. The two-byte trailer is the string `"'<newline>"`.
>
> Only the name field has any provision for overflow. If any filename is more than 16 characters in length or contains an embedded space, the string `"#1/"` followed by the ASCII length of the name is written in the name field. The file size (stored in the archive header) is incremented by the length of the name. The name is then written immediately following the archive header.
>
> Any unused characters in any of these fields are written as <space> characters. If any fields are their particular maximum number of characters in length, there is no separation between the fields.
>
> Objects in the archive are always an even number of bytes long; files that are an odd number of bytes long are padded with a <newline>, although the size in the header does not reflect this.

The *ar* utility description requires that (when all its members are valid object files) *ar* produce an object code library, which the linkage editor can use to extract object modules. If the linkage editor needs a symbol table to permit random access to the archive, *ar* must provide it; however, *ar* does not require a symbol table.

The BSD **–o** option was omitted. It is a rare conforming application that uses *ar* to extract object

code from a library with concern for its modification time, since this can only be of importance to *make*. Hence, since this functionality is not deemed important for applications portability, the modification time of the extracted files is set to the current time.

There is at least one known implementation (for a small computer) that can accommodate only object files for that system, disallowing mixed object and other files. The ability to handle any type of file is not only historical practice for most implementations, but is also a reasonable expectation.

Consideration was given to changing the output format of *ar* **–tv** to the same format as the output of *ls* **–l**. This would have made parsing the output of *ar* the same as that of *ls*. This was rejected in part because the current *ar* format is commonly used and changes would break historical usage. Second, *ar* gives the user ID and group ID in numeric format separated by a <slash>. Changing this to be the user name and group name would not be correct if the archive were moved to a machine that contained a different user database. Since *ar* cannot know whether the archive was generated on the same machine, it cannot tell what to report.

The text on the **–ur** option combination is historical practice—since one filename can easily represent two different files (for example, **/a/foo** and **/b/foo**), it is reasonable to replace the file in the archive even when the modification time in the archive is identical to that in the file system.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 215), **<unistd.h>**, description of {POSIX_NO_TRUNC}

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the Software Development Utilities option.

The STDOUT description is changed for the **–v** option to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #198 is applied, changing the description to consistently use "file" to refer to a file in the file system hierarchy, "archive" to refer to the archive being operated upon by the *ar* utility, and "file in the archive" to refer to a copy of a file that is contained in the archive.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/10 is applied, making corrections to the SYNOPSIS. The change was needed since the **–a**, **–b**, and **–i** options are mutually-exclusive, and *posname* is required if any of these options is specified.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/11 is applied, correcting the description of the two-byte trailer in RATIONALE which had missed out a backquote. The correct trailer is a backquote followed by a <newline>.

Issue 7

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The description of the **–t** option is changed to say "Only the files specified ...".

NAME

asa — interpret carriage-control characters

SYNOPSIS

FR

```
asa [file...]
```

DESCRIPTION

The *asa* utility shall write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences in an implementation-defined manner.

The first character of every line shall be removed from the input, and the following actions are performed.

If the character removed is:

<space> The rest of the line is output without change.

0 A <newline> is output, then the rest of the input line.

1 One or more implementation-defined characters that causes an advance to the next page shall be output, followed by the rest of the input line.

+ The <newline> of the previous line shall be replaced with one or more implementation-defined characters that causes printing to return to column position 1, followed by the rest of the input line. If the `'+'` is the first character in the input, it shall be equivalent to <space>.

The action of the *asa* utility is unspecified upon encountering any character other than those listed above as the first character in a line.

OPTIONS

None.

OPERANDS

file A pathname of a text file used for input. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *asa*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be the text from the input file modified as described in the DESCRIPTION section.

STDERR

None.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

1. The following command:

   ```
   asa file
   ```

   permits the viewing of *file* (created by a program using FORTRAN-style carriage-control characters) on a terminal.

2. The following command:

   ```
   a.out | asa | lp
   ```

   formats the FORTRAN output of **a.out** and directs it to the printer.

RATIONALE

The *asa* utility is needed to map "standard" FORTRAN 77 output into a form acceptable to contemporary printers. Usually, *asa* is used to pipe data to the *lp* utility; see *lp*.

This utility is generally used only by FORTRAN programs. The standard developers decided to retain *asa* to avoid breaking the historical large base of FORTRAN applications that put carriage-control characters in their output files. There is no requirement that a system have a FORTRAN compiler in order to run applications that need *asa*.

Historical implementations have used an ASCII <form-feed> in response to a 1 and an ASCII <carriage-return> in response to a '+'. It is suggested that implementations treat characters other than 0, 1, and '+' as <space> in the absence of any compelling reason to do otherwise.

However, the action is listed here as "unspecified", permitting an implementation to provide extensions to access fast multiple-line slewing and channel seeking in a non-portable manner.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the FORTRAN Runtime Utilities option.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

at — execute commands at a later time

SYNOPSIS

```
at [–m] [–f file] [–q queuename] –t time_arg
at [–m] [–f file] [–q queuename] timespec...
at –r at_job_id...
at –l –q queuename
at –l [at_job_id...]
```

DESCRIPTION

The *at* utility shall read commands from standard input and group them together as an *at-job*, to be executed at a later time.

The at-job shall be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask, and other implementation-defined execution-time attributes in effect when the *at* utility is executed shall be retained and used when the at-job is executed.

When the at-job is submitted, the *at_job_id* and scheduled time shall be written to standard error. The *at_job_id* is an identifier that shall be a string consisting solely of alphanumeric characters and the <period> character. The *at_job_id* shall be assigned by the system when the job is scheduled such that it uniquely identifies a particular job.

User notification and the processing of the job's standard output and standard error are described under the **–m** option.

XSI Users shall be permitted to use *at* if their name appears in the file **at.allow** which is located in an implementation-defined directory. If that file does not exist, the file **at.deny**, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to *at*. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only **at.deny** exists and is empty, global usage shall be permitted. The **at.allow** and **at.deny** files shall consist of one user name per line.

OPTIONS

The *at* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–f *file* Specify the pathname of a file to be used as the source of the at-job, instead of standard input.

–l (The letter ell.) Report all jobs scheduled for the invoking user if no *at_job_id* operands are specified. If *at_job_id*s are specified, report only information for these jobs. The output shall be written to standard output.

–m Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job shall be mailed to the user as well, unless redirected elsewhere. Mail shall be sent even if the job produces no output.

If **–m** is not used, the job's standard output and standard error shall be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the implementation need not notify the user of the job's completion.

76740 −**q** *queuename*

76741 Specify in which queue to schedule a job for submission. When used with the −**l**
76742 option, limit the search to that particular queue. By default, at-jobs shall be
76743 scheduled in queue *a*. In contrast, queue *b* shall be reserved for batch jobs; see
76744 *batch*. The meanings of all other *queuename*s are implementation-defined. If −**q** is
76745 specified along with either of the −**t** *time_arg* or *timespec* arguments, the results are
76746 unspecified.

76747 −**r** Remove the jobs with the specified *at_job_id* operands that were previously
76748 scheduled by the *at* utility.

76749 −**t** *time_arg* Submit the job to be run at the time specified by the *time* option-argument, which
76750 the application shall ensure has the format as specified by the *touch* −**t** *time* utility.

76751 **OPERANDS**

76752 The following operands shall be supported:

76753 *at_job_id* The name reported by a previous invocation of the *at* utility at the time the job was
76754 scheduled.

76755 *timespec* Submit the job to be run at the date and time specified. All of the *timespec* operands
76756 are interpreted as if they were separated by <space> characters and concatenated,
76757 and shall be parsed as described in the grammar at the end of this section. The date
76758 and time shall be interpreted as being in the timezone of the user (as determined
76759 by the *TZ* variable), unless a timezone name appears as part of *time*, below.

76760 In the POSIX locale, the following describes the three parts of the time specification
76761 string. All of the values from the *LC_TIME* categories in the POSIX locale shall be
76762 recognized in a case-insensitive manner.

76763 *time* The time can be specified as one, two, or four digits. One-digit and
76764 two-digit numbers shall be taken to be hours; four-digit numbers to
76765 be hours and minutes. The time can alternatively be specified as two
76766 numbers separated by a <colon>, meaning *hour*:*minute*. An AM/PM
76767 indication (one of the values from the **am_pm** keywords in the
76768 *LC_TIME* locale category) can follow the time; otherwise, a 24-hour
76769 clock time shall be understood. A timezone name can also follow to
76770 further qualify the time. The acceptable timezone names are
76771 implementation-defined, except that they shall be case-insensitive
76772 and the string **utc** is supported to indicate the time is in Coordinated
76773 Universal Time. In the POSIX locale, the *time* field can also be one of
76774 the following tokens:

76775 **midnight** Indicates the time 12:00 am (00:00).

76776 **noon** Indicates the time 12:00 pm.

76777 **now** Indicates the current day and time. Invoking *at* <**now**>
76778 shall submit an at-job for potentially immediate
76779 execution (that is, subject only to unspecified
76780 scheduling delays).

76781 *date* An optional *date* can be specified as either a month name (one of the
76782 values from the **mon** or **abmon** keywords in the *LC_TIME* locale
76783 category) followed by a day number (and possibly year number
76784 preceded by a comma), or a day of the week (one of the values from
76785 the **day** or **abday** keywords in the *LC_TIME* locale category). In the

POSIX locale, two special days shall be recognized:

today Indicates the current day.

tomorrow Indicates the day following the current day.

If no *date* is given, **today** shall be assumed if the given time is greater than the current time, and **tomorrow** shall be assumed if it is less. If the given month is less than the current month (and no year is given), next year shall be assumed.

increment The optional *increment* shall be a number preceded by a <plus-sign> ('+') and suffixed by one of the following: **minutes**, **hours**, **days**, **weeks**, **months**, or **years**. (The singular forms shall also be accepted.) The keyword **next** shall be equivalent to an increment number of +1. For example, the following are equivalent commands:

```
at 2pm + 1 week
at 2pm next week
```

The following grammar describes the precise format of *timespec* in the POSIX locale. The general conventions for this style of grammar are described in Section 1.3 (on page 2287). This formal syntax shall take precedence over the preceding text syntax description. The longest possible token or delimiter shall be recognized at a given point. When used in a *timespec*, white space shall also delimit tokens.

```
%token hr24clock_hr_min
%token hr24clock_hour
/*
  An hr24clock_hr_min is a one, two, or four-digit number. A one-digit
  or two-digit number constitutes an hr24clock_hour. An hr24clock_hour
  may be any of the single digits [0,9], or may be double digits, ranging
  from [00,23]. If an hr24clock_hr_min is a four-digit number, the
  first two digits shall be a valid hr24clock_hour, while the last two
  represent the number of minutes, from [00,59].
*/

%token wallclock_hr_min
%token wallclock_hour
/*
  A wallclock_hr_min is a one, two-digit, or four-digit number.
  A one-digit or two-digit number constitutes a wallclock_hour.
  A wallclock_hour may be any of the single digits [1,9], or may
  be double digits, ranging from [01,12]. If a wallclock_hr_min
  is a four-digit number, the first two digits shall be a valid
  wallclock_hour, while the last two represent the number of
  minutes, from [00,59].

76903                     | "day" | "days"
76904                     | "week" | "weeks"
76905                     | "month" | "months"
76906                     | "year" | "years"
76907                     ;
```

76908 **STDIN**

76909 The standard input shall be a text file consisting of commands acceptable to the shell command
76910 language described in Chapter 2 (on page 2297). The standard input shall only be used if no **–f**
76911 *file* option is specified.

76912 **INPUT FILES**

76913 See the STDIN section.

76914 XSI The text files **at.allow** and **at.deny**, which are located in an implementation-defined directory,
76915 shall contain zero or more user names, one per line, of users who are, respectively, authorized or
76916 denied access to the *at* and *batch* utilities.

76917 **ENVIRONMENT VARIABLES**

76918 The following environment variables shall affect the execution of *at*:

76919 *LANG* Provide a default value for the internationalization variables that are unset or null.
76920 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
76921 variables used to determine the values of locale categories.)

76922 *LC_ALL* If set to a non-empty string value, override the values of all the other
76923 internationalization variables.

76924 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
76925 characters (for example, single-byte as opposed to multi-byte characters in
76926 arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LC_TIME Determine the format and contents for date and time strings written and accepted by *at*.

SHELL Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, *sh* shall be used. If it is set to a value other than a name for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use the login shell from the user database; or any of the preceding accompanied by a warning diagnostic about which was chosen.

TZ Determine the timezone. The job shall be submitted for execution at the time specified by *timespec* or **–t** *time* relative to the timezone specified by the *TZ* variable. If *timespec* specifies a timezone, it shall override *TZ*. If *timespec* does not specify a timezone and *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

In the POSIX locale, the following shall be written to the standard output for each job when jobs are listed in response to the **–l** option:

```
"%s\t%s\n", at_job_id, <date>
```

where *date* shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the *TZ* variable).

STDERR

In the POSIX locale, the following shall be written to standard error when a job has been successfully submitted:

```
"job %s at %s\n", at_job_id, <date>
```

where *date* has the same format as that described in the STDOUT section. Neither this, nor warning messages concerning the selection of the command interpreter, shall be considered a diagnostic that changes the exit status.

Diagnostic messages, if any, shall be written to standard error.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The *at* utility successfully submitted, removed, or listed a job or jobs.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The job shall not be scheduled, removed, or listed.

APPLICATION USAGE

The format of the *at* command line shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps, and priority inherited from the invoking environment are lost.

Some implementations do not allow substitution of different shells using *SHELL*. System V systems, for example, have used the login shell value for the user in **/etc/passwd**. To select reliably another command interpreter, the user must include it as part of the script, such as:

```
$ at 1800
myshell myscript
EOT
job ... at ...
$
```

EXAMPLES

1. This sequence can be used at a terminal:

   ```
   at –m 0730 tomorrow
   sort < file >outfile
   EOT
   ```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

   ```
   at now + 1 hour <<!
   diff file1 file2 2>&1 >outfile | mailx mygroup
   !
   ```

3. To have a job reschedule itself, *at* can be invoked from within the at-job. For example, this daily processing script named **my.daily** runs every day (although *crontab* is a more appropriate vehicle for such work):

   ```
   # my.daily runs every day
   daily processing
   at now tomorrow < my.daily
   ```

4. The spacing of the three portions of the POSIX locale *timespec* is quite flexible as long as there are no ambiguities. Examples of various times and operand presentation include:

   ```
   at 0815am Jan 24
   at 8 :15amjan24
   at now "+ 1day"
   at 5 pm FRIday
   at ’17
   ```

```
77012                utc+
77013                30minutes'
```

77014 **RATIONALE**

77015 The *at* utility reads from standard input the commands to be executed at a later time. It may be
77016 useful to redirect standard output and standard error within the specified commands.

77017 The –**t** *time* option was added as a new capability to support an internationalized way of
77018 specifying a time for execution of the submitted job.

77019 Early proposals added a "jobname" concept as a way of giving submitted jobs names that are
77020 meaningful to the user submitting them. The historical, system-specified *at_job_id* gives no
77021 indication of what the job is. Upon further reflection, it was decided that the benefit of this was
77022 not worth the change in historical interface. The *at* functionality is useful in simple
77023 environments, but in large or complex situations, the functionality provided by the Batch
77024 Services option is more suitable.

77025 The –**q** option historically has been an undocumented option, used mainly by the *batch* utility.

77026 The System V –**m** option was added to provide a method for informing users that an at-job had
77027 completed. Otherwise, users are only informed when output to standard error or standard
77028 output are not redirected.

77029 The behavior of *at* <**now**> was changed in an early proposal from being unspecified to
77030 submitting a job for potentially immediate execution. Historical BSD *at* implementations support
77031 this. Historical System V implementations give an error in that case, but a change to the System
77032 V versions should have no backwards-compatibility ramifications.

77033 On BSD-based systems, a –**u** *user* option has allowed those with appropriate privileges to access
77034 the work of other users. Since this is primarily a system administration feature and is not
77035 universally implemented, it has been omitted. Similarly, a specification for the output format for
77036 a user with appropriate privileges viewing the queues of other users has been omitted.

77037 The –**f** *file* option from System V is used instead of the BSD method of using the last operand as
77038 the pathname. The BSD method is ambiguous—does:

77039 `at 1200 friday`

77040 mean the same thing if there is a file named **friday** in the current directory?

77041 The *at_job_id* is composed of a limited character set in historical practice, and it is mandated here
77042 to invalidate systems that might try using characters that require shell quoting or that could not
77043 be easily parsed by shell scripts.

77044 The *at* utility varies between System V and BSD systems in the way timezones are used. On
77045 System V systems, the *TZ* variable affects the at-job submission times and the times displayed
77046 for the user. On BSD systems, *TZ* is not taken into account. The BSD behavior is easily achieved
77047 with the current specification. If the user wishes to have the timezone default to that of the
77048 system, they merely need to issue the *at* command immediately following an unsetting or null
77049 assignment to *TZ*. For example:

77050 `TZ= at noon ...`

77051 gives the desired BSD result.

77052 While the *yacc*-like grammar specified in the OPERANDS section is lexically unambiguous with
77053 respect to the digit strings, a lexical analyzer would probably be written to look for and return
77054 digit strings in those cases. The parser could then check whether the digit string returned is a
77055 valid *day_number*, *year_number*, and so on, based on the context.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- If **–m** is not used, the job's standard output and standard error are provided to the user by mail.

The effects of using the **–q** and **–t** options as defined in the IEEE P1003.2b draft standard are specified.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

The *at* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the *at* utility.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

77078 **NAME**

77079 awk — pattern scanning and processing language

77080 **SYNOPSIS**

77081 `awk [–F ERE] [–v assignment]... program [argument...]`

77082 `awk [–F ERE] –f progfile [–f progfile]... [–v assignment]...`
77083 `[argument...]`

77084 **DESCRIPTION**

77085 The *awk* utility shall execute programs written in the *awk* programming language, which is
77086 specialized for textual data manipulation. An *awk* program is a sequence of patterns and
77087 corresponding actions. When input is read that matches a pattern, the action associated with that
77088 pattern is carried out.

77089 Input shall be interpreted as a sequence of records. By default, a record is a line, less its
77090 terminating <newline>, but this can be changed by using the **RS** built-in variable. Each record of
77091 input shall be matched in turn against each pattern in the program. For each pattern matched,
77092 the associated action shall be executed.

77093 The *awk* utility shall interpret each input record as a sequence of fields where, by default, a field
77094 is a string of non-<blank> characters. This default white-space field delimiter can be changed by
77095 using the **FS** built-in variable or **–F** *ERE*. The *awk* utility shall denote the first field in a record $1,
77096 the second $2, and so on. The symbol $0 shall refer to the entire record; setting any other field
77097 causes the re-evaluation of $0. Assigning to $0 shall reset the values of all other fields and the **NF**
77098 built-in variable.

77099 **OPTIONS**

77100 The *awk* utility shall conform to XBD Section 12.2 (on page 215).

77101 The following options shall be supported:

77102 **–F** *ERE* Define the input field separator to be the extended regular expression *ERE*, before
77103 any input is read; see Regular Expressions (on page 2439).

77104 **–f** *progfile* Specify the pathname of the file *progfile* containing an *awk* program. If multiple
77105 instances of this option are specified, the concatenation of the files specified as
77106 *progfile* in the order specified shall be the *awk* program. The *awk* program can
77107 alternatively be specified in the command line as a single argument.

77108 **–v** *assignment*
77109 The application shall ensure that the *assignment* argument is in the same form as an
77110 *assignment* operand. The specified variable assignment shall occur prior to
77111 executing the *awk* program, including the actions associated with **BEGIN** patterns
77112 (if any). Multiple occurrences of this option can be specified.

77113 **OPERANDS**

77114 The following operands shall be supported:

77115 *program* If no **–f** option is specified, the first operand to *awk* shall be the text of the *awk*
77116 program. The application shall supply the *program* operand as a single argument to
77117 *awk*. If the text does not end in a <newline>, *awk* shall interpret the text as if it did.

77118 *argument* Either of the following two types of *argument* can be intermixed:

77119 *file* A pathname of a file that contains the input to be read, which is
77120 matched against the set of patterns in the program. If no *file* operands
77121 are specified, or if a *file* operand is `'–'`, the standard input shall be
77122 used.

assignment An operand that begins with an <underscore> or alphabetic character from the portable character set (see the table in XBD Section 6.1, on page 125), followed by a sequence of underscores, digits, and alphabetics from the portable character set, followed by the `'='` character, shall specify a variable assignment rather than a pathname. The characters before the `'='` represent the name of an *awk* variable; if that name is an *awk* reserved word (see Grammar, on page 2447) the behavior is undefined. The characters following the <equals-sign> shall be interpreted as if they appeared in the *awk* program preceded and followed by a double-quote (`'"'`) character, as a **STRING** token (see Grammar, on page 2447), except that if the last character is an unescaped <backslash>, it shall be interpreted as a literal <backslash> rather than as the first character of the sequence `"\""`. The variable shall be assigned the value of that **STRING** token and, if appropriate, shall be considered a *numeric string* (see Expressions in awk, on page 2433), the variable shall also be assigned its numeric value. Each such variable assignment shall occur just prior to the processing of the following *file*, if any. Thus, an assignment before the first *file* argument shall be executed after the **BEGIN** actions (if any), while an assignment after the last *file* argument shall occur before the **END** actions (if any). If there are no *file* arguments, assignments shall be executed before processing the standard input.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'-'`; see the INPUT FILES section. If the *awk* program contains no actions and no patterns, but is otherwise a valid *awk* program, standard input and any *file* operands shall not be read and *awk* shall exit with a return status of zero.

INPUT FILES

Input files to the *awk* program from any of the following sources shall be text files:

- Any *file* operands or their equivalents, achieved by modifying the *awk* variables **ARGV** and **ARGC**
- Standard input in the absence of any *file* operands
- Arguments to the **getline** function

Whether the variable **RS** is set to a value other than a <newline> or not, for these files, implementations shall support records terminated with the specified separator up to {LINE_MAX} bytes and may support longer records.

If **−f** *progfile* is specified, the application shall ensure that the files named by each of the *progfile* option-arguments are text files and their concatenation, in the same order as they appear in the arguments, is an *awk* program.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *awk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

77168 *LC_ALL* If set to a non-empty string value, override the values of all the other
77169 internationalization variables.

77170 *LC_COLLATE*
77171 Determine the locale for the behavior of ranges, equivalence classes, and multi-
77172 character collating elements within regular expressions and in comparisons of
77173 string values.

77174 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
77175 characters (for example, single-byte as opposed to multi-byte characters in
77176 arguments and input files), the behavior of character classes within regular
77177 expressions, the identification of characters as letters, and the mapping of
77178 uppercase and lowercase characters for the **toupper** and **tolower** functions.

77179 *LC_MESSAGES*
77180 Determine the locale that should be used to affect the format and contents of
77181 diagnostic messages written to standard error.

77182 *LC_NUMERIC*
77183 Determine the radix character used when interpreting numeric input, performing
77184 conversions between numeric and string values, and formatting numeric output.
77185 Regardless of locale, the <period> character (the decimal-point character of the
77186 POSIX locale) is the decimal-point character recognized in processing *awk*
77187 programs (including assignments in command line arguments).

77188 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

77189 *PATH* Determine the search path when looking for commands executed by *system*(*expr*),
77190 or input and output pipes; see XBD Chapter 8 (on page 173).

77191 In addition, all environment variables shall be visible via the *awk* variable **ENVIRON**.

77192 **ASYNCHRONOUS EVENTS**
77193 Default.

77194 **STDOUT**
77195 The nature of the output files depends on the *awk* program.

77196 **STDERR**
77197 The standard error shall be used only for diagnostic messages.

77198 **OUTPUT FILES**
77199 The nature of the output files depends on the *awk* program.

77200 **EXTENDED DESCRIPTION**

77201 **Overall Program Structure**

77202 An *awk* program is composed of pairs of the form:

77203 ```
pattern { action }
```

77204 Either the pattern or the action (including the enclosing brace characters) can be omitted.

77205 A missing pattern shall match any record of input, and a missing action shall be equivalent to:

77206 ```
{ print }
```

77207 Execution of the *awk* program shall start by first executing the actions associated with all **BEGIN**
77208 patterns in the order they occur in the program. Then each *file* operand (or standard input if no
77209 files were specified) shall be processed in turn by reading data from the file until a record

77210 separator is seen (<newline> by default). Before the first reference to a field in the record is
77211 evaluated, the record shall be split into fields, according to the rules in Regular Expressions (on
77212 page 2439), using the value of **FS** that was current at the time the record was read. Each pattern
77213 in the program then shall be evaluated in the order of occurrence, and the action associated with
77214 each pattern that matches the current record executed. The action for a matching pattern shall be
77215 executed before evaluating subsequent patterns. Finally, the actions associated with all **END**
77216 patterns shall be executed in the order they occur in the program.

77217 **Expressions in awk**

77218 Expressions describe computations used in *patterns* and *actions*. In the following table, valid
77219 expression operations are given in groups from highest precedence first to lowest precedence
77220 last, with equal-precedence operators grouped between horizontal lines. In expression
77221 evaluation, where the grammar is formally ambiguous, higher precedence operators shall be
77222 evaluated before lower precedence operators. In this table *expr*, *expr1*, *expr2*, and *expr3* represent
77223 any expression, while lvalue represents any entity that can be assigned to (that is, on the left side
77224 of an assignment operator). The precise syntax of expressions is given in Grammar (on page
77225 2447).

77226 **Table 4-1** Expressions in Decreasing Precedence in *awk*

77227 | Syntax | Name | Type of Result | Associativity |
|---|---|---|---|
77228 | `( expr )` | Grouping | Type of *expr* | N/A |
77229 | `$expr` | Field reference | String | N/A |
77230 | `lvalue ++` | Post-increment | Numeric | N/A |
77231 | `lvalue --` | Post-decrement | Numeric | N/A |
77232 | `++ lvalue` | Pre-increment | Numeric | N/A |
77233 | `-- lvalue` | Pre-decrement | Numeric | N/A |
77234 | `expr ^ expr` | Exponentiation | Numeric | Right |
77235 | `! expr` | Logical not | Numeric | N/A |
77236 | `+ expr` | Unary plus | Numeric | N/A |
77237 | `- expr` | Unary minus | Numeric | N/A |
77238 | `expr * expr` | Multiplication | Numeric | Left |
77239 | `expr / expr` | Division | Numeric | Left |
77240 | `expr % expr` | Modulus | Numeric | Left |
77241 | `expr + expr` | Addition | Numeric | Left |
77242 | `expr - expr` | Subtraction | Numeric | Left |
77243 | `expr expr` | String concatenation | String | Left |
77244 | `expr < expr` | Less than | Numeric | None |
77245 | `expr <= expr` | Less than or equal to | Numeric | None |
77246 | `expr != expr` | Not equal to | Numeric | None |
77247 | `expr == expr` | Equal to | Numeric | None |
77248 | `expr > expr` | Greater than | Numeric | None |
77249 | `expr >= expr` | Greater than or equal to | Numeric | None |
77250 | `expr ~ expr` | ERE match | Numeric | None |
77251 | `expr !~ expr` | ERE non-match | Numeric | None |
77252 | `expr in array` | Array membership | Numeric | Left |
77253 | `( index ) in array` | Multi-dimension array | Numeric | Left |

Syntax	Name	Type of Result	Associativity
	membership		
expr `&&` *expr*	Logical AND	Numeric	Left
expr `||` *expr*	Logical OR	Numeric	Left
expr1 `?` *expr2* `:` *expr3*	Conditional expression	Type of selected *expr2* or *expr3*	Right
`lvalue ^=` *expr*	Exponentiation assignment	Numeric	Right
`lvalue %=` *expr*	Modulus assignment	Numeric	Right
`lvalue *=` *expr*	Multiplication assignment	Numeric	Right
`lvalue /=` *expr*	Division assignment	Numeric	Right
`lvalue +=` *expr*	Addition assignment	Numeric	Right
`lvalue -=` *expr*	Subtraction assignment	Numeric	Right
`lvalue =` *expr*	Assignment	Type of *expr*	Right

Each expression shall have either a string value, a numeric value, or both. Except as stated for specific contexts, the value of an expression shall be implicitly converted to the type needed for the context in which it is used. A string value shall be converted to a numeric value either by the equivalent of the following calls to functions defined by the ISO C standard:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

or by converting the initial portion of the string to type **double** representation as follows:

> The input string is decomposed into two parts: an initial, possibly empty, sequence of white-space characters (as specified by *isspace*()) and a subject sequence interpreted as a floating-point constant.
>
> The expected form of the subject sequence is an optional `'+'` or `'-'` sign, then a non-empty sequence of digits optionally containing a <period>, then an optional exponent part. An exponent part consists of `'e'` or `'E'`, followed by an optional sign, followed by one or more decimal digits.
>
> The sequence starting with the first digit or the <period> (whichever occurs first) is interpreted as a floating constant of the C language, and if neither an exponent part nor a <period> appears, a <period> is assumed to follow the last digit in the string. If the subject sequence begins with a minus-sign, the value resulting from the conversion is negated.

A numeric value that is exactly equal to the value of an integer (see Section 1.1.2, on page 2283) shall be converted to a string by the equivalent of a call to the **sprintf** function (see String Functions, on page 2444) with the string `"%d"` as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. Any other numeric value shall be converted to a string by the equivalent of a call to the **sprintf** function with the value of the variable **CONVFMT** as the *fmt* argument and the numeric value being converted as the first and only *expr* argument. The result of the conversion is unspecified if the value of **CONVFMT** is not a floating-point format specification. This volume of POSIX.1-200x specifies no explicit conversions between numbers and strings. An application can force an expression to be treated as a number by adding zero to it, or can force it to be treated as a string by concatenating the null string (`""`) to it.

A string value shall be considered a *numeric string* if it comes from one of the following:

1. Field variables

2. Input from the *getline*( ) function
3. **FILENAME**
4. **ARGV** array elements
5. **ENVIRON** array elements
6. Array elements created by the *split*( ) function
7. A command line variable assignment
8. Variable assignment from another numeric string variable

and an implementation-dependent condition corresponding to either case (a) or (b) below is met.

a. After the equivalent of the following calls to functions defined by the ISO C standard, *string_value_end* would differ from *string_value*, and any characters before the terminating null character in *string_value_end* would be <blank> characters:

```
char *string_value_end;
setlocale(LC_NUMERIC, "");
numeric_value = strtod (string_value, &string_value_end);
```

b. After all the following conversions have been applied, the resulting string would lexically be recognized as a **NUMBER** token as described by the lexical conventions in Grammar (on page 2447):

   — All leading and trailing <blank> characters are discarded.

   — If the first non-<blank> is `'+'` or `'-'`, it is discarded.

   — Each occurrence of the decimal point character from the current locale is changed to a <period>.

In case (a) the numeric value of the *numeric string* shall be the value that would be returned by the *strtod*( ) call. In case (b) if the first non-<blank> is `'-'`, the numeric value of the *numeric string* shall be the negation of the numeric value of the recognized **NUMBER** token; otherwise, the numeric value of the *numeric string* shall be the numeric value of the recognized **NUMBER** token. Whether or not a string is a *numeric string* shall be relevant only in contexts where that term is used in this section.

When an expression is used in a Boolean context, if it has a numeric value, a value of zero shall be treated as false and any other value shall be treated as true. Otherwise, a string value of the null string shall be treated as false and any other value shall be treated as true. A Boolean context shall be one of the following:

- The first subexpression of a conditional expression
- An expression operated on by logical NOT, logical AND, or logical OR
- The second expression of a **for** statement
- The expression of an **if** statement
- The expression of the **while** clause in either a **while** or **do**...**while** statement
- An expression used as a pattern (as in Overall Program Structure)

All arithmetic shall follow the semantics of floating-point arithmetic as specified by the ISO C standard (see Section 1.1.2, on page 2283).

The value of the expression:

77339 *expr1* ^ *expr2*

77340 shall be equivalent to the value returned by the ISO C standard function call:

77341 pow(*expr1*, *expr2*)

77342 The expression:

77343 lvalue ^= *expr*

77344 shall be equivalent to the ISO C standard expression:

77345 lvalue = pow(lvalue, *expr*)

77346 except that lvalue shall be evaluated only once. The value of the expression:

77347 *expr1* % *expr2*

77348 shall be equivalent to the value returned by the ISO C standard function call:

77349 fmod(*expr1*, *expr2*)

77350 The expression:

77351 lvalue %= *expr*

77352 shall be equivalent to the ISO C standard expression:

77353 lvalue = fmod(lvalue, *expr*)

77354 except that lvalue shall be evaluated only once.

77355 Variables and fields shall be set by the assignment statement:

77356 lvalue = *expression*

77357 and the type of *expression* shall determine the resulting variable type. The assignment includes
77358 the arithmetic assignments ("+=", "−=", "*=", "/=", "%=", "^=", "++", "−−") all of which
77359 shall produce a numeric result. The left-hand side of an assignment and the target of increment
77360 and decrement operators can be one of a variable, an array with index, or a field selector.

77361 The *awk* language supplies arrays that are used for storing numbers or strings. Arrays need not
77362 be declared. They shall initially be empty, and their sizes shall change dynamically. The
77363 subscripts, or element identifiers, are strings, providing a type of associative array capability. An
77364 array name followed by a subscript within square brackets can be used as an lvalue and thus as
77365 an expression, as described in the grammar; see Grammar (on page 2447). Unsubscripted array
77366 names can be used in only the following contexts:

77367 • A parameter in a function definition or function call

77368 • The **NAME** token following any use of the keyword **in** as specified in the grammar (see
77369 Grammar, on page 2447); if the name used in this context is not an array name, the
77370 behavior is undefined

77371 A valid array *index* shall consist of one or more <comma>-separated expressions, similar to the
77372 way in which multi-dimensional arrays are indexed in some programming languages. Because
77373 *awk* arrays are really one-dimensional, such a <comma>-separated list shall be converted to a
77374 single string by concatenating the string values of the separate expressions, each separated from
77375 the other by the value of the **SUBSEP** variable. Thus, the following two index operations shall be
77376 equivalent:

77377 *var*[*expr1*, *expr2*, ... *exprn*]

77378 *var*[*expr1* SUBSEP *expr2* SUBSEP ... SUBSEP *exprn*]

The application shall ensure that a multi-dimensioned *index* used with the **in** operator is parenthesized. The **in** operator, which tests for the existence of a particular array element, shall not cause that element to exist. Any other reference to a nonexistent array element shall automatically create it.

Comparisons (with the '<', "<=", "!=", "==", '>', and ">=" operators) shall be made numerically if both operands are numeric, if one is numeric and the other has a string value that is a numeric string, or if one is numeric and the other has the uninitialized value. Otherwise, operands shall be converted to strings as required and a string comparison shall be made using the locale-specific collation sequence. The value of the comparison expression shall be 1 if the relation is true, or 0 if the relation is false.

Variables and Special Variables

Variables can be used in an *awk* program by referencing them. With the exception of function parameters (see User-Defined Functions, on page 2446), they are not explicitly declared. Function parameter names shall be local to the function; all other variable names shall be global. The same name shall not be used as both a function parameter name and as the name of a function or a special *awk* variable. The same name shall not be used both as a variable name with global scope and as the name of a function. The same name shall not be used within the same scope both as a scalar variable and as an array. Uninitialized variables, including scalar variables, array elements, and field variables, shall have an uninitialized value. An uninitialized value shall have both a numeric value of zero and a string value of the empty string. Evaluation of variables with an uninitialized value, to either string or numeric, shall be determined by the context in which they are used.

Field variables shall be designated by a '$' followed by a number or numerical expression. The effect of the field number *expression* evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables can be created by assigning a value to them. References to nonexistent fields (that is, fields after $**NF**), shall evaluate to the uninitialized value. Such references shall not create new fields. However, assigning to a nonexistent field (for example, $(**NF**+2)=5) shall increase the value of **NF**; create any intervening fields with the uninitialized value; and cause the value of $0 to be recomputed, with the fields being separated by the value of **OFS**. Each field variable shall have a string value or an uninitialized value when created. Field variables shall have the uninitialized value when created from $0 using **FS** and the variable does not contain any characters. If appropriate, the field variable shall be considered a numeric string (see Expressions in awk, on page 2433).

Implementations shall support the following other special variables that are set by *awk*:

ARGC The number of elements in the **ARGV** array.

ARGV An array of command line arguments, excluding options and the *program* argument, numbered from zero to **ARGC**–1.

The arguments in **ARGV** can be modified or added to; **ARGC** can be altered. As each input file ends, *awk* shall treat the next non-null element of **ARGV**, up to the current value of **ARGC**–1, inclusive, as the name of the next input file. Thus, setting an element of **ARGV** to null means that it shall not be treated as an input file. The name '–' indicates the standard input. If an argument matches the format of an *assignment* operand, this argument shall be treated as an *assignment* rather than a *file* argument.

77424 **CONVFMT** The **printf** format for converting numbers to strings (except for output statements,
77425 where **OFMT** is used); `"%.6g"` by default.

77426 **ENVIRON** An array representing the value of the environment, as described in the *exec*
77427 functions defined in the System Interfaces volume of POSIX.1-200x. The indices of
77428 the array shall be strings consisting of the names of the environment variables, and
77429 the value of each array element shall be a string consisting of the value of that
77430 variable. If appropriate, the environment variable shall be considered a *numeric*
77431 *string* (see Expressions in awk, on page 2433); the array element shall also have its
77432 numeric value.

77433 In all cases where the behavior of *awk* is affected by environment variables
77434 (including the environment of any commands that *awk* executes via the **system**
77435 function or via pipeline redirections with the **print** statement, the **printf** statement,
77436 or the **getline** function), the environment used shall be the environment at the time
77437 *awk* began executing; it is implementation-defined whether any modification of
77438 **ENVIRON** affects this environment.

77439 **FILENAME** A pathname of the current input file. Inside a **BEGIN** action the value is
77440 undefined. Inside an **END** action the value shall be the name of the last input file
77441 processed.

77442 **FNR** The ordinal number of the current record in the current file. Inside a **BEGIN** action
77443 the value shall be zero. Inside an **END** action the value shall be the number of the
77444 last record processed in the last file processed.

77445 **FS** Input field separator regular expression; a <space> by default.

77446 **NF** The number of fields in the current record. Inside a **BEGIN** action, the use of **NF** is
77447 undefined unless a **getline** function without a *var* argument is executed previously.
77448 Inside an **END** action, **NF** shall retain the value it had for the last record read,
77449 unless a subsequent, redirected, **getline** function without a *var* argument is
77450 performed prior to entering the **END** action.

77451 **NR** The ordinal number of the current record from the start of input. Inside a **BEGIN**
77452 action the value shall be zero. Inside an **END** action the value shall be the number
77453 of the last record processed.

77454 **OFMT** The **printf** format for converting numbers to strings in output statements (see
77455 Output Statements, on page 2442); `"%.6g"` by default. The result of the conversion
77456 is unspecified if the value of **OFMT** is not a floating-point format specification.

77457 **OFS** The **print** statement output field separator; <space> by default.

77458 **ORS** The **print** statement output record separator; a <newline> by default.

77459 **RLENGTH** The length of the string matched by the **match** function.

77460 **RS** The first character of the string value of **RS** shall be the input record separator; a
77461 <newline> by default. If **RS** contains more than one character, the results are
77462 unspecified. If **RS** is null, then records are separated by sequences consisting of a
77463 <newline> plus one or more blank lines, leading or trailing blank lines shall not
77464 result in empty records at the beginning or end of the input, and a <newline> shall
77465 always be a field separator, no matter what the value of **FS** is.

77466 **RSTART** The starting position of the string matched by the **match** function, numbering from
77467 1. This shall always be equivalent to the return value of the **match** function.

77468 **SUBSEP** The subscript separator string for multi-dimensional arrays; the default value is
77469 implementation-defined.

77470 **Regular Expressions**

77471 The *awk* utility shall make use of the extended regular expression notation (see XBD Section 9.4,
77472 on page 188) except that it shall allow the use of C-language conventions for escaping special
77473 characters within the EREs, as specified in the table in XBD Chapter 5 (on page 121) (`'\\'`,
77474 `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) and the following table; these escape sequences
77475 shall be recognized both inside and outside bracket expressions. Note that records need not be
77476 separated by <newline> characters and string constants can contain <newline> characters, so
77477 even the `"\n"` sequence is valid in *awk* EREs. Using a <slash> character within an ERE requires
77478 the escaping shown in the following table.

77479 **Table 4-2** Escape Sequences in *awk*

77480 77481 77482 77483 77484 77485 77486 77487 77488 77489 77490 77491 77492 77493 77494 77495

Escape Sequence	Description	Meaning
`\"`	<backslash> <quotation-mark>	<quotation-mark> character
`\/`	<backslash> <slash>	<slash> character
`\ddd`	A <backslash> character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <backslash> for each byte.
`\c`	A <backslash> character followed by any character not described in this table or in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`).	Undefined

77496 A regular expression can be matched against a specific field or string by using one of the two
77497 regular expression matching operators, `'~'` and `"!~"`. These operators shall interpret their
77498 right-hand operand as a regular expression and their left-hand operand as a string. If the regular
77499 expression matches the string, the `'~'` expression shall evaluate to a value of 1, and the `"!~"`
77500 expression shall evaluate to a value of 0. (The regular expression matching operation is as
77501 defined by the term matched in XBD Section 9.1 (on page 181), where a match occurs on any part
77502 of the string unless the regular expression is limited with the <circumflex> or <dollar-sign>
77503 special characters.) If the regular expression does not match the string, the `'~'` expression shall
77504 evaluate to a value of 0, and the `"!~"` expression shall evaluate to a value of 1. If the right-hand
77505 operand is any expression other than the lexical token **ERE**, the string value of the expression
77506 shall be interpreted as an extended regular expression, including the escape conventions
77507 described above. Note that these same escape conventions shall also be applied in determining
77508 the value of a string literal (the lexical token **STRING**), and thus shall be applied a second time
77509 when a string literal is used in this context.

77510 When an **ERE** token appears as an expression in any context other than as the right-hand of the
77511 `'~'` or `"!~"` operator or as one of the built-in function arguments described below, the value of
77512 the resulting expression shall be the equivalent of:

77513 `$0 ~ /ere/`

77514 The *ere* argument to the **gsub**, **match**, **sub** functions, and the *fs* argument to the **split** function
77515 (see String Functions, on page 2444) shall be interpreted as extended regular expressions. These
77516 can be either **ERE** tokens or arbitrary expressions, and shall be interpreted in the same manner
77517 as the right-hand side of the `'~'` or `"!~"` operator.

77518 An extended regular expression can be used to separate fields by using the –**F** *ERE* option or by
77519 assigning a string containing the expression to the built-in variable **FS**. The default value of the
77520 **FS** variable shall be a single <space>. The following describes **FS** behavior:

77521 1. If **FS** is a null string, the behavior is unspecified.

77522 2. If **FS** is a single character:

77523 a. If **FS** is <space>, skip leading and trailing <blank> characters; fields shall be
77524 delimited by sets of one or more <blank> characters.

77525 b. Otherwise, if **FS** is any other character *c*, fields shall be delimited by each single
77526 occurrence of *c*.

77527 3. Otherwise, the string value of **FS** shall be considered to be an extended regular
77528 expression. Each occurrence of a sequence matching the extended regular expression shall
77529 delimit fields.

77530 Except for the `'~'` and `"!~"` operators, and in the **gsub**, **match**, **split**, and **sub** built-in functions,
77531 ERE matching shall be based on input records; that is, record separator characters (the first
77532 character of the value of the variable **RS**, <newline> by default) cannot be embedded in the
77533 expression, and no expression shall match the record separator character. If the record separator
77534 is not <newline>, <newline> characters embedded in the expression can be matched. For the
77535 `'~'` and `"!~"` operators, and in those four built-in functions, ERE matching shall be based on
77536 text strings; that is, any character (including <newline> and the record separator) can be
77537 embedded in the pattern, and an appropriate pattern shall match any character. However, in all
77538 *awk* ERE matching, the use of one or more NUL characters in the pattern, input record, or text
77539 string produces undefined results.

77540 **Patterns**

77541 A *pattern* is any valid *expression*, a range specified by two expressions separated by a comma, or
77542 one of the two special patterns **BEGIN** or **END**.

77543 **Special Patterns**

77544 The *awk* utility shall recognize two special patterns, **BEGIN** and **END**. Each **BEGIN** pattern
77545 shall be matched once and its associated action executed before the first record of input is read—
77546 except possibly by use of the **getline** function (see Input/Output and General Functions, on
77547 page 2445) in a prior **BEGIN** action—and before command line assignment is done. Each **END**
77548 pattern shall be matched once and its associated action executed after the last record of input has
77549 been read. These two patterns shall have associated actions.

77550 **BEGIN** and **END** shall not combine with other patterns. Multiple **BEGIN** and **END** patterns
77551 shall be allowed. The actions associated with the **BEGIN** patterns shall be executed in the order
77552 specified in the program, as are the **END** actions. An **END** pattern can precede a **BEGIN** pattern
77553 in a program.

77554 If an *awk* program consists of only actions with the pattern **BEGIN**, and the **BEGIN** action
77555 contains no **getline** function, *awk* shall exit without reading its input when the last statement in
77556 the last **BEGIN** action is executed. If an *awk* program consists of only actions with the pattern

77557 **END** or only actions with the patterns **BEGIN** and **END**, the input shall be read before the
77558 statements in the **END** actions are executed.

77559 **Expression Patterns**

77560 An expression pattern shall be evaluated as if it were an expression in a Boolean context. If the
77561 result is true, the pattern shall be considered to match, and the associated action (if any) shall be
77562 executed. If the result is false, the action shall not be executed.

77563 **Pattern Ranges**

77564 A pattern range consists of two expressions separated by a comma; in this case, the action shall
77565 be performed for all records between a match of the first expression and the following match of
77566 the second expression, inclusive. At this point, the pattern range can be repeated starting at
77567 input records subsequent to the end of the matched range.

77568 **Actions**

77569 An action is a sequence of statements as shown in the grammar in Grammar (on page 2447).
77570 Any single statement can be replaced by a statement list enclosed in curly braces. The
77571 application shall ensure that statements in a statement list are separated by <newline> or
77572 <semicolon> characters. Statements in a statement list shall be executed sequentially in the order
77573 that they appear.

77574 The *expression* acting as the conditional in an **if** statement shall be evaluated and if it is non-zero
77575 or non-null, the following statement shall be executed; otherwise, if **else** is present, the statement
77576 following the **else** shall be executed.

77577 The **if**, **while**, **do**...**while**, **for**, **break**, and **continue** statements are based on the ISO C standard
77578 (see Section 1.1.2, on page 2283), except that the Boolean expressions shall be treated as
77579 described in Expressions in awk (on page 2433), and except in the case of:

77580 `for (`*`variable`* `in` *`array`*`)`

77581 which shall iterate, assigning each *index* of *array* to *variable* in an unspecified order. The results of
77582 adding new elements to *array* within such a **for** loop are undefined. If a **break** or **continue**
77583 statement occurs outside of a loop, the behavior is undefined.

77584 The **delete** statement shall remove an individual array element. Thus, the following code deletes
77585 an entire array:

```
77586 for (index in array)
77587     delete array[index]
```

77588 The **next** statement shall cause all further processing of the current input record to be
77589 abandoned. The behavior is undefined if a **next** statement appears or is invoked in a **BEGIN** or
77590 **END** action.

77591 The **exit** statement shall invoke all **END** actions in the order in which they occur in the program
77592 source and then terminate the program without reading further input. An **exit** statement inside
77593 an **END** action shall terminate the program without further execution of **END** actions. If an
77594 expression is specified in an **exit** statement, its numeric value shall be the exit status of *awk*,
77595 unless subsequent errors are encountered or a subsequent **exit** statement with an expression is
77596 executed.

77597 **Output Statements**

77598 Both **print** and **printf** statements shall write to standard output by default. The output shall be
77599 written to the location specified by *output_redirection* if one is supplied, as follows:

77600 `> expression`
77601 `>> expression`
77602 `| expression`

77603 In all cases, the *expression* shall be evaluated to produce a string that is used as a pathname into
77604 which to write (for `'>'` or `">>"`) or as a command to be executed (for `'|'`). Using the first two
77605 forms, if the file of that name is not currently open, it shall be opened, creating it if necessary
77606 and using the first form, truncating the file. The output then shall be appended to the file. As
77607 long as the file remains open, subsequent calls in which *expression* evaluates to the same string
77608 value shall simply append output to the file. The file remains open until the **close** function (see
77609 Input/Output and General Functions, on page 2445) is called with an expression that evaluates
77610 to the same string value.

77611 The third form shall write output onto a stream piped to the input of a command. The stream
77612 shall be created if no stream is currently open with the value of *expression* as its command name.
77613 The stream created shall be equivalent to one created by a call to the *popen*( ) function defined in
77614 the System Interfaces volume of POSIX.1-200x with the value of *expression* as the *command*
77615 argument and a value of *w* as the *mode* argument. As long as the stream remains open,
77616 subsequent calls in which *expression* evaluates to the same string value shall write output to the
77617 existing stream. The stream shall remain open until the **close** function (see Input/Output and
77618 General Functions, on page 2445) is called with an expression that evaluates to the same string
77619 value. At that time, the stream shall be closed as if by a call to the *pclose*( ) function defined in
77620 the System Interfaces volume of POSIX.1-200x.

77621 As described in detail by the grammar in Grammar (on page 2447), these output statements shall
77622 take a <comma>-separated list of *expressions* referred to in the grammar by the non-terminal
77623 symbols **expr_list**, **print_expr_list**, or **print_expr_list_opt**. This list is referred to here as the
77624 *expression list*, and each member is referred to as an *expression argument*.

77625 The **print** statement shall write the value of each expression argument onto the indicated output
77626 stream separated by the current output field separator (see variable **OFS** above), and terminated
77627 by the output record separator (see variable **ORS** above). All expression arguments shall be
77628 taken as strings, being converted if necessary; this conversion shall be as described in
77629 Expressions in awk (on page 2433), with the exception that the **printf** format in **OFMT** shall be
77630 used instead of the value in **CONVFMT**. An empty expression list shall stand for the whole
77631 input record ($0).

77632 The **printf** statement shall produce output based on a notation similar to the File Format
77633 Notation used to describe file formats in this volume of POSIX.1-200x (see XBD Chapter 5, on
77634 page 121). Output shall be produced as specified with the first *expression* argument as the string
77635 *format* and subsequent *expression* arguments as the strings *arg1* to *argn*, inclusive, with the
77636 following exceptions:

77637 1. The *format* shall be an actual character string rather than a graphical representation.
77638 Therefore, it cannot contain empty character positions. The <space> in the *format* string,
77639 in any context other than a *flag* of a conversion specification, shall be treated as an
77640 ordinary character that is copied to the output.

77641 2. If the character set contains a `'Δ'` character and that character appears in the *format*
77642 string, it shall be treated as an ordinary character that is copied to the output.

3. The *escape sequences* beginning with a <backslash> character shall be treated as sequences of ordinary characters that are copied to the output. Note that these same sequences shall be interpreted lexically by *awk* when they appear in literal strings, but they shall not be treated specially by the **printf** statement.

4. A *field width* or *precision* can be specified as the `'*'` character instead of a digit string. In this case the next argument from the expression list shall be fetched and its numeric value taken as the field width or precision.

5. The implementation shall not precede or follow output from the `d` or `u` conversion specifier characters with <blank> characters not specified by the *format* string.

6. The implementation shall not precede output from the `o` conversion specifier character with leading zeros not specified by the *format* string.

7. For the `c` conversion specifier character: if the argument has a numeric value, the character whose encoding is that value shall be output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value shall be output; if the string does not contain any characters, the behavior is undefined.

8. For each conversion specification that consumes an argument, the next expression argument shall be evaluated. With the exception of the `c` conversion specifier character, the value shall be converted (according to the rules specified in Expressions in awk, on page 2433) to the appropriate type for the conversion specification.

9. If there are insufficient expression arguments to satisfy all the conversion specifications in the *format* string, the behavior is undefined.

10. If any character sequence in the *format* string begins with a `'%'` character, but does not form a valid conversion specification, the behavior is unspecified.

Both **print** and **printf** can output at least {LINE_MAX} bytes.

Functions

The *awk* language has a variety of built-in functions: arithmetic, string, input/output, and general.

Arithmetic Functions

The arithmetic functions, except for **int**, shall be based on the ISO C standard (see Section 1.1.2, on page 2283). The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar (see Grammar, on page 2447) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the `"[]"` brackets), such use is undefined.

atan2(y,x) Return arctangent of y/x in radians in the range $[-\pi,\pi]$.

cos(x) Return cosine of x, where x is in radians.

sin(x) Return sine of x, where x is in radians.

exp(x) Return the exponential function of x.

log(x) Return the natural logarithm of x.

77683 **sqrt**(*x*) Return the square root of *x*.

77684 **int**(*x*) Return the argument truncated to an integer. Truncation shall be toward 0 when
77685 *x*>0.

77686 **rand**( ) Return a random number *n*, such that 0≤*n*<1.

77687 **srand**([*expr*]) Set the seed value for *rand* to *expr* or use the time of day if *expr* is omitted. The
77688 previous seed value shall be returned.

77689 **String Functions**

77690 The string functions in the following list shall be supported. Although the grammar (see
77691 Grammar, on page 2447) permits built-in functions to appear with no arguments or parentheses,
77692 unless the argument or parentheses are indicated as optional in the following list (by displaying
77693 them within the "[]" brackets), such use is undefined.

77694 **gsub**(*ere*, *repl*[, *in*])
77695 Behave like **sub** (see below), except that it shall replace all occurrences of the
77696 regular expression (like the *ed* utility global substitute) in $0 or in the *in* argument,
77697 when specified.

77698 **index**(*s*, *t*) Return the position, in characters, numbering from 1, in string *s* where string *t* first
77699 occurs, or zero if it does not occur at all.

77700 **length**[([*s*])] Return the length, in characters, of its argument taken as a string, or of the whole
77701 record, $0, if there is no argument.

77702 **match**(*s*, *ere*) Return the position, in characters, numbering from 1, in string *s* where the
77703 extended regular expression *ere* occurs, or zero if it does not occur at all. RSTART
77704 shall be set to the starting position (which is the same as the returned value), zero
77705 if no match is found; RLENGTH shall be set to the length of the matched string, –1
77706 if no match is found.

77707 **split**(*s*, *a*[, *fs*])
77708 Split the string *s* into array elements *a*[1], *a*[2], ..., *a*[*n*], and return *n*. All elements
77709 of the array shall be deleted before the split is performed. The separation shall be
77710 done with the ERE *fs* or with the field separator **FS** if *fs* is not given. Each array
77711 element shall have a string value when created and, if appropriate, the array
77712 element shall be considered a numeric string (see Expressions in awk, on page
77713 2433). The effect of a null string as the value of *fs* is unspecified.

77714 **sprintf**(*fmt*, *expr*, *expr*, ...)
77715 Format the expressions according to the **printf** format given by *fmt* and return the
77716 resulting string.

77717 **sub**(*ere*, *repl*[, *in*])
77718 Substitute the string *repl* in place of the first instance of the extended regular
77719 expression *ERE* in string *in* and return the number of substitutions. An
77720 <ampersand> ('&') appearing in the string *repl* shall be replaced by the string
77721 from *in* that matches the ERE. An <ampersand> preceded with a <backslash> shall -
77722 be interpreted as the literal <ampersand> character. An occurrence of two
77723 consecutive <backslash> characters shall be interpreted as just a single literal
77724 <backslash> character. Any other occurrence of a <backslash> (for example,
77725 preceding any other character) shall be treated as a literal <backslash> character.
77726 Note that if *repl* is a string literal (the lexical token **STRING**; see Grammar, on page
77727 2447), the handling of the <ampersand> character occurs after any lexical

77728 processing, including any lexical <backslash>-escape sequence processing. If *in* is
77729 specified and it is not an lvalue (see Expressions in awk, on page 2433), the
77730 behavior is undefined. If *in* is omitted, *awk* shall use the current record ($0) in its
77731 place.

77732 **substr**(*s*, *m*[, *n*])
77733 Return the at most *n*-character substring of *s* that begins at position *m*, numbering
77734 from 1. If *n* is omitted, or if *n* specifies more characters than are left in the string,
77735 the length of the substring shall be limited by the length of the string *s*.

77736 **tolower**(*s*) Return a string based on the string *s*. Each character in *s* that is an uppercase letter
77737 specified to have a **tolower** mapping by the *LC_CTYPE* category of the current
77738 locale shall be replaced in the returned string by the lowercase letter specified by
77739 the mapping. Other characters in *s* shall be unchanged in the returned string.

77740 **toupper**(*s*) Return a string based on the string *s*. Each character in *s* that is a lowercase letter
77741 specified to have a **toupper** mapping by the *LC_CTYPE* category of the current
77742 locale is replaced in the returned string by the uppercase letter specified by the
77743 mapping. Other characters in *s* are unchanged in the returned string.

77744 All of the preceding functions that take *ERE* as a parameter expect a pattern or a string valued
77745 expression that is a regular expression as defined in Regular Expressions (on page 2439).

77746 **Input/Output and General Functions**

77747 The input/output and general functions are:

77748 **close**(*expression*)
77749 Close the file or pipe opened by a **print** or **printf** statement or a call to **getline** with
77750 the same string-valued *expression*. The limit on the number of open *expression*
77751 arguments is implementation-defined. If the close was successful, the function
77752 shall return zero; otherwise, it shall return non-zero.

77753 *expression* | **getline** [*var*]
77754 Read a record of input from a stream piped from the output of a command. The
77755 stream shall be created if no stream is currently open with the value of *expression* as
77756 its command name. The stream created shall be equivalent to one created by a call
77757 to the *popen*( ) function with the value of *expression* as the *command* argument and a
77758 value of *r* as the *mode* argument. As long as the stream remains open, subsequent
77759 calls in which *expression* evaluates to the same string value shall read subsequent
77760 records from the stream. The stream shall remain open until the **close** function is
77761 called with an expression that evaluates to the same string value. At that time, the
77762 stream shall be closed as if by a call to the *pclose*( ) function. If *var* is omitted, $0 and
77763 **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered
77764 a numeric string (see Expressions in awk, on page 2433).

77765 The **getline** operator can form ambiguous constructs when there are
77766 unparenthesized operators (including concatenate) to the left of the `'|'` (to the
77767 beginning of the expression containing **getline**). In the context of the `'$'` operator,
77768 `'|'` shall behave as if it had a lower precedence than `'$'`. The result of evaluating
77769 other operators is unspecified, and conforming applications shall parenthesize
77770 properly all such usages.

77771 **getline** Set $0 to the next input record from the current input file. This form of **getline** shall
77772 set the **NF**, **NR**, and **FNR** variables.

77773 **getline** *var* Set variable *var* to the next input record from the current input file and, if
77774 appropriate, *var* shall be considered a numeric string (see Expressions in awk, on
77775 page 2433). This form of **getline** shall set the **FNR** and **NR** variables.

77776 **getline** [*var*] < *expression*
77777 Read the next record of input from a named file. The *expression* shall be evaluated
77778 to produce a string that is used as a pathname. If the file of that name is not
77779 currently open, it shall be opened. As long as the stream remains open, subsequent
77780 calls in which *expression* evaluates to the same string value shall read subsequent
77781 records from the file. The file shall remain open until the **close** function is called
77782 with an expression that evaluates to the same string value. If *var* is omitted, $0 and
77783 **NF** shall be set; otherwise, *var* shall be set and, if appropriate, it shall be considered
77784 a numeric string (see Expressions in awk, on page 2433).

77785 The **getline** operator can form ambiguous constructs when there are
77786 unparenthesized binary operators (including concatenate) to the right of the `'<'`
77787 (up to the end of the expression containing the **getline**). The result of evaluating
77788 such a construct is unspecified, and conforming applications shall parenthesize
77789 properly all such usages.

77790 **system**(*expression*)
77791 Execute the command given by *expression* in a manner equivalent to the *system*()
77792 function defined in the System Interfaces volume of POSIX.1-200x and return the
77793 exit status of the command.

77794 All forms of **getline** shall return 1 for successful input, zero for end-of-file, and –1 for an error.

77795 Where strings are used as the name of a file or pipeline, the application shall ensure that the
77796 strings are textually identical. The terminology "same string value" implies that "equivalent
77797 strings", even those that differ only by <space> characters, represent different files.

77798 **User-Defined Functions**

77799 The *awk* language also provides user-defined functions. Such functions can be defined as:

77800 `function` *`name`*`(`[*`parameter`*`, ...]) { `*`statements`*` }`

77801 A function can be referred to anywhere in an *awk* program; in particular, its use can precede its
77802 definition. The scope of a function is global.

77803 Function parameters, if present, can be either scalars or arrays; the behavior is undefined if an
77804 array name is passed as a parameter that the function uses as a scalar, or if a scalar expression is
77805 passed as a parameter that the function uses as an array. Function parameters shall be passed by
77806 value if scalar and by reference if array name.

77807 The number of parameters in the function definition need not match the number of parameters
77808 in the function call. Excess formal parameters can be used as local variables. If fewer arguments
77809 are supplied in a function call than are in the function definition, the extra parameters that are
77810 used in the function body as scalars shall evaluate to the uninitialized value until they are
77811 otherwise initialized, and the extra parameters that are used in the function body as arrays shall
77812 be treated as uninitialized arrays where each element evaluates to the uninitialized value until
77813 otherwise initialized.

77814 When invoking a function, no white space can be placed between the function name and the
77815 opening parenthesis. Function calls can be nested and recursive calls can be made upon
77816 functions. Upon return from any nested or recursive function call, the values of all of the calling
77817 function's parameters shall be unchanged, except for array parameters passed by reference. The

77818 **return** statement can be used to return a value. If a **return** statement appears outside of a
77819 function definition, the behavior is undefined.

77820 In the function definition, <newline> characters shall be optional before the opening brace and
77821 after the closing brace. Function definitions can appear anywhere in the program where a
77822 *pattern-action* pair is allowed.

77823 **Grammar**

77824 The grammar in this section and the lexical conventions in the following section shall together
77825 describe the syntax for *awk* programs. The general conventions for this style of grammar are
77826 described in Section 1.3 (on page 2287). A valid program can be represented as the non-terminal
77827 symbol *program* in the grammar. This formal syntax shall take precedence over the preceding
77828 text syntax description.

                ;
```

This grammar has several ambiguities that shall be resolved as follows:

- Operator precedence and associativity shall be as described in Table 4-1 (on page 2433).
- In case of ambiguity, an **else** shall be associated with the most immediately preceding **if** that would satisfy the grammar.
- In some contexts, a <slash> (`'/'`) that is used to surround an ERE could also be the division operator. This shall be resolved in such a way that wherever the division operator could appear, a <slash> is assumed to be the division operator. (There is no unary division operator.)

Each expression in an *awk* program shall conform to the precedence and associativity rules, even when this is not needed to resolve an ambiguity. For example, because `'$'` has higher precedence than `'++'`, the string `"$x++--"` is not a valid *awk* expression, even though it is unambiguously parsed by the grammar as `"$(x++)--"`.

One convention that might not be obvious from the formal grammar is where <newline> characters are acceptable. There are several obvious placements such as terminating a statement, and a <backslash> can be used to escape <newline> characters between any lexical tokens. In addition, <newline> characters without <backslash> characters can follow a comma, an open brace, logical AND operator (`"&&"`), logical OR operator (`"||"`), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print  $1,
         $2 }
```

Lexical Conventions

The lexical conventions for *awk* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *awk* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the <number-sign> character and terminated by, but excluding the next occurrence of, a <newline>. Comments shall have no effect, except to delimit lexical tokens.
3. The <newline> shall be recognized as the token **NEWLINE**.
4. A <backslash> character immediately followed by a <newline> shall have no effect.
5. The token **STRING** shall represent a string constant. A string constant shall begin with the character `'"'`. Within a string constant, a <backslash> character shall be considered to begin an escape sequence as specified in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in Table 4-2 (on page 2439) shall be recognized. A <newline> shall not occur within a string constant. A string constant shall be terminated by the first unescaped occurrence of the character `'"'` after the one that begins the string constant. The value of the string

78149 shall be the sequence of all unescaped characters and values of escape sequences
78150 between, but not including, the two delimiting '"' characters.

78151 6. The token **ERE** represents an extended regular expression constant. An ERE constant
78152 shall begin with the <slash> character. Within an ERE constant, a <backslash> character
78153 shall be considered to begin an escape sequence as specified in the table in XBD Chapter 5
78154 (on page 121). In addition, the escape sequences in Table 4-2 (on page 2439) shall be
78155 recognized. The application shall ensure that a <newline> does not occur within an ERE
78156 constant. An ERE constant shall be terminated by the first unescaped occurrence of the
78157 <slash> character after the one that begins the ERE constant. The extended regular
78158 expression represented by the ERE constant shall be the sequence of all unescaped
78159 characters and values of escape sequences between, but not including, the two delimiting
78160 <slash> characters.

78161 7. A <blank> shall have no effect, except to delimit lexical tokens or within **STRING** or **ERE**
78162 tokens.

78163 8. The token **NUMBER** shall represent a numeric constant. Its form and numeric value shall
78164 either be equivalent to the **decimal-floating-constant** token as specified by the ISO C
78165 standard, or it shall be a sequence of decimal digits and shall be evaluated as an integer
78166 constant in decimal. In addition, implementations may accept numeric constants with the
78167 form and numeric value equivalent to the **hexadecimal-constant** and **hexadecimal-**
78168 **floating-constant** tokens as specified by the ISO C standard.

78169 If the value is too large or too small to be representable (see Section 1.1.2, on page 2283),
78170 the behavior is undefined.

78171 9. A sequence of underscores, digits, and alphabetics from the portable character set (see
78172 XBD Section 6.1, on page 125), beginning with an <underscore> or alphabetic character,
78173 shall be considered a word.

78174 10. The following words are keywords that shall be recognized as individual tokens; the
78175 name of the token is the same as the keyword:

78176 **BEGIN**	**delete**	**END**	**function**	**in**	**printf**
78177 **break**	**do**	**exit**	**getline**	**next**	**return**
78178 **continue**	**else**	**for**	**if**	**print**	**while**

78179 11. The following words are names of built-in functions and shall be recognized as the token
78180 **BUILTIN_FUNC_NAME**:

78181 **atan2**	**gsub**	**log**	**split**	**sub**	**toupper**
78182 **close**	**index**	**match**	**sprintf**	**substr**	
78183 **cos**	**int**	**rand**	**sqrt**	**system**	
78184 **exp**	**length**	**sin**	**srand**	**tolower**	

78185 The above-listed keywords and names of built-in functions are considered reserved
78186 words.

78187 12. The token **NAME** shall consist of a word that is not a keyword or a name of a built-in
78188 function and is not followed immediately (without any delimiters) by the '(' character.

78189 13. The token **FUNC_NAME** shall consist of a word that is not a keyword or a name of a
78190 built-in function, followed immediately (without any delimiters) by the '(' character.
78191 The '(' character shall not be included as part of the token.

14. The following two-character sequences shall be recognized as the named tokens:

Token Name	Sequence	Token Name	Sequence
ADD_ASSIGN	+=	**NO_MATCH**	!~
SUB_ASSIGN	–=	**EQ**	==
MUL_ASSIGN	*=	**LE**	<=
DIV_ASSIGN	/=	**GE**	>=
MOD_ASSIGN	%=	**NE**	!=
POW_ASSIGN	^=	**INCR**	++
OR	||	**DECR**	––
AND	&&	**APPEND**	>>

15. The following single characters shall be recognized as tokens whose names are the character:

    ```
    <newline> { } ( ) [ ] , ; + – * % ^ ! > < | ? : ~ $ =
    ```

There is a lexical ambiguity between the token **ERE** and the tokens `'/'` and **DIV_ASSIGN**. When an input sequence begins with a <slash> character in any syntactic context where the token `'/'` or **DIV_ASSIGN** could appear as the next token in a valid program, the longer of those two tokens that can be recognized shall be recognized. In any other syntactic context where the token **ERE** could appear as the next token in a valid program, the token **ERE** shall be recognized.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 An error occurred.

The exit status can be altered within the program by using an **exit** expression.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *awk* shall write a diagnostic message to standard error and terminate without any further action.

If the program specified by either the *program* operand or a *progfile* operand is not a valid *awk* program (as specified in the EXTENDED DESCRIPTION section), the behavior is undefined.

APPLICATION USAGE

The **index**, **length**, **match**, and **substr** functions should not be confused with similar functions in the ISO C standard; the *awk* versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

EXAMPLES

The *awk* program specified in the command line is most easily specified within single-quotes (for example, *'program'*) for applications using *sh*, because *awk* programs commonly contain characters that are special to the shell, including double-quotes. In the cases where an *awk* program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/'\''/ { print "quote:", $0 }'
```

78236 prints all lines from the standard input containing a single-quote character, prefixed with *quote*:.

78237 The following are examples of simple *awk* programs:

78238 1. Write to the standard output all input lines for which field 3 is greater than 5:

78239 ```
$3 > 5
```

78240 2. Write every tenth line:

78241 ```
(NR % 10) == 0
```

78242 3. Write any line with a substring matching the regular expression:

78243 ```
/(G|D)(2[0–9][[:alpha:]]*)/
```

78244 4. Print any line with a substring containing a `'G'` or `'D'`, followed by a sequence of digits
78245 and characters. This example uses character classes **digit** and **alpha** to match language-
78246 independent digit and alphabetic characters respectively:

78247 ```
/(G|D)([[:digit:][:alpha:]]*)/
```

78248 5. Write any line in which the second field matches the regular expression and the fourth
78249 field does not:

78250 ```
$2 ~ /xyz/ && $4 !~ /xyz/
```

78251 6. Write any line in which the second field contains a <backslash>:

78252 ```
$2 ~ /\\/
```

78253 7. Write any line in which the second field contains a <backslash>. Note that
78254 <backslash>-escapes are interpreted twice; once in lexical processing of the string and
78255 once in processing the regular expression:

78256 ```
$2 ~ "\\\\"
```

78257 8. Write the second to the last and the last field in each line. Separate the fields by a <colon>:

78258 ```
{OFS=":";print $(NF–1), $NF}
```

78259 9. Write the line number and number of fields in each line. The three strings representing
78260 the line number, the <colon>, and the number of fields are concatenated and that string is
78261 written to standard output:

78262 ```
{print NR ":" NF}
```

78263 10. Write lines longer than 72 characters:

78264 ```
length($0) > 72
```

78265 11. Write the first two fields in opposite order separated by **OFS**:

78266 ```
{ print $2, $1 }
```

78267 12. Same, with input fields separated by a <comma> or <space> and <tab> characters, or
78268 both:

78269 ```
BEGIN { FS = ",[ \t]*|[ \t]+" }
78270       { print $2, $1 }
```

78271 13. Add up the first column, print sum, and average:

78272 ```
      {s += $1 }
78273 END   {print "sum is ", s, " average is", s/NR}
```
```

14. Write fields in reverse order, one per line (many lines out for each line in):

```
{ for (i = NF; i > 0; --i) print $i }
```

15. Write all lines between occurrences of the strings **start** and **stop**:

```
/start/, /stop/
```

16. Write all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

17. Simulate *echo*:

```
BEGIN  {
        for (i = 1; i < ARGC; ++i)
        printf("%s%s", ARGV[i], i==ARGC-1?"\n":" ")
}
```

18. Write the path prefixes contained in the *PATH* environment variable, one per line:

```
BEGIN  {
        n = split (ENVIRON["PATH"], path, ":")
        for (i = 1; i <= n; ++i)
        print path[i]
}
```

19. If there is a file named **input** containing page headers of the form:

    Page #

    and a file named **program** that contains:

```
/Page/   { $2 = n++; }
         { print }
```

    then the command line:

```
awk -f program n=5 input
```

    prints the file **input**, filling in page numbers starting at 5.

RATIONALE

This description is based on the new *awk*, "nawk", (see the referenced *The AWK Programming Language*), which introduced a number of new features to the historical *awk*:

1. New keywords: **delete**, **do**, **function**, **return**
2. New built-in functions: **atan2**, **close**, **cos**, **gsub**, **match**, **rand**, **sin**, **srand**, **sub**, **system**
3. New predefined variables: **FNR**, **ARGC**, **ARGV**, **RSTART**, **RLENGTH**, **SUBSEP**
4. New expression operators: **?**, **:**, **,,** **^**
5. The **FS** variable and the third argument to **split**, now treated as extended regular expressions.
6. The operator precedence, changed to more closely match the C language. Two examples of code that operate differently are:

```
while ( n /= 10 > 1) ...
if (!"wk" ~ /bwk/) ...
```

Several features have been added based on newer implementations of *awk*:

- Multiple instances of **–f** *progfile* are permitted.
- The new option **–v** *assignment*.
- The new predefined variable **ENVIRON**.
- New built-in functions **toupper** and **tolower**.
- More formatting capabilities are added to **printf** to match the ISO C standard.

The overall *awk* syntax has always been based on the C language, with a few features from the shell command language and other sources. Because of this, it is not completely compatible with any other language, which has caused confusion for some users. It is not the intent of the standard developers to address such issues. A few relatively minor changes toward making the language more compatible with the ISO C standard were made; most of these changes are based on similar changes in recent implementations, as described above. There remain several C-language conventions that are not in *awk*. One of the notable ones is the <comma> operator, which is commonly used to specify multiple expressions in the C language **for** statement. Also, there are various places where *awk* is more restrictive than the C language regarding the type of expression that can be used in a given context. These limitations are due to the different features that the *awk* language does provide.

Regular expressions in *awk* have been extended somewhat from historical implementations to make them a pure superset of extended regular expressions, as defined by POSIX.1-200x (see XBD Section 9.4, on page 188). The main extensions are internationalization features and interval expressions. Historical implementations of *awk* have long supported <backslash>-escape sequences as an extension to extended regular expressions, and this extension has been retained despite inconsistency with other utilities. The number of escape sequences recognized in both extended regular expressions and strings has varied (generally increasing with time) among implementations. The set specified by POSIX.1-200x includes most sequences known to be supported by popular implementations and by the ISO C standard. One sequence that is not supported is hexadecimal value escapes beginning with `'\x'`. This would allow values expressed in more than 9 bits to be used within *awk* as in the ISO C standard. However, because this syntax has a non-deterministic length, it does not permit the subsequent character to be a hexadecimal digit. This limitation can be dealt with in the C language by the use of lexical string concatenation. In the *awk* language, concatenation could also be a solution for strings, but not for extended regular expressions (either lexical ERE tokens or strings used dynamically as regular expressions). Because of this limitation, the feature has not been added to POSIX.1-200x.

When a string variable is used in a context where an extended regular expression normally appears (where the lexical token ERE is used in the grammar) the string does not contain the literal <slash> characters.

Some versions of *awk* allow the form:

```
func name(args, ... ) { statements }
```

This has been deprecated by the authors of the language, who asked that it not be specified.

Historical implementations of *awk* produce an error if a **next** statement is executed in a **BEGIN** action, and cause *awk* to terminate if a **next** statement is executed in an **END** action. This behavior has not been documented, and it was not believed that it was necessary to standardize it.

The specification of conversions between string and numeric values is much more detailed than in the documentation of historical implementations or in the referenced *The AWK Programming Language*. Although most of the behavior is designed to be intuitive, the details are necessary to

ensure compatible behavior from different implementations. This is especially important in relational expressions since the types of the operands determine whether a string or numeric comparison is performed. From the perspective of an application developer, it is usually sufficient to expect intuitive behavior and to force conversions (by adding zero or concatenating a null string) when the type of an expression does not obviously match what is needed. The intent has been to specify historical practice in almost all cases. The one exception is that, in historical implementations, variables and constants maintain both string and numeric values after their original value is converted by any use. This means that referencing a variable or constant can have unexpected side-effects. For example, with historical implementations the following program:

```
{
    a = "+2"
    b = 2
    if (NR % 2)
        c = a + b
    if (a == b)
        print "numeric comparison"
    else
        print "string comparison"
}
```

would perform a numeric comparison (and output numeric comparison) for each odd-numbered line, but perform a string comparison (and output string comparison) for each even-numbered line. POSIX.1-200x ensures that comparisons will be numeric if necessary. With historical implementations, the following program:

```
BEGIN {
    OFMT = "%e"
    print 3.14
    OFMT = "%f"
    print 3.14
}
```

would output `"3.140000e+00"` twice, because in the second **print** statement the constant `"3.14"` would have a string value from the previous conversion. POSIX.1-200x requires that the output of the second **print** statement be `"3.140000"`. The behavior of historical implementations was seen as too unintuitive and unpredictable.

It was pointed out that with the rules contained in early drafts, the following script would print nothing:

```
BEGIN {
    y[1.5] = 1
    OFMT = "%e"
    print y[1.5]
}
```

Therefore, a new variable, **CONVFMT**, was introduced. The **OFMT** variable is now restricted to affecting output conversions of numbers to strings and **CONVFMT** is used for internal conversions, such as comparisons or array indexing. The default value is the same as that for **OFMT**, so unless a program changes **CONVFMT** (which no historical program would do), it will receive the historical behavior associated with internal string conversions.

The POSIX *awk* lexical and syntactic conventions are specified more formally than in other sources. Again the intent has been to specify historical practice. One convention that may not be

obvious from the formal grammar as in other verbal descriptions is where <newline> characters are acceptable. There are several obvious placements such as terminating a statement, and a <backslash> can be used to escape <newline> characters between any lexical tokens. In addition, <newline> characters without <backslash> characters can follow a comma, an open brace, a logical AND operator ("&&"), a logical OR operator ("||"), the **do** keyword, the **else** keyword, and the closing parenthesis of an **if**, **for**, or **while** statement. For example:

```
{ print $1,
        $2 }
```

The requirement that *awk* add a trailing <newline> to the program argument text is to simplify the grammar, making it match a text file in form. There is no way for an application or test suite to determine whether a literal <newline> is added or whether *awk* simply acts as if it did.

POSIX.1-200x requires several changes from historical implementations in order to support internationalization. Probably the most subtle of these is the use of the decimal-point character, defined by the *LC_NUMERIC* category of the locale, in representations of floating-point numbers. This locale-specific character is used in recognizing numeric input, in converting between strings and numeric values, and in formatting output. However, regardless of locale, the <period> character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing *awk* programs (including assignments in command line arguments). This is essentially the same convention as the one used in the ISO C standard. The difference is that the C language includes the *setlocale*() function, which permits an application to modify its locale. Because of this capability, a C application begins executing with its locale set to the C locale, and only executes in the environment-specified locale after an explicit call to *setlocale*(). However, adding such an elaborate new feature to the *awk* language was seen as inappropriate for POSIX.1-200x. It is possible to execute an *awk* program explicitly in any desired locale by setting the environment in the shell.

The undefined behavior resulting from NULs in extended regular expressions allows future extensions for the GNU *gawk* program to process binary data.

The behavior in the case of invalid *awk* programs (including lexical, syntactic, and semantic errors) is undefined because it was considered overly limiting on implementations to specify. In most cases such errors can be expected to produce a diagnostic and a non-zero exit status. However, some implementations may choose to extend the language in ways that make use of certain invalid constructs. Other invalid constructs might be deemed worthy of a warning, but otherwise cause some reasonable behavior. Still other constructs may be very difficult to detect in some implementations. Also, different implementations might detect a given error during an initial parsing of the program (before reading any input files) while others might detect it when executing the program after reading some input. Implementors should be aware that diagnosing errors as early as possible and producing useful diagnostics can ease debugging of applications, and thus make an implementation more usable.

The unspecified behavior from using multi-character **RS** values is to allow possible future extensions based on extended regular expressions used for record separators. Historical implementations take the first character of the string and ignore the others.

Unspecified behavior when *split*(*string*,*array*,<null>) is used is to allow a proposed future extension that would split up a string into an array of individual characters.

In the context of the **getline** function, equally good arguments for different precedences of the | and **<** operators can be made. Historical practice has been that:

```
getline < "a" "b"
```

is parsed as:

```
( getline < "a" ) "b"
```

although many would argue that the intent was that the file **ab** should be read. However:

```
getline < "x" + 1
```

parses as:

```
getline < ( "x" + 1 )
```

Similar problems occur with the | version of **getline**, particularly in combination with **$**. For example:

```
$"echo hi" | getline
```

(This situation is particularly problematic when used in a **print** statement, where the |**getline** part might be a redirection of the **print**.)

Since in most cases such constructs are not (or at least should not) be used (because they have a natural ambiguity for which there is no conventional parsing), the meaning of these constructs has been made explicitly unspecified. (The effect is that a conforming application that runs into the problem must parenthesize to resolve the ambiguity.) There appeared to be few if any actual uses of such constructs.

Grammars can be written that would cause an error under these circumstances. Where backwards-compatibility is not a large consideration, implementors may wish to use such grammars.

Some historical implementations have allowed some built-in functions to be called without an argument list, the result being a default argument list chosen in some "reasonable" way. Use of **length** as a synonym for **length($0)** is the only one of these forms that is thought to be widely known or widely used; this particular form is documented in various places (for example, most historical *awk* reference pages, although not in the referenced *The AWK Programming Language*) as legitimate practice. With this exception, default argument lists have always been undocumented and vaguely defined, and it is not at all clear how (or if) they should be generalized to user-defined functions. They add no useful functionality and preclude possible future extensions that might need to name functions without calling them. Not standardizing them seems the simplest course. The standard developers considered that **length** merited special treatment, however, since it has been documented in the past and sees possibly substantial use in historical programs. Accordingly, this usage has been made legitimate, but Issue 5 removed the obsolescent marking for XSI-conforming implementations and many otherwise conforming applications depend on this feature.

In **sub** and **gsub**, if *repl* is a string literal (the lexical token **STRING**), then two consecutive <backslash> characters should be used in the string to ensure a single <backslash> will precede the <ampersand> when the resultant string is passed to the function. (For example, to specify one literal <ampersand> in the replacement string, use **gsub**(**ERE**, `"\\&"`).)

Historically, the only special character in the *repl* argument of **sub** and **gsub** string functions was the <ampersand> (`'&'`) character and preceding it with the <backslash> character was used to turn off its special meaning.

The description in the ISO POSIX-2:1993 standard introduced behavior such that the <backslash> character was another special character and it was unspecified whether there were any other special characters. This description introduced several portability problems, some of which are described below, and so it has been replaced with the more historical description. Some of the problems include:

- Historically, to create the replacement string, a script could use **gsub**(**ERE**, `"\\&"`), but with the ISO POSIX-2:1993 standard wording, it was necessary to use **gsub**(**ERE**, `"\\\\&"`). The <backslash> characters are doubled here because all string literals are subject to lexical analysis, which would reduce each pair of <backslash> characters to a single <backslash> before being passed to **gsub**.
- Since it was unspecified what the special characters were, for portable scripts to guarantee that characters are printed literally, each character had to be preceded with a <backslash>. (For example, a portable script had to use **gsub**(**ERE**, `"\\h\\i"`) to produce a replacement string of `"hi"`.)

The description for comparisons in the ISO POSIX-2:1993 standard did not properly describe historical practice because of the way numeric strings are compared as numbers. The current rules cause the following code:

```
if (0 == "000")
    print "strange, but true"
else
    print "not true"
```

to do a numeric comparison, causing the **if** to succeed. It should be intuitively obvious that this is incorrect behavior, and indeed, no historical implementation of *awk* actually behaves this way.

To fix this problem, the definition of *numeric string* was enhanced to include only those values obtained from specific circumstances (mostly external sources) where it is not possible to determine unambiguously whether the value is intended to be a string or a numeric.

Variables that are assigned to a numeric string shall also be treated as a numeric string. (For example, the notion of a numeric string can be propagated across assignments.) In comparisons, all variables having the uninitialized value are to be treated as a numeric operand evaluating to the numeric value zero.

Uninitialized variables include all types of variables including scalars, array elements, and fields. The definition of an uninitialized value in Variables and Special Variables (on page 2437) is necessary to describe the value placed on uninitialized variables and on fields that are valid (for example, **< $NF**) but have no characters in them and to describe how these variables are to be used in comparisons. A valid field, such as **$1**, that has no characters in it can be obtained from an input line of `"\t\t"` when **FS=**`'\t'`. Historically, the comparison (**$1<**10) was done numerically after evaluating **$1** to the value zero.

The phrase "... also shall have the numeric value of the numeric string" was removed from several sections of the ISO POSIX-2:1993 standard because is specifies an unnecessary implementation detail. It is not necessary for POSIX.1-200x to specify that these objects be assigned two different values. It is only necessary to specify that these objects may evaluate to two different values depending on context.

Historical implementations of *awk* did not parse hexadecimal integer or floating constants like `"0xa"` and `"0xap0"`. Due to an oversight, the 2001 through 2004 editions of this standard required support for hexadecimal floating constants. This was due to the reference to *atof*(). This version of the standard allows but does not require implementations to use *atof*() and includes a description of how floating-point numbers are recognized as an alternative to match historic behavior. The intent of this change is to allow implementations to recognize floating-point constants according to either the ISO/IEC 9899:1990 standard or ISO/IEC 9899:1999 standard, and to allow (but not require) implementations to recognize hexadecimal integer constants.

Historical implementations of *awk* did not support floating-point infinities and NaNs in *numeric*

strings; e.g., `"−INF"` and `"NaN"`. However, implementations that use the *atof*() or *strtod*() functions to do the conversion picked up support for these values if they used a ISO/IEC 9899:1999 standard version of the function instead of a ISO/IEC 9899:1990 standard version. Due to an oversight, the 2001 through 2004 editions of this standard did not allow support for infinities and NaNs, but in this revision support is allowed (but not required). This is a silent change to the behavior of *awk* programs; for example, in the POSIX locale the expression:

```
("-INF" + 0 < 0)
```

formerly had the value 0 because `"−INF"` converted to 0, but now it may have the value 0 or 1.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The *awk* utility is aligned with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE PASC Interpretation 1003.2 #211 is applied, adding the sentence "An occurrence of two consecutive <backslash> characters shall be interpreted as just a single literal <backslash> character." into the description of the **sub** string function.

Issue 7

PASC Interpretation 1003.2-1992 #107 (SD5-XCU-ERN-73) is applied, updating the description of the **OFS** variable.

Austin Group Interpretation 1003.1-2001 #189 is applied.

Austin Group Interpretation 1003.1-2001 #201 is applied, permitting implementations to support infinities and NaNs.

SD5-XCU-ERN-79 is applied, restoring the horizontal lines to Table 4-1 (on page 2433), and SD5-XCU-ERN-80 is applied, changing the order of some table entries.

SD5-XCU-ERN-87 is applied, updating the descriptive text of the Grammar.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The EXTENDED DESCRIPTION is changed to make the support of hexadecimal integer and floating constants optional.

NAME

basename — return non-directory portion of a pathname

SYNOPSIS

```
basename string [suffix]
```

DESCRIPTION

The *string* operand shall be treated as a pathname, as defined in XBD Section 3.266 (on page 75). The string *string* shall be converted to the filename corresponding to the last pathname component in *string* and then the suffix string *suffix*, if present, shall be removed. This shall be done by performing actions equivalent to the following steps in order:

1. If *string* is a null string, it is unspecified whether the resulting string is `'.'` or a null string. In either case, skip steps 2 through 6.
2. If *string* is `"//"`, it is implementation-defined whether steps 3 to 6 are skipped or processed.
3. If *string* consists entirely of <slash> characters, *string* shall be set to a single <slash> character. In this case, skip steps 4 to 6.
4. If there are any trailing <slash> characters in *string*, they shall be removed.
5. If there are any <slash> characters remaining in *string*, the prefix of *string* up to and including the last <slash> character in *string* shall be removed.
6. If the *suffix* operand is present, is not identical to the characters remaining in *string*, and is identical to a suffix of the characters remaining in *string*, the suffix *suffix* shall be removed from *string*. Otherwise, *string* is not modified by this step. It shall not be considered an error if *suffix* is not found in *string*.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

string A string.

suffix A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *basename*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The *basename* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The definition of *pathname* specifies implementation-defined behavior for pathnames starting with two <slash> characters. Therefore, applications shall not arbitrarily add <slash> characters to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES
If the string *string* is a valid pathname:

```
$(basename "string")
```

produces a filename that could be used to open the file named by *string* in the directory returned by:

```
$(dirname "string")
```

If the string *string* is not a valid pathname, the same algorithm is used, but the result need not be a valid filename. The *basename* utility is not expected to make any judgements about the validity of *string* as a pathname; it just follows the specified algorithm to produce a result string.

The following shell script compiles **/usr/src/cmd/cat.c** and moves the output to a file named **cat** in the current directory when invoked with the argument **/usr/src/cmd/cat** or with the argument **/usr/src/cmd/cat.c**:

```
c99 $(dirname "$1")/$(basename "$1" .c).c
mv a.out $(basename "$1" .c)
```

78665 **RATIONALE**

78666 The behaviors of *basename* and *dirname* have been coordinated so that when *string* is a valid
78667 pathname:

78668 `$(basename "string")`

78669 would be a valid filename for the file in the directory:

78670 `$(dirname "string")`

78671 This would not work for the early proposal versions of these utilities due to the way it specified
78672 handling of trailing <slash> characters.

78673 Since the definition of *pathname* specifies implementation-defined behavior for pathnames
78674 starting with two <slash> characters, this volume of POSIX.1-200x specifies similar
78675 implementation-defined behavior for the *basename* and *dirname* utilities.

78676 **FUTURE DIRECTIONS**

78677 None.

78678 **SEE ALSO**

78679 Section 2.5 (on page 2301), *dirname*

78680 XBD Section 3.266 (on page 75), Chapter 8 (on page 173)

78681 **CHANGE HISTORY**

78682 First released in Issue 2.

78683 **Issue 6**

78684 IEEE PASC Interpretation 1003.2 #164 is applied.

78685 The normative text is reworded to avoid use of the term "must" for application requirements.

78686 **NAME**

78687 batch — schedule commands to be executed in a batch queue

78688 **SYNOPSIS**

78689 `batch`

78690 **DESCRIPTION**

78691 The *batch* utility shall read commands from standard input and schedule them for execution in a
78692 batch queue. It shall be the equivalent of the command:

78693 `at -q b -m now`

78694 where queue *b* is a special *at* queue, specifically for batch jobs. Batch jobs shall be submitted to
78695 the batch queue with no time constraints and shall be run by the system using algorithms, based
78696 on unspecified factors, that may vary with each invocation of *batch*.

78697 XSI Users shall be permitted to use *batch* if their name appears in the file **at.allow** which is located in
78698 an implementation-defined directory. If that file does not exist, the file **at.deny**, which is located
78699 in an implementation-defined directory, shall be checked to determine whether the user shall be
78700 denied access to *batch*. If neither file exists, only a process with appropriate privileges shall be
78701 allowed to submit a job. If only **at.deny** exists and is empty, global usage shall be permitted. The
78702 **at.allow** and **at.deny** files shall consist of one user name per line.

78703 **OPTIONS**

78704 None.

78705 **OPERANDS**

78706 None.

78707 **STDIN**

78708 The standard input shall be a text file consisting of commands acceptable to the shell command
78709 language described in Chapter 2 (on page 2297).

78710 **INPUT FILES**

78711 XSI The text files **at.allow** and **at.deny**, which are located in an implementation-defined directory,
78712 shall contain zero or more user names, one per line, of users who are, respectively, authorized or
78713 denied access to the *at* and *batch* utilities.

78714 **ENVIRONMENT VARIABLES**

78715 The following environment variables shall affect the execution of *batch*:

78716 *LANG* Provide a default value for the internationalization variables that are unset or null.
78717 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
78718 variables used to determine the values of locale categories.)

78719 *LC_ALL* If set to a non-empty string value, override the values of all the other
78720 internationalization variables.

78721 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
78722 characters (for example, single-byte as opposed to multi-byte characters in
78723 arguments and input files).

78724 *LC_MESSAGES*

78725 Determine the locale that should be used to affect the format and contents of
78726 diagnostic messages written to standard error and informative messages written to
78727 standard output.

78728 *LC_TIME* Determine the format and contents for date and time strings written by *batch*.

78729 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

78730 *SHELL* Determine the name of a command interpreter to be used to invoke the at-job. If
78731 the variable is unset or null, *sh* shall be used. If it is set to a value other than a name
78732 for *sh*, the implementation shall do one of the following: use that shell; use *sh*; use
78733 the login shell from the user database; any of the preceding accompanied by a
78734 warning diagnostic about which was chosen.

78735 *TZ* Determine the timezone. The job shall be submitted for execution at the time
78736 specified by *timespec* or **–t** *time* relative to the timezone specified by the *TZ*
78737 variable. If *timespec* specifies a timezone, it overrides *TZ*. If *timespec* does not
78738 specify a timezone and *TZ* is unset or null, an unspecified default timezone shall
78739 be used.

78740 **ASYNCHRONOUS EVENTS**

78741 Default.

78742 **STDOUT**

78743 When standard input is a terminal, prompts of unspecified format for each line of the user input
78744 described in the STDIN section may be written to standard output.

78745 **STDERR**

78746 The following shall be written to standard error when a job has been successfully submitted:

78747 `"job %s at %s\n", at_job_id, <date>`

78748 where *date* shall be equivalent in format to the output of:

78749 `date +"%a %b %e %T %Y"`

78750 The date and time written shall be adjusted so that they appear in the timezone of the user (as
78751 determined by the *TZ* variable).

78752 Neither this, nor warning messages concerning the selection of the command interpreter, are
78753 considered a diagnostic that changes the exit status.

78754 Diagnostic messages, if any, shall be written to standard error.

78755 **OUTPUT FILES**

78756 None.

78757 **EXTENDED DESCRIPTION**

78758 None.

78759 **EXIT STATUS**

78760 The following exit values shall be returned:

78761 0 Successful completion.

78762 >0 An error occurred.

78763 **CONSEQUENCES OF ERRORS**

78764 The job shall not be scheduled.

APPLICATION USAGE

It may be useful to redirect standard output within the specified commands.

EXAMPLES

1. This sequence can be used at a terminal:

```
batch
sort < file >outfile
EOT
```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
batch <<!
diff file1 file2 2>&1 >outfile | mailx mygroup
!
```

RATIONALE

Early proposals described *batch* in a manner totally separated from *at*, even though the historical model treated it almost as a synonym for *at* **−qb**. A number of features were added to list and control batch work separately from those in *at*. Upon further reflection, it was decided that the benefit of this did not merit the change to the historical interface.

The **−m** option was included on the equivalent *at* command because it is historical practice to mail results to the submitter, even if all job-produced output is redirected. As explained in the RATIONALE for *at*, the **now** keyword submits the job for immediate execution (after scheduling delays), despite some historical systems where *at* **now** would have been considered an error.

FUTURE DIRECTIONS

None.

SEE ALSO

at

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The NAME is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

The *batch* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the *batch* utility.

78802 **NAME**

78803 bc — arbitrary-precision arithmetic language

78804 **SYNOPSIS**

78805 `bc [-l] [file...]`

78806 **DESCRIPTION**

78807 The *bc* utility shall implement an arbitrary precision calculator. It shall take input from any files
78808 given, then read from the standard input. If the standard input and standard output to *bc* are
78809 attached to a terminal, the invocation of *bc* shall be considered to be *interactive*, causing
78810 behavioral constraints described in the following sections.

78811 **OPTIONS**

78812 The *bc* utility shall conform to XBD Section 12.2 (on page 215).

78813 The following option shall be supported:

78814 **–l** (The letter ell.) Define the math functions and initialize *scale* to 20, instead of the
78815 default zero; see the EXTENDED DESCRIPTION section.

78816 **OPERANDS**

78817 The following operand shall be supported:

78818 *file* A pathname of a text file containing *bc* program statements. After all *file*s have
78819 been read, *bc* shall read the standard input.

78820 **STDIN**

78821 See the INPUT FILES section.

78822 **INPUT FILES**

78823 Input files shall be text files containing a sequence of comments, statements, and function
78824 definitions that shall be executed as they are read.

78825 **ENVIRONMENT VARIABLES**

78826 The following environment variables shall affect the execution of *bc*:

78827 *LANG* Provide a default value for the internationalization variables that are unset or null.
78828 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
78829 variables used to determine the values of locale categories.)

78830 *LC_ALL* If set to a non-empty string value, override the values of all the other
78831 internationalization variables.

78832 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
78833 characters (for example, single-byte as opposed to multi-byte characters in
78834 arguments and input files).

78835 *LC_MESSAGES*
78836 Determine the locale that should be used to affect the format and contents of
78837 diagnostic messages written to standard error.

78838 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

78839 **ASYNCHRONOUS EVENTS**

78840 Default.

78841 **STDOUT**

78842 The output of the *bc* utility shall be controlled by the program read, and consist of zero or more
78843 lines containing the value of all executed expressions without assignments. The radix and
78844 precision of the output shall be controlled by the values of the **obase** and **scale** variables; see the
78845 EXTENDED DESCRIPTION section.

78846 **STDERR**

78847 The standard error shall be used only for diagnostic messages.

78848 **OUTPUT FILES**

78849 None.

78850 **EXTENDED DESCRIPTION**

78851 **Grammar**

78852 The grammar in this section and the lexical conventions in the following section shall together
78853 describe the syntax for *bc* programs. The general conventions for this style of grammar are
78854 described in Section 1.3 (on page 2287). A valid program can be represented as the non-terminal
78855 symbol **program** in the grammar. This formal syntax shall take precedence over the text syntax
78856 description.

```
78857 %token    EOF NEWLINE STRING LETTER NUMBER
78858 %token    MUL_OP

```

Lexical Conventions in bc

The lexical conventions for *bc* programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, *bc* shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the two adjacent characters "/*" and terminated by the next occurrence of the two adjacent characters "*/". Comments shall have no effect except to delimit lexical tokens.
3. The <newline> shall be recognized as the token **NEWLINE**.
4. The token **STRING** shall represent a string constant; it shall consist of any characters beginning with the double-quote character ('"') and terminated by another occurrence of the double-quote character. The value of the string is the sequence of all characters between, but not including, the two double-quote characters. All characters shall be taken literally from the input, and there is no way to specify a string containing a double-quote character. The length of the value of each string shall be limited to {BC_STRING_MAX} bytes.
5. A <blank> shall have no effect except as an ordinary character if it appears within a **STRING** token, or to delimit a lexical token other than **STRING**.
6. The combination of a <backslash> character immediately followed by a <newline> shall have no effect other than to delimit lexical tokens with the following exceptions:

78978 - It shall be interpreted as the character sequence "\<newline>" in **STRING** tokens.
78979 - It shall be ignored as part of a multi-line **NUMBER** token.

78980 7. The token **NUMBER** shall represent a numeric constant. It shall be recognized by the
78981 following grammar:

```
78982 NUMBER  : integer
78983         | '.' integer
78984         | integer '.'
78985         | integer '.' integer
78986         ;

78987 integer : digit
78988         | integer digit
78989         ;

78990 digit   : 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7
78991         | 8 | 9 | A | B | C | D | E | F
78992         ;
```

78993 8. The value of a **NUMBER** token shall be interpreted as a numeral in the base specified by
78994 the value of the internal register **ibase** (described below). Each of the **digit** characters
78995 shall have the value from 0 to 15 in the order listed here, and the <period> character shall
78996 represent the radix point. The behavior is undefined if digits greater than or equal to the
78997 value of **ibase** appear in the token. However, note the exception for single-digit values
78998 being assigned to **ibase** and **obase** themselves, in Operations in bc (on page 2475).

78999 9. The following keywords shall be recognized as tokens:

79000 **auto** | **ibase** | **length** | **return** | **while** |
79001 **break** | **if** | **obase** | **scale** | |
79002 **define** | **for** | **quit** | **sqrt** | |

79003 10. Any of the following characters occurring anywhere except within a keyword shall be
79004 recognized as the token **LETTER**:

79005 `a b c d e f g h i j k l m n o p q r s t u v w x y z`

79006 11. The following single-character and two-character sequences shall be recognized as the
79007 token **ASSIGN_OP**:

79008 `=  +=  -=  *=  /=  %=  ^=`

79009 12. If an '=' character, as the beginning of a token, is followed by a '-' character with no
79010 intervening delimiter, the behavior is undefined.

79011 13. The following single-characters shall be recognized as the token **MUL_OP**:

79012 `*  /  %`

79013 14. The following single-character and two-character sequences shall be recognized as the
79014 token **REL_OP**:

79015 `==  <=  >=  !=  <  >`

79016 15. The following two-character sequences shall be recognized as the token **INCR_DECR**:

79017 `++  --`

16. The following single characters shall be recognized as tokens whose names are the character:

    `<newline>  (  )  ,  +  -  ;  [  ]  ^  {  }`

17. The token **EOF** is returned when the end of input is reached.

Operations in bc

There are three kinds of identifiers: ordinary identifiers, array identifiers, and function identifiers. All three types consist of single lowercase letters. Array identifiers shall be followed by square brackets (`"[]"`). An array subscript is required except in an argument or auto list. Arrays are singly dimensioned and can contain up to {BC_DIM_MAX} elements. Indexing shall begin at zero so an array is indexed from 0 to {BC_DIM_MAX}−1. Subscripts shall be truncated to integers. The application shall ensure that function identifiers are followed by parentheses, possibly enclosing arguments. The three types of identifiers do not conflict.

The following table summarizes the rules for precedence and associativity of all operators. Operators on the same line shall have the same precedence; rows are in order of decreasing precedence.

Table 4-3 Operators in *bc*

Operator	Associativity
`++, --`	N/A
`unary -`	N/A
`^`	Right to left
`*, /, %`	Left to right
`+, binary -`	Left to right
`=, +=, -=, *=, /=, %=, ^=`	Right to left
`==, <=, >=, !=, <, >`	None

Each expression or named expression has a *scale*, which is the number of decimal digits that shall be maintained as the fractional portion of the expression.

Named expressions are places where values are stored. Named expressions shall be valid on the left side of an assignment. The value of a named expression shall be the value stored in the place named. Simple identifiers and array elements are named expressions; they have an initial value of zero and an initial scale of zero.

The internal registers **scale**, **ibase**, and **obase** are all named expressions. The scale of an expression consisting of the name of one of these registers shall be zero; values assigned to any of these registers are truncated to integers. The **scale** register shall contain a global value used in computing the scale of expressions (as described below). The value of the register **scale** is limited to 0 ≤ **scale** ≤ {BC_SCALE_MAX} and shall have a default value of zero. The **ibase** and **obase** registers are the input and output number radix, respectively. The value of **ibase** shall be limited to:

`2 ≤ ibase ≤ 16`

The value of **obase** shall be limited to:

`2 ≤ obase ≤ {BC_BASE_MAX}`

When either **ibase** or **obase** is assigned a single **digit** value from the list in Lexical Conventions in bc (on page 2473), the value shall be assumed in hexadecimal. (For example, **ibase**=A sets to base ten, regardless of the current **ibase** value.) Otherwise, the behavior is undefined when

79061 digits greater than or equal to the value of **ibase** appear in the input. Both **ibase** and **obase** shall
79062 have initial values of 10.

79063 Internal computations shall be conducted as if in decimal, regardless of the input and output
79064 bases, to the specified number of decimal digits. When an exact result is not achieved (for
79065 example, **scale**=0; 3.2/1)**,** the result shall be truncated.

79066 For all values of **obase** specified by this volume of POSIX.1-200x, *bc* shall output numeric values
79067 by performing each of the following steps in order:

79068 1. If the value is less than zero, a <hyphen> (`'-'`) character shall be output.

79069 2. One of the following is output, depending on the numerical value:

79070 • If the absolute value of the numerical value is greater than or equal to one, the
79071 integer portion of the value shall be output as a series of digits appropriate to **obase**
79072 (as described below), most significant digit first. The most significant non-zero digit
79073 shall be output next, followed by each successively less significant digit.

79074 • If the absolute value of the numerical value is less than one but greater than zero
79075 and the scale of the numerical value is greater than zero, it is unspecified whether
79076 the character 0 is output.

79077 • If the numerical value is zero, the character 0 shall be output.

79078 3. If the scale of the value is greater than zero and the numeric value is not zero, a <period>
79079 character shall be output, followed by a series of digits appropriate to **obase** (as described
79080 below) representing the most significant portion of the fractional part of the value. If *s*
79081 represents the scale of the value being output, the number of digits output shall be *s* if
79082 **obase** is 10, less than or equal to *s* if **obase** is greater than 10, or greater than or equal to *s*
79083 if **obase** is less than 10. For **obase** values other than 10, this should be the number of
79084 digits needed to represent a precision of 10^s.

79085 For **obase** values from 2 to 16, valid digits are the first **obase** of the single characters:

79086 `0 1 2 3 4 5 6 7 8 9 A B C D E F`

79087 which represent the values zero to 15, inclusive, respectively.

79088 For bases greater than 16, each digit shall be written as a separate multi-digit decimal number.
79089 Each digit except the most significant fractional digit shall be preceded by a single <space>. For
79090 bases from 17 to 100, *bc* shall write two-digit decimal numbers; for bases from 101 to 1 000, three-
79091 digit decimal strings, and so on. For example, the decimal number 1 024 in base 25 would be
79092 written as:

79093 `Δ01Δ15Δ24`

79094 and in base 125, as:

79095 `Δ008Δ024`

79096 Very large numbers shall be split across lines with 70 characters per line in the POSIX locale;
79097 other locales may split at different character boundaries. Lines that are continued shall end with
79098 a <backslash>.

79099 A function call shall consist of a function name followed by parentheses containing a
79100 <comma>-separated list of expressions, which are the function arguments. A whole array
79101 passed as an argument shall be specified by the array name followed by empty square brackets.
79102 All function arguments shall be passed by value. As a result, changes made to the formal
79103 parameters shall have no effect on the actual arguments. If the function terminates by executing

a **return** statement, the value of the function shall be the value of the expression in the parentheses of the **return** statement or shall be zero if no expression is provided or if there is no **return** statement.

The result of **sqrt**(*expression*) shall be the square root of the expression. The result shall be truncated in the least significant decimal place. The scale of the result shall be the scale of the expression or the value of **scale**, whichever is larger.

The result of **length**(*expression*) shall be the total number of significant decimal digits in the expression. The scale of the result shall be zero.

The result of **scale**(*expression*) shall be the scale of the expression. The scale of the result shall be zero.

A numeric constant shall be an expression. The scale shall be the number of digits that follow the radix point in the input representing the constant, or zero if no radix point appears.

The sequence (*expression*) shall be an expression with the same value and scale as *expression*. The parentheses can be used to alter the normal precedence.

The semantics of the unary and binary operators are as follows:

–expression
: The result shall be the negative of the *expression*. The scale of the result shall be the scale of *expression*.

The unary increment and decrement operators shall not modify the scale of the named expression upon which they operate. The scale of the result shall be the scale of that named expression.

++named-expression
: The named expression shall be incremented by one. The result shall be the value of the named expression after incrementing.

––named-expression
: The named expression shall be decremented by one. The result shall be the value of the named expression after decrementing.

named-expression++
: The named expression shall be incremented by one. The result shall be the value of the named expression before incrementing.

named-expression––
: The named expression shall be decremented by one. The result shall be the value of the named expression before decrementing.

The exponentiation operator, <circumflex> (`'^'`), shall bind right to left.

expression^expression
: The result shall be the first *expression* raised to the power of the second *expression*. If the second expression is not an integer, the behavior is undefined. If *a* is the scale of the left expression and *b* is the absolute value of the right expression, the scale of the result shall be:

```
if b >= 0 min(a * b, max(scale, a)) if b < 0 scale
```

The multiplicative operators (`'*'`, `'/'`, `'%'`) shall bind left to right.

*expression*expression*
: The result shall be the product of the two expressions. If *a* and *b* are the scales of the two expressions, then the scale of the result shall be:

79147 `min(a+b,max(scale,a,b))`

79148 *expression*/*expression*

79149 The result shall be the quotient of the two expressions. The scale of the result shall be the
79150 value of **scale**.

79151 *expression*%*expression*

79152 For expressions *a* and *b*, *a*%*b* shall be evaluated equivalent to the steps:

79153 1. Compute *a*/*b* to current scale.

79154 2. Use the result to compute:

79155 `a - (a / b) * b`

79156 to scale:

79157 `max(scale + scale(b), scale(a))`

79158 The scale of the result shall be:

79159 `max(scale + scale(b), scale(a))`

79160 When **scale** is zero, the `'%'` operator is the mathematical remainder operator.

79161 The additive operators (`'+'`, `'-'`) shall bind left to right.

79162 *expression*+*expression*

79163 The result shall be the sum of the two expressions. The scale of the result shall be the
79164 maximum of the scales of the expressions.

79165 *expression*–*expression*

79166 The result shall be the difference of the two expressions. The scale of the result shall be the
79167 maximum of the scales of the expressions.

79168 The assignment operators (`'='`, `"+="`, `"-="`, `"*="`, `"/="`, `"%="`, `"^="`) shall bind right to left.

79169 *named-expression*=*expression*

79170 This expression shall result in assigning the value of the expression on the right to the
79171 named expression on the left. The scale of both the named expression and the result shall be
79172 the scale of *expression*.

79173 The compound assignment forms:

79174 *`named-expression <operator>= expression`*

79175 shall be equivalent to:

79176 *`named-expression=named-expression <operator> expression`*

79177 except that the *named-expression* shall be evaluated only once.

79178 Unlike all other operators, the relational operators (`'<'`, `'>'`, `"<="`, `">="`, `"=="`, `"!="`) shall be
79179 only valid as the object of an **if**, **while**, or inside a **for** statement.

79180 *expression1*<*expression2*

79181 The relation shall be true if the value of *expression1* is strictly less than the value of
79182 *expression2*.

79183 *expression1*>*expression2*

79184 The relation shall be true if the value of *expression1* is strictly greater than the value of
79185 *expression2*.

79186 *expression1*<=*expression2*
79187 The relation shall be true if the value of *expression1* is less than or equal to the value of
79188 *expression2*.

79189 *expression1*>=*expression2*
79190 The relation shall be true if the value of *expression1* is greater than or equal to the value of
79191 *expression2*.

79192 *expression1*==*expression2*
79193 The relation shall be true if the values of *expression1* and *expression2* are equal.

79194 *expression1*!=*expression2*
79195 The relation shall be true if the values of *expression1* and *expression2* are unequal.

79196 There are only two storage classes in *bc*: global and automatic (local). Only identifiers that are
79197 local to a function need be declared with the **auto** command. The arguments to a function shall
79198 be local to the function. All other identifiers are assumed to be global and available to all
79199 functions. All identifiers, global and local, have initial values of zero. Identifiers declared as auto
79200 shall be allocated on entry to the function and released on returning from the function. They
79201 therefore do not retain values between function calls. Auto arrays shall be specified by the array
79202 name followed by empty square brackets. On entry to a function, the old values of the names
79203 that appear as parameters and as automatic variables shall be pushed onto a stack. Until the
79204 function returns, reference to these names shall refer only to the new values.

79205 References to any of these names from other functions that are called from this function also
79206 refer to the new value until one of those functions uses the same name for a local variable.

79207 When a statement is an expression, unless the main operator is an assignment, execution of the
79208 statement shall write the value of the expression followed by a <newline>.

79209 When a statement is a string, execution of the statement shall write the value of the string.

79210 Statements separated by <semicolon> or <newline> characters shall be executed sequentially. In
79211 an interactive invocation of *bc*, each time a <newline> is read that satisfies the grammatical
79212 production:

79213 `input_item : semicolon_list NEWLINE`

79214 the sequential list of statements making up the **semicolon_list** shall be executed immediately
79215 and any output produced by that execution shall be written without any delay due to buffering.

79216 In an **if** statement (**if**(*relation*) *statement*), the *statement* shall be executed if the relation is true.

79217 The **while** statement (**while**(*relation*) *statement*) implements a loop in which the *relation* is tested;
79218 each time the *relation* is true, the *statement* shall be executed and the *relation* retested. When the
79219 *relation* is false, execution shall resume after *statement*.

79220 A **for** statement(**for**(*expression*; *relation*; *expression*) *statement*) shall be the same as:

```
79221 first-expression
79222 while (relation) {
79223     statement
79224     last-expression
79225 }
```

79226 The application shall ensure that all three expressions are present.

79227 The **break** statement shall cause termination of a **for** or **while** statement.

79228 The **auto** statement (**auto** *identifier* [,*identifier*] ...) shall cause the values of the identifiers to be

pushed down. The identifiers can be ordinary identifiers or array identifiers. Array identifiers shall be specified by following the array name by empty square brackets. The application shall ensure that the **auto** statement is the first statement in a function definition.

A **define** statement:

```
define LETTER ( opt_parameter_list ) {
    opt_auto_define_list
    statement_list
}
```

defines a function named **LETTER**. If a function named **LETTER** was previously defined, the **define** statement shall replace the previous definition. The expression:

```
LETTER ( opt_argument_list )
```

shall invoke the function named **LETTER**. The behavior is undefined if the number of arguments in the invocation does not match the number of parameters in the definition. Functions shall be defined before they are invoked. A function shall be considered to be defined within its own body, so recursive calls are valid. The values of numeric constants within a function shall be interpreted in the base specified by the value of the **ibase** register when the function is invoked.

The **return** statements (**return** and **return**(*expression*)) shall cause termination of a function, popping of its auto variables, and specification of the result of the function. The first form shall be equivalent to **return**(0). The value and scale of the result returned by the function shall be the value and scale of the expression returned.

The **quit** statement (**quit**) shall stop execution of a *bc* program at the point where the statement occurs in the input, even if it occurs in a function definition, or in an **if**, **for**, or **while** statement.

The following functions shall be defined when the **–l** option is specified:

s(*expression*)
: Sine of argument in radians.

c(*expression*)
: Cosine of argument in radians.

a(*expression*)
: Arctangent of argument.

l(*expression*)
: Natural logarithm of argument.

e(*expression*)
: Exponential function of argument.

j(*expression*, *expression*)
: Bessel function of integer order.

The scale of the result returned by these functions shall be the value of the **scale** register at the time the function is invoked. The value of the **scale** register after these functions have completed their execution shall be the same value it had upon invocation. The behavior is undefined if any of these functions is invoked with an argument outside the domain of the mathematical function.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

unspecified An error occurred.

CONSEQUENCES OF ERRORS

If any *file* operand is specified and the named file cannot be accessed, *bc* shall write a diagnostic message to standard error and terminate without any further action.

In an interactive invocation of *bc*, the utility should print an error message and recover following any error in the input. In a non-interactive invocation of *bc*, invalid input causes undefined behavior.

APPLICATION USAGE

Automatic variables in *bc* do not work in exactly the same way as in either C or PL/1.

For historical reasons, the exit status from *bc* cannot be relied upon to indicate that an error has occurred. Returning zero after an error is possible. Therefore, *bc* should be used primarily by interactive users (who can react to error messages) or by application programs that can somehow validate the answers returned as not including error messages.

The *bc* utility always uses the <period> (`'.'`) character to represent a radix point, regardless of any decimal-point character specified as part of the current locale. In languages like C or *awk*, the <period> character is used in program source, so it can be portable and unambiguous, while the locale-specific character is used in input and output. Because there is no distinction between source and input in *bc*, this arrangement would not be possible. Using the locale-specific character in *bc*'s input would introduce ambiguities into the language; consider the following example in a locale with a <comma> as the decimal-point character:

```
define f(a,b) {
    ...
}
...
f(1,2,3)
```

Because of such ambiguities, the <period> character is used in input. Having input follow different conventions from output would be confusing in either pipeline usage or interactive usage, so the <period> is also used in output.

EXAMPLES

In the shell, the following assigns an approximation of the first ten digits of `'`π`'` to the variable *x*:

```
x=$(printf "%s\n" 'scale = 10; 104348/33215' | bc)
```

The following *bc* program prints the same approximation of `'`π`'`, with a label, to standard output:

```
scale = 10
"pi equals "
104348 / 33215
```

The following defines a function to compute an approximate value of the exponential function (note that such a function is predefined if the **–l** option is specified):

```
scale = 20
define e(x){
    auto a, b, c, i, s
```

```
        a = 1
        b = 1
        s = 1
        for (i = 1; 1 == 1; i++){
            a = a*x
            b = b*i
            c = a/b
            if (c == 0) {
                 return(s)
            }
            s = s+c
        }
    }
```

The following prints approximate values of the exponential function of the first ten integers:

```
for (i = 1; i <= 10; ++i) {
    e(i)
}
```

RATIONALE

The *bc* utility is implemented historically as a front-end processor for *dc*; *dc* was not selected to be part of this volume of POSIX.1-200x because *bc* was thought to have a more intuitive programmatic interface. Current implementations that implement *bc* using *dc* are expected to be compliant.

The exit status for error conditions has been left unspecified for several reasons:

- The *bc* utility is used in both interactive and non-interactive situations. Different exit codes may be appropriate for the two uses.
- It is unclear when a non-zero exit should be given; divide-by-zero, undefined functions, and syntax errors are all possibilities.
- It is not clear what utility the exit status has.
- In the 4.3 BSD, System V, and Ninth Edition implementations, *bc* works in conjunction with *dc*. The *dc* utility is the parent, *bc* is the child. This was done to cleanly terminate *bc* if *dc* aborted.

The decision to have *bc* exit upon encountering an inaccessible input file is based on the belief that *bc file1 file2* is used most often when at least *file1* contains data/function declarations/initializations. Having *bc* continue with prerequisite files missing is probably not useful. There is no implication in the CONSEQUENCES OF ERRORS section that *bc* must check all its files for accessibility before opening any of them.

There was considerable debate on the appropriateness of the language accepted by *bc*. Several reviewers preferred to see either a pure subset of the C language or some changes to make the language more compatible with C. While the *bc* language has some obvious similarities to C, it has never claimed to be compatible with any version of C. An interpreter for a subset of C might be a very worthwhile utility, and it could potentially make *bc* obsolete. However, no such utility is known in historical practice, and it was not within the scope of this volume of POSIX.1-200x to define such a language and utility. If and when they are defined, it may be appropriate to include them in a future version of this standard. This left the following alternatives:

1. Exclude any calculator language from this volume of POSIX.1-200x.

   The consensus of the standard developers was that a simple programmatic calculator language is very useful for both applications and interactive users. The only arguments for excluding any calculator were that it would become obsolete if and when a C-compatible one emerged, or that the absence would encourage the development of such a C-compatible one. These arguments did not sufficiently address the needs of current application developers.

2. Standardize the historical *dc*, possibly with minor modifications.

   The consensus of the standard developers was that *dc* is a fundamentally less usable language and that that would be far too severe a penalty for avoiding the issue of being similar to but incompatible with C.

3. Standardize the historical *bc*, possibly with minor modifications.

   This was the approach taken. Most of the proponents of changing the language would not have been satisfied until most or all of the incompatibilities with C were resolved. Since most of the changes considered most desirable would break historical applications and require significant modification to historical implementations, almost no modifications were made. The one significant modification that was made was the replacement of the historical *bc* assignment operators "=+", and so on, with the more modern "+=", and so on. The older versions are considered to be fundamentally flawed because of the lexical ambiguity in uses like *a*=−1.

   In order to permit implementations to deal with backwards-compatibility as they see fit, the behavior of this one ambiguous construct was made undefined. (At least three implementations have been known to support this change already, so the degree of change involved should not be great.)

The '%' operator is the mathematical remainder operator when **scale** is zero. The behavior of this operator for other values of **scale** is from historical implementations of *bc*, and has been maintained for the sake of historical applications despite its non-intuitive nature.

Historical implementations permit setting **ibase** and **obase** to a broader range of values. This includes values less than 2, which were not seen as sufficiently useful to standardize. These implementations do not interpret input properly for values of **ibase** that are greater than 16. This is because numeric constants are recognized syntactically, rather than lexically, as described in this volume of POSIX.1-200x. They are built from lexical tokens of single hexadecimal digits and <period> characters. Since <blank> characters between tokens are not visible at the syntactic level, it is not possible to recognize the multi-digit "digits" used in the higher bases properly. The ability to recognize input in these bases was not considered useful enough to require modifying these implementations. Note that the recognition of numeric constants at the syntactic level is not a problem with conformance to this volume of POSIX.1-200x, as it does not impact the behavior of conforming applications (and correct *bc* programs). Historical implementations also accept input with all of the digits '0'–'9' and 'A'–'F' regardless of the value of **ibase**; since digits with value greater than or equal to **ibase** are not really appropriate, the behavior when they appear is undefined, except for the common case of:

```
ibase=8;
    /* Process in octal base. */
...
ibase=A
    /* Restore decimal base. */
```

In some historical implementations, if the expression to be written is an uninitialized array

element, a leading <space> and/or up to four leading 0 characters may be output before the character zero. This behavior is considered a bug; it is unlikely that any currently conforming application relies on:

```
echo 'b[3]' | bc
```

returning 00000 rather than 0.

Exact calculation of the number of fractional digits to output for a given value in a base other than 10 can be computationally expensive. Historical implementations use a faster approximation, and this is permitted. Note that the requirements apply only to values of **obase** that this volume of POSIX.1-200x requires implementations to support (in particular, not to 1, 0, or negative bases, if an implementation supports them as an extension).

Historical implementations of *bc* did not allow array parameters to be passed as the last parameter to a function. New implementations are encouraged to remove this restriction even though it is not required by the grammar.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

Updated to align with the IEEE P1003.2b draft standard, which included resolution of several interpretations of the ISO POSIX-2: 1993 standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

bg — run jobs in the background

SYNOPSIS

UP

```
bg [job_id...]
```

DESCRIPTION

If job control is enabled (see the description of *set* –**m**), the *bg* utility shall resume suspended jobs from the current environment (see Section 2.12, on page 2331) by running them as background jobs. If the job specified by *job_id* is already a running background job, the *bg* utility shall have no effect and shall exit successfully.

Using *bg* to place a job into the background shall cause its process ID to become "known in the current shell execution environment", as if it had been started as an asynchronous list; see Section 2.9.3.1 (on page 2319).

OPTIONS

None.

OPERANDS

The following operand shall be supported:

job_id Specify the job to be resumed as a background job. If no *job_id* operand is given, the most recently suspended job shall be used. The format of *job_id* is described in XBD Section 3.203 (on page 65).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *bg*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output of *bg* shall consist of a line in the format:

```
"[%d] %s\n", <job-number>, <command>
```

where the fields are as follows:

<*job-number*> A number that can be used to identify the job to the *wait*, *fg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.

<*command*> The associated command that was given to the shell.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If job control is disabled, the *bg* utility shall exit with an error and no job shall be placed in the background.

APPLICATION USAGE

A job is generally suspended by typing the SUSP character (<control>-Z on most systems); see XBD Chapter 11 (on page 199). At that point, *bg* can put the job into the background. This is most effective when the job is expecting no terminal input and its output has been redirected to non-terminal files. A background job can be forced to stop when it has terminal output by issuing the command:

```
stty tostop
```

A background job can be stopped with the command:

```
kill –s stop job ID
```

The *bg* utility does not work as expected when it is operating in its own utility execution environment because that environment has no suspended jobs. In the following examples:

```
... | xargs bg
(bg)
```

each *bg* operates in a different environment and does not share its parent shell's understanding of jobs. For this reason, *bg* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

The extensions to the shell specified in this volume of POSIX.1-200x have mostly been based on features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of POSIX.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

The *bg* utility is expected to wrap its output if the output exceeds the number of display columns.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The JC margin marker on the SYNOPSIS is removed since support for Job Control is mandatory in this version. This is a FIPS requirement.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

79532 **NAME**

79533 c99 — compile standard C programs

79534 **SYNOPSIS**

79535 CD
```
c99 [options...] pathname [[pathname] [–I directory]
    [–L directory] [–l library]]...
```

79537 **DESCRIPTION**

79538 The *c99* utility is an interface to the standard C compilation system; it shall accept source code
79539 conforming to the ISO C standard. The system conceptually consists of a compiler and link
79540 editor. The input files referenced by *pathname* operands and **–l** option-arguments shall be
79541 compiled and linked to produce an executable file. (It is unspecified whether the linking occurs
79542 entirely within the operation of *c99*; some implementations may produce objects that are not
79543 fully resolved until the file is executed.)

79544 If the **–c** option is specified, for all pathname operands of the form *file***.c**, the files:

79545 `$(basename pathname .c).o`

79546 shall be created as the result of successful compilation. If the **–c** option is not specified, it is
79547 unspecified whether such **.o** files are created or deleted for the *file***.c** operands.

79548 If there are no options that prevent link editing (such as **–c** or **–E**), and all input files compile and
79549 link without error, the resulting executable file shall be written according to the **–o** *outfile* option
79550 (if present) or to the file **a.out**.

79551 The executable file shall be created as specified in Section 1.1.1.4 (on page 2280), except that the
79552 file permission bits shall be set to:

79553 S_IRWXO | S_IRWXG | S_IRWXU

79554 and the bits specified by the *umask* of the process shall be cleared.

79555 **OPTIONS**

79556 The *c99* utility shall conform to XBD Section 12.2 (on page 215), except that:

79557 • Options can be interspersed with operands.

79558 • The order of specifying the **–I**, **–L**, and **–l** options, and the order of specifying **–l** options
79559 with respect to *pathname* operands is significant.

79560 • Conforming applications shall specify each option separately; that is, grouping option
79561 letters (for example, **–cO**) need not be recognized by all implementations.

79562 The following options shall be supported:

79563 **–c** Suppress the link-edit phase of the compilation, and do not remove any object files
79564 that are produced.

79565 **–D** *name*[**=***value*]
79566 Define *name* as if by a C-language **#define** directive. If no =*value* is given, a value of
79567 1 shall be used. The **–D** option has lower precedence than the **–U** option. That is, if
79568 *name* is used in both a **–U** and a **–D** option, *name* shall be undefined regardless of
79569 the order of the options. Additional implementation-defined *name*s may be
79570 provided by the compiler. Implementations shall support at least 2 048 bytes of **–D**
79571 definitions and 256 *names*.

79572 **–E** Copy C-language source files to standard output, expanding all preprocessor
79573 directives; no compilation shall be performed. If any operand is not a text file, the
79574 effects are unspecified.

79575 **–g** Produce symbolic information in the object or executable files; the nature of this
79576 information is unspecified, and may be modified by implementation-defined
79577 interactions with other options.

79578 **–I** *directory* Change the algorithm for searching for headers whose names are not absolute
79579 pathnames to look in the directory named by the *directory* pathname before looking
79580 in the usual places. Thus, headers whose names are enclosed in double-quotes (" ")
79581 shall be searched for first in the directory of the file with the **#include** line, then in
79582 directories named in **–I** options, and last in the usual places. For headers whose
79583 names are enclosed in angle brackets ("<>"), the header shall be searched for only
79584 in directories named in **–I** options and then in the usual places. Directories named
79585 in **–I** options shall be searched in the order specified. Implementations shall
79586 support at least ten instances of this option in a single *c99* command invocation.

79587 **–L** *directory* Change the algorithm of searching for the libraries named in the **–l** objects to look
79588 in the directory named by the *directory* pathname before looking in the usual
79589 places. Directories named in **–L** options shall be searched in the order specified.
79590 Implementations shall support at least ten instances of this option in a single *c99*
79591 command invocation. If a directory specified by a **–L** option contains files with
79592 names starting with any of the strings `"libc."`, `"libl."`, `"libpthread."`,
79593 `"libm."`, `"librt."`, `"libtrace."`, `"libxnet."`, or `"liby."`, the results are
79594 unspecified.

79595 **–l** *library* Search the library named **liblibrary.a**. A library shall be searched when its name is
79596 encountered, so the placement of a **–l** option is significant. Several standard
79597 libraries can be specified in this manner, as described in the EXTENDED
79598 DESCRIPTION section. Implementations may recognize implementation-defined
79599 suffixes other than **.a** as denoting libraries.

79600 **–O** *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit
79601 `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the
79602 nature of the optimization is unspecified. If the **–O** option is omitted, the nature of
79603 the system's default optimization is unspecified. It is unspecified whether code
79604 generated in the presence of the **–O** 0 option is the same as that generated when
79605 **–O** is omitted. Other *optlevel* values may be supported.

79606 **–o** *outfile* Use the pathname *outfile*, instead of the default **a.out**, for the executable file
79607 produced. If the **–o** option is present with **–c** or **–E**, the result is unspecified.

79608 **–s** Produce object or executable files, or both, from which symbolic and other
79609 information not required for proper execution using the *exec* family defined in the
79610 System Interfaces volume of POSIX.1-200x has been removed (stripped). If both **–g**
79611 and **–s** options are present, the action taken is unspecified.

79612 **–U** *name* Remove any initial definition of *name*.

79613 Multiple instances of the **–D**, **–I**, **–L**, **–l**, and **–U** options can be specified.

79614 **OPERANDS**

79615 The application shall ensure that at least one *pathname* operand is specified. The following forms
79616 for *pathname* operands shall be supported:

79617 *file*.**c** A C-language source file to be compiled and optionally linked. The application
79618 shall ensure that the operand is of this form if the **–c** option is used.

79619 *file*.**a** A library of object files typically produced by the *ar* utility, and passed directly to
79620 the link editor. Implementations may recognize implementation-defined suffixes
79621 other than **.a** as denoting object file libraries.

79622 *file*.**o** An object file produced by *c99* **–c** and passed directly to the link editor.
79623 Implementations may recognize implementation-defined suffixes other than **.o** as
79624 denoting object files.

79625 The processing of other files is implementation-defined.

79626 **STDIN**

79627 Not used.

79628 **INPUT FILES**

79629 The input file shall be one of the following: a text file containing a C-language source program,
79630 an object file in the format produced by *c99* **–c**, or a library of object files, in the format produced
79631 by archiving zero or more object files, using *ar*. Implementations may supply additional utilities
79632 that produce files in these formats. Additional input file formats are implementation-defined.

79633 **ENVIRONMENT VARIABLES**

79634 The following environment variables shall affect the execution of *c99*:

79635 *LANG* Provide a default value for the internationalization variables that are unset or null.
79636 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
79637 variables used to determine the values of locale categories.)

79638 *LC_ALL* If set to a non-empty string value, override the values of all the other
79639 internationalization variables.

79640 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
79641 characters (for example, single-byte as opposed to multi-byte characters in
79642 arguments and input files).

79643 *LC_MESSAGES*
79644 Determine the locale that should be used to affect the format and contents of
79645 diagnostic messages written to standard error.

79646 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

79647 *TMPDIR* Provide a pathname that should override the default directory for temporary files,
79648 XSI if any. On XSI-conforming systems, provide a pathname that shall override the
79649 default directory for temporary files, if any.

79650 **ASYNCHRONOUS EVENTS**

79651 Default.

79652 **STDOUT**

79653 If more than one *pathname* operand ending in **.c** (or possibly other unspecified suffixes) is given,
79654 for each such file:

79655 `"%s:\n", <pathname>`

79656 may be written. These messages, if written, shall precede the processing of each input file; they
79657 shall not be written to the standard output if they are written to the standard error, as described
79658 in the STDERR section.

79659 If the **–E** option is specified, the standard output shall be a text file that represents the results of

the preprocessing stage of the language; it may contain extra information appropriate for subsequent compilation passes.

STDERR

The standard error shall be used only for diagnostic messages. If more than one *pathname* operand ending in **.c** (or possibly other unspecified suffixes) is given, for each such file:

```
"%s:\n", <pathname>
```

may be written to allow identification of the diagnostic and warning messages with the appropriate input file. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard error if they are written to the standard output, as described in the STDOUT section.

This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

OUTPUT FILES

Object files or executable files or both are produced in unspecified formats. If the pathname of an object file or executable file to be created by *c99* resolves to an existing directory entry for a file that is not a regular file, it is unspecified whether *c99* shall attempt to create the file or shall issue a diagnostic and exit with a non-zero exit status.

EXTENDED DESCRIPTION

Standard Libraries

The *c99* utility shall recognize the following **–l** options for standard libraries:

–l c This option shall make available all interfaces referenced in the System Interfaces volume of POSIX.1-200x, with the possible exception of those interfaces listed as residing in **<aio.h>**, **<arpa/inet.h>**, **<complex.h>**, **<fenv.h>**, **<math.h>**, **<mqueue.h>**, **<netdb.h>**, **<net/if.h>**, **<netinet/in.h>**, **<pthread.h>**, **<sched.h>**, **<semaphore.h>**, **<spawn.h>**, **<sys/socket.h>**, *pthread_kill*( ), and *pthread_sigmask*( ) in **<signal.h>**, **<trace.h>**, interfaces marked as optional in **<sys/mman.h>**, interfaces marked as ADV (Advisory Information) in **<fcntl.h>**, and interfaces beginning with the prefix clock_ or time_ in **<time.h>**. This option shall not be required to be present to cause a search of this library.

–l l This option shall make available all interfaces required by the C-language output of *lex* that are not made available through the **–l c** option.

–l pthread This option shall make available all interfaces referenced in **<pthread.h>** and *pthread_kill*( ) and *pthread_sigmask*( ) referenced in **<signal.h>**. An implementation may search this library in the absence of this option.

–l m This option shall make available all interfaces referenced in **<math.h>**, **<complex.h>**, and **<fenv.h>**. An implementation may search this library in the absence of this option.

–l rt This option shall make available all interfaces referenced in **<aio.h>**, **<mqueue.h>**, **<sched.h>**, **<semaphore.h>**, and **<spawn.h>**, interfaces marked as optional in **<sys/mman.h>**, interfaces marked as ADV (Advisory Information) in **<fcntl.h>**, and interfaces beginning with the prefix clock_ and time_ in **<time.h>**. An implementation may search this library in the absence of this option.

79702 OB **–l trace** This option shall make available all interfaces referenced in **<trace.h>**. An
79703 implementation may search this library in the absence of this option.

79704 **–l xnet** This option shall make available all interfaces referenced in **<arpa/inet.h>**,
79705 **<netdb.h>**, **<net/if.h>**, **<netinet/in.h>**, and **<sys/socket.h>**. An implementation
79706 may search this library in the absence of this option.

79707 **–l y** This option shall make available all interfaces required by the C-language output
79708 of *yacc* that are not made available through the **–l c** option.

79709 In the absence of options that inhibit invocation of the link editor, such as **–c** or **–E**, the *c99* utility
79710 shall cause the equivalent of a **–l c** option to be passed to the link editor after the last *pathname*
79711 operand or **–l** option, causing it to be searched after all other object files and libraries are loaded.

79712 OB It is unspecified whether the libraries **libc.a**, **libl.a**, **libm.a**, **libpthread.a**, **librt.a**, **libtrace.a**,
79713 **libxnet.a**, or **liby.a** exist as regular files. The implementation may accept as **–l** option-arguments
79714 names of objects that do not exist as regular files.

79715 **External Symbols**

79716 The C compiler and link editor shall support the significance of external symbols up to a length
79717 of at least 31 bytes; the action taken upon encountering symbols exceeding the implementation-
79718 defined maximum symbol length is unspecified.

79719 The compiler and link editor shall support a minimum of 511 external symbols per source or
79720 object file, and a minimum of 4 095 external symbols in total. A diagnostic message shall be
79721 written to the standard output if the implementation-defined limit is exceeded; other actions are
79722 unspecified.

79723 **Programming Environments**

79724 All implementations shall support one of the following programming environments as a default.
79725 Implementations may support more than one of the following programming environments.
79726 Applications can use *sysconf*( ) or *getconf* to determine which programming environments are
79727 supported.

79728 **Table 4-4** Programming Environments: Type Sizes

79729 79730 **Programming Environment** *getconf* **Name**	**Bits in int**	**Bits in long**	**Bits in pointer**	**Bits in off_t**
79731 _POSIX_V7_ILP32_OFF32	32	32	32	32
79732 _POSIX_V7_ILP32_OFFBIG	32	32	32	≥64
79733 _POSIX_V7_LP64_OFF64	32	64	64	64
79734 _POSIX_V7_LPBIG_OFFBIG	≥32	≥64	≥64	≥64

79735 All implementations shall support one or more environments where the widths of the following
79736 types are no greater than the width of type **long**:

79737 **blksize_t**	**ptrdiff_t**	**tcflag_t**
79738 **cc_t**	**size_t**	**wchar_t**
79739 **mode_t**	**speed_t**	**wint_t**
79740 **nfds_t**	**ssize_t**	
79741 **pid_t**	**suseconds_t**	

79742 The executable files created when these environments are selected shall be in a proper format for

execution by the *exec* family of functions. Each environment may be one of the ones in Table 4-4 (on page 2492), or it may be another environment. The names for the environments that meet this requirement shall be output by a *getconf* command using the POSIX_V7_WIDTH_RESTRICTED_ENVS argument, as a <newline>-separated list of names suitable for use with the *getconf* **–v** option. If more than one environment meets the requirement, the names of all such environments shall be output on separate lines. Any of these names can then be used in a subsequent *getconf* command to obtain the flags specific to that environment with the following suffixes added as appropriate:

_CFLAGS To get the C compiler flags.

_LDFLAGS To get the linker/loader flags.

_LIBS To get the libraries.

This requirement may be removed in a future version.

When this utility processes a file containing a function called *main*( ), it shall be defined with a return type equivalent to **int**. Using return from the initial call to *main*( ) shall be equivalent (other than with respect to language scope issues) to calling *exit*( ) with the returned value. Reaching the end of the initial call to *main*( ) shall be equivalent to calling *exit*(0). The implementation shall not declare a prototype for this function.

Implementations provide configuration strings for C compiler flags, linker/loader flags, and libraries for each supported environment. When an application needs to use a specific programming environment rather than the implementation default programming environment while compiling, the application shall first verify that the implementation supports the desired environment. If the desired programming environment is supported, the application shall then invoke *c99* with the appropriate C compiler flags as the first options for the compile, the appropriate linker/loader flags after any other options except **–l** but before any operands or **–l** options, and the appropriate libraries at the end of the operands and **–l** options.

Conforming applications shall not attempt to link together object files compiled for different programming models. Applications shall also be aware that binary data placed in shared memory or in files might not be recognized by applications built for other programming models.

Table 4-5 Programming Environments: *c99* Arguments

Programming Environment *getconf* **Name**	**Use**	*c99* **Arguments** *getconf* **Name**
_POSIX_V7_ILP32_OFF32	C Compiler Flags Linker/Loader Flags Libraries	POSIX_V7_ILP32_OFF32_CFLAGS POSIX_V7_ILP32_OFF32_LDFLAGS POSIX_V7_ILP32_OFF32_LIBS
_POSIX_V7_ILP32_OFFBIG	C Compiler Flags Linker/Loader Flags Libraries	POSIX_V7_ILP32_OFFBIG_CFLAGS POSIX_V7_ILP32_OFFBIG_LDFLAGS POSIX_V7_ILP32_OFFBIG_LIBS
_POSIX_V7_LP64_OFF64	C Compiler Flags Linker/Loader Flags Libraries	POSIX_V7_LP64_OFF64_CFLAGS POSIX_V7_LP64_OFF64_LDFLAGS POSIX_V7_LP64_OFF64_LIBS
_POSIX_V7_LPBIG_OFFBIG	C Compiler Flags Linker/Loader Flags Libraries	POSIX_V7_LPBIG_OFFBIG_CFLAGS POSIX_V7_LPBIG_OFFBIG_LDFLAGS POSIX_V7_LPBIG_OFFBIG_LIBS

In addition to the type size programming environments above, all implementations also support

a multi-threaded programming environment that is orthogonal to all of the programming environments listed above. The *getconf* utility can be used to get flags for the threaded programming environment, as indicated in Table 4-6.

Table 4-6 Threaded Programming Environment: *c99* Arguments

Programming Environment *getconf* **Name**	**Use**	*c99* **Arguments** *getconf* **Name**
_POSIX_THREADS	C Compiler Flags	POSIX_V7_THREADS_CFLAGS
	Linker/Loader Flags	POSIX_V7_THREADS_LDFLAGS

These programming environment flags may be used in conjunction with any of the type size programming environments supported by the implementation.

EXIT STATUS

The following exit values shall be returned:

0 Successful compilation or link edit.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When *c99* encounters a compilation error that causes an object file not to be created, it shall write a diagnostic to standard error and continue to compile other source code operands, but it shall not perform the link phase and return a non-zero exit status. If the link edit is unsuccessful, a diagnostic message shall be written to standard error and *c99* exits with a non-zero status. A conforming application shall rely on the exit status of *c99*, rather than on the existence or mode of the executable file.

APPLICATION USAGE

Since the *c99* utility usually creates files in the current directory during the compilation process, it is typically necessary to run the *c99* utility in a directory in which a file can be created.

On systems providing POSIX Conformance (see XBD Chapter 2, on page 15), *c99* is required only with the C-Language Development option; XSI-conformant systems always provide *c99*.

Some historical implementations have created **.o** files when **–c** is not specified and more than one source file is given. Since this area is left unspecified, the application cannot rely on **.o** files being created, but it also must be prepared for any related **.o** files that already exist being deleted at the completion of the link edit.

There is the possible implication that if a user supplies versions of the standard functions (before they would be encountered by an implicit **–l c** or explicit **–l m**), that those versions would be used in place of the standard versions. There are various reasons this might not be true (functions defined as macros, manipulations for clean name space, and so on), so the existence of files named in the same manner as the standard libraries within the **–L** directories is explicitly stated to produce unspecified behavior.

All of the functions specified in the System Interfaces volume of POSIX.1-200x may be made visible by implementations when the Standard C Library is searched. Conforming applications must explicitly request searching the other standard libraries when functions made visible by those libraries are used.

In the ISO C standard the mapping from physical source characters to the C source character set is implementation-defined. Implementations may strip white-space characters before the terminating <newline> of a (physical) line as part of this mapping and, as a consequence of this,

one or more white-space characters (and no other characters) between a <backslash> character and the <newline> character that terminates the line produces implementation-defined results. Portable applications should not use such constructs.

Some *c99* compilers not conforming to POSIX.1-200x do not support trigraphs by default.

EXAMPLES

1. The following usage example compiles **foo.c** and creates the executable file **foo**:

   ```
   c99 –o foo foo.c
   ```

   The following usage example compiles **foo.c** and creates the object file **foo.o**:

   ```
   c99 –c foo.c
   ```

   The following usage example compiles **foo.c** and creates the executable file **a.out**:

   ```
   c99 foo.c
   ```

   The following usage example compiles **foo.c**, links it with **bar.o**, and creates the executable file **a.out**. It may also create and leave **foo.o**:

   ```
   c99 foo.c bar.o
   ```

2. The following example shows how an application using threads interfaces can test for support of and use a programming environment supporting 32-bit **int**, **long**, and **pointer** types and an **off_t** type using at least 64 bits:

   ```
   offbig_env=$(getconf _POSIX_V7_ILP32_OFFBIG)
   if [ $offbig_env != "-1" ] && [ $offbig_env != "undefined" ]
   then
       c99 $(getconf POSIX_V7_ILP32_OFFBIG_CFLAGS) \
       $(getconf POSIX_V7_THREADS_CFLAGS) -D_XOPEN_SOURCE=700 \
       $(getconf POSIX_V7_ILP32_OFFBIG_LDFLAGS) \
       $(getconf POSIX_V7_THREADS_LDFLAGS) foo.c -o foo \
       $(getconf POSIX_V7_ILP32_OFFBIG_LIBS) \
       -l pthread
   else
       echo ILP32_OFFBIG programming environment not supported
       exit 1
   fi
   ```

3. The following examples clarify the use and interactions of –**L** and –**l** options.

   Consider the case in which module **a.c** calls function *f*( ) in library **libQ.a**, and module **b.c** calls function *g*( ) in library **libp.a**. Assume that both libraries reside in **/a/b/c**. The command line to compile and link in the desired way is:

   ```
   c99 –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this case the –**L** option need only precede the first –**l** option, since both **libQ.a** and **libp.a** reside in the same directory.

   Multiple –**L** options can be used when library name collisions occur. Building on the previous example, suppose that the user wants to use a new **libp.a**, in **/a/a/a**, but still wants *f*( ) from **/a/b/c/libQ.a**:

   ```
   c99 –L /a/a/a –L /a/b/c main.o a.c –l Q b.c –l p
   ```

   In this example, the linker searches the –**L** options in the order specified, and finds

/a/a/a/libp.a before **/a/b/c/libp.a** when resolving references for **b.c**. The order of the **–l** options is still important, however.

4. The following example shows how an application can use a programming environment where the widths of the following types:

   blksize_t, **cc_t**, **mode_t**, **nfds_t**, **pid_t**, **ptrdiff_t**, **size_t**, **speed_t**, **ssize_t**, **suseconds_t**, **tcflag_t**, **wchar_t**, **wint_t**

   are no greater than the width of type **long**:

```
# First choose one of the listed environments ...
# ... if there are no additional constraints, the first one will do:
CENV=$(getconf POSIX_V7_WIDTH_RESTRICTED_ENVS | head -n 1)
# ... or, if an environment that supports large files is preferred,
# look for names that contain "OFF64" or "OFFBIG". (This chooses
# the last one in the list if none match.)
for CENV in $(getconf POSIX_V7_WIDTH_RESTRICTED_ENVS)
do
    case $CENV in
    *OFF64*|*OFFBIG*) break ;;
    esac
done
# The chosen environment name can now be used like this:
c99 $(getconf ${CENV}_CFLAGS) -D _POSIX_C_SOURCE=200xxxL \
$(getconf ${CENV}_LDFLAGS) foo.c -o foo \
$(getconf ${CENV}_LIBS)
```

RATIONALE

The *c99* utility is based on the *c89* utility originally introduced in the ISO POSIX-2: 1993 standard.

Some of the changes from *c89* include the ability to intersperse options and operands (which many *c89* implementations allowed despite it not being specified), the description of **–l** as an option instead of an operand, and the modification to the contents of the Standard Libraries section to account for new headers and options; for example, **<spawn.h>** added to the description of **–l rt**, and **–l trace** added for the Tracing option.

POSIX.1-200x specifies that the *c99* utility must be able to use regular files for ***.o** files and for **a.out** files. Implementations are free to overwrite existing files of other types when attempting to create object files and executable files, but are not required to do so. If something other than a regular file is specified and using it fails for any reason, *c99* is required to issue a diagnostic message and exit with a non-zero exit status. But for some file types, the problem may not be noticed for a long time. For example, if a FIFO named **a.out** exists in the current directory, *c99* may attempt to open **a.out** and will hang in the *open*( ) call until another process opens the FIFO for reading. Then *c99* may write most of the **a.out** to the FIFO and fail when it tries to seek back close to the start of the file to insert a timestamp (FIFOs are not seekable files). The *c99* utility is also allowed to issue a diagnostic immediately if it encounters an **a.out** or ***.o** file that is not a regular file. For portable use, applications should ensure that any **a.out**, **–o** option-argument, or ***.o** files corresponding to any ***.c** files do not conflict with names already in use that are not regular files or symbolic links that point to regular files.

On many systems, multi-threaded applications run in a programming environment that is

distinct from that used by single-threaded applications. This multi-threaded programming environment (in addition to needing to specify **–l pthread** at link time) may require additional flags to be set when headers are processed at compile time (**–D_REENTRANT** being common). This programming environment is orthogonal to the type size programming environments discussed above and listed in Table 4-4 (on page 2492). This version of the standard adds *getconf* utility calls to provide the C compiler flags and linker/loader flags needed to support multi-threaded applications. Note that on a system where single-threaded applications are a special case of a multi-threaded application, both of these *getconf* calls may return NULL strings; on other implementations both of these strings may be non-NULL strings.

The C standardization committee invented trigraphs (e.g., `"??!"` to represent `'~'`) to address character portability problems in development environments based on national variants of the 7-bit ISO/IEC 646:1991 standard character set. However, these environments were already obsolete by the time the first ISO C standard was published, and in practice trigraphs have not been used for their intended purpose, and usually are intended to have their original meaning in K&R C. For example, in practice a C-language source string like `"What??!"` is usually intended to end in two <question-mark> characters and an <exclamation-mark>, not in `'~'`.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 6. Included for alignment with the ISO/IEC 9899:1999 standard.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/12 is applied, correcting the EXTENDED DESCRIPTION of **–l c** and **–l m**. Previously, the text did not take into account the presence of the *c99* math headers.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/13 is applied, changing the reference to the **libxnet** library to **libxnet.a**.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/5 is applied, updating the OPTIONS section, so that the names of files contained in the directory specified by the **–L** option are not assumed to end in the **.a** suffix. The set of library prefixes is also updated.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/6 is applied, removing the lead underscore from the POSIX_V6_WIDTH_RESTRICTED_ENVS variable in the EXTENDED DESCRIPTION and the EXAMPLES sections.

Issue 7

Austin Group Interpretation 1003.1-2001 #020 (SD5-XCU-ERN-10) is applied, adding to the OUTPUT FILES section and also adding associated RATIONALE.

Austin Group Interpretation 1003.1-2001 #095 is applied, clarifying the **–l** *library* operand.

Austin Group Interpretation 1003.1-2001 #166 is applied.

Austin Group Interpretation 1003.1-2001 #190 is applied, clarifying the handling of trailing white-space characters.

Austin Group Interpretation 1003.1-2001 #191 is applied, adding APPLICATION USAGE and RATIONALE regarding C-language trigraphs.

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply (options can be interspersed with operands).

SD5-XCU-ERN-11 is applied, adding the **<net/if.h>** header to the descriptions of **–l c** and **–l xnet**.

SD5-XCU-ERN-65 is applied, updating the EXAMPLES section.

SD5-XCU-ERN-67 and SD5-XCU-ERN-97 are applied, updating the SYNOPSIS.

SD5-XCU-ERN-133 is applied, updating the EXTENDED DESCRIPTION.

The *getconf* variables for the supported programming environments are updated to be V7.

The **–l trace** operand is marked obsolescent.

The *c99* reference page is rewritten to describe **–l** as an option rather than an operand.

NAME

cal — print a calendar

SYNOPSIS

XSI `cal [[`*month*`] `*year*`]`

DESCRIPTION

The *cal* utility shall write a calendar to standard output using the Julian calendar for dates from January 1, 1 through September 2, 1752 and the Gregorian calendar for dates from September 14, 1752 through December 31, 9999 as though the Gregorian calendar had been adopted on September 14, 1752.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

month Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default shall be the current month.

year Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999. The default shall be the current year.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cal*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

LC_TIME Determine the format and contents of the calendar.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone used to calculate the value of the current month.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used to display the calendar, in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Note that:

```
cal 83
```

refers to A.D. 83, not 1983.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

A future version of this standard may support locale-specific recognition of the date of adoption of the Gregorian calendar.

SEE ALSO

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The DESCRIPTION is updated to allow for traditional behavior for years before the adoption of the Gregorian calendar.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

80045 **NAME**

80046 cat — concatenate and print files

80047 **SYNOPSIS**

80048 `cat [-u] [file...]`

80049 **DESCRIPTION**

80050 The *cat* utility shall read files in sequence and shall write their contents to the standard output in
80051 the same sequence.

80052 **OPTIONS**

80053 The *cat* utility shall conform to XBD Section 12.2 (on page 215).

80054 The following option shall be supported:

80055 **-u** Write bytes from the input file to the standard output without delay as each is
80056 read.

80057 **OPERANDS**

80058 The following operand shall be supported:

80059 *file* A pathname of an input file. If no *file* operands are specified, the standard input
80060 shall be used. If a *file* is `'-'`, the *cat* utility shall read from the standard input at
80061 that point in the sequence. The *cat* utility shall not close and reopen standard input
80062 when it is referenced in this way, but shall accept multiple occurrences of `'-'` as a
80063 *file* operand.

80064 **STDIN**

80065 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'-'`.
80066 See the INPUT FILES section.

80067 **INPUT FILES**

80068 The input files can be any file type.

80069 **ENVIRONMENT VARIABLES**

80070 The following environment variables shall affect the execution of *cat*:

80071 *LANG* Provide a default value for the internationalization variables that are unset or null.
80072 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
80073 variables used to determine the values of locale categories.)

80074 *LC_ALL* If set to a non-empty string value, override the values of all the other
80075 internationalization variables.

80076 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
80077 characters (for example, single-byte as opposed to multi-byte characters in
80078 arguments).

80079 *LC_MESSAGES*

80080 Determine the locale that should be used to affect the format and contents of
80081 diagnostic messages written to standard error.

80082 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

80083 **ASYNCHRONOUS EVENTS**

80084 Default.

80085 **STDOUT**

80086 The standard output shall contain the sequence of bytes read from the input files. Nothing else
80087 shall be written to the standard output.

80088 **STDERR**

80089 The standard error shall be used only for diagnostic messages.

80090 **OUTPUT FILES**

80091 None.

80092 **EXTENDED DESCRIPTION**

80093 None.

80094 **EXIT STATUS**

80095 The following exit values shall be returned:

80096 0 All input files were output successfully.

80097 >0 An error occurred.

80098 **CONSEQUENCES OF ERRORS**

80099 Default.

80100 **APPLICATION USAGE**

80101 The –**u** option has value in prototyping non-blocking reads from FIFOs. The intent is to support
80102 the following sequence:

80103 ```
mkfifo foo
80104 cat –u foo > /dev/tty13 &
80105 cat –u > foo
```

80106 It is unspecified whether standard output is or is not buffered in the default case. This is
80107 sometimes of interest when standard output is associated with a terminal, since buffering may
80108 delay the output. The presence of the –**u** option guarantees that unbuffered I/O is available. It is
80109 implementation-defined whether the *cat* utility buffers output if the –**u** option is not specified.
80110 Traditionally, the –**u** option is implemented using the equivalent of the *setvbuf*( ) function
80111 defined in the System Interfaces volume of POSIX.1-200x.

80112 **EXAMPLES**

80113 The following command:

80114 ```
cat myfile
```

80115 writes the contents of the file **myfile** to standard output.

80116 The following command:

80117 ```
cat doc1 doc2 > doc.all
```

80118 concatenates the files **doc1** and **doc2** and writes the result to **doc.all**.

80119 Because of the shell language mechanism used to perform output redirection, a command such
80120 as this:

80121 ```
cat doc doc.end > doc
```

80122 causes the original data in **doc** to be lost.

80123 The command:

80124 ```
cat start – middle – end > file
```

80125 when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a
```

single invocation of *cat*. Note, however, that if standard input is a regular file, this would be equivalent to the command:

```
cat start - middle /dev/null end > file
```

because the entire contents of the file would be consumed by *cat* the first time '-' was used as a *file* operand and an end-of-file condition would be detected immediately when '-' was referenced the second time.

RATIONALE

Historical versions of the *cat* utility include the **-e**, **-t**, and **-v**, options which permit the ends of lines, <tab> characters, and invisible characters, respectively, to be rendered visible in the output. The standard developers omitted these options because they provide too fine a degree of control over what is made visible, and similar output can be obtained using a command such as:

```
sed -n l pathname
```

The latter also has the advantage that its output is unambiguous, whereas the output of historical *cat* **-etv** is not.

The **-s** option was omitted because it corresponds to different functions in BSD and System V-based systems. The BSD **-s** option to squeeze blank lines can be accomplished by the shell script shown in the following example:

```
sed -n '
# Write non-empty lines.
/./   {
      p
      d
      }
# Write a single empty line, then look for more empty lines.
/^$/  p
# Get next line, discard the held <newline> (empty line),
# and look for more empty lines.
:Empty
/^$/  {
      N
      s/.//
      b Empty
      }
# Write the non-empty line before going back to search
# for the first in a set of empty lines.
      p
'
```

The System V **-s** option to silence error messages can be accomplished by redirecting the standard error. Note that the BSD documentation for *cat* uses the term "blank line" to mean the same as the POSIX "empty line": a line consisting only of a <newline>.

The BSD **-n** option was omitted because similar functionality can be obtained from the **-n** option of the *pr* utility.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-174 is applied, changing the RATIONALE.

NAME

cd — change the working directory

SYNOPSIS

```
cd [–L|–P] [directory]
cd –
```

DESCRIPTION

The *cd* utility shall change the working directory of the current shell execution environment (see Section 2.12, on page 2331) by executing the following steps in sequence. (In the following steps, the symbol **curpath** represents an intermediate value used to simplify the description of the algorithm used by *cd*. There is no requirement that **curpath** be made visible to the application.)

1. If no *directory* operand is given and the *HOME* environment variable is empty or undefined, the default behavior is implementation-defined and no further steps shall be taken.
2. If no *directory* operand is given and the *HOME* environment variable is set to a non-empty value, the *cd* utility shall behave as if the directory named in the *HOME* environment variable was specified as the *directory* operand.
3. If the *directory* operand begins with a <slash> character, set **curpath** to the operand and proceed to step 7.
4. If the first component of the *directory* operand is dot or dot-dot, proceed to step 6.
5. Starting with the first pathname in the <colon>-separated pathnames of *CDPATH* (see the ENVIRONMENT VARIABLES section) if the pathname is non-null, test if the concatenation of that pathname, a <slash> character if that pathname did not end with a <slash> character, and the *directory* operand names a directory. If the pathname is null, test if the concatenation of dot, a <slash> character, and the operand names a directory. In either case, if the resulting string names an existing directory, set **curpath** to that string and proceed to step 7. Otherwise, repeat this step with the next pathname in *CDPATH* until all pathnames have been tested.
6. If the **–P** option is in effect, set **curpath** to the *directory* operand. Otherwise, set **curpath** to the string formed by the concatenation of the value of *PWD*, a <slash> character if the value of *PWD* did not end with a <slash> character, and the operand.
7. If the **–P** option is in effect, proceed to step 10. If **curpath** does not begin with a <slash> character, set **curpath** to the string formed by the concatenation of the value of *PWD*, a <slash> character if the value of *PWD* did not end with a <slash> character, and **curpath**.
8. The **curpath** value shall then be converted to canonical form as follows, considering each component from beginning to end, in sequence:
   a. Dot components and any <slash> characters that separate them from the next component shall be deleted.
   b. For each dot-dot component, if there is a preceding component and it is neither root nor dot-dot, then:
      i. If the preceding component does not refer (in the context of pathname resolution with symbolic links followed) to a directory, then the *cd* utility shall display an appropriate error message and no further steps shall be taken.

ii. The preceding component, all <slash> characters separating the preceding component from dot-dot, dot-dot, and all <slash> characters separating dot-dot from the following component (if any) shall be deleted.

c. An implementation may further simplify **curpath** by removing any trailing <slash> characters that are not also leading <slash> characters, replacing multiple non-leading consecutive <slash> characters with a single <slash>, and replacing three or more leading <slash> characters with a single <slash>. If, as a result of this canonicalization, the **curpath** variable is null, no further steps shall be taken.

9. If **curpath** is longer than {PATH_MAX} bytes (including the terminating null) and the *directory* operand was not longer than {PATH_MAX} bytes (including the terminating null), then **curpath** shall be converted from an absolute pathname to an equivalent relative pathname if possible. This conversion shall always be considered possible if the value of *PWD*, with a trailing <slash> added if it does not already have one, is an initial substring of **curpath**. Whether or not it is considered possible under other circumstances is unspecified. Implementations may also apply this conversion if **curpath** is not longer than {PATH_MAX} bytes or the *directory* operand was longer than {PATH_MAX} bytes.

10. The *cd* utility shall then perform actions equivalent to the *chdir*( ) function called with **curpath** as the *path* argument. If these actions fail for any reason, the *cd* utility shall display an appropriate error message and the remainder of this step shall not be executed. If the **–P** option is not in effect, the *PWD* environment variable shall be set to the value that **curpath** had on entry to step 9 (i.e., before conversion to a relative pathname). If the **–P** option is in effect, the *PWD* environment variable shall be set to the string that would be output by *pwd* **–P**. If there is insufficient permission on the new directory, or on any parent of that directory, to determine the current working directory, the value of the *PWD* environment variable is unspecified.

If, during the execution of the above steps, the *PWD* environment variable is changed, the *OLDPWD* environment variable shall also be changed to the value of the old working directory (that is the current working directory immediately prior to the call to *cd*).

OPTIONS

The *cd* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported by the implementation:

–L Handle the operand dot-dot logically; symbolic link components shall not be resolved before dot-dot components are processed (see steps 8. and 9. in the DESCRIPTION).

–P Handle the operand dot-dot physically; symbolic link components shall be resolved before dot-dot components are processed (see step 7. in the DESCRIPTION).

If both **–L** and **–P** options are specified, the last of these options shall be used and all others ignored. If neither **–L** nor **–P** is specified, the operand shall be handled dot-dot logically; see the DESCRIPTION.

OPERANDS

The following operands shall be supported:

directory An absolute or relative pathname of the directory that shall become the new working directory. The interpretation of a relative pathname by *cd* depends on the **–L** option and the *CDPATH* and *PWD* environment variables. If *directory* is an empty string, the results are unspecified.

– When a <hyphen> is used as the operand, this shall be equivalent to the command:

```
cd "$OLDPWD" && pwd
```

which changes to the previous working directory and then writes its name.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cd*:

CDPATH A <colon>-separated list of pathnames that refer to directories. The *cd* utility shall use this list in its attempt to change the directory, as described in the DESCRIPTION. An empty string in place of a directory pathname represents the current directory. If *CDPATH* is not set, it shall be treated as if it were an empty string.

HOME The name of the directory, used when no *directory* operand is specified.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

OLDPWD A pathname of the previous working directory, used by *cd* –.

PWD This variable shall be set as specified in the DESCRIPTION. If an application sets or unsets the value of *PWD*, the behavior of *cd* is unspecified.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If a non-empty directory name from *CDPATH* is used, or if *cd* – is used, an absolute pathname of the new working directory shall be written to the standard output as follows:

```
"%s\n", <new directory>
```

Otherwise, there shall be no output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The directory was successfully changed.

>0 An error occurred.

CONSEQUENCES OF ERRORS

The working directory shall remain unchanged.

APPLICATION USAGE

Since *cd* affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(cd /tmp)
nohup cd
find . –exec cd {} \;
```

it does not affect the working directory of the caller's environment.

The user must have execute (search) permission in *directory* in order to change to it.

EXAMPLES

None.

RATIONALE

The use of the *CDPATH* was introduced in the System V shell. Its use is analogous to the use of the *PATH* variable in the shell. The BSD C shell used a shell parameter *cdpath* for this purpose.

A common extension when *HOME* is undefined is to get the login directory from the user database for the invoking user. This does not occur on System V implementations.

Some historical shells, such as the KornShell, took special actions when the directory name contained a dot-dot component, selecting the logical parent of the directory, rather than the actual parent directory; that is, it moved up one level toward the '//' in the pathname, remembering what the user typed, rather than performing the equivalent of:

```
chdir("..");
```

In such a shell, the following commands would not necessarily produce equivalent output for all directories:

```
cd .. && ls      ls ..
```

This behavior is now the default. It is not consistent with the definition of dot-dot in most historical practice; that is, while this behavior has been optionally available in the KornShell, other shells have historically not supported this functionality. The logical pathname is stored in the *PWD* environment variable when the *cd* utility completes and this value is used to construct the next directory name if *cd* is invoked with the **–L** option.

FUTURE DIRECTIONS

None.

XSH *chdir*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The *cd* – operand, *PWD*, and *OLDPWD* are added.

The **–L** and **–P** options are added to align with the IEEE P1003.2b draft standard. This also includes the introduction of a new description to include the effect of these options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/14 is applied, changing the SYNOPSIS to make it clear that the **–L** and **–P** options are mutually-exclusive.

Issue 7

Austin Group Interpretation 1003.1-2001 #037 is applied.

Austin Group Interpretation 1003.1-2001 #199 is applied, clarifying how the *od* utility handles concatenation of two pathnames when the first pathname ends in a <slash> character.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Step 7 of the processing performed by *cd* is revised to refer to **curpath** instead of "the operand".

Changes to the *pwd* utility and *PWD* environment variable have been made to match the changes to the *getcwd*( ) function made for Austin Group Interpretation 1003.1-2001 #140.

80370 **NAME**

80371 cflow — generate a C-language flowgraph (**DEVELOPMENT**)

80372 **SYNOPSIS**

80373 XSI
```
cflow [–r] [–d num] [–D name[=def]]... [–i incl] [–I dir]...
    [–U dir]... file...
```
80374

80375 **DESCRIPTION**

80376 The *cflow* utility shall analyze a collection of object files or assembler, C-language, *lex*, or *yacc*
80377 source files, and attempt to build a graph, written to standard output, charting the external
80378 references.

80379 **OPTIONS**

80380 The *cflow* utility shall conform to XBD Section 12.2 (on page 215), except that the order of the **–D**,
80381 **–I**, and **–U** options (which are identical to their interpretation by *c99*) is significant.

80382 The following options shall be supported:

80383 **–d** *num* Indicate the depth at which the flowgraph is cut off. The application shall ensure
80384 that the argument *num* is a decimal integer. By default this is a very large number
80385 (typically greater than 32 000). Attempts to set the cut-off depth to a non-positive
80386 integer shall be ignored.

80387 **–i** *incl* Increase the number of included symbols. The *incl* option-argument is one of the
80388 following characters:

80389 *x* Include external and static data symbols. The default shall be to include only
80390 functions in the flowgraph.

80391 _ (Underscore) Include names that begin with an <underscore>. The default
80392 shall be to exclude these functions (and data if **–i x** is used).

80393 **–r** Reverse the caller:callee relationship, producing an inverted listing showing the
80394 callers of each function. The listing shall also be sorted in lexicographical order by
80395 callee.

80396 **OPERANDS**

80397 The following operand is supported:

80398 *file* The pathname of a file for which a graph is to be generated. Filenames suffixed by
80399 **.l** shall shall be taken to be *lex* input, **.y** as *yacc* input, **.c** as *c99* input, and **.i** as the
80400 output of *c99* **–E**. Such files shall be processed as appropriate, determined by their
80401 suffix.

80402 Files suffixed by **.s** (conventionally assembler source) may have more limited
80403 information extracted from them.

80404 **STDIN**

80405 Not used.

80406 **INPUT FILES**

80407 The input files shall be object files or assembler, C-language, *lex*, or *yacc* source files.

80408 **ENVIRONMENT VARIABLES**

80409 The following environment variables shall affect the execution of *cflow*:

80410 *LANG* Provide a default value for the internationalization variables that are unset or null.
80411 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
80412 variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the ordering of the output when the **–r** option is used.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
The flowgraph written to standard output shall be formatted as follows:

`"%d %s:%s\n", <reference number>, <global>, <definition>`

Each line of output begins with a reference (that is, line) number, followed by indentation of at least one column position per level. This is followed by the name of the global, a <colon>, and its definition. Normally globals are only functions not defined as an external or beginning with an <underscore>; see the OPTIONS section for the **–i** inclusion option. For information extracted from C-language source, the definition consists of an abstract type declaration (for example, **char** *) and, delimited by angle brackets, the name of the source file and the line number where the definition was found. Definitions extracted from object files indicate the filename and location counter under which the symbol appeared (for example, *text*).

Once a definition of a name has been written, subsequent references to that name contain only the reference number of the line where the definition can be found. For undefined references, only `"<>"` shall be written.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE

Files produced by *lex* and *yacc* cause the reordering of line number declarations, and this can confuse *cflow*. To obtain proper results, the input of *yacc* or *lex* must be directed to *cflow*.

EXAMPLES

Given the following in **file.c**:

```
int i;
int f();
int g();
int h();
int
main()
{
    f();
    g();
    f();
}
int
f()
{
    i = h();
}
```

The command:

```
cflow –i x file.c
```

produces the output:

```
1 main: int(), <file.c 6>
2    f: int(), <file.c 13>
3         h: <>
4         i: int, <file.c 1>
5    g: <>
```

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

chgrp — change the file group ownership

SYNOPSIS

```
chgrp [–h] group file...
chgrp –R [–H|–L|–P] group file...
```

DESCRIPTION

The *chgrp* utility shall set the group ID of the file named by each *file* operand to the group ID specified by the *group* operand.

For each *file* operand, or, if the –**R** option is used, each file encountered while walking the directory trees specified by the *file* operands, the *chgrp* utility shall perform actions equivalent to the *chown*( ) function defined in the System Interfaces volume of POSIX.1-200x, called with the following arguments:

- The *file* operand shall be used as the *path* argument.
- The user ID of the file shall be used as the *owner* argument.
- The specified group ID shall be used as the *group* argument.

Unless *chgrp* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chgrp* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported by the implementation:

–h If the system supports group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chgrp* shall attempt to set the group ID of the symbolic link instead of the file referenced by the symbolic link. If the system does not support group IDs for symbolic links, for each *file* operand that names a file of type symbolic link, *chgrp* shall do nothing more with the current file and shall go on to any remaining files.

–H If the –**R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

–L If the –**R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

–P If the –**R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chgrp* shall change the group ID of the symbolic link if the system supports this operation. The *chgrp* utility shall not follow the symbolic link to any other part of the file hierarchy.

–R Recursively change file group IDs. For each *file* operand that names a directory, *chgrp* shall change the group of the directory and all files in the file hierarchy below it. Unless a –**H**, –**L**, or –**P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options –**H**, –**L**, and –**P** shall not be considered an error. The last option specified shall determine the behavior of the utility.

80538 **OPERANDS**

80539 The following operands shall be supported:

80540 *group* A group name from the group database or a numeric group ID. Either specifies a
80541 group ID to be given to each file named by one of the *file* operands. If a numeric
80542 *group* operand exists in the group database as a group name, the group ID number
80543 associated with that group name is used as the group ID.

80544 *file* A pathname of a file whose group ID is to be modified.

80545 **STDIN**

80546 Not used.

80547 **INPUT FILES**

80548 None.

80549 **ENVIRONMENT VARIABLES**

80550 The following environment variables shall affect the execution of *chgrp*:

80551 *LANG* Provide a default value for the internationalization variables that are unset or null.
80552 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
80553 variables used to determine the values of locale categories.)

80554 *LC_ALL* If set to a non-empty string value, override the values of all the other
80555 internationalization variables.

80556 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
80557 characters (for example, single-byte as opposed to multi-byte characters in
80558 arguments).

80559 *LC_MESSAGES*
80560 Determine the locale that should be used to affect the format and contents of
80561 diagnostic messages written to standard error.

80562 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

80563 **ASYNCHRONOUS EVENTS**

80564 Default.

80565 **STDOUT**

80566 Not used.

80567 **STDERR**

80568 The standard error shall be used only for diagnostic messages.

80569 **OUTPUT FILES**

80570 None.

80571 **EXTENDED DESCRIPTION**

80572 None.

80573 **EXIT STATUS**

80574 The following exit values shall be returned:

80575 0 The utility executed successfully and all requested changes were made.

80576 >0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of *chgrp* to a user with appropriate privileges when the *group* specified is not the effective group ID or one of the supplementary group IDs of the calling process.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. The standard developers chose to mask these by specifying only 0 and >0 as exit values.

The functionality of *chgrp* is described substantially through references to *chown*( ). In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

FUTURE DIRECTIONS

None.

SEE ALSO

chmod, *chown*

CHANGE HISTORY

First released in Issue 2.

Issue 6

New options **–H**, **–L**, and **–P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to "Default.".

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/15 is applied, changing the SYNOPSIS to make it clear that **–h** and **–R** are optional.

Issue 7

SD5-XCU-ERN-8 is applied, removing the **–R** from the first line of the SYNOPSIS.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

chmod — change the file modes

SYNOPSIS

```
chmod [–R] mode file...
```

DESCRIPTION

The *chmod* utility shall change any or all of the file mode bits of the file named by each *file* operand in the way specified by the *mode* operand.

It is implementation-defined whether and how the *chmod* utility affects any alternate or additional file access control mechanism (see XBD Section 4.4, on page 108) being used for the specified file.

Only a process whose effective user ID matches the user ID of the file, or a process with appropriate privileges, shall be permitted to change the file mode bits of a file.

Upon successfully changing the file mode bits of a file, the *chmod* utility shall mark for update the last file status change timestamp of the file.

OPTIONS

The *chmod* utility shall conform to XBD Section 12.2 (on page 215).

The following option shall be supported:

–R Recursively change file mode bits. For each *file* operand that names a directory, *chmod* shall change the file mode bits of the directory and all files in the file hierarchy below it.

OPERANDS

The following operands shall be supported:

mode Represents the change to be made to the file mode bits of each file named by one of the *file* operands; see the EXTENDED DESCRIPTION section.

file A pathname of a file whose file mode bits shall be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chmod*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

The *mode* operand shall be either a *symbolic_mode* expression or a non-negative octal integer. The *symbolic_mode* form is described by the grammar later in this section.

Each **clause** shall specify an operation to be performed on the current file mode bits of each *file*. The operations shall be performed on each *file* in the order in which the **clause**s are specified.

The **who** symbols **u**, **g**, and **o** shall specify the *user*, *group*, and *other* parts of the file mode bits, respectively. A **who** consisting of the symbol **a** shall be equivalent to **ugo**.

The **perm** symbols **r**, **w**, and **x** represent the *read*, *write*, and *execute/search* portions of file mode bits, respectively. The **perm** symbol **s** shall represent the *set-user-ID-on-execution* (when **who** contains or implies **u**) and *set-group-ID-on-execution* (when **who** contains or implies **g**) bits.

The **perm** symbol **X** shall represent the execute/search portion of the file mode bits if the file is a directory or if the current (unmodified) file mode bits have at least one of the execute bits (S_IXUSR, S_IXGRP, or S_IXOTH) set. It shall be ignored if the file is not a directory and none of the execute bits are set in the current file mode bits.

The **permcopy** symbols **u**, **g**, and **o** shall represent the current permissions associated with the user, group, and other parts of the file mode bits, respectively. For the remainder of this section, **perm** refers to the non-terminals **perm** and **permcopy** in the grammar.

If multiple **actionlist**s are grouped with a single **wholist** in the grammar, each **actionlist** shall be applied in the order specified with that **wholist**. The *op* symbols shall represent the operation performed, as follows:

+ If **perm** is not specified, the '+' operation shall not change the file mode bits.

  If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

  Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

– If **perm** is not specified, the '–' operation shall not change the file mode bits.

  If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be cleared.

  Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be cleared.

= Clear the file mode bits specified by the **who** value, or, if no **who** value is specified, all of the file mode bits specified in this volume of POSIX.1-200x.

If **perm** is not specified, the '=' operation shall make no further modifications to the file mode bits.

If **who** is not specified, the file mode bits represented by **perm** for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.

Otherwise, the file mode bits represented by the specified **who** and **perm** values shall be set.

When using the symbolic mode form on a regular file, it is implementation-defined whether or not:

- Requests to set the set-user-ID-on-execution or set-group-ID-on-execution bit when all execute bits are currently clear and none are being set are ignored.
- Requests to clear all execute bits also clear the set-user-ID-on-execution and set-group-ID-on-execution bits.
- Requests to clear the set-user-ID-on-execution or set-group-ID-on-execution bits when all execute bits are currently clear are ignored. However, if the command *ls* **–l** *file* writes an *s* in the position indicating that the set-user-ID-on-execution or set-group-ID-on-execution is set, the commands *chmod* **u–s** *file* or *chmod* **g–s** *file*, respectively, shall not be ignored.

When using the symbolic mode form on other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

If the **who** symbol **o** is used in conjunction with the **perm** symbol **s** with no other **who** symbols being specified, the set-user-ID-on-execution and set-group-ID-on-execution bits shall not be modified. It shall not be an error to specify the **who** symbol **o** in conjunction with the **perm** symbol **s**.

XSI The **perm** symbol **t** shall specify the S_ISVTX bit. When used with a file of type directory, it can be used with the **who** symbol **a**, or with no **who** symbol. It shall not be an error to specify a **who** symbol of **u**, **g**, or **o** in conjunction with the **perm** symbol **t**, but the meaning of these combinations is unspecified. The effect when using the **perm** symbol **t** with any file type other than directory is unspecified.

For an octal integer *mode* operand, the file mode bits shall be set absolutely.

For each bit set in the octal number, the corresponding file permission bit shown in the following table shall be set; all other file permission bits shall be cleared. For regular files, for each bit set in the octal number corresponding to the set-user-ID-on-execution or the set-group-ID-on-execution, bits shown in the following table shall be set; if these bits are not set in the octal number, they are cleared. For other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

Octal	Mode Bit	Octal	Mode Bit	Octal	Mode Bit	Octal	Mode Bit
4000	S_ISUID	**0400**	S_IRUSR	**0040**	S_IRGRP	**0004**	S_IROTH
2000	S_ISGID	**0200**	S_IWUSR	**0020**	S_IWGRP	**0002**	S_IWOTH
XSI **1000**	S_ISVTX	**0100**	S_IXUSR	**0010**	S_IXGRP	**0001**	S_IXOTH

When bits are set in the octal number other than those listed in the table above, the behavior is unspecified.

80739 **Grammar for chmod**

80740 The grammar and lexical conventions in this section describe the syntax for the *symbolic_mode*
80741 operand. The general conventions for this style of grammar are described in Section 1.3 (on page
80742 2287). A valid *symbolic_mode* can be represented as the non-terminal symbol *symbolic_mode* in
80743 the grammar. This formal syntax shall take precedence over the preceding text syntax
80744 description.

80745 The lexical processing is based entirely on single characters. Implementations need not allow
80746 <blank> characters within the single argument being processed.

```
80747 %start    symbolic_mode
80748 %%
80749 symbolic_mode    : clause
80750                  | symbolic_mode ',' clause
80751                  ;
80752 clause           : actionlist
80753                  | wholist actionlist
80754                  ;
80755 wholist          : who
80756                  | wholist who
80757                  ;
80758 who              : 'u' | 'g' | 'o' | 'a'
80759                  ;
80760 actionlist       : action
80761                  | actionlist action
80762                  ;
80763 action           : op
80764                  | op permlist
80765                  | op permcopy
80766                  ;
80767 permcopy         : 'u' | 'g' | 'o'
80768                  ;
80769 op               : '+' | '-' | '='
80770                  ;
80771 permlist         : perm
80772                  | perm permlist
80773                  ;
80774 XSI  perm         : 'r' | 'w' | 'x' | 'X' | 's' | 't'
80775                  ;
```

80776 **EXIT STATUS**

80777 The following exit values shall be returned:

80778 0 The utility executed successfully and all requested changes were made.

80779 >0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Some implementations of the *chmod* utility change the mode of a directory before the files in the directory when performing a recursive (**–R** option) change; others change the directory mode after the files in the directory. If an application tries to remove read or search permission for a file hierarchy, the removal attempt fails if the directory is changed first; on the other hand, trying to re-enable permissions to a restricted hierarchy fails if directories are changed last. Users should not try to make a hierarchy inaccessible to themselves.

Some implementations of *chmod* never used the *umask* of the process when changing modes; systems conformant with this volume of POSIX.1-200x do so when **who** is not specified. Note the difference between:

```
chmod a–w file
```

which removes all write permissions, and:

```
chmod –– –w file
```

which removes write permissions that would be allowed if **file** was created with the same *umask*.

Conforming applications should never assume that they know how the set-user-ID and set-group-ID bits on directories are interpreted.

EXAMPLES

Mode	Results
a+=	Equivalent to *a+,a=*; clears all file mode bits.
go+–w	Equivalent to *go+,go–w*; clears group and other write bits.
g=o–w	Equivalent to *g=o,g–w*; sets group bit to match other bits and then clears group write bit.
g–r+w	Equivalent to *g–r,g+w*; clears group read bit and sets group write bit.
uo=g	Sets owner bits to match group bits and sets other bits to match group bits.

RATIONALE

The functionality of *chmod* is described substantially through references to concepts defined in the System Interfaces volume of POSIX.1-200x. In this way, there is less duplication of effort required for describing the interactions of permissions. However, the behavior of this utility is not described in terms of the *chmod*() function from the System Interfaces volume of POSIX.1-200x because that specification requires certain side-effects upon alternate file access control mechanisms that might not be appropriate, depending on the implementation.

Implementations that support mandatory file and record locking as specified by the 1984 /usr/group standard historically used the combination of set-group-ID bit set and group execute bit clear to indicate mandatory locking. This condition is usually set or cleared with the symbolic mode **perm** symbol **l** instead of the **perm** symbols **s** and **x** so that the mandatory locking mode is not changed without explicit indication that that was what the user intended. Therefore, the details on how the implementation treats these conditions must be defined in the documentation. This volume of POSIX.1-200x does not require mandatory locking (nor does the System Interfaces volume of POSIX.1-200x), but does allow it as an extension. However, this volume of POSIX.1-200x does require that the *ls* and *chmod* utilities work consistently in this

area. If *ls* **–l** *file* indicates that the set-group-ID bit is set, *chmod* **g–s** *file* must clear it (assuming appropriate privileges exist to change modes).

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. This problem is avoided here by specifying only 0 and >0 as exit values.

The System Interfaces volume of POSIX.1-200x indicates that implementation-defined restrictions may cause the S_ISUID and S_ISGID bits to be ignored. This volume of POSIX.1-200x allows the *chmod* utility to choose to modify these bits before calling *chmod*( ) (or some function providing equivalent capabilities) for non-regular files. Among other things, this allows implementations that use the set-user-ID and set-group-ID bits on directories to enable extended features to handle these extensions in an intelligent manner.

The **X perm** symbol was adopted from BSD-based systems because it provides commonly desired functionality when doing recursive (**–R** option) modifications. Similar functionality is not provided by the *find* utility. Historical BSD versions of *chmod*, however, only supported **X** with *op*+; it has been extended in this volume of POSIX.1-200x because it is also useful with *op*=. (It has also been added for *op*– even though it duplicates **x**, in this case, because it is intuitive and easier to explain.)

The grammar was extended with the *permcopy* non-terminal to allow historical-practice forms of symbolic modes like **o=u –g** (that is, set the "other" permissions to the permissions of "owner" minus the permissions of "group").

FUTURE DIRECTIONS

None.

XSH *chmod*( )

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Octal modes have been kept and made mandatory despite being marked obsolescent in the ISO POSIX-2: 1993 standard.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to "Default.".

The Open Group Base Resolution bwg2001-010 is applied, adding the description of the S_ISVTX bit and the **t perm** symbol as part of the XSI option.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/16 is applied, changing the XSI shaded text in the EXTENDED DESCRIPTION from:

> "The **perm** symbol **t** shall specify the S_ISVTX bit and shall apply to directories only. The effect when using it with any other file type is unspecified. It can be used with the **who** symbols **o**, **a**, or with no **who** symbol. It shall not be an error to specify a **who** symbol of **u** or **g** in conjunction with the **perm** symbol **t**; it shall be ignored for **u** and **g**."

to:

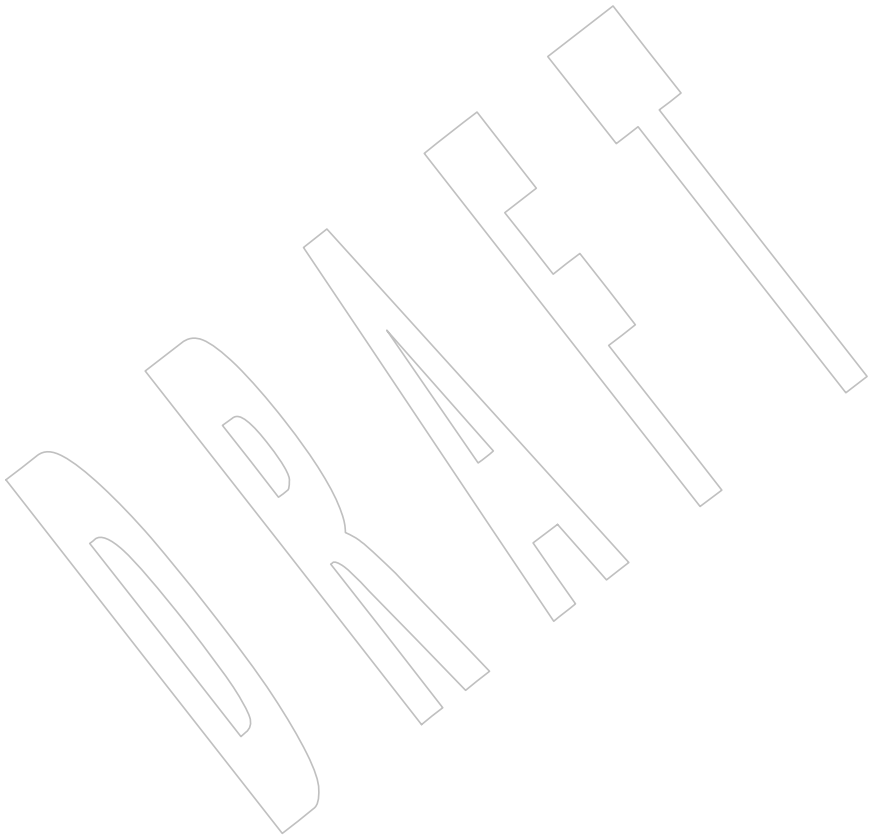
> "The **perm** symbol **t** shall specify the S_ISVTX bit. When used with a file of type directory, it can be used with the **who** symbol **a**, or with no **who** symbol. It shall not be an error to specify a **who** symbol of **u**, **g**, or **o** in conjunction with the **perm** symbol **t**, but the meaning of these combinations is unspecified. The effect when using the **perm** symbol **t** with any file type other than directory is unspecified."

This change is to permit historical behavior.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #130 is applied, adding text to the DESCRIPTION about about marking for update the last file status change timestamp of the file.



NAME

chown — change the file ownership

SYNOPSIS

```
chown [–h] owner[:group] file...
chown –R [–H|–L|–P] owner[:group] file...
```

DESCRIPTION

The *chown* utility shall set the user ID of the file named by each *file* operand to the user ID specified by the *owner* operand.

For each *file* operand, or, if the **–R** option is used, each file encountered while walking the directory trees specified by the *file* operands, the *chown* utility shall perform actions equivalent to the *chown*( ) function defined in the System Interfaces volume of POSIX.1-200x, called with the following arguments:

1. The *file* operand shall be used as the *path* argument.
2. The user ID indicated by the *owner* portion of the first operand shall be used as the *owner* argument.
3. If the *group* portion of the first operand is given, the group ID indicated by it shall be used as the *group* argument; otherwise, the group ownership shall not be changed.

Unless *chown* is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

OPTIONS

The *chown* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported by the implementation:

–h For each file operand that names a file of type symbolic link, *chown* shall attempt to set the user ID of the symbolic link. If a group ID was specified, for each file operand that names a file of type symbolic link, *chown* shall attempt to set the group ID of the symbolic link.

–H If the **–R** option is specified and a symbolic link referencing a file of type directory is specified on the command line, *chown* shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

–L If the **–R** option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, *chown* shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

–P If the **–R** option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *chown* shall change the owner ID (and group ID, if specified) of the symbolic link. The *chown* utility shall not follow the symbolic link to any other part of the file hierarchy.

–R Recursively change file user and group IDs. For each *file* operand that names a directory, *chown* shall change the user ID (and group ID, if specified) of the directory and all files in the file hierarchy below it. Unless a **–H**, **–L**, or **–P** option is specified, it is unspecified which of these options will be used as the default.

Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be

considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operands shall be supported:

owner[:*group*] A user ID and optional group ID to be assigned to *file*. The *owner* portion of this operand shall be a user name from the user database or a numeric user ID. Either specifies a user ID which shall be given to each file named by one of the *file* operands. If a numeric *owner* operand exists in the user database as a user name, the user ID number associated with that user name shall be used as the user ID. Similarly, if the *group* portion of this operand is present, it shall be a group name from the group database or a numeric group ID. Either specifies a group ID which shall be given to each file. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name shall be used as the group ID.

file A pathname of a file whose user ID is to be modified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *chown*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of *chown* to a user with appropriate privileges.

EXAMPLES

None.

RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. These are masked by specifying only 0 and >0 as exit values.

The functionality of *chown* is described substantially through references to functions in the System Interfaces volume of POSIX.1-200x. In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

The 4.3 BSD method of specifying both owner and group was included in this volume of POSIX.1-200x because:

- There are cases where the desired end condition could not be achieved using the *chgrp* and *chown* (that only changed the user ID) utilities. (If the current owner is not a member of the desired group and the desired owner is not a member of the current group, the *chown*( ) function could fail unless both owner and group are changed at the same time.)
- Even if they could be changed independently, in cases where both are being changed, there is a 100% performance penalty caused by being forced to invoke both utilities.

The BSD syntax *user*[.*group*] was changed to *user*[:*group*] in this volume of POSIX.1-200x because the <period> is a valid character in login names (as specified by the Base Definitions volume of POSIX.1-200x, login names consist of characters in the portable filename character set). The <colon> character was chosen as the replacement for the <period> character because it would never be allowed as a character in a user name or group name on historical implementations.

The **−R** option is considered by some observers as an undesirable departure from the historical UNIX system tools approach; since a tool, *find*, already exists to recurse over directories, there seemed to be no good reason to require other tools to have to duplicate that functionality. However, the **−R** option was deemed an important user convenience, is far more efficient than forking a separate process for each element of the directory hierarchy, and is in widespread historical use.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

New options **–h**, **–H**, **–L**, and **–P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE PASC Interpretation 1003.2 #172 is applied, changing the CONSEQUENCES OF ERRORS section to "Default.".

The "otherwise, ..." text in item 3. of the DESCRIPTION is changed to "otherwise, the group ownership shall not be changed".

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/17 is applied, changing the SYNOPSIS to make it clear that **–h** and **–R** are optional.

Issue 7

SD5-XCU-ERN-9 is applied, removing the **–R** from the first line of the SYNOPSIS.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The description of the **–h** and **–P** options is revised.

NAME

cksum — write file checksums and sizes

SYNOPSIS

```
cksum [file...]
```

DESCRIPTION

The *cksum* utility shall calculate and write to standard output a cyclic redundancy check (CRC) for each input file, and also write to standard output the number of octets in each file. The CRC used is based on the polynomial used for CRC error checking in the ISO/IEC 8802-3:1996 standard (Ethernet).

The encoding for the CRC checksum is defined by the generating polynomial:

$$G(x)=x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

Mathematically, the CRC value corresponding to a given file shall be defined by the following procedure:

1. The n bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These n bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer shall be used.
2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31.
3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.
4. The bit sequence is complemented and the result is the CRC.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be checked. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'-'` and the implementation treats the `'-'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cksum*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

81071 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
81072 characters (for example, single-byte as opposed to multi-byte characters in
81073 arguments).

81074 *LC_MESSAGES*
81075 Determine the locale that should be used to affect the format and contents of
81076 diagnostic messages written to standard error.

81077 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

81078 **ASYNCHRONOUS EVENTS**
81079 Default.

81080 **STDOUT**
81081 For each file processed successfully, the *cksum* utility shall write in the following format:

81082 `"%u %d %s\n", <checksum>, <# of octets>, <pathname>`

81083 If no *file* operand was specified, the pathname and its leading <space> shall be omitted.

81084 **STDERR**
81085 The standard error shall be used only for diagnostic messages.

81086 **OUTPUT FILES**
81087 None.

81088 **EXTENDED DESCRIPTION**
81089 None.

81090 **EXIT STATUS**
81091 The following exit values shall be returned:

81092 0 All files were processed successfully.

81093 >0 An error occurred.

81094 **CONSEQUENCES OF ERRORS**
81095 Default.

81096 **APPLICATION USAGE**
81097 The *cksum* utility is typically used to quickly compare a suspect file against a trusted version of
81098 the same, such as to ensure that files transmitted over noisy media arrive intact. However, this
81099 comparison cannot be considered cryptographically secure. The chances of a damaged file
81100 producing the same CRC as the original are small; deliberate deception is difficult, but probably
81101 not impossible.

81102 Although input files to *cksum* can be any type, the results need not be what would be expected
81103 on character special device files or on file types not described by the System Interfaces volume of
81104 POSIX.1-200x. Since this volume of POSIX.1-200x does not specify the block size used when
81105 doing input, checksums of character special files need not process all of the data in those files.

81106 The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted
81107 between two systems and undergoes any data transformation (such as changing little-endian
81108 byte ordering to big-endian), identical CRC values cannot be expected. Implementations
81109 performing such transformations may extend *cksum* to handle such situations.

81110 **EXAMPLES**
81111 None.

RATIONALE

The following C-language program can be used as a model to describe the algorithm. It assumes that a **char** is one octet. It also assumes that the entire file is available for one pass through the function. This was done for simplicity in demonstrating the algorithm, rather than as an implementation model.

```
static unsigned long crctab[] = {
0x00000000,

81170       };

81171       unsigned long memcrc(const unsigned char *b, size_t n)
81172       {
81173       /*  Input arguments:
81174        *  const char*   b == byte sequence to checksum
81175        *  size_t        n == length of sequence
81176        */

81177           register unsigned   i, c, s = 0;

81178           for (i = n; i > 0; --i) {
81179               c = (unsigned)(*b++);
81180               s = (s << 8) ^ crctab[(s >> 24) ^ c];
81181           }

81182           /* Extend with the length of the string. */
81183           while (n != 0) {
81184               c = n & 0377;
81185               n >>= 8;
81186               s = (s << 8) ^ crctab[(s >> 24) ^ c];
81187           }

81188           return ~s;
81189       }
```

81190 The historical practice of writing the number of "blocks" has been changed to writing the
81191 number of octets, since the latter is not only more useful, but also since historical
81192 implementations have not been consistent in defining what a "block" meant.

81193 The algorithm used was selected to increase the operational robustness of *cksum*. Neither the
81194 System V nor BSD *sum* algorithm was selected. Since each of these was different and each was
81195 the default behavior on those systems, no realistic compromise was available if either were
81196 selected—some set of historical applications would break. Therefore, the name was changed to
81197 *cksum*. Although the historical *sum* commands will probably continue to be provided for many
81198 years, programs designed for portability across systems should use the new name.

81199 The algorithm selected is based on that used by the ISO/IEC 8802-3: 1996 standard (Ethernet) for
81200 the frame check sequence field. The algorithm used does not match the technical definition of a
81201 *checksum*; the term is used for historical reasons. The length of the file is included in the CRC
81202 calculation because this parallels inclusion of a length field by Ethernet in its CRC, but also
81203 because it guards against inadvertent collisions between files that begin with different series of
81204 zero octets. The chance that two different files produce identical CRCs is much greater when
81205 their lengths are not considered. Keeping the length and the checksum of the file itself separate
81206 would yield a slightly more robust algorithm, but historical usage has always been that a single
81207 number (the checksum as printed) represents the signature of the file. It was decided that
81208 historical usage was the more important consideration.

81209 Early proposals contained modifications to the Ethernet algorithm that involved extracting table

values whenever an intermediate result became zero. This was demonstrated to be less robust than the current method and mathematically difficult to describe or justify.

The calculation used is identical to that given in pseudo-code in the referenced Sarwate article. The pseudo-code rendition is:

```
X <– 0; Y <– 0;
for i <– m –1 step –1 until 0 do
    begin
    T <– X(1) ^ A[i];
    X(1) <– X(0); X(0) <– Y(1); Y(1) <– Y(0); Y(0) <– 0;
    comment: f[T] and f’[T] denote the T-th words in the
        table f and f’ ;
    X <– X ^ f[T]; Y <– Y ^ f’[T];
    end
```

The pseudo-code is reproduced exactly as given; however, note that in the case of *cksum*, **A[i]** represents a byte of the file, the words **X** and **Y** are treated as a single 32-bit value, and the tables **f** and **f’** are a single table containing 32-bit values.

The referenced Sarwate article also discusses generating the table.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

cmp — compare two files

SYNOPSIS

```
cmp [-l|-s] file1 file2
```

DESCRIPTION

The *cmp* utility shall compare two files. The *cmp* utility shall write no output if the files are the same. Under default options, if they differ, it shall write to standard output the byte and line number at which the first difference occurred. Bytes and lines shall be numbered beginning with 1.

OPTIONS

The *cmp* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

-l (Lowercase ell.) Write the byte number (decimal) and the differing bytes (octal) for each difference.

-s Write nothing for differing files; return exit status only.

OPERANDS

The following operands shall be supported:

file1 A pathname of the first file to be compared. If *file1* is `'-'`, the standard input shall be used.

file2 A pathname of the second file to be compared. If *file2* is `'-'`, the standard input shall be used.

If both *file1* and *file2* refer to standard input or refer to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if the *file1* or *file2* operand refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files can be any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cmp*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

81278 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

81279 **ASYNCHRONOUS EVENTS**

81280 Default.

81281 **STDOUT**

81282 In the POSIX locale, results of the comparison shall be written to standard output. When no
81283 options are used, the format shall be:

81284 `"%s %s differ: char %d, line %d\n", file1, file2,`
81285 `    <byte number>, <line number>`

81286 When the **–l** option is used, the format shall be:

81287 `"%d %o %o\n", <byte number>, <differing byte>,`
81288 `    <differing byte>`

81289 for each byte that differs. The first <*differing byte*> number is from *file1* while the second is from
81290 *file2*. In both cases, <*byte number*> shall be relative to the beginning of the file, beginning with 1.

81291 No output shall be written to standard output when the **–s** option is used.

81292 **STDERR**

81293 The standard error shall be used only for diagnostic messages. If the **–l** option is used and *file1*
81294 and *file2* differ in length, or if the **–s** option is not used and *file1* and *file2* are identical for the
81295 entire length of the shorter file, in the POSIX locale the following diagnostic message shall be
81296 written:

81297 `"cmp: EOF on %s%s\n", <name of shorter file>, <additional info>`

81298 The <*additional info*> field shall either be null or a string that starts with a <blank> and contains
81299 no <newline> characters. Some implementations report on the number of lines in this case.

81300 **OUTPUT FILES**

81301 None.

81302 **EXTENDED DESCRIPTION**

81303 None.

81304 **EXIT STATUS**

81305 The following exit values shall be returned:

81306 0 The files are identical.

81307 1 The files are different; this includes the case where one file is identical to the first part of the
81308 other.

81309 >1 An error occurred.

81310 **CONSEQUENCES OF ERRORS**

81311 Default.

APPLICATION USAGE

Although input files to *cmp* can be any type, the results might not be what would be expected on character special device files or on file types not described by the System Interfaces volume of POSIX.1-200x. Since this volume of POSIX.1-200x does not specify the block size used when doing input, comparisons of character special files need not compare all of the data in those files.

For files which are not text files, line numbers simply reflect the presence of a <newline>, without any implication that the file is organized into lines.

EXAMPLES

None.

RATIONALE

The global language in Section 1.4 (on page 2288) indicates that using two mutually-exclusive options together produces unspecified results. Some System V implementations consider the option usage:

```
cmp -l -s ...
```

to be an error. They also treat:

```
cmp -s -l ...
```

as if no options were specified. Both of these behaviors are considered bugs, but are allowed.

The word **char** in the standard output format comes from historical usage, even though it is actually a byte number. When *cmp* is supported in other locales, implementations are encouraged to use the word *byte* or its equivalent in another language. Users should not interpret this difference to indicate that the functionality of the utility changed between locales.

Some implementations report on the number of lines in the identical-but-shorter file case. This is allowed by the inclusion of the <*additional info*> fields in the output format. The restriction on having a leading <blank> and no <newline> characters is to make parsing for the filename easier. It is recognized that some filenames containing white-space characters make parsing difficult anyway, but the restriction does aid programs used on systems where the names are predominantly well behaved.

FUTURE DIRECTIONS

None.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

comm — select or reject lines common to two files

SYNOPSIS

```
comm [–123] file1 file2
```

DESCRIPTION

The *comm* utility shall read *file1* and *file2*, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in *file1*, lines only in *file2*, and lines in both files.

If the lines in both files are not ordered according to the collating sequence of the current locale, the results are unspecified.

OPTIONS

The *comm* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–1 Suppress the output column of lines unique to *file1*.

–2 Suppress the output column of lines unique to *file2*.

–3 Suppress the output column of lines duplicated in *file1* and *file2*.

OPERANDS

The following operands shall be supported:

file1 A pathname of the first file to be compared. If *file1* is '–', the standard input shall be used.

file2 A pathname of the second file to be compared. If *file2* is '–', the standard input shall be used.

If both *file1* and *file2* refer to standard input or to the same FIFO special, block special, or character special file, the results are undefined.

STDIN

The standard input shall be used only if one of the *file1* or *file2* operands refers to standard input. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *comm*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the collating sequence *comm* expects to have been used when the input files were sorted.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *comm* utility shall produce output depending on the options selected. If the **–1**, **–2**, and **–3** options are all selected, *comm* shall write nothing to standard output.

If the **–1** option is not selected, lines contained only in *file1* shall be written using the format:

```
"%s\n", <line in file1>
```

If the **–2** option is not selected, lines contained only in *file2* are written using the format:

```
"%s%s\n", <lead>, <line in file2>
```

where the string <*lead*> is as follows:

<tab> The **–1** option is not selected.

null string The **–1** option is selected.

If the **–3** option is not selected, lines contained in both files shall be written using the format:

```
"%s%s\n", <lead>, <line in both>
```

where the string <*lead*> is as follows:

<tab><tab> Neither the **–1** nor the **–2** option is selected.

<tab> Exactly one of the **–1** and **–2** options is selected.

null string Both the **–1** and **–2** options are selected.

If the input files were ordered according to the collating sequence of the current locale, the lines written shall be in the collating sequence of the original lines.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were successfully output as specified.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the input files are not properly presorted, the output of *comm* might not be useful.

EXAMPLES

If a file named **xcu** contains a sorted list of the utilities in this volume of POSIX.1-200x, a file named **xpg3** contains a sorted list of the utilities specified in the X/Open Portability Guide, Issue 3, and a file named **svid89** contains a sorted list of the utilities in the System V Interface Definition Third Edition:

```
comm –23 xcu xpg3 | comm –23 – svid89
```

would print a list of utilities in this volume of POSIX.1-200x not specified by either of the other documents:

```
comm –12 xcu xpg3 | comm –12 – svid89
```

would print a list of utilities specified by all three documents, and:

```
comm –12 xpg3 svid89 | comm –23 – xcu
```

would print a list of utilities specified by both XPG3 and the SVID, but not specified in this volume of POSIX.1-200x.

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.

NAME

command — execute a simple command

SYNOPSIS

```
command [–p] command_name [argument...]
command [–p][–v|–V] command_name
```

DESCRIPTION

The *command* utility shall cause the shell to treat the arguments as a simple command, suppressing the shell function lookup that is described in Section 2.9.1.1 (on page 2317), item 1b.

If the *command_name* is the same as the name of one of the special built-in utilities, the special properties in the enumerated list at the beginning of Section 2.14 (on page 2334) shall not occur. In every other respect, if *command_name* is not the name of a function, the effect of *command* (with no options) shall be the same as omitting *command*.

When the **–v** or **–V** option is used, the *command* utility shall provide information concerning how a command name is interpreted by the shell.

OPTIONS

The *command* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–p Perform the command search using a default value for *PATH* that is guaranteed to find all of the standard utilities.

–v Write a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment (see Section 2.12, on page 2331), to invoke *command_name*, but do not invoke *command_name*.

- Utilities, regular built-in utilities, *command_name*s including a <slash> character, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1, on page 2317), shall be written as absolute pathnames.
- Shell functions, special built-in utilities, regular built-in utilities not associated with a *PATH* search, and shell reserved words shall be written as just their names.
- An alias shall be written as a command line that represents its alias definition.
- Otherwise, no output shall be written and the exit status shall reflect that the name was not found.

–V Write a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment (see Section 2.12, on page 2331), but do not invoke *command_name*. Although the format of this string is unspecified, it shall indicate in which of the following categories *command_name* falls and shall include the information stated:

- Utilities, regular built-in utilities, and any implementation-defined functions that are found using the *PATH* variable (as described in Section 2.9.1.1, on page 2317), shall be identified as such and include the absolute pathname in the string.

- Other shell functions shall be identified as functions.
- Aliases shall be identified as aliases and their definitions included in the string.
- Special built-in utilities shall be identified as special built-in utilities.
- Regular built-in utilities not associated with a *PATH* search shall be identified as regular built-in utilities. (The term "regular" need not be used.)
- Shell reserved words shall be identified as reserved words.

OPERANDS

The following operands shall be supported:

argument One of the strings treated as an argument to *command_name*.

command_name
The name of a utility or a special built-in utility.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *command*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path used during the command search described in Section 2.9.1.1 (on page 2317), except as described under the **–p** option.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–v** option is specified, standard output shall be formatted as:

```
"%s\n", <pathname or command>
```

When the **–V** option is specified, standard output shall be formatted as:

```
"%s\n", <unspecified>
```

81536 **STDERR**

81537 The standard error shall be used only for diagnostic messages.

81538 **OUTPUT FILES**

81539 None.

81540 **EXTENDED DESCRIPTION**

81541 None.

81542 **EXIT STATUS**

81543 When the **–v** or **–V** options are specified, the following exit values shall be returned:

81544 0 Successful completion.

81545 >0 The *command_name* could not be found or an error occurred.

81546 Otherwise, the following exit values shall be returned:

81547 126 The utility specified by *command_name* was found but could not be invoked.

81548 127 An error occurred in the *command* utility or the utility specified by *command_name* could not
81549 be found.

81550 Otherwise, the exit status of *command* shall be that of the simple command specified by the
81551 arguments to *command*.

81552 **CONSEQUENCES OF ERRORS**

81553 Default.

81554 **APPLICATION USAGE**

81555 The order for command search allows functions to override regular built-ins and path searches.
81556 This utility is necessary to allow functions that have the same name as a utility to call the utility
81557 (instead of a recursive call to the function).

81558 The system default path is available using *getconf*; however, since *getconf* may need to have the
81559 *PATH* set up before it can be called itself, the following can be used:

81560 `command –p getconf PATH`

81561 There are some advantages to suppressing the special characteristics of special built-ins on
81562 occasion. For example:

81563 `command exec > unwritable-file`

81564 does not cause a non-interactive script to abort, so that the output status can be checked by the
81565 script.

81566 The *command*, *env*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an
81567 error occurs so that applications can distinguish "failure to find a utility" from "invoked utility
81568 exited with an error indication". The value 127 was chosen because it is not commonly used for
81569 other meanings; most utilities use small values for "normal error conditions" and the values
81570 above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen
81571 in a similar manner to indicate that the utility could be found, but not invoked. Some scripts
81572 produce meaningful error messages differentiating the 126 and 127 cases. The distinction
81573 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
81574 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for
81575 any other reason.

81576 Since the **–v** and **–V** options of *command* produce output in relation to the current shell execution
81577 environment, *command* is generally provided as a shell regular built-in. If it is called in a subshell
81578 or separate utility execution environment, such as one of the following:

```
(PATH=foo command –v)
 nohup command –v
```

it does not necessarily produce correct results. For example, when called with *nohup* or an *exec* function, in a separate utility execution environment, most implementations are not able to identify aliases, functions, or special built-ins.

Two types of regular built-ins could be encountered on a system and these are described separately by *command*. The description of command search in Section 2.9.1.1 (on page 2317) allows for a standard utility to be implemented as a regular built-in as long as it is found in the appropriate place in a *PATH* search. So, for example, *command* **–v** *true* might yield **/bin/true** or some similar pathname. Other implementation-defined utilities that are not defined by this volume of POSIX.1-200x might exist only as built-ins and have no pathname associated with them. These produce output identified as (regular) built-ins. Applications encountering these are not able to count on *exec*ing them, using them with *nohup*, overriding them with a different *PATH*, and so on.

EXAMPLES

1. Make a version of *cd* that always prints out the new working directory exactly once:

```
cd() {
    command cd "$@" >/dev/null
    pwd
}
```

2. Start off a "secure shell script" in which the script avoids being spoofed by its parent:

```
IFS='
'
#    The preceding value should be <space><tab><newline>.
#    Set IFS to its default value.

\unalias –a
#    Unset all possible aliases.
#    Note that unalias is escaped to prevent an alias
#    being used for unalias.

unset –f command
#    Ensure command is not a user function.

PATH="$(command –p getconf PATH):$PATH"
#    Put on a reliable PATH prefix.

#    ...
```

At this point, given correct permissions on the directories called by *PATH*, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this volume of POSIX.1-200x, but it is not prohibited as an extension. For example, the *ENV* variable precedes the invocation of the script with a user start-up script. Such a script could define functions to spoof the application.

RATIONALE

Since *command* is a regular built-in utility it is always found prior to the *PATH* search.

There is nothing in the description of *command* that implies the command line is parsed any differently from that of any other simple command. For example:

```
command a | b ; c
```

is not parsed in any special way that causes '|' or ';' to be treated other than a pipe operator or <semicolon> or that prevents function lookup on **b** or **c**.

The *command* utility is somewhat similar to the Eighth Edition shell *builtin* command, but since *command* also goes to the file system to search for utilities, the name *builtin* would not be intuitive.

The *command* utility is most likely to be provided as a regular built-in. It is not listed as a special built-in for the following reasons:

- The removal of exportable functions made the special precedence of a special built-in unnecessary.
- A special built-in has special properties (see Section 2.14, on page 2334) that were inappropriate for invoking other utilities. For example, two commands such as:

  ```
  date > unwritable-file
  ```

  ```
  command date > unwritable-file
  ```

  would have entirely different results; in a non-interactive script, the former would continue to execute the next command, the latter would abort. Introducing this semantic difference along with suppressing functions was seen to be non-intuitive.

The **–p** option is present because it is useful to be able to ensure a safe path search that finds all the standard utilities. This search might not be identical to the one that occurs through one of the *exec* functions (as defined in the System Interfaces volume of POSIX.1-200x) when *PATH* is unset. At the very least, this feature is required to allow the script to access the correct version of *getconf* so that the value of the default path can be accurately retrieved.

The *command* **–v** and **–V** options were added to satisfy requirements from users that are currently accomplished by three different historical utilities: *type* in the System V shell, *whence* in the KornShell, and *which* in the C shell. Since there is no historical agreement on how and what to accomplish here, the POSIX *command* utility was enhanced and the historical utilities were left unmodified. The C shell *which* merely conducts a path search. The KornShell *whence* is more elaborate—in addition to the categories required by POSIX, it also reports on tracked aliases, exported aliases, and undefined functions.

The output format of **–V** was left mostly unspecified because human users are its only audience. Applications should not be written to care about this information; they can use the output of **–v** to differentiate between various types of commands, but the additional information that may be emitted by the more verbose **–V** is not needed and should not be arbitrarily constrained in its verbosity or localization for application parsing reasons.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

XSH *exec*

CHANGE HISTORY

First released in Issue 4.

Issue 7

Austin Group Interpretation 1003.1-2001 #196 is applied, changing the SYNOPSIS to allow **–p** to be used with **–v** (or **–V**).

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *command* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

The APPLICATION USAGE and EXAMPLES are revised to replace the non-standard *getconf*_CS_PATH with *getconf PATH*.

NAME

compress — compress data

SYNOPSIS

XSI

```
compress [–fv] [–b bits] [file...]
compress [–cfv] [–b bits] [file]
```

DESCRIPTION

The *compress* utility shall attempt to reduce the size of the named files by using adaptive Lempel-Ziv coding algorithm.

Note: Lempel-Ziv is US Patent 4464650, issued to William Eastman, Abraham Lempel, Jacob Ziv, Martin Cohn on August 7th, 1984, and assigned to Sperry Corporation.

Lempel-Ziv-Welch compression is covered by US Patent 4558302, issued to Terry A. Welch on December 10th, 1985, and assigned to Sperry Corporation.

On systems not supporting adaptive Lempel-Ziv coding algorithm, the input files shall not be changed and an error value greater than two shall be returned. Except when the output is to the standard output, each file shall be replaced by one with the extension **.Z**. If the invoking process has appropriate privileges, the ownership, modes, access time, and modification time of the original file are preserved. If appending the **.Z** to the filename would make the name exceed {NAME_MAX} bytes, the command shall fail. If no files are specified, the standard input shall be compressed to the standard output.

OPTIONS

The *compress* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–b *bits* Specify the maximum number of bits to use in a code. For a conforming application, the *bits* argument shall be:

```
9 <= bits <= 14
```

The implementation may allow *bits* values of greater than 14. The default is 14, 15, or 16.

–c Cause *compress* to write to the standard output; the input file is not changed, and no **.Z** files are created.

–f Force compression of *file*, even if it does not actually reduce the size of the file, or if the corresponding *file***.Z** file already exists. If the **–f** option is not given, and the process is not running in the background, the user is prompted as to whether an existing *file***.Z** file should be overwritten. If the response is affirmative, the existing file will be overwritten.

–v Write the percentage reduction of each file to standard error.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be compressed.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

81714 **INPUT FILES**

81715 If *file* operands are specified, the input files contain the data to be compressed.

81716 **ENVIRONMENT VARIABLES**

81717 The following environment variables shall affect the execution of *compress*:

81718 *LANG* Provide a default value for the internationalization variables that are unset or null.
81719 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
81720 variables used to determine the values of locale categories.)

81721 *LC_ALL* If set to a non-empty string value, override the values of all the other
81722 internationalization variables.

81723 *LC_COLLATE*
81724 Determine the locale for the behavior of ranges, equivalence classes, and multi-
81725 character collating elements used in the extended regular expression defined for
81726 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

81727 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
81728 characters (for example, single-byte as opposed to multi-byte characters in
81729 arguments), the behavior of character classes used in the extended regular
81730 expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

81731 *LC_MESSAGES*
81732 Determine the locale used to process affirmative responses, and the locale used to
81733 affect the format and contents of diagnostic messages, prompts, and the output
81734 from the **−v** option written to standard error.

81735 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

81736 **ASYNCHRONOUS EVENTS**

81737 Default.

81738 **STDOUT**

81739 If no *file* operands are specified, or if a *file* operand is `'−'`, or if the **−c** option is specified, the
81740 standard output contains the compressed output.

81741 **STDERR**

81742 The standard error shall be used only for diagnostic and prompt messages and the output from
81743 **−v**.

81744 **OUTPUT FILES**

81745 The output files shall contain the compressed output. The format of compressed files is
81746 unspecified and interchange of such files between implementations (including access via
81747 unspecified file sharing mechanisms) is not required by POSIX.1-200x.

81748 **EXTENDED DESCRIPTION**

81749 None.

81750 **EXIT STATUS**

81751 The following exit values shall be returned:

81752 0 Successful completion.

81753 1 An error occurred.

81754 2 One or more files were not compressed because they would have increased in size (and the
81755 **−f** option was not specified).

>2 An error occurred.

CONSEQUENCES OF ERRORS

The input file shall remain unmodified.

APPLICATION USAGE

The amount of compression obtained depends on the size of the input, the number of *bits* per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50-60%. Compression is generally much better than that achieved by Huffman coding or adaptive Huffman coding (*compact*), and takes less time to compute.

Although *compress* strictly follows the default actions upon receipt of a signal or when an error occurs, some unexpected results may occur. In some implementations it is likely that a partially compressed file is left in place, alongside its uncompressed input file. Since the general operation of *compress* is to delete the uncompressed file only after the **.Z** file has been successfully filled, an application should always carefully check the exit status of *compress* before arbitrarily deleting files that have like-named neighbors with **.Z** suffixes.

The limit of 14 on the *bits* option-argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Austin Group Interpretation 1003.1-2001 #125 is applied, revising the ENVIRONMENT VARIABLES section.

NAME

cp — copy files

SYNOPSIS

```
cp [–Pfip] source_file target_file
cp [–Pfip] source_file... target
cp –R [–H|–L|–P] [–fip] source_file... target
```

DESCRIPTION

The first synopsis form is denoted by two operands, neither of which are existing files of type directory. The *cp* utility shall copy the contents of *source_file* (or, if *source_file* is a file of type symbolic link, the contents of the file referenced by *source_file*) to the destination path named by *target_file.*

The second synopsis form is denoted by two or more operands where the **–R** option is not specified and the first synopsis form is not applicable. It shall be an error if any *source_file* is a file of type directory, if *target* does not exist, or if *target* does not name a directory. The *cp* utility shall copy the contents of each *source_file* (or, if *source_file* is a file of type symbolic link, the contents of the file referenced by *source_file*) to the destination path named by the concatenation of *target*, a single <slash> character if *target* did not end in a <slash>, and the last component of *source_file*.

The third synopsis form is denoted by two or more operands where the **–R** option is specified. The *cp* utility shall copy each file in the file hierarchy rooted in each *source_file* to a destination path named as follows:

- If *target* exists and names an existing directory, the name of the corresponding destination path for each file in the file hierarchy shall be the concatenation of *target*, a single <slash> character if *target* did not end in a <slash>, and the pathname of the file relative to the directory containing *source_file*.
- If *target* does not exist and two operands are specified, the name of the corresponding destination path for *source_file* shall be *target*; the name of the corresponding destination path for all other files in the file hierarchy shall be the concatenation of *target*, a <slash> character, and the pathname of the file relative to *source_file*.

It shall be an error if *target* does not exist and more than two operands are specified, or if *target* exists and does not name a directory.

In the following description, the term *dest_file* refers to the file named by the destination path. The term *source_file* refers to the file that is being copied, whether specified as an operand or a file in a file hierarchy rooted in a *source_file* operand. If *source_file* is a file of type symbolic link:

- If the **–R** option was not specified, *cp* shall take actions based on the type and contents of the file referenced by the symbolic link, and not by the symbolic link itself, unless the **–P** option was specified.
- If the **–R** option was specified:
  - — If none of the options **–H**, **–L**, nor **–P** were specified, it is unspecified which of **–H**, **–L**, or **–P** will be used as a default.
  - — If the **–H** option was specified, *cp* shall take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.
  - — If the **–L** option was specified, *cp* shall take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand or any symbolic links encountered during traversal of a file hierarchy.

— If the **−P** option was specified, *cp* shall copy any symbolic link specified as a *source_file* operand and any symbolic links encountered during traversal of a file hierarchy, and shall not follow any symbolic links.

For each *source_file*, the following steps shall be taken:

1. If *source_file* references the same file as *dest_file*, *cp* may write a diagnostic message to standard error; it shall do nothing more with *source_file* and shall go on to any remaining files.

2. If *source_file* is of type directory, the following steps shall be taken:

   a. If the **−R** option was not specified, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

   b. If *source_file* was not specified as an operand and *source_file* is dot or dot-dot, *cp* shall do nothing more with *source_file* and go on to any remaining files.

   c. If *dest_file* exists and it is a file type not specified by the System Interfaces volume of POSIX.1-200x, the behavior is implementation-defined.

   d. If *dest_file* exists and it is not of type directory, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file* or any files below *source_file* in the file hierarchy, and go on to any remaining files.

   e. If the directory *dest_file* does not exist, it shall be created with file permission bits set to the same value as those of *source_file*, modified by the file creation mask of the user if the **−p** option was not specified, and then bitwise-inclusively OR'ed with S_IRWXU. If *dest_file* cannot be created, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files. It is unspecified if *cp* attempts to copy files in the file hierarchy rooted in *source_file*.

   f. The files in the directory *source_file* shall be copied to the directory *dest_file*, taking the four steps (1 to 4) listed here with the files as *source_file*s.

   g. If *dest_file* was created, its file permission bits shall be changed (if necessary) to be the same as those of *source_file*, modified by the file creation mask of the user if the **−p** option was not specified.

   h. The *cp* utility shall do nothing more with *source_file* and go on to any remaining files.

3. If *source_file* is of type regular file, the following steps shall be taken:

   a. The behavior is unspecified if *dest_file* exists and was written by a previous step. Otherwise, if *dest_file* exists, the following steps shall be taken:

      i. If the **−i** option is in effect, the *cp* utility shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, *cp* shall do nothing more with *source_file* and go on to any remaining files.

      ii. A file descriptor for *dest_file* shall be obtained by performing actions equivalent to the *open*( ) function defined in the System Interfaces volume of POSIX.1-200x called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_TRUNC as the *oflag* argument.

      iii. If the attempt to obtain a file descriptor fails and the **−f** option is in effect, *cp* shall attempt to remove the file by performing actions equivalent to the *unlink*( ) function defined in the System Interfaces volume of POSIX.1-200x

called using *dest_file* as the *path* argument. If this attempt succeeds, *cp* shall continue with step 3b.

b. If *dest_file* does not exist, a file descriptor shall be obtained by performing actions equivalent to the *open*() function defined in the System Interfaces volume of POSIX.1-200x called using *dest_file* as the *path* argument, and the bitwise-inclusive OR of O_WRONLY and O_CREAT as the *oflag* argument. The file permission bits of *source_file* shall be the *mode* argument.

c. If the attempt to obtain a file descriptor fails, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

d. The contents of *source_file* shall be written to the file descriptor. Any write errors shall cause *cp* to write a diagnostic message to standard error and continue to step 3e.

e. The file descriptor shall be closed.

f. The *cp* utility shall do nothing more with *source_file*. If a write error occurred in step 3d, it is unspecified if *cp* continues with any remaining files. If no write error occurred in step 3d, *cp* shall go on to any remaining files.

4. Otherwise, the **–R** option was specified, and the following steps shall be taken:

a. The *dest_file* shall be created with the same file type as *source_file*.

b. If *source_file* is a file of type FIFO, the file permission bits shall be the same as those of *source_file,* modified by the file creation mask of the user if the **–p** option was not specified. Otherwise, the permissions, owner ID, and group ID of *dest_file* are implementation-defined.

If this creation fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

c. If *source_file* is a file of type symbolic link, and the options require the symbolic link itself to be acted upon, the pathname contained in *dest_file* shall be the same as the pathname contained in *source_file*.

If this fails for any reason, *cp* shall write a diagnostic message to standard error, do nothing more with *source_file*, and go on to any remaining files.

If the implementation provides additional or alternate access control mechanisms (see XBD Section 4.4, on page 108), their effect on copies of files is implementation-defined.

OPTIONS

The *cp* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–f If a file descriptor for a destination file cannot be obtained, as described in step 3.a.ii., attempt to unlink the destination file and proceed.

–H Take actions based on the type and contents of the file referenced by any symbolic link specified as a *source_file* operand.

–i Write a prompt to standard error before copying to any existing non-directory destination file. If the response from the standard input is affirmative, the copy shall be attempted; otherwise, it shall not.

81920 **–L** Take actions based on the type and contents of the file referenced by any symbolic
81921 link specified as a *source_file* operand or any symbolic links encountered during
81922 traversal of a file hierarchy.

81923 **–P** Take actions on any symbolic link specified as a *source_file* operand or any
81924 symbolic link encountered during traversal of a file hierarchy.

81925 **–p** Duplicate the following characteristics of each source file in the corresponding
81926 destination file:

81927 1. The time of last data modification and time of last access. If this duplication
81928 fails for any reason, *cp* shall write a diagnostic message to standard error.

81929 2. The user ID and group ID. If this duplication fails for any reason, it is
81930 unspecified whether *cp* writes a diagnostic message to standard error.

81931 3. The file permission bits and the S_ISUID and S_ISGID bits. Other,
81932 implementation-defined, bits may be duplicated as well. If this duplication
81933 fails for any reason, *cp* shall write a diagnostic message to standard error.

81934 If the user ID or the group ID cannot be duplicated, the file permission bits
81935 S_ISUID and S_ISGID shall be cleared. If these bits are present in the source file but
81936 are not duplicated in the destination file, it is unspecified whether *cp* writes a
81937 diagnostic message to standard error.

81938 The order in which the preceding characteristics are duplicated is unspecified. The
81939 *dest_file* shall not be deleted if these characteristics cannot be preserved.

81940 **–R** Copy file hierarchies.

81941 Specifying more than one of the mutually-exclusive options **–H**, **–L**, and **–P** shall not be
81942 considered an error. The last option specified shall determine the behavior of the utility.

81943 **OPERANDS**

81944 The following operands shall be supported:

81945 *source_file* A pathname of a file to be copied. If a *source_file* operand is `'–'`, it shall refer to a
81946 file named –; implementations shall not treat it as meaning standard input.

81947 *target_file* A pathname of an existing or nonexistent file, used for the output when a single
81948 file is copied. If a *target_file* operand is `'–'`, it shall refer to a file named –;
81949 implementations shall not treat it as meaning standard output.

81950 *target* A pathname of a directory to contain the copied files.

81951 **STDIN**

81952 The standard input shall be used to read an input line in response to each prompt specified in
81953 the STDERR section. Otherwise, the standard input shall not be used.

81954 **INPUT FILES**

81955 The input files specified as operands may be of any file type.

81956 **ENVIRONMENT VARIABLES**

81957 The following environment variables shall affect the execution of *cp*:

81958 *LANG* Provide a default value for the internationalization variables that are unset or null.
81959 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
81960 variables used to determine the values of locale categories.)

81961 *LC_ALL* If set to a non-empty string value, override the values of all the other
81962 internationalization variables.

81963 *LC_COLLATE*
81964 Determine the locale for the behavior of ranges, equivalence classes, and multi-
81965 character collating elements used in the extended regular expression defined for
81966 the **yesexpr** locale keyword in the *LC_MESSAGES* category.

81967 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
81968 characters (for example, single-byte as opposed to multi-byte characters in
81969 arguments and input files) and the behavior of character classes used in the
81970 extended regular expression defined for the **yesexpr** locale keyword in the
81971 *LC_MESSAGES* category.

81972 *LC_MESSAGES*
81973 Determine the locale used to process affirmative responses, and the locale used to
81974 affect the format and contents of diagnostic messages and prompts written to
81975 standard error.

81976 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

81977 **ASYNCHRONOUS EVENTS**
81978 Default.

81979 **STDOUT**
81980 Not used.

81981 **STDERR**
81982 A prompt shall be written to standard error under the conditions specified in the DESCRIPTION
81983 section. The prompt shall contain the destination pathname, but its format is otherwise
81984 unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

81985 **OUTPUT FILES**
81986 The output files may be of any type.

81987 **EXTENDED DESCRIPTION**
81988 None.

81989 **EXIT STATUS**
81990 The following exit values shall be returned:

81991 0 All files were copied successfully.

81992 >0 An error occurred.

81993 **CONSEQUENCES OF ERRORS**
81994 If *cp* is prematurely terminated by a signal or error, files or file hierarchies may be only partially
81995 copied and files and directories may have incorrect permissions or access and modification
81996 times.

APPLICATION USAGE

The set-user-ID and set-group-ID bits are explicitly cleared when files are created. This is to prevent users from creating programs that are set-user-ID or set-group-ID to them when copying files or to make set-user-ID or set-group-ID files accessible to new groups of users. For example, if a file is set-user-ID and the copy has a different group ID than the source, a new group of users has execute permission to a set-user-ID program than did previously. In particular, this is a problem for superusers copying users' trees.

EXAMPLES

None.

RATIONALE

The **–i** option exists on BSD systems, giving applications and users a way to avoid accidentally removing files when copying. Although the 4.3 BSD version does not prompt if the standard input is not a terminal, the standard developers decided that use of **–i** is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds on standard input.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application using the **–i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The **–p** option is historical practice on BSD systems, duplicating the time of last data modification and time of last access. This volume of POSIX.1-200x extends it to preserve the user and group IDs, as well as the file permissions. This requirement has obvious problems in that the directories are almost certainly modified after being copied. This volume of POSIX.1-200x requires that the modification times be preserved. The statement that the order in which the characteristics are duplicated is unspecified is to permit implementations to provide the maximum amount of security for the user. Implementations should take into account the obvious security issues involved in setting the owner, group, and mode in the wrong order or creating files with an owner, group, or mode different from the final value.

It is unspecified whether *cp* writes diagnostic messages when the user and group IDs cannot be set due to the widespread practice of users using **–p** to duplicate some portion of the file characteristics, indifferent to the duplication of others. Historic implementations only write diagnostic messages on errors other than [EPERM].

Earlier versions of this standard included support for the **–r** option to copy file hierarchies. The **–r** option is historical practice on BSD and BSD-derived systems. This option is no longer specified by POSIX.1-200x but may be present in some implementations. The **–R** option was added as a close synonym to the **–r** option, selected for consistency with all other options in this volume of POSIX.1-200x that do recursive directory descent.

The difference between **–R** and the removed **–r** option is in the treatment by *cp* of file types other than regular and directory. It was implementation-defined how the – option treated special files to allow both historical implementations and those that chose to support **–r** with the same abilities as **–R** defined by this volume of POSIX.1-200x. The original **–r** flag, for historic reasons, did not handle special files any differently from regular files, but always read the file and copied its contents. This had obvious problems in the presence of special file types; for example, character devices, FIFOs, and sockets.

When a failure occurs during the copying of a file hierarchy, *cp* is required to attempt to copy files that are on the same level in the hierarchy or above the file where the failure occurred. It is unspecified if *cp* shall attempt to copy files below the file where the failure occurred (which

cannot succeed in any case).

Permissions, owners, and groups of created special file types have been deliberately left as implementation-defined. This is to allow systems to satisfy special requirements (for example, allowing users to create character special devices, but requiring them to be owned by a certain group). In general, it is strongly suggested that the permissions, owner, and group be the same as if the user had run the historical *mknod*, *ln*, or other utility to create the file. It is also probable that additional privileges are required to create block, character, or other implementation-defined special file types.

Additionally, the **–p** option explicitly requires that all set-user-ID and set-group-ID permissions be discarded if any of the owner or group IDs cannot be set. This is to keep users from unintentionally giving away special privilege when copying programs.

When creating regular files, historical versions of *cp* use the mode of the source file as modified by the file mode creation mask. Other choices would have been to use the mode of the source file unmodified by the creation mask or to use the same mode as would be given to a new file created by the user (plus the execution bits of the source file) and then modify it by the file mode creation mask. In the absence of any strong reason to change historic practice, it was in large part retained.

When creating directories, historical versions of *cp* use the mode of the source directory, plus read, write, and search bits for the owner, as modified by the file mode creation mask. This is done so that *cp* can copy trees where the user has read permission, but the owner does not. A side-effect is that if the file creation mask denies the owner permissions, *cp* fails. Also, once the copy is done, historical versions of *cp* set the permissions on the created directory to be the same as the source directory, unmodified by the file creation mask.

This behavior has been modified so that *cp* is always able to create the contents of the directory, regardless of the file creation mask. After the copy is done, the permissions are set to be the same as the source directory, as modified by the file creation mask. This latter change from historical behavior is to prevent users from accidentally creating directories with permissions beyond those they would normally set and for consistency with the behavior of *cp* in creating files.

It is not a requirement that *cp* detect attempts to copy a file to itself; however, implementations are strongly encouraged to do so. Historical implementations have detected the attempt in most cases.

There are two methods of copying subtrees in this volume of POSIX.1-200x. The other method is described as part of the *pax* utility (see *pax*). Both methods are historical practice. The *cp* utility provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy, while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

The wording allowing *cp* to copy a directory to implementation-defined file types not specified by the System Interfaces volume of POSIX.1-200x is provided so that implementations supporting symbolic links are not required to prohibit copying directories to symbolic links. Other extensions to the System Interfaces volume of POSIX.1-200x file types may need to use this loophole as well.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The –**r** option is marked obsolescent.

The new options –**H**, –**L**, and –**P** are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 #194 is applied, adding a description of the –**P** option.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/18 is applied, correcting an error in the SEE ALSO section.

Issue 7

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

Austin Group Interpretations 1003.1-2001 #092, #164, #165, and #168 are applied.

SD5-XCU-ERN-31 and SD5-XCU-ERN-42 are applied, updating the DESCRIPTION.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-102 is applied, clarifying the –**i** option within the OPTIONS section.

The obsolescent –**r** option is removed.

The –**P** option is added to the SYNOPSIS and to the DESCRIPTION with respect to the –**R** option.

NAME

crontab — schedule periodic background work

SYNOPSIS

```
crontab [file]
UP  crontab [-e|-l|-r]
```

DESCRIPTION

UP The *crontab* utility shall create, replace, or edit a user's crontab entry; a crontab entry is a list of commands and the times at which they shall be executed. The new crontab entry can be input by UP specifying *file* or input from standard input if no *file* operand is specified, or by using an editor, if **–e** is specified.

Upon execution of a command from a crontab entry, the implementation shall supply a default environment, defining at least the following environment variables:

HOME A pathname of the user's home directory.

LOGNAME The user's login name.

PATH A string representing a search path guaranteed to find all of the standard utilities.

SHELL A pathname of the command interpreter. When *crontab* is invoked as specified by this volume of POSIX.1-200x, the value shall be a pathname for *sh*.

The values of these variables when *crontab* is invoked as specified by this volume of POSIX.1-200x shall not affect the default values provided when the scheduled command is run.

If standard output and standard error are not redirected by commands executed from the crontab entry, any generated output or errors shall be mailed, via an implementation-defined method, to the user.

XSI Users shall be permitted to use *crontab* if their names appear in the file **cron.allow** which is located in an implementation-defined directory. If that file does not exist, the file **cron.deny**, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to *crontab*. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only **cron.deny** exists and is empty, global usage shall be permitted. The **cron.allow** and **cron.deny** files shall consist of one user name per line.

OPTIONS

The *crontab* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

UP **–e** Edit a copy of the invoking user's crontab entry, or create an empty entry to edit if the crontab entry does not exist. When editing is complete, the entry shall be installed as the user's crontab entry.

–l (The letter ell.) List the invoking user's crontab entry.

–r Remove the invoking user's crontab entry.

OPERANDS

The following operand shall be supported:

file The pathname of a file that contains specifications, in the format defined in the INPUT FILES section, for crontab entries.

82154 **STDIN**

82155 See the INPUT FILES section.

82156 **INPUT FILES**

82157 In the POSIX locale, the user or application shall ensure that a crontab entry is a text file
82158 consisting of lines of six fields each. The fields shall be separated by <blank> characters. The
82159 first five fields shall be integer patterns that specify the following:

82160 1. Minute [0,59]
82161 2. Hour [0,23]
82162 3. Day of the month [1,31]
82163 4. Month of the year [1,12]
82164 5. Day of the week ([0,6] with 0=Sunday)

82165 Each of these patterns can be either an <asterisk> (meaning all valid values), an element, or a list
82166 of elements separated by <comma> characters. An element shall be either a number or two
82167 numbers separated by a <hyphen> (meaning an inclusive range). The specification of days can
82168 be made by two fields (day of the month and day of the week). If month, day of month, and day
82169 of week are all <asterisk> characters, every day shall be matched. If either the month or day of
82170 month is specified as an element or list, but the day of week is an <asterisk>, the month and day
82171 of month fields shall specify the days that match. If both month and day of month are specified
82172 as an <asterisk>, but day of week is an element or list, then only the specified days of the week
82173 match. Finally, if either the month or day of month is specified as an element or list, and the day
82174 of week is also specified as an element or list, then any day matching either the month and day
82175 of month, or the day of week, shall be matched.

82176 The sixth field of a line in a crontab entry is a string that shall be executed by *sh* at the specified
82177 times. A <percent-sign> character in this field shall be translated to a <newline>. Any character
82178 preceded by a <backslash> (including the `'%'`) shall cause that character to be treated literally.
82179 Only the first line (up to a `'%'` or end-of-line) of the command field shall be executed by the
82180 command interpreter. The other lines shall be made available to the command as standard input.

82181 Blank lines and those whose first non-<blank> is `'#'` shall be ignored.

82182 XSI The text files **cron.allow** and **cron.deny**, which are located in an implementation-defined
82183 directory, shall contain zero or more user names, one per line, of users who are, respectively,
82184 authorized or denied access to the service underlying the *crontab* utility.

82185 **ENVIRONMENT VARIABLES**

82186 The following environment variables shall affect the execution of *crontab*:

82187 *EDITOR* Determine the editor to be invoked when the **–e** option is specified. The default
82188 editor shall be *vi*.

82189 *LANG* Provide a default value for the internationalization variables that are unset or null.
82190 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
82191 variables used to determine the values of locale categories.)

82192 *LC_ALL* If set to a non-empty string value, override the values of all the other
82193 internationalization variables.

82194 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
82195 characters (for example, single-byte as opposed to multi-byte characters in
82196 arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the **–l** option is specified, the crontab entry shall be written to the standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

UP The user's crontab entry is not submitted, removed, edited, or listed.

APPLICATION USAGE

The format of the crontab entry shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.

The default settings of the *HOME*, *LOGNAME*, *PATH*, and *SHELL* variables that are given to the scheduled job are not affected by the settings of those variables when *crontab* is run; as stated, they are defaults. The text about "invoked as specified by this volume of POSIX.1-200x" means that the implementation may provide extensions that allow these variables to be affected at runtime, but that the user has to take explicit action in order to access the extension, such as give a new option flag or modify the format of the crontab entry.

A typical user error is to type only *crontab*; this causes the system to wait for the new crontab entry on standard input. If end-of-file is typed (generally <control>-D), the crontab entry is replaced by an empty file. In this case, the user should type the interrupt character, which prevents the crontab entry from being replaced.

EXAMPLES

1. Clean up **core** files every weekday morning at 3:15 am:

```
15 3 * * 1-5 find "$HOME" –name core –exec rm –f {} + 2>/dev/null
```

2. Mail a birthday greeting:

```
0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.
```

3. As an example of specifying the two types of days:

```
0 0 1,15 * 1
```

would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to '*'; for example:

```
0 0 * * 1
```

would run a command only on Mondays.

RATIONALE

All references to a *cron* daemon and to *cron files* have been omitted. Although historical implementations have used this arrangement, there is no reason to limit future implementations.

This description of *crontab* is designed to support only users with normal privileges. The format of the input is based on the System V *crontab*; however, there is no requirement here that the actual system database used by the *cron* daemon (or a similar mechanism) use this format internally. For example, systems derived from BSD are likely to have an additional field appended that indicates the user identity to be used when the job is submitted.

The **–e** option was adopted from the SVID as a user convenience, although it does not exist in all historical implementations.

FUTURE DIRECTIONS

None.

SEE ALSO

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

The *crontab* utility (except for the **–e** option) is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the *crontab* utility.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The first example is changed to remove the unreliable use of *find* | *xargs*.

NAME

csplit — split files based on context

SYNOPSIS

```
csplit [–ks] [–f prefix] [–n number] file arg...
```

DESCRIPTION

The *csplit* utility shall read the file named by the *file* operand, write all or part of that file into other files as directed by the *arg* operands, and write the sizes of the files.

OPTIONS

The *csplit* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–f *prefix* Name the created files *prefix***00**, *prefix***01**, ..., *prefix**n*. The default is **xx00** ... **xx***n*. If the *prefix* argument would create a filename exceeding {NAME_MAX} bytes, an error shall result, *csplit* shall exit with a diagnostic message, and no files shall be created.

–k Leave previously created files intact. By default, *csplit* shall remove created files if an error occurs.

–n *number* Use *number* decimal digits to form filenames for the file pieces. The default shall be 2.

–s Suppress the output of file size messages.

OPERANDS

The following operands shall be supported:

file The pathname of a text file to be split. If *file* is `'–'`, the standard input shall be used.

Each *arg* operand can be one of the following:

/rexp/[*offset*]

A file shall be created using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with *offset*, if any, applied. The regular expression *rexp* shall follow the rules for basic regular expressions described in XBD Section 9.3 (on page 183). The application shall use the sequence `"\/"` to specify a <slash> character within the *rexp*. The optional offset shall be a positive or negative integer value representing a number of lines. A positive integer value can be preceded by `'+'`. If the selection of lines from an *offset* expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line shall be set to the line that results from the evaluation of the regular expression with any offset applied. If the current line is the first line in the file and a regular expression operation has not yet been performed, the pattern match of *rexp* shall be applied from the current line to the end of the file. Otherwise, the pattern match of *rexp* shall be applied from the line following the current line to the end of the file.

%rexp%[*offset*]

Equivalent to */rexp/*[*offset*], except that no file shall be created for the selected section of the input file. The application shall use the sequence `"\%"` to specify a <percent-sign> character within the *rexp*.

line_no Create a file from the current line up to (but not including) the line number *line_no*. Lines in the file shall be numbered starting at one. The current line becomes *line_no*.

{*num*} Repeat operand. This operand can follow any of the operands described previously. If it follows a *rexp* type operand, that operand shall be applied *num* more times. If it follows a *line_no* operand, the file shall be split every *line_no* lines, *num* times, from that point.

An error shall be reported if an operand does not reference a line between the current position and the end of the file.

STDIN

See the INPUT FILES section.

INPUT FILES

The input file shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *csplit*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

If the **–k** option is specified, created files shall be retained. Otherwise, the default action occurs.

STDOUT

Unless the **–s** option is used, the standard output shall consist of one line per file created, with a format as follows:

```
"%d\n", <file size in bytes>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files shall contain portions of the original input file; otherwise, unchanged.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

By default, created files shall be removed if an error occurs. When the **–k** option is specified, created files shall not be removed if an error occurs.

APPLICATION USAGE

None.

EXAMPLES

1. This example creates four files, **cobol00** . . . **cobol03**:

   ```
   csplit –f cobol file '/procedure division/' /par5./ /par16./
   ```

   After editing the split files, they can be recombined as follows:

   ```
   cat cobol0[0–3] > file
   ```

   Note that this example overwrites the original file.

2. This example would split the file after the first 99 lines, and every 100 lines thereafter, up to 9 999 lines; this is because lines in the file are numbered from 1 rather than zero, for historical reasons:

   ```
   csplit –k file  100  {99}
   ```

3. Assuming that **prog.c** follows the C-language coding convention of ending routines with a '}' at the beginning of the line, this example creates a file containing each separate C routine (up to 21) in **prog.c**:

   ```
   csplit –k prog.c '%main(%'  '/^}/+1' {20}
   ```

RATIONALE

The **–n** option was added to extend the range of filenames that could be handled.

Consideration was given to adding a **–a** flag to use the alphabetic filename generation used by the historical *split* utility, but the functionality added by the **–n** option was deemed to make alphabetic naming unnecessary.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The description of regular expression operands is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

The *csplit* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The SYNOPSIS and OPERANDS sections are revised to use a single *arg* to split a file into two pieces.

NAME

ctags — create a tags file (**DEVELOPMENT**, **FORTRAN**)

SYNOPSIS

SD

```
ctags [–a] [–f tagsfile] pathname...
ctags –x pathname...
```

DESCRIPTION

The *ctags* utility shall be provided on systems that support the the Software Development Utilities option, and either or both of the C-Language Development Utilities option and FORTRAN Development Utilities option. On other systems, it is optional.

The *ctags* utility shall write a *tagsfile* or an index of objects from C-language or FORTRAN source files specified by the *pathname* operands. The *tagsfile* shall list the locators of language-specific objects within the source files. A locator consists of a name, pathname, and either a search pattern or a line number that can be used in searching for the object definition. The objects that shall be recognized are specified in the EXTENDED DESCRIPTION section.

OPTIONS

The *ctags* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–a Append to *tagsfile*.

–f *tagsfile* Write the object locator lists into *tagsfile* instead of the default file named **tags** in the current directory.

–x Produce a list of object names, the line number, and filename in which each is defined, as well as the text of that line, and write this to the standard output. A *tagsfile* shall not be created when **–x** is specified.

OPERANDS

The following *pathname* operands are supported:

*file***.c** Files with basenames ending with the **.c** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.

*file***.h** Files with basenames ending with the **.h** suffix shall be treated as C-language source code. Such files that are not valid input to *c99* produce unspecified results.

*file***.f** Files with basenames ending with the **.f** suffix shall be treated as FORTRAN-language source code. Such files that are not valid input to *fort77* produce unspecified results.

The handling of other files is implementation-defined.

STDIN

See the INPUT FILES section.

INPUT FILES

The input files shall be text files containing source code in the language indicated by the operand filename suffixes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ctags*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the order in which output is sorted for the **–x** option. The POSIX locale determines the order in which the *tagsfile* is written.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). When processing C-language source code, if the locale is not compatible with the C locale described by the ISO C standard, the results are unspecified.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The list of object name information produced by the **–x** option shall be written to standard output in the following format:

```
"%s %d %s %s", <object-name>, <line-number>, <filename>, <text>
```

where <*text*> is the text of line <*line-number*> of file <*filename*>.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

When the **–x** option is not specified, the format of the output file shall be:

```
"%s\t%s\t/%s/\n", <identifier>, <filename>, <pattern>
```

where <*pattern*> is a search pattern that could be used by an editor to find the defining instance of <*identifier*> in <*filename*> (where *defining instance* is indicated by the declarations listed in the EXTENDED DESCRIPTION).

An optional <circumflex> (`'^'`) can be added as a prefix to <*pattern*>, and an optional <dollar-sign> can be appended to <*pattern*> to indicate that the pattern is anchored to the beginning (end) of a line of text. Any <slash> or <backslash> characters in <*pattern*> shall be preceded by a <backslash> character. The anchoring <circumflex>, <dollar-sign>, and escaping <backslash> characters shall not be considered part of the search pattern. All other characters in the search pattern shall be considered literal characters.

An alternative format is:

`"%s\t%s\t?%s?\n", <identifier>, <filename>, <pattern>`

which is identical to the first format except that <slash> characters in <*pattern*> shall not be preceded by escaping <backslash> characters, and <question-mark> characters in <*pattern*> shall be preceded by <backslash> characters.

A second alternative format is:

`"%s\t%s\t%d\n", <identifier>, <filename>, <lineno>`

where <*lineno*> is a decimal line number that could be used by an editor to find <*identifier*> in <*filename*>.

Neither alternative format shall be produced by *ctags* when it is used as described by POSIX.1-200x, but the standard utilities that process tags files shall be able to process those formats as well as the first format.

In any of these formats, the file shall be sorted by identifier, based on the collation sequence in the POSIX locale.

EXTENDED DESCRIPTION

If the operand identifies C-language source, the *ctags* utility shall attempt to produce an output line for each of the following objects:

- Function definitions
- Type definitions
- Macros with arguments

It may also produce output for any of the following objects:

- Function prototypes
- Structures
- Unions
- Global variable definitions
- Enumeration types
- Macros without arguments
- **#define** statements
- **#line** statements

Any **#if** and **#ifdef** statements shall produce no output. The tag **main** is treated specially in C programs. The tag formed shall be created by prefixing **M** to the name of the file, with the trailing **.c**, and leading pathname components (if any) removed.

On systems that do not support the C-Language Development Utilities option, *ctags* produces unspecified results for C-language source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

If the operand identifies FORTRAN source, the *ctags* utility shall produce an output line for each function definition. It may also produce output for any of the following objects:

- Subroutine definitions

- COMMON statements
- PARAMETER statements
- DATA and BLOCK DATA statements
- Statement numbers

On systems that do not support the FORTRAN Development Utilities option, *ctags* produces unspecified results for FORTRAN source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

It is implementation-defined what other objects (including duplicate identifiers) produce output.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The output with **–x** is meant to be a simple index that can be written out as an off-line readable function index. If the input files to *ctags* (such as **.c** files) were not created using the same locale as that in effect when *ctags* **–x** is run, results might not be as expected.

The description of C-language processing says "attempts to" because the C language can be greatly confused, especially through the use of **#define**s, and this utility would be of no use if the real C preprocessor were run to identify them. The output from *ctags* may be fooled and incorrect for various constructs.

EXAMPLES

None.

RATIONALE

The option list was significantly reduced from that provided by historical implementations. The **–F** option was omitted as redundant, since it is the default. The **–B** option was omitted as being of very limited usefulness. The **–t** option was omitted since the recognition of **typedef**s is now required for C source files. The **–u** option was omitted because the update function was judged to be not only inefficient, but also rarely needed.

An early proposal included a **–w** option to suppress warning diagnostics. Since the types of such diagnostics could not be described, the option was omitted as being not useful.

The text for *LC_CTYPE* about compatibility with the C locale acknowledges that the ISO C standard imposes requirements on the locale used to process C source. This could easily be a superset of that known as "the C locale" by way of implementation extensions, or one of a few alternative locales for systems supporting different codesets. No statement is made for FORTRAN because the ANSI X3.9-1978 standard (FORTRAN 77) does not (yet) define a similar locale concept. However, a general rule in this volume of POSIX.1-200x is that any time that locales do not match (preparing a file for one locale and processing it in another), the results are suspect.

The collation sequence of the tags file is not affected by *LC_COLLATE* because it is typically not used by human readers, but only by programs such as *vi* to locate the tag within the source files. Using the POSIX locale eliminates some of the problems of coordinating locales between the *ctags* file creator and the *vi* file reader.

Historically, the tags file has been used only by *ex* and *vi*. However, the format of the tags file has been published to encourage other programs to use the tags in new ways. The format allows either patterns or line numbers to find the identifiers because the historical *vi* recognizes either. The *ctags* utility does not produce the format using line numbers because it is not useful following any source file changes that add or delete lines. The documented search patterns match historical practice. It should be noted that literal leading <circumflex> or trailing <dollar-sign> characters in the search pattern will only behave correctly if anchored to the beginning of the line or end of the line by an additional <circumflex> or <dollar-sign> character.

Historical implementations also understand the objects used by the languages Pascal and sometimes LISP, and they understand the C source output by *lex* and *yacc*. The *ctags* utility is not required to accommodate these languages, although implementors are encouraged to do so.

The following historical option was not specified, as *vgrind* is not included in this volume of POSIX.1-200x:

–v If the **–v** flag is given, an index of the form expected by *vgrind* is produced on the standard output. This listing contains the function name, filename, and page number (assuming 64-line pages). Since the output is sorted into lexicographic order, it may be desired to run the output through *sort* **–f**. Sample use:

```
ctags –v files | sort –f > index vgrind –x index
```

The special treatment of the tag **main** makes the use of *ctags* practical in directories with more than one program.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The OUTPUT FILES section is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE PASC Interpretation 1003.2 #168 is applied, changing "create" to "write" in the DESCRIPTION.

Issue 7

The *ctags* utility is no longer dependent on support for the User Portability Utilities option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

cut — cut out selected fields of each line of a file

SYNOPSIS

```
cut –b list [–n] [file...]
cut –c list [file...]
cut –f list [–d delim] [–s] [file...]
```

DESCRIPTION

The *cut* utility shall cut out bytes (**–b** option), characters (**–c** option), or character-delimited fields (**–f** option) from each line in one or more files, concatenate them, and write them to standard output.

OPTIONS

The *cut* utility shall conform to XBD Section 12.2 (on page 215).

The application shall ensure that the option-argument *list* (see options **–b**, **–c**, and **–f** below) is a <comma>-separated list or <blank>-separated list of positive numbers and ranges. Ranges can be in three forms. The first is two positive numbers separated by a <hyphen> (*low–high*), which represents all fields from the first number to the second number. The second is a positive number preceded by a <hyphen> (*–high*), which represents all fields from field number 1 to that number. The third is a positive number followed by a <hyphen> (*low–*), which represents that number to the last field, inclusive. The elements in *list* can be repeated, can overlap, and can be specified in any order, but the bytes, characters, or fields selected shall be written in the order of the input data. If an element appears in the selection list more than once, it shall be written exactly once.

The following options shall be supported:

–b *list* Cut based on a *list* of bytes. Each selected byte shall be output unless the **–n** option is also specified. It shall not be an error to select bytes not present in the input line.

–c *list* Cut based on a *list* of characters. Each selected character shall be output. It shall not be an error to select characters not present in the input line.

–d *delim* Set the field delimiter to the character *delim*. The default is the <tab>.

–f *list* Cut based on a *list* of fields, assumed to be separated in the file by a delimiter character (see **–d**). Each selected field shall be output. Output fields shall be separated by a single occurrence of the field delimiter character. Lines with no field delimiters shall be passed through intact, unless **–s** is specified. It shall not be an error to select fields not present in the input line.

–n Do not split characters. When specified with the **–b** option, each element in *list* of the form *low–high* (<hyphen>-separated numbers) shall be modified as follows:

- If the byte selected by *low* is not the first byte of a character, *low* shall be decremented to select the first byte of the character originally selected by *low*. If the byte selected by *high* is not the last byte of a character, *high* shall be decremented to select the last byte of the character prior to the character originally selected by *high*, or zero if there is no prior character. If the resulting range element has *high* equal to zero or *low* greater than *high*, the list element shall be dropped from *list* for that input line without causing an error.

Each element in *list* of the form *low–* shall be treated as above with *high* set to the number of bytes in the current line, not including the terminating <newline>. Each

element in *list* of the form *–high* shall be treated as above with *low* set to 1. Each element in *list* of the form *num* (a single number) shall be treated as above with *low* set to *num* and *high* set to *num*.

–s Suppress lines with no delimiter characters, when used with the **–f** option. Unless specified, lines with no delimiters shall be passed through untouched.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, or if a *file* operand is `'–'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cut*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *cut* utility output shall be a concatenation of the selected bytes, characters, or fields (one of the following):

```
"%s\n", <concatenation of bytes>
"%s\n", <concatenation of characters>
"%s\n", <concatenation of fields and field delimiters>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *cut* and *fold* utilities can be used to create text files out of files with arbitrary line lengths. The *cut* utility should be used when the number of lines (or records) needs to remain constant. The *fold* utility should be used when the contents of long lines need to be kept contiguous.

Earlier versions of the *cut* utility worked in an environment where bytes and characters were considered equivalent (modulo <backspace> and <tab> processing in some implementations). In the extended world of multi-byte characters, the new **–b** option has been added. The **–n** option (used with **–b**) allows it to be used to act on bytes rounded to character boundaries. The algorithm specified for **–n** guarantees that:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

ends up with all the characters in **file** appearing exactly once in **file1** or **file2**. (There is, however, a <newline> in both **file1** and **file2** for each <newline> in **file**.)

EXAMPLES

Examples of the option qualifier list:

1,4,7 Select the first, fourth, and seventh bytes, characters, or fields and field delimiters.

1–3,8 Equivalent to 1,2,3,8.

–5,10 Equivalent to 1,2,3,4,5,10.

3– Equivalent to third to last, inclusive.

The *low–high* forms are not always equivalent when used with **–b** and **–n** and multi-byte characters; see the description of **–n**.

The following command:

```
cut –d : –f 1,6 /etc/passwd
```

reads the System V password file (user database) and produces lines of the form:

```
<user ID>:<home directory>
```

Most utilities in this volume of POSIX.1-200x work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if **file** contains long lines:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline>) and **file2** that contains the remainder of the data from **file**. (Note that **file2** is not a text file if there are lines in

file that are longer than 500 + {LINE_MAX} bytes.) The original file can be recreated from **file1** and **file2** using the command:

```
paste –d "\0" file1 file2 > file
```

RATIONALE

Some historical implementations do not count <backspace> characters in determining character counts with the **–c** option. This may be useful for using *cut* for processing *nroff* output. It was deliberately decided not to have the **–c** option treat either <backspace> or <tab> characters in any special fashion. The *fold* utility does treat these characters specially.

Unlike other utilities, some historical implementations of *cut* exit after not finding an input file, rather than continuing to process the remaining *file* operands. This behavior is prohibited by this volume of POSIX.1-200x, where only the exit status is affected by this problem.

The behavior of *cut* when provided with either mutually-exclusive options or options that do not work logically together has been deliberately left unspecified in favor of global wording in Section 1.4 (on page 2288).

The OPTIONS section was changed in response to IEEE PASC Interpretation 1003.2 #149. The change represents historical practice on all known systems. The original standard was ambiguous on the nature of the output.

The *list* option-arguments are historically used to select the portions of the line to be written, but do not affect the order of the data. For example:

```
echo abcdefghi | cut –c6,2,4–7,1
```

yields `"abdefg"`.

A proposal to enhance *cut* with the following option:

–o Preserve the selected field order. When this option is specified, each byte, character, or field (or ranges of such) shall be written in the order specified by the *list* option-argument, even if this requires multiple outputs of the same bytes, characters, or fields.

was rejected because this type of enhancement is outside the scope of the IEEE P1003.2b draft standard.

FUTURE DIRECTIONS

None.

NAME

cxref — generate a C-language program cross-reference table (**DEVELOPMENT**)

SYNOPSIS

XSI
```
cxref [–cs] [–o file] [–w num] [–D name[=def]]... [–I dir]...
    [–U name]... file...
```

DESCRIPTION

The *cxref* utility shall analyze a collection of C-language *file*s and attempt to build a cross-reference table. Information from **#define** lines shall be included in the symbol table. A sorted listing shall be written to standard output of all symbols (auto, static, and global) in each *file* separately, or with the **–c** option, in combination. Each symbol shall contain an <asterisk> before the declaring reference.

OPTIONS

The *cxref* utility shall conform to XBD Section 12.2 (on page 215), except that the order of the **–D**, **–I**, and **–U** options (which are identical to their interpretation by *c99*) is significant. The following options shall be supported:

–c Write a combined cross-reference of all input files.

–s Operate silently; do not print input filenames.

–o *file* Direct output to named *file*.

–w *num* Format output no wider than *num* (decimal) columns. This option defaults to 80 if *num* is not specified or is less than 51.

–D Equivalent to *c99*.

–I Equivalent to *c99*.

–U Equivalent to *c99*.

OPERANDS

The following operand shall be supported:

file A pathname of a C-language source file.

STDIN

Not used.

INPUT FILES

The input files are C-language source files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *cxref*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the ordering of the output.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be used for the cross-reference listing, unless the **−o** option is used to select a different output file.

The format of standard output is unspecified, except that the following information shall be included:

- If the **−c** option is not specified, each portion of the listing shall start with the name of the input file on a separate line.
- The name line shall be followed by a sorted list of symbols, each with its associated location pathname, the name of the function in which it appears (if it is not a function name itself), and line number references.
- Each line number may be preceded by an <asterisk> (`'*'`) flag, meaning that this is the declaring reference. Other single-character flags, with implementation-defined meanings, may be included.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output file named by the **−o** option shall be used instead of standard output.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

NAME

date — write the date and time

SYNOPSIS

```
date [–u] [+format]
```

XSI

```
date [–u] mmddhhmm[[cc]yy]
```

DESCRIPTION

XSI The *date* utility shall write the date and time to standard output or attempt to set the system date and time. By default, the current date and time shall be written. If an operand beginning with '+' is specified, the output format of *date* shall be controlled by the conversion specifications and other text in the operand.

OPTIONS

The *date* utility shall conform to XBD Section 12.2 (on page 215).

The following option shall be supported:

–u Perform operations as if the *TZ* environment variable was set to the string "UTC0", or its equivalent historical value of "GMT0". Otherwise, *date* shall use the timezone indicated by the *TZ* environment variable or the system default if that variable is unset or null.

OPERANDS

The following operands shall be supported:

+format When the format is specified, each conversion specifier shall be replaced in the standard output by its corresponding value. All other characters shall be copied to the output without change. The output shall always be terminated with a <newline>.

Conversion Specifications

%a	Locale's abbreviated weekday name.
%A	Locale's full weekday name.
%b	Locale's abbreviated month name.
%B	Locale's full month name.
%c	Locale's appropriate date and time representation.
%C	Century (a year divided by 100 and truncated to an integer) as a decimal number [00,99].
%d	Day of the month as a decimal number [01,31].
%D	Date in the format *mm/dd/yy*.
%e	Day of the month as a decimal number [1,31] in a two-digit field with leading <space> character fill.
%h	A synonym for %b.
%H	Hour (24-hour clock) as a decimal number [00,23].
%I	Hour (12-hour clock) as a decimal number [01,12].

82900 `%j` Day of the year as a decimal number [001,366].

82901 `%m` Month as a decimal number [01,12].

82902 `%M` Minute as a decimal number [00,59].

82903 `%n` A <newline>.

82904 `%p` Locale's equivalent of either AM or PM.

82905 `%r` 12-hour clock time [01,12] using the AM/PM notation; in the POSIX
82906 locale, this shall be equivalent to `%I:%M:%S %p`.

82907 `%S` Seconds as a decimal number [00,60].

82908 `%t` A <tab>.

82909 `%T` 24-hour clock time [00,23] in the format *HH*:*MM*:*SS*.

82910 `%u` Weekday as a decimal number [1,7] (1=Monday).

82911 `%U` Week of the year (Sunday as the first day of the week) as a decimal
82912 number [00,53]. All days in a new year preceding the first Sunday shall be
82913 considered to be in week 0.

82914 `%V` Week of the year (Monday as the first day of the week) as a decimal
82915 number [01,53]. If the week containing January 1 has four or more days in
82916 the new year, then it shall be considered week 1; otherwise, it shall be the
82917 last week of the previous year, and the next week shall be week 1.

82918 `%w` Weekday as a decimal number [0,6] (0=Sunday).

82919 `%W` Week of the year (Monday as the first day of the week) as a decimal
82920 number [00,53]. All days in a new year preceding the first Monday shall
82921 be considered to be in week 0.

82922 `%x` Locale's appropriate date representation.

82923 `%X` Locale's appropriate time representation.

82924 `%y` Year within century [00,99].

82925 `%Y` Year with century as a decimal number.

82926 `%Z` Timezone name, or no characters if no timezone is determinable.

82927 `%%` A <percent-sign> character.

82928 See XBD Section 7.3.5 (on page 158) for the conversion specifier values in the
82929 POSIX locale.

82930 **Modified Conversion Specifications**

82931 Some conversion specifiers can be modified by the `E` and `O` modifier characters to
82932 indicate a different format or specification as specified in the *LC_TIME* locale
82933 description (see XBD Section 7.3.5, on page 158). If the corresponding keyword
82934 (see **era**, **era_year**, **era_d_fmt**, and **alt_digits** in XBD Section 7.3.5, on page 158) is
82935 not specified or not supported for the current locale, the unmodified conversion
82936 specifier value shall be used.

82937 `%Ec` Locale's alternative appropriate date and time representation.

82938 %EC The name of the base year (period) in the locale's alternative
82939 representation.

82940 %Ex Locale's alternative date representation.

82941 %EX Locale's alternative time representation.

82942 %Ey Offset from %EC (year only) in the locale's alternative representation.

82943 %EY Full alternative year representation.

82944 %Od Day of month using the locale's alternative numeric symbols.

82945 %Oe Day of month using the locale's alternative numeric symbols.

82946 %OH Hour (24-hour clock) using the locale's alternative numeric symbols.

82947 %OI Hour (12-hour clock) using the locale's alternative numeric symbols.

82948 %Om Month using the locale's alternative numeric symbols.

82949 %OM Minutes using the locale's alternative numeric symbols.

82950 %OS Seconds using the locale's alternative numeric symbols.

82951 %Ou Weekday as a number in the locale's alternative representation (Monday
82952 = 1).

82953 %OU Week number of the year (Sunday as the first day of the week) using the
82954 locale's alternative numeric symbols.

82955 %OV Week number of the year (Monday as the first day of the week, rules
82956 corresponding to %V), using the locale's alternative numeric symbols.

82957 %Ow Weekday as a number in the locale's alternative representation (Sunday =
82958 0).

82959 %OW Week number of the year (Monday as the first day of the week) using the
82960 locale's alternative numeric symbols.

82961 %Oy Year (offset from %C) in alternative representation.

82962 XSI *mmddhhmm*[[*cc*]*yy*]

82963 Attempt to set the system date and time from the value given in the operand. This
82964 is only possible if the user has appropriate privileges and the system permits the
82965 setting of the system date and time. The first *mm* is the month (number); *dd* is the
82966 day (number); *hh* is the hour (number, 24-hour system); the second *mm* is the
82967 minute (number); *cc* is the century and is the first two digits of the year (this is
82968 optional); *yy* is the last two digits of the year and is optional. If century is not
82969 specified, then values in the range [69,99] shall refer to years 1969 to 1999 inclusive,
82970 and values in the range [00,68] shall refer to years 2000 to 2068 inclusive. The
82971 current year is the default if *yy* is omitted.

82972 **Note:** It is expected that in a future version of this standard the default century inferred
82973 from a 2-digit year will change. (This would apply to all commands accepting a
82974 2-digit year as input.)

82975 **STDIN**

82976 Not used.

82977 **INPUT FILES**

82978 None.

82979 **ENVIRONMENT VARIABLES**

82980 The following environment variables shall affect the execution of *date*:

82981 *LANG* Provide a default value for the internationalization variables that are unset or null.
82982 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
82983 variables used to determine the values of locale categories.)

82984 *LC_ALL* If set to a non-empty string value, override the values of all the other
82985 internationalization variables.

82986 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
82987 characters (for example, single-byte as opposed to multi-byte characters in
82988 arguments).

82989 *LC_MESSAGES*
82990 Determine the locale that should be used to affect the format and contents of
82991 diagnostic messages written to standard error.

82992 *LC_TIME* Determine the format and contents of date and time strings written by *date*.

82993 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

82994 *TZ* Determine the timezone in which the time and date are written, unless the **−u**
82995 option is specified. If the *TZ* variable is unset or null and **−u** is not specified, an
82996 unspecified system default timezone is used.

82997 **ASYNCHRONOUS EVENTS**

82998 Default.

82999 **STDOUT**

83000 When no formatting operand is specified, the output in the POSIX locale shall be equivalent to
83001 specifying:

83002 `date "+%a %b %e %H:%M:%S %Z %Y"`

83003 **STDERR**

83004 The standard error shall be used only for diagnostic messages.

83005 **OUTPUT FILES**

83006 None.

83007 **EXTENDED DESCRIPTION**

83008 None.

83009 **EXIT STATUS**

83010 The following exit values shall be returned:

83011 0 The date was written successfully.

83012 >0 An error occurred.

83013 **CONSEQUENCES OF ERRORS**

83014 Default.

APPLICATION USAGE

Conversion specifiers are of unspecified format when not in the POSIX locale. Some of them can contain <newline> characters in some locales, so it may be difficult to use the format shown in standard output for parsing the output of *date* in those locales.

The range of values for `%S` extends from 0 to 60 seconds to accommodate the occasional leap second.

Although certain of the conversion specifiers in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these fields may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The date string formatting capabilities are intended for use in Gregorian-style calendars, possibly with a different starting year (or years). The `%x` and `%c` conversion specifications, however, are intended for local representation; these may be based on a different, non-Gregorian calendar.

The `%C` conversion specification was introduced to allow a fallback for the `%EC` (alternative year format base year); it can be viewed as the base of the current subdivision in the Gregorian calendar. The century number is calculated as the year divided by 100 and truncated to an integer; it should not be confused with the use of ordinal numbers for centuries (for example, "twenty-first century".) Both the `%Ey` and `%y` can then be viewed as the offset from `%EC` and `%C`, respectively.

The `E` and `O` modifiers modify the traditional conversion specifiers, so that they can always be used, even if the implementation (or the current locale) does not support the modifier.

The `E` modifier supports alternative date formats, such as the Japanese Emperor's Era, as long as these are based on the Gregorian calendar system. Extending the `E` modifiers to other date elements may provide an implementation-defined extension capable of supporting other calendar systems, especially in combination with the `O` modifier.

The `O` modifier supports time and date formats using the locale's alternative numerical symbols, such as Kanji or Hindi digits or ordinal number representation.

Non-European locales, whether they use Latin digits in computational items or not, often have local forms of the digits for use in date formats. This is not totally unknown even in Europe; a variant of dates uses Roman numerals for the months: the third day of September 1991 would be written as 3.IX.1991. In Japan, Kanji digits are regularly used for dates; in Arabic-speaking countries, Hindi digits are used. The `%d`, `%e`, `%H`, `%I`, `%m`, `%S`, `%U`, `%w`, `%W`, and `%y` conversion specifications always return the date and time field in Latin digits (that is, 0 to 9). The `%O` modifier was introduced to support the use for display purposes of non-Latin digits. In the *LC_TIME* category in *localedef*, the optional **alt_digits** keyword is intended for this purpose. As an example, assume the following (partial) *localedef* source:

```
alt_digits  "";"I";"II";"III";"IV";"V";"VI";"VII";"VIII" \
            "IX";"X";"XI";"XII"
d_fmt       "%e.%Om.%Y"
```

With the above date, the command:

```
date "+%x"
```

would yield 3.IX.1991. With the same **d_fmt**, but without the **alt_digits**, the command would yield 3.9.1991.

EXAMPLES

1. The following are input/output examples of *date* used at arbitrary times in the POSIX locale:

```
$ date
Tue Jun 26 09:58:10 PDT 1990

$ date "+DATE: %m/%d/%y%nTIME: %H:%M:%S"
DATE: 11/02/91
TIME: 13:36:16

$ date "+TIME: %r"
TIME: 01:36:32 PM
```

2. Examples for Denmark, where the default date and time format is %a %d %b %Y %T %Z:

```
$ LANG=da_DK.iso_8859-1 date
ons 02 okt 1991 15:03:32 CET

$ LANG=da_DK.iso_8859-1 \
    date "+DATO: %A den %e. %B %Y%nKLOKKEN: %H:%M:%S"
DATO: onsdag den 2. oktober 1991
KLOKKEN: 15:03:56
```

3. Examples for Germany, where the default date and time format is %a %d.%h.%Y, %T %Z:

```
$ LANG=De_DE.88591 date
Mi 02.Okt.1991, 15:01:21 MEZ

$ LANG=De_DE.88591 date "+DATUM: %A, %d. %B %Y%nZEIT: %H:%M:%S"
DATUM: Mittwoch, 02. Oktober 1991
ZEIT: 15:02:02
```

4. Examples for France, where the default date and time format is %a %d %h %Y %Z %T:

```
$ LANG=Fr_FR.88591 date
Mer 02 oct 1991 MET 15:03:32

$ LANG=Fr_FR.88591 date "+JOUR: %A %d %B %Y%nHEURE: %H:%M:%S"
JOUR: Mercredi 02 octobre 1991
HEURE: 15:03:56
```

RATIONALE

Some of the new options for formatting are from the ISO C standard. The **-u** option was introduced to allow portable access to Coordinated Universal Time (UTC). The string "GMT0" is allowed as an equivalent *TZ* value to be compatible with all of the systems using the BSD implementation, where this option originated.

The %e format conversion specification (adopted from System V) was added because the ISO C standard conversion specifications did not provide any way to produce the historical default *date* output during the first nine days of any month.

There are two varieties of day and week numbering supported (in addition to any others created with the locale-dependent %E and %O modifier characters):

- The historical variety in which Sunday is the first day of the week and the weekdays preceding the first Sunday of the year are considered week 0. These are represented by %w and %U. A variant of this is %W, using Monday as the first day of the week, but still referring to week 0. This view of the calendar was retained because so many historical

applications depend on it and the ISO C standard *strftime*( ) function, on which many *date* implementations are based, was defined in this way.

- The international standard, based on the ISO 8601: 2004 standard where Monday is the first weekday and the algorithm for the first week number is more complex: If the week (Monday to Sunday) containing January 1 has four or more days in the new year, then it is week 1; otherwise, it is week 53 of the previous year, and the next week is week 1. These are represented by the new conversion specifications %u and %V, added as a result of international comments.

FUTURE DIRECTIONS

None.

XSH *fprintf*( ), *strftime*( )

CHANGE HISTORY

First released in Issue 2.

Issue 5

Changes are made for Year 2000 alignment.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The %EX modified conversion specification is added.

The Open Group Corrigendum U048/2 is applied, correcting the examples.

The DESCRIPTION is updated to refer to conversion specifications, instead of field descriptors for consistency with the *LC_TIME* category.

A clarification is made such that the current year is the default if the *yy* argument is omitted when setting the system date and time.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/19 is applied, correcting the CHANGE HISTORY section.

NAME

dd — convert and copy a file

SYNOPSIS

```
dd [operand...]
```

DESCRIPTION

The *dd* utility shall copy the specified input file to the specified output file with possible conversions using specific input and output block sizes. It shall read the input one block at a time, using the specified input block size; it shall then process the block of data actually returned, which could be smaller than the requested block size. It shall apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size. If the **bs**=*expr* operand is specified and no conversions other than **sync**, **noerror**, or **notrunc** are requested, the data returned from each input block shall be written as a separate output block; if the read returns less than a full block and the **sync** conversion is not specified, the resulting output block shall be the same size as the input block. If the **bs**=*expr* operand is not specified, or a conversion other than **sync**, **noerror**, or **notrunc** is requested, the input shall be processed and collected into full-sized output blocks until the end of the input is reached.

The processing order shall be as follows:

1. An input block is read.
2. If the input block is shorter than the specified input block size and the **sync** conversion is specified, null bytes shall be appended to the input data up to the specified size. (If either **block** or **unblock** is also specified, <space> characters shall be appended instead of null bytes.) The remaining conversions and output shall include the pad characters as if they had been read from the input.
3. If the **bs**=*expr* operand is specified and no conversion other than **sync** or **noerror** is requested, the resulting data shall be written to the output as a single block, and the remaining steps are omitted.
4. If the **swab** conversion is specified, each pair of input data bytes shall be swapped. If there is an odd number of bytes in the input block, the last byte in the input record shall not be swapped.
5. Any remaining conversions (**block**, **unblock**, **lcase**, and **ucase**) shall be performed. These conversions shall operate on the input data independently of the input blocking; an input or output fixed-length record may span block boundaries.
6. The data resulting from input or conversion or both shall be aggregated into output blocks of the specified size. After the end of input is reached, any remaining output shall be written as a block without padding if **conv**=**sync** is not specified; thus, the final output block may be shorter than the output block size.

OPTIONS

None.

OPERANDS

All of the operands shall be processed before any input is read. The following operands shall be supported:

if=*file* Specify the input pathname; the default is standard input.

of=*file* Specify the output pathname; the default is standard output. If the **seek**=*expr* conversion is not also specified, the output file shall be truncated before the copy begins if an explicit **of**=*file* operand is specified, unless **conv**=**notrunc** is specified.

If **seek**=*expr* is specified, but **conv**=**notrunc** is not, the effect of the copy shall be to preserve the blocks in the output file over which *dd* seeks, but no other portion of the output file shall be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file shall be shortened by the copy. If the input file is empty and either the size of the seek is greater than the previous size of the output file or the output file did not previously exist, the size of the output file shall be set to the file offset after the seek.)

ibs=*expr* Specify the input block size, in bytes, by *expr* (default is 512).

obs=*expr* Specify the output block size, in bytes, by *expr* (default is 512).

bs=*expr* Set both input and output block sizes to *expr* bytes, superseding **ibs**= and **obs**=. If no conversion other than **sync**, **noerror**, and **notrunc** is specified, each input block shall be copied to the output as a single block without aggregating short blocks.

cbs=*expr* Specify the conversion block size for **block** and **unblock** in bytes by *expr* (default is zero). If **cbs**= is omitted or given a value of zero, using **block** or **unblock** produces unspecified results.

XSI The application shall ensure that this operand is also specified if the **conv**= operand is specified with a value of **ascii**, **ebcdic**, or **ibm**. For a **conv**= operand with an **ascii** value, the input is handled as described for the **unblock** value, except that characters are converted to ASCII before any trailing <space> characters are deleted. For **conv**= operands with **ebcdic** or **ibm** values, the input is handled as described for the **block** value except that the characters are converted to EBCDIC or IBM EBCDIC, respectively, after any trailing <space> characters are added.

skip=*n* Skip *n* input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation shall read the blocks or seek past them; on non-seekable files, the blocks shall be read and the data shall be discarded.

seek=*n* Skip *n* blocks (using the specified output block size) from the beginning of the output file before copying. On non-seekable files, existing blocks shall be read and space from the current end-of-file to the specified offset, if any, filled with null bytes; on seekable files, the implementation shall seek to the specified offset or read the blocks as described for non-seekable files.

count=*n* Copy only *n* input blocks.

conv=*value*[,*value* ...]

Where *value*s are <comma>-separated symbols from the following list:

XSI **ascii** Convert EBCDIC to ASCII; see Table 4-7 (on page 2585).

XSI **ebcdic** Convert ASCII to EBCDIC; see Table 4-7 (on page 2585).

XSI **ibm** Convert ASCII to a different EBCDIC set; see Table 4-8 (on page 2586).

XSI The **ascii**, **ebcdic**, and **ibm** values are mutually-exclusive.

block Treat the input as a sequence of <newline>-terminated or end-of-file-terminated variable-length records independent of the input block boundaries. Each record shall be converted to a record with a fixed length specified by the conversion block size. Any <newline> shall be removed from the input line; <space> characters shall be appended to lines that are shorter than their conversion block size to fill the

block. Lines that are longer than the conversion block size shall be truncated to the largest number of characters that fit into that size; the number of truncated lines shall be reported (see the STDERR section).

The **block** and **unblock** values are mutually-exclusive.

unblock Convert fixed-length records to variable length. Read a number of bytes equal to the conversion block size (or the number of bytes remaining in the input, if less than the conversion block size), delete all trailing <space> characters, and append a <newline>.

lcase Map uppercase characters specified by the *LC_CTYPE* keyword **tolower** to the corresponding lowercase character. Characters for which no mapping is specified shall not be modified by this conversion.

The **lcase** and **ucase** symbols are mutually-exclusive.

ucase Map lowercase characters specified by the *LC_CTYPE* keyword **toupper** to the corresponding uppercase character. Characters for which no mapping is specified shall not be modified by this conversion.

swab Swap every pair of input bytes.

noerror Do not stop processing on an input error. When an input error occurs, a diagnostic message shall be written on standard error, followed by the current input and output block counts in the same format as used at completion (see the STDERR section). If the **sync** conversion is specified, the missing input shall be replaced with null bytes and processed normally; otherwise, the input block shall be omitted from the output.

notrunc Do not truncate the output file. Preserve blocks in the output file not explicitly written by this invocation of the *dd* utility. (See also the preceding **of**=*file* operand.)

sync Pad every input block to the size of the **ibs**= buffer, appending null bytes. (If either **block** or **unblock** is also specified, append <space> characters, rather than null bytes.)

The behavior is unspecified if operands other than **conv**= are specified more than once.

For the **bs**=, **cbs**=, **ibs**=, and **obs**= operands, the application shall supply an expression specifying a size in bytes. The expression, *expr*, can be:

1. A positive decimal number
2. A positive decimal number followed by *k*, specifying multiplication by 1 024
3. A positive decimal number followed by *b*, specifying multiplication by 512
4. Two or more positive decimal numbers (with or without *k* or *b*) separated by *x*, specifying the product of the indicated values

All of the operands are processed before any input is read.

XSI The following two tables display the octal number character values used for the **ascii** and **ebcdic** conversions (first table) and for the **ibm** conversion (second table). In both tables, the ASCII

values are the row and column headers and the EBCDIC values are found at their intersections. For example, ASCII 0012 (LF) is the second row, third column, yielding 0045 in EBCDIC. The inverted tables (for EBCDIC to ASCII conversion) are not shown, but are in one-to-one correspondence with these tables. The differences between the two tables are highlighted by small boxes drawn around five entries.

83271 **STDIN**

83272 If no **if**= operand is specified, the standard input shall be used. See the INPUT FILES section.

83273 **INPUT FILES**

83274 The input file can be any file type.

83275 **ENVIRONMENT VARIABLES**

83276 The following environment variables shall affect the execution of *dd*:

83277 *LANG* Provide a default value for the internationalization variables that are unset or null.
83278 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
83279 variables used to determine the values of locale categories.)

83280 *LC_ALL* If set to a non-empty string value, override the values of all the other
83281 internationalization variables.

83282 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
83283 characters (for example, single-byte as opposed to multi-byte characters in
83284 arguments and input files), the classification of characters as uppercase or
83285 lowercase, and the mapping of characters from one case to the other.

83286 *LC_MESSAGES*
83287 Determine the locale that should be used to affect the format and contents of
83288 diagnostic messages written to standard error and informative messages written to
83289 standard output.

83290 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

83291 **ASYNCHRONOUS EVENTS**

83292 For SIGINT, the *dd* utility shall interrupt its current processing, write status information to
83293 standard error, and exit as though terminated by SIGINT. It shall take the standard action for all
83294 other signals; see the ASYNCHRONOUS EVENTS section in Section 1.4 (on page 2288).

83295 **STDOUT**

83296 If no **of**= operand is specified, the standard output shall be used. The nature of the output
83297 depends on the operands selected.

83298 **STDERR**

83299 On completion, *dd* shall write the number of input and output blocks to standard error. In the
83300 POSIX locale the following formats shall be used:

83301 `"%u+%u records in\n", <number of whole input blocks>,`
83302 `    <number of partial input blocks>`

83303 `"%u+%u records out\n", <number of whole output blocks>,`
83304 `    <number of partial output blocks>`

83305 A partial input block is one for which *read*() returned less than the input block size. A partial
83306 output block is one that was written with fewer bytes than specified by the output block size.

83307 In addition, when there is at least one truncated block, the number of truncated blocks shall be
83308 written to standard error. In the POSIX locale, the format shall be:

83309 `"%u truncated %s\n", <number of truncated blocks>, "record" (if`
83310 `    <number of truncated blocks> is one) "records" (otherwise)`

83311 Diagnostic messages may also be written to standard error.

OUTPUT FILES

If the **of**= operand is used, the output shall be the same as described in the STDOUT section.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The input file was copied successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If an input error is detected and the **noerror** conversion has not been specified, any partial output block shall be written to the output file, a diagnostic message shall be written, and the copy operation shall be discontinued. If some other error is detected, a diagnostic message shall be written and the copy operation shall be discontinued.

APPLICATION USAGE

The input and output block size can be specified to take advantage of raw physical I/O.

There are many different versions of the EBCDIC codesets. The ASCII and EBCDIC conversions specified for the *dd* utility perform conversions for the version specified by the tables.

EXAMPLES

The following command:

```
dd if=/dev/rmt0h  of=/dev/rmt1h
```

copies from tape drive 0 to tape drive 1, using a common historical device naming convention.

The following command:

```
dd ibs=10  skip=1
```

strips the first 10 bytes from standard input.

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file **x**:

```
dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase
```

RATIONALE

The OPTIONS section is listed as "None" because there are no options recognized by historical *dd* utilities. Certainly, many of the operands could have been designed to use the Utility Syntax Guidelines, which would have resulted in the classic hyphenated option letters. In this version of this volume of POSIX.1-200x, *dd* retains its curious JCL-like syntax due to the large number of applications that depend on the historical implementation.

A suggested implementation technique for **conv**=**noerror**,**sync** is to zero (or <space>-fill, if **block**ing or **unblock**ing) the input buffer before each read and to write the contents of the input buffer to the output even after an error. In this manner, any data transferred to the input buffer before the error was detected is preserved. Another point is that a failed read on a regular file or a disk generally does not increment the file offset, and *dd* must then seek past the block on which the error occurred; otherwise, the input error occurs repetitively. When the input is a magnetic tape, however, the tape normally has passed the block containing the error when the error is reported, and thus no seek is necessary.

The default **ibs**= and **obs**= sizes are specified as 512 bytes because there are historical (largely portable) scripts that assume these values. If they were left unspecified, unusual results could

occur if an implementation chose an odd block size.

Historical implementations of *dd* used *creat*() when processing **of**=*file*. This makes the **seek**= operand unusable except on special files. The **conv**=**notrunc** feature was added because more recent BSD-based implementations use *open*() (without O_TRUNC) instead of *creat*(), but they fail to delete output file contents after the data copied.

The *w* multiplier (historically meaning *word*), is used in System V to mean 2 and in 4.2 BSD to mean 4. Since *word* is inherently non-portable, its use is not supported by this volume of POSIX.1-200x.

Standard EBCDIC does not have the characters '[' and ']'. The values used in the table are taken from a common print train that does contain them. Other than those characters, the print train values are not filled in, but appear to provide some of the motivation for the historical choice of translations reflected here.

The Standard EBCDIC table provides a 1:1 translation for all 256 bytes.

The IBM EBCDIC table does not provide such a translation. The marked cells in the tables differ in such a way that:

1. EBCDIC 0112 ('¢') and 0152 (broken pipe) do not appear in the table.
2. EBCDIC 0137 ('¬') translates to/from ASCII 0236 ('^'). In the standard table, EBCDIC 0232 (no graphic) is used.
3. EBCDIC 0241 ('~') translates to/from ASCII 0176 ('~'). In the standard table, EBCDIC 0137 ('¬') is used.
4. 0255 ('[') and 0275 (']') appear twice, once in the same place as for the standard table and once in place of 0112 ('¢') and 0241 ('~').

In net result:

EBCDIC 0275 (']') displaced EBCDIC 0241 ('~') in cell 0345.

That displaced EBCDIC 0137 ('¬') in cell 0176.

That displaced EBCDIC 0232 (no graphic) in cell 0136.

That replaced EBCDIC 0152 (broken pipe) in cell 0313.

EBCDIC 0255 ('[') replaced EBCDIC 0112 ('¢').

This translation, however, reflects historical practice that (ASCII) '~' and '¬' were often mapped to each other, as were '[' and '¢'; and ']' and (EBCDIC) '~'.

The **cbs** operand is required if any of the **ascii**, **ebcdic**, or **ibm** operands are specified. For the **ascii** operand, the input is handled as described for the **unblock** operand except that characters are converted to ASCII before the trailing <space> characters are deleted. For the **ebcdic** and **ibm** operands, the input is handled as described for the **block** operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing <space> characters are added.

The **block** and **unblock** keywords are from historical BSD practice.

The consistent use of the word **record** in standard error messages matches most historical practice. An earlier version of System V used **block**, but this has been updated in more recent releases.

Early proposals only allowed two numbers separated by **x** to be used in a product when specifying **bs**=, **cbs**=, **ibs**=, and **obs**= sizes. This was changed to reflect the historical practice of

allowing multiple numbers in the product as provided by Version 7 and all releases of System V and BSD.

A change to the **swab** conversion is required to match historical practice and is the result of IEEE PASC Interpretations 1003.2 #03 and #04, submitted for the ISO POSIX-2: 1993 standard.

A change to the handling of SIGINT is required to match historical practice and is the result of IEEE PASC Interpretation 1003.2 #06 submitted for the ISO POSIX-2: 1993 standard.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The second paragraph of the **cbs**= description is reworded and marked EX.

The FUTURE DIRECTIONS section is added.

Issue 6

Changes are made to **swab** conversion and SIGINT handling to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE PASC Interpretation 1003.2 #209 is applied, clarifying the interaction between *dd* **of**=*file* and **conv**=**notrunc**.

Issue 7

Austin Group Interpretation 1003.1-2001 #102 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

delta — make a delta (change) to an SCCS file (**DEVELOPMENT**)

SYNOPSIS

XSI

```
delta [–nps] [–g list] [–m mrlist] [–r SID] [–y[comment]] file...
```

DESCRIPTION

The *delta* utility shall be used to permanently introduce into the named SCCS files changes that were made to the files retrieved by *get* (called the *g-files*, or generated files).

OPTIONS

The *delta* utility shall conform to XBD Section 12.2 (on page 215), except that the –**y** option has an optional option-argument. This optional option-argument shall not be presented as a separate argument.

The following options shall be supported:

–**r** *SID* Uniquely identify which delta is to be made to the SCCS file. The use of this option shall be necessary only if two or more outstanding *get* commands for editing (*get* –**e**) on the same SCCS file were done by the same person (login name). The SID value specified with the –**r** option can be either the SID specified on the *get* command line or the SID to be made as reported by the *get* utility; see *get* (on page 2764).

–**s** Suppress the report to standard output of the activity associated with each *file*. See the STDOUT section.

–**n** Specify retention of the edited *g-file* (normally removed at completion of delta processing).

–**g** *list* Specify a *list* (see *get* for the definition of *list*) of deltas that shall be ignored when the file is accessed at the change level (SID) created by this delta.

–**m** *mrlist* Specify a modification request (MR) number that the application shall supply as the reason for creating the new delta. This shall be used if the SCCS file has the **v** flag set; see *admin*.

If –**m** is not used and `'–'` is not specified as a file argument, and the standard input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued.

MRs in a list shall be separated by <blank> characters or escaped <newline> characters. An unescaped <newline> shall terminate the MR list. The escape character is <backslash>.

If the **v** flag has a value, it shall be taken to be the name of a program which validates the correctness of the MR numbers. If a non-zero exit status is returned from the MR number validation program, the *delta* utility shall terminate. (It is assumed that the MR numbers were not all valid.)

–**y**[*comment*] Describe the reason for making the delta. The *comment* shall be an arbitrary group of lines that would meet the definition of a text file. Implementations shall support *comment*s from zero to 512 bytes and may support longer values. A null string (specified as either –**y**, –**y**`""`, or in response to a prompt for a comment) shall be considered a valid *comment*.

If –**y** is not specified and `'–'` is not specified as a file argument, and the standard

input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued. An unescaped <newline> shall terminate the comment text. The escape character is <backslash>.

The **−y** option shall be required if the *file* operand is specified as `'−'`.

−p Write (to standard output) the SCCS file differences before and after the delta is applied in *diff* format; see *diff*.

OPERANDS

The following operand shall be supported:

file A pathname of an existing SCCS file or a directory. If *file* is a directory, the *delta* utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with **s.**) and unreadable files shall be silently ignored.

If exactly one *file* operand appears, and it is `'−'`, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

STDIN

The standard input shall be a text file used only in the following cases:

- To read an *mrlist* or a *comment* (see the **−m** and **−y** options).
- A *file* operand shall be specified as `'−'`. In this case, the **−y** option must be used to specify the comment, and if the SCCS file has the **v** flag set, the **−m** option must also be used to specify the MR list.

INPUT FILES

Input files shall be text files whose data is to be included in the SCCS files. If the first character of any line of an input file is <SOH> in the POSIX locale, the results are unspecified. If this file contains more than 99 999 lines, the number of lines recorded in the header for this file shall be 99 999 for this delta.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *delta*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone in which the time and date are written in the SCCS file. If the *TZ* variable is unset or NULL, an unspecified system default timezone is used.

ASYNCHRONOUS EVENTS

If SIGINT is caught, temporary files shall be cleaned up and *delta* shall exit with a non-zero exit code. The standard action shall be taken for all other signals; see Section 1.4 (on page 2288).

STDOUT

The standard output shall be used only for the following messages in the POSIX locale:

- Prompts (see the –**m** and –**y** options) in the following formats:

  ```
  "MRs? "
  ```

  ```
  "comments? "
  ```

  The MR prompt, if written, shall always precede the comments prompt.

- A report of each file's activities (unless the –**s** option is specified) in the following format:

  ```
  "%s\n%d inserted\n%d deleted\n%d unchanged\n", <New SID>,
      <number of lines inserted>, <number of lines deleted>,
      <number of lines unchanged>
  ```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

Any SCCS files updated shall be files of an unspecified format.

EXTENDED DESCRIPTION

System Date and Time

When a delta is added to an SCCS file, the system date and time shall be recorded for the new delta. If a *get* is performed using an SCCS file with a date recorded apparently in the future, the behavior is unspecified.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Problems can arise if the system date and time have been modified (for example, put forward and then back again, or unsynchronized clocks across a network) and can also arise when different values of the *TZ* environment variable are used.

Problems of a similar nature can also arise for the operation of the *get* utility, which records the date and time in the file body.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

None.

SEE ALSO

Section 1.4 (on page 2288), *admin*, *diff*, *get*, *prs*, *rmdel*

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The output format description in the STDOUT section is corrected.

Issue 6

The APPLICATION USAGE section is added.

The normative text is reworded to avoid use of the term "must" for application requirements.

The Open Group Base Resolution bwg2001-007 is applied as follows:

- The use of `'-'` as a file argument is clarified.
- The use of STDIN is added.
- The ASYNCHRONOUS EVENTS section is updated to remove the implicit requirement that implementations re-signal themselves when catching a normally fatal signal.
- New text is added to the INPUT FILES section warning that the maximum lines recorded in the file is 99 999.

New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections regarding how the system date and time may be taken into account, and the *TZ* environment variable is added to the ENVIRONMENT VARIABLES section as per The Open Group Base Resolution bwg2001-007.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

df — report free disk space

SYNOPSIS

XSI `df [-k] [-P|-t] [file...]`

DESCRIPTION

XSI The *df* utility shall write the amount of available space and file slots for file systems on which the invoking user has appropriate read access. File systems shall be specified by the *file* operands; when none are specified, information shall be written for all file systems. The format of the default output from *df* is unspecified, but all space figures are reported in 512-byte units, unless the **-k** option is specified. This output shall contain at least the file system names, amount XSI of available space on each of these file systems, and the number of free file slots, or *inodes*, available; when **-t** is specified, the output shall contain the total allocated space as well.

OPTIONS

The *df* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

-k Use 1 024-byte units, instead of the default 512-byte units, when writing space figures.

-P Produce output in the format described in the STDOUT section.

XSI **-t** Include total allocated-space figures in the output.

OPERANDS

The following operand shall be supported:

file A pathname of a file within the hierarchy of the desired file system. If a file other XSI than a FIFO, a regular file, a directory, or a special file representing the device containing the file system (for example, **/dev/dsk/0s1**) is specified, the results are unspecified. If the *file* operand names a file other than a special file containing a file system, *df* shall write the amount of free space in the file system containing the XSI specified *file* operand. Otherwise, *df* shall write the amount of free space in that file system.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *df*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
When both the –**k** and –**P** options are specified, the following header line shall be written (in the POSIX locale):

```
"Filesystem 1024-blocks Used Available Capacity Mounted on\n"
```

When the –**P** option is specified without the –**k** option, the following header line shall be written (in the POSIX locale):

```
"Filesystem 512-blocks Used Available Capacity Mounted on\n"
```

The implementation may adjust the spacing of the header line and the individual data lines so that the information is presented in orderly columns.

The remaining output with –**P** shall consist of one line of information for each specified file system. These lines shall be formatted as follows:

```
"%s %d %d %d %d%% %s\n", <file system name>, <total space>,
    <space used>, <space free>, <percentage used>,
    <file system root>
```

In the following list, all quantities expressed in 512-byte units (1 024-byte when –**k** is specified) shall be rounded up to the next higher unit. The fields are:

<file system name>
The name of the file system, in an implementation-defined format.

<total space> The total size of the file system in 512-byte units. The exact meaning of this figure is implementation-defined, but should include *<space used>*, *<space free>*, plus any space reserved by the system not normally available to a user.

<space used> The total amount of space allocated to existing files in the file system, in 512-byte units.

<space free> The total amount of space available within the file system for the creation of new files by unprivileged users, in 512-byte units. When this figure is less than or equal to zero, it shall not be possible to create any new files on the file system without first deleting others, unless the process has appropriate privileges. The figure written may be less than zero.

<percentage used>
The percentage of the normally available space that is currently allocated to all files on the file system. This shall be calculated using the fraction:

```
<space used>/( <space used>+ <space free>)
```

expressed as a percentage. This percentage may be greater than 100 if *<space free>* is less than zero. The percentage value shall be expressed as a positive integer, with any fractional result causing it to be rounded to the next highest integer.

83656 *<file system root>*

83657 The directory below which the file system hierarchy appears.

83658 XSI The output format is unspecified when **–t** is used.

83659 **STDERR**

83660 The standard error shall be used only for diagnostic messages.

83661 **OUTPUT FILES**

83662 None.

83663 **EXTENDED DESCRIPTION**

83664 None.

83665 **EXIT STATUS**

83666 The following exit values shall be returned:

83667 0 Successful completion.

83668 >0 An error occurred.

83669 **CONSEQUENCES OF ERRORS**

83670 Default.

83671 **APPLICATION USAGE**

83672 On most systems, the "name of the file system, in an implementation-defined format" is the
83673 special file on which the file system is mounted.

83674 On large file systems, the calculation specified for percentage used can create huge rounding
83675 errors.

83676 **EXAMPLES**

83677 1. The following example writes portable information about the **/usr** file system:

83678 ```
df –P /usr
```

83679 2. Assuming that **/usr/src** is part of the **/usr** file system, the following produces the same
83680 output as the previous example:

83681 ```
df –P /usr/src
```

83682 **RATIONALE**

83683 The behavior of *df* with the **–P** option is the default action of the 4.2 BSD *df* utility. The uppercase
83684 **–P** was selected to avoid collision with a known industry extension using **–p**.

83685 Historical *df* implementations vary considerably in their default output. It was therefore
83686 necessary to describe the default output in a loose manner to accommodate all known historical
83687 implementations and to add a portable option (**–P**) to provide information in a portable format.

83688 The use of 512-byte units is historical practice and maintains compatibility with *ls* and other
83689 utilities in this volume of POSIX.1-200x. This does not mandate that the file system itself be
83690 based on 512-byte blocks. The **–k** option was added as a compromise measure. It was agreed by
83691 the standard developers that 512 bytes was the best default unit because of its complete
83692 historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and
83693 that a **–k** option to switch to 1 024-byte units was a good compromise. Users who prefer the
83694 more logical 1 024-byte quantity can easily alias *df* to *df* **–k** without breaking many historical
83695 scripts relying on the 512-byte units.

83696 It was suggested that *df* and the various related utilities be modified to access a *BLOCKSIZE*
83697 environment variable to achieve consistency and user acceptance. Since this is not historical

practice on any system, it is left as a possible area for system extensions and will be re-evaluated in a future version if it is widely implemented.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Issue 7

Austin Group Interpretation 1003.1-2001 #099 is applied.

The *df* utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

diff — compare two files

SYNOPSIS

```
diff [-c|-e|-f|-u|-C n|-U n] [-br] file1 file2
```

DESCRIPTION

The *diff* utility shall compare the contents of *file1* and *file2* and write to standard output a list of changes necessary to convert *file1* into *file2*. This list should be minimal. No output shall be produced if the files are identical.

OPTIONS

The *diff* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

-b Cause any amount of white space at the end of a line to be treated as a single <newline> (that is, the white-space characters preceding the <newline> are ignored) and other strings of white-space characters, not including <newline> characters, to compare equal.

-c Produce output in a form that provides three lines of copied context.

-C *n* Produce output in a form that provides *n* lines of copied context (where *n* shall be interpreted as a positive decimal integer).

-e Produce output in a form suitable as input for the *ed* utility, which can then be used to convert *file1* into *file2*.

-f Produce output in an alternative form, similar in format to **-e**, but not intended to be suitable as input for the *ed* utility, and in the opposite order.

-r Apply *diff* recursively to files and directories of the same name when *file1* and *file2* are both directories.

The *diff* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *diff* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

-u Produce output in a form that provides three lines of unified context.

-U *n* Produce output in a form that provides *n* lines of unified context (where *n* shall be interpreted as a non-negative decimal integer).

OPERANDS

The following operands shall be supported:

file1, *file2* A pathname of a file to be compared. If either the *file1* or *file2* operand is `'-'`, the standard input shall be used in its place.

If both *file1* and *file2* are directories, *diff* shall not compare block special files, character special files, or FIFO special files to any files and shall not compare regular files to directories. Further details are as specified in Diff Directory Comparison Format (on page 2600). The behavior of *diff* on other file types is implementation-defined when found in directories.

If only one of *file1* and *file2* is a directory, *diff* shall be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.

83756 **STDIN**

83757 The standard input shall be used only if one of the *file1* or *file2* operands references standard
83758 input. See the INPUT FILES section.

83759 **INPUT FILES**

83760 The input files may be of any type.

83761 **ENVIRONMENT VARIABLES**

83762 The following environment variables shall affect the execution of *diff*:

83763 *LANG* Provide a default value for the internationalization variables that are unset or null.
83764 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
83765 variables used to determine the values of locale categories.)

83766 *LC_ALL* If set to a non-empty string value, override the values of all the other
83767 internationalization variables.

83768 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
83769 characters (for example, single-byte as opposed to multi-byte characters in
83770 arguments and input files).

83771 *LC_MESSAGES*

83772 Determine the locale that should be used to affect the format and contents of
83773 diagnostic messages written to standard error and informative messages written to
83774 standard output.

83775 *LC_TIME* Determine the locale for affecting the format of file timestamps written with the **−C**
83776 and **−c** options.

83777 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

83778 *TZ* Determine the timezone used for calculating file timestamps written with a context
83779 format. If *TZ* is unset or null, an unspecified default timezone shall be used.

83780 **ASYNCHRONOUS EVENTS**

83781 Default.

83782 **STDOUT**

83783 **Diff Directory Comparison Format**

83784 If both *file1* and *file2* are directories, the following output formats shall be used.

83785 In the POSIX locale, each file that is present in only one directory shall be reported using the
83786 following format:

83787 `"Only in %s: %s\n", <directory pathname>, <filename>`

83788 In the POSIX locale, subdirectories that are common to the two directories may be reported with
83789 the following format:

83790 `"Common subdirectories: %s and %s\n", <directory1 pathname>,`
83791 `<directory2 pathname>`

83792 For each file common to the two directories, if the two files are not to be compared: if the two
83793 files have the same device ID and file serial number, or are both block special files that refer to
83794 the same device, or are both character special files that refer to the same device, in the POSIX
83795 locale the output format is unspecified. Otherwise, in the POSIX locale an unspecified format
83796 shall be used that contains the pathnames of the two files.

83797 For each file common to the two directories, if the files are compared and are identical, no

output shall be written. If the two files differ, the following format is written:

"diff %s %s %s\n", <*diff_options*>, <*filename1*>, <*filename2*>

where <*diff_options*> are the options as specified on the command line.

All directory pathnames listed in this section shall be relative to the original command line arguments. All other names of files listed in this section shall be filenames (pathname components).

Diff Binary Output Format

In the POSIX locale, if one or both of the files being compared are not text files, it is implementation-defined whether *diff* uses the binary file output format or the other formats as specified below. The binary file output format shall contain the pathnames of two files being compared and the string "differ".

If both files being compared are text files, depending on the options specified, one of the following formats shall be used to write the differences.

Diff Default Output Format

The default (without **–e**, **–f**, **–c**, **–C**, **–u**, or **–U** options) *diff* utility output shall contain lines of these forms:

"%da%d\n", <*num1*>, <*num2*>

"%da%d,%d\n", <*num1*>, <*num2*>, <*num3*>

"%dd%d\n", <*num1*>, <*num2*>

"%d,%dd%d\n", <*num1*>, <*num2*>, <*num3*>

"%dc%d\n", <*num1*>, <*num2*>

"%d,%dc%d\n", <*num1*>, <*num2*>, <*num3*>

"%dc%d,%d\n", <*num1*>, <*num2*>, <*num3*>

"%d,%dc%d,%d\n", <*num1*>, <*num2*>, <*num3*>, <*num4*>

These lines resemble *ed* subcommands to convert *file1* into *file2*. The line numbers before the action letters shall pertain to *file1*; those after shall pertain to *file2*. Thus, by exchanging *a* for *d* and reading the line in reverse order, one can also determine how to convert *file2* into *file1*. As in *ed*, identical pairs (where *num1*= *num2*) are abbreviated as a single number.

Following each of these lines, *diff* shall write to standard output all lines affected in the first file using the format:

"<Δ%s", <*line*>

and all lines affected in the second file using the format:

">Δ%s", <*line*>

If there are lines affected in both *file1* and *file2* (as with the **c** subcommand), the changes are separated with a line consisting of three <hyphen> characters:

"---\n"

Diff –e Output Format

With the –**e** option, a script shall be produced that shall, when provided as input to *ed*, along with an appended **w** (write) command, convert *file1* into *file2*. Only the **a** (append), **c** (change), **d** (delete), **i** (insert), and **s** (substitute) commands of *ed* shall be used in this script. Text lines, except those consisting of the single character <period> (`'.'`), shall be output as they appear in the file.

Diff –f Output Format

With the –**f** option, an alternative format of script shall be produced. It is similar to that produced by –**e**, with the following differences:

1. It is expressed in reverse sequence; the output of –**e** orders changes from the end of the file to the beginning; the –**f** from beginning to end.
2. The command form <*lines*> <*command-letter*> used by –**e** is reversed. For example, 10*c* with –**e** would be *c*10 with –**f**.
3. The form used for ranges of line numbers is <space>-separated, rather than <comma>-separated.

Diff –c or –C Output Format

With the –**c** or –**C** option, the output format shall consist of affected lines along with surrounding lines of context. The affected lines shall show which ones need to be deleted or changed in *file1*, and those added from *file2*. With the –**c** option, three lines of context, if available, shall be written before and after the affected lines. With the –**C** option, the user can specify how many lines of context are written. The exact format follows.

The name and last modification time of each file shall be output in the following format:

```
"*** %s %s\n", file1, <file1 timestamp>
"--- %s %s\n", file2, <file2 timestamp>
```

Each <*file*> field shall be the pathname of the corresponding file being compared. The pathname written for standard input is unspecified.

In the POSIX locale, each <*timestamp*> field shall be equivalent to the output from the following command:

```
date "+%a %b %e %T %Y"
```

without the trailing <newline>, executed at the time of last modification of the corresponding file (or the current time, if the file is standard input).

Then, the following output formats shall be applied for every set of changes.

First, a line shall be written in the following format:

```
"***************\n"
```

Next, the range of lines in *file1* shall be written in the following format if the range contains two or more lines:

```
"*** %d,%d ****\n", <beginning line number>, <ending line number>
```

and the following format otherwise:

```
"*** %d ****\n", <ending line number>
```

The ending line number of an empty range shall be the number of the preceding line, or 0 if the

range is at the start of the file.

Next, the affected lines along with lines of context (unaffected lines) shall be written. Unaffected lines shall be written in the following format:

`"ΔΔ%s", <unaffected_line>`

Deleted lines shall be written as:

`"–Δ%s", <deleted_line>`

Changed lines shall be written as:

`"!Δ%s", <changed_line>`

Next, the range of lines in *file2* shall be written in the following format if the range contains two or more lines:

`"––– %d,%d ––––\n", <beginning line number>, <ending line number>`

and the following format otherwise:

`"––– %d ––––\n", <ending line number>`

Then, lines of context and changed lines shall be written as described in the previous formats. Lines added from *file2* shall be written in the following format:

`"+Δ%s", <added_line>`

Diff –u or –U Output Format

The **–u** or **–U** options behave like the **–c** or **–C** options, except that the context lines are not repeated; instead, the context, deleted, and added lines are shown together, interleaved. The exact format follows.

The name and last modification time of each file shall be output in the following format:

```
"---Δ%s%s%sΔ%s0, file1, <file1 timestamp>, <file1 frac>, <file1 zone>
"+++Δ%s%s%sΔ%s0, file2, <file2 timestamp>, <file2 frac>, <file2 zone>
```

Each <*file*> field shall be the pathname of the corresponding file being compared, or the single character `'–'` if standard input is being compared. However, if the pathname contains a <tab> or a <newline>, or if it does not consist entirely of characters taken from the portable character set, the behavior is implementation-defined.

Each <*timestamp*> field shall be equivalent to the output from the following command:

`date '+%Y-%m-%dΔ%H:%M:%S'`

without the trailing <newline>, executed at the time of last modification of the corresponding file (or the current time, if the file is standard input).

Each <*frac*> field shall be either empty, or a decimal point followed by at least one decimal digit, indicating the fractional-seconds part (if any) of the file timestamp. The number of fractional digits shall be at least the number needed to represent the file's timestamp without loss of information.

Each <*zone*> field shall be of the form `"shhmm"`, where `"shh"` is a signed two-digit decimal number in the range –24 through +25, and `"mm"` is an unsigned two-digit decimal number in the range 00 through 59. It represents the timezone of the timestamp as the number of hours (hh) and minutes (mm) east (+) or west (–) of UTC for the timestamp. If the hours and minutes are both zero, the sign shall be `'+'`. However, if the timezone is not an integral number of minutes

83914 away from UTC, the <*zone*> field is implementation-defined.

83915 Then, the following output formats shall be applied for every set of changes.

83916 First, the range of lines in each file shall be written in the following format:

83917 `"@@Δ-%sΔ+%sΔ@@", <file1 range>, <file2 range>`

83918 Each <*range*> field shall be of the form:

83919 `"%1d", <beginning line number>`

83920 if the range contains exactly one line, and:

83921 `"%1d,%1d", <beginning line number>, <number of lines>`

83922 otherwise. If a range is empty, its beginning line number shall be the number of the line just
83923 before the range, or 0 if the empty range starts the file.

83924 Next, the affected lines along with lines of context shall be written. Each non-empty unaffected
83925 line shall be written in the following format:

83926 `"Δ%s", <unaffected_line>`

83927 where the contents of the unaffected line shall be taken from *file1*. It is implementation-defined
83928 whether an empty unaffected line is written as an empty line or a line containing a single
83929 <space> character. This line also represents the same line of *file2*, even though *file2*'s line may
83930 contain different contents due to the **–b**. Deleted lines shall be written as:

83931 `"-%s", <deleted_line>`

83932 Added lines shall be written as:

83933 `"+%s", <added_line>`

83934 The order of lines written shall be the same as that of the corresponding file. A deleted line shall
83935 never be written immediately after an added line.

83936 If **–U** *n* is specified, the output shall contain no more than *n* consecutive unaffected lines; and if
83937 the output contains an affected line and this line is adjacent to up to *n* consecutive unaffected
83938 lines in the corresponding file, the output shall contain these unaffected lines. **–u** shall act like
83939 **–U**3.

83940 **STDERR**

83941 The standard error shall be used only for diagnostic messages.

83942 **OUTPUT FILES**

83943 None.

83944 **EXTENDED DESCRIPTION**

83945 None.

83946 **EXIT STATUS**

83947 The following exit values shall be returned:

83948 0 No differences were found.

83949 1 Differences were found.

83950 >1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If lines at the end of a file are changed and other lines are added, *diff* output may show this as a delete and add, as a change, or as a change and add; *diff* is not expected to know which happened and users should not care about the difference in output as long as it clearly shows the differences between the files.

EXAMPLES

If **dir1** is a directory containing a directory named **x**, **dir2** is a directory containing a directory named **x**, **dir1/x** and **dir2/x** both contain files named **date.out**, and **dir2/x** contains a file named **y**, the command:

```
diff –r dir1 dir2
```

could produce output similar to:

```
Common subdirectories: dir1/x and dir2/x
Only in dir2/x: y
diff –r dir1/x/date.out dir2/x/date.out
1c1
< Mon Jul  2 13:12:16 PDT 1990
---
> Tue Jun 19 21:41:39 PDT 1990
```

RATIONALE

The **–h** option was omitted because it was insufficiently specified and does not add to applications portability.

Historical implementations employ algorithms that do not always produce a minimum list of differences; the current language about making every effort is the best this volume of POSIX.1-200x can do, as there is no metric that could be employed to judge the quality of implementations against any and all file contents. The statement "This list should be minimal" clearly implies that implementations are not expected to provide the following output when comparing two 100-line files that differ in only one character on a single line:

```
1,100c1,100
all 100 lines from file1 preceded with "< "
---
all 100 lines from file2 preceded with "> "
```

The "Only in" messages required when the **–r** option is specified are not used by most historical implementations if the **–e** option is also specified. It is required here because it provides useful information that must be provided to update a target directory hierarchy to match a source hierarchy. The "Common subdirectories" messages are written by System V and 4.3 BSD when the **–r** option is specified. They are allowed here but are not required because they are reporting on something that is the same, not reporting a difference, and are not needed to update a target hierarchy.

The **–c** option, which writes output in a format using lines of context, has been included. The format is useful for a variety of reasons, among them being much improved readability and the ability to understand difference changes when the target file has line numbers that differ from another similar, but slightly different, copy. The *patch* utility is most valuable when working with difference listings using a context format. The BSD version of **–c** takes an optional argument specifying the amount of context. Rather than overloading **–c** and breaking the Utility Syntax Guidelines for *diff*, the standard developers decided to add a separate option for

specifying a context diff with a specified amount of context (**–C**). Also, the format for context *diff*s was extended slightly in 4.3 BSD to allow multiple changes that are within context lines from each other to be merged together. The output format contains an additional four <asterisk> characters after the range of affected lines in the first filename. This was to provide a flag for old programs (like old versions of *patch*) that only understand the old context format. The version of context described here does not require that multiple changes within context lines be merged, but it does not prohibit it either. The extension is upwards-compatible, so any vendors that wish to retain the old version of *diff* can do so by adding the extra four <asterisk> characters (that is, utilities that currently use *diff* and understand the new merged format will also understand the old unmerged format, but not *vice versa*).

The **–u** and **–U** options of GNU *diff* have been included. Their output format, designed by Wayne Davison, takes up less space than **–c** and **–C** format, and in many cases is easier to read. The format's timestamps do not vary by locale, so *LC_TIME* does not affect it. The format's line numbers are rendered with the `%1d` format, not `%d`, because the file format notation rules would allow extra <blank> characters to appear around the numbers.

The substitute command was added as an additional format for the **–e** option. This was added to provide implementations with a way to fix the classic "dot alone on a line" bug present in many versions of *diff*. Since many implementations have fixed this bug, the standard developers decided not to standardize broken behavior, but rather to provide the necessary tool for fixing the bug. One way to fix this bug is to output two periods whenever a lone period is needed, then terminate the append command with a period, and then use the substitute command to convert the two periods into one period.

The BSD-derived **–r** option was added to provide a mechanism for using *diff* to compare two file system trees. This behavior is useful, is standard practice on all BSD-derived systems, and is not easily reproducible with the *find* utility.

The requirement that *diff* not compare files in some circumstances, even though they have the same name, is based on the actual output of historical implementations. The specified behavior precludes the problems arising from running into FIFOs and other files that would cause *diff* to hang waiting for input with no indication to the user that *diff* was hung. An earlier version of this standard specified the output format more precisely, but in practice this requirement was widely ignored and the benefit of standardization seemed small, so it is now unspecified. In most common usage, *diff* **–r** should indicate differences in the file hierarchies, not the difference of contents of devices pointed to by the hierarchies.

Many early implementations of *diff* require seekable files. Since the System Interfaces volume of POSIX.1-200x supports named pipes, the standard developers decided that such a restriction was unreasonable. Note also that the allowed filename – almost always refers to a pipe.

No directory search order is specified for *diff*. The historical ordering is, in fact, not optimal, in that it prints out all of the differences at the current level, including the statements about all common subdirectories before recursing into those subdirectories.

The message:

`"diff %s %s %s\n", <diff_options>, <filename1>, <filename2>`

does not vary by locale because it is the representation of a command, not an English sentence.

FUTURE DIRECTIONS

None.

cmp, *comm*, *ed*, *find*

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–f** option is added.

The output format for **–c** or **–C** format is changed to align with changes to the IEEE P1003.2b draft standard resulting from IEEE PASC Interpretation 1003.2 #71.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/20 is applied, changing the STDOUT section. This changes the specification of *diff* **–c** so that it agrees with existing practice when contexts contain zero lines or one line.

Issue 7

Austin Group Interpretations 1003.1-2001 #115 and #114 are applied.

Austin Group Interpretation 1003.1-2001 #192 is applied, clarifying the behavior if both files are non-text files.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-103 and SD5-XCU-ERN-120 are applied, adding the **–u** option.

NAME

dirname — return the directory portion of a pathname

SYNOPSIS

```
dirname string
```

DESCRIPTION

The *string* operand shall be treated as a pathname, as defined in XBD Section 3.266 (on page 75). The string *string* shall be converted to the name of the directory containing the filename corresponding to the last pathname component in *string*, performing actions equivalent to the following steps in order:

1. If *string* is //, skip steps 2 to 5.
2. If *string* consists entirely of <slash> characters, *string* shall be set to a single <slash> character. In this case, skip steps 3 to 8.
3. If there are any trailing <slash> characters in *string*, they shall be removed.
4. If there are no <slash> characters remaining in *string*, *string* shall be set to a single <period> character. In this case, skip steps 5 to 8.
5. If there are any trailing non-<slash> characters in *string*, they shall be removed.
6. If the remaining *string* is //, it is implementation-defined whether steps 7 and 8 are skipped or processed.
7. If there are any trailing <slash> characters in *string*, they shall be removed.
8. If the remaining *string* is empty, *string* shall be set to a single <slash> character.

The resulting string shall be written to standard output.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

string A string.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *dirname*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *dirname* utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The definition of *pathname* specifies implementation-defined behavior for pathnames starting with two <slash> characters. Therefore, applications shall not arbitrarily add <slash> characters to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

EXAMPLES

Command	Results
dirname /	*/*
dirname //	*/* or *//*
dirname /a/b/	*/a*
dirname //a//b//	*//a*
dirname	Unspecified
dirname a	. ($? = 0)
dirname ""	. ($? = 0)
dirname /a	*/*
dirname /a/b	*/a*
dirname a/b	*a*

RATIONALE

The *dirname* utility originated in System III. It has evolved through the System V releases to a version that matches the requirements specified in this description in System V Release 3. 4.3 BSD and earlier versions did not include *dirname*.

The behaviors of *basename* and *dirname* in this volume of POSIX.1-200x have been coordinated so

that when *string* is a valid pathname:

```
$(basename "string")
```

would be a valid filename for the file in the directory:

```
$(dirname "string")
```

This would not work for the versions of these utilities in early proposals due to the way processing of trailing <slash> characters was specified. Consideration was given to leaving processing unspecified if there were trailing <slash> characters, but this cannot be done; XBD Section 3.266 (on page 75) allows trailing <slash> characters. The *basename* and *dirname* utilities have to specify consistent handling for all valid pathnames.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

NAME

du — estimate file space usage

SYNOPSIS

```
du [–a|–s] [–kx] [–H|–L] [file...]
```

DESCRIPTION

By default, the *du* utility shall write to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. By default, when a symbolic link is encountered on the command line or in the file hierarchy, *du* shall count the size of the symbolic link (rather than the file referenced by the link), and shall not follow the link to another portion of the file hierarchy. The size of the file space allocated to a file of type directory shall be defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself.

When *du* cannot *stat*( ) files or *stat*( ) or read directories, it shall report an error condition and the final exit status is affected. Files with multiple links shall be counted and written for only one entry. The directory entry that is selected in the report is unspecified. By default, file sizes shall be written in 512-byte units, rounded up to the next 512-byte unit.

OPTIONS

The *du* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–a In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. Regardless of the presence of the **–a** option, non-directories given as *file* operands shall always be listed.

–H If a symbolic link is specified on the command line, *du* shall count the size of the file or file hierarchy referenced by the link.

–k Write the files sizes in units of 1 024 bytes, rather than the default 512-byte units.

–L If a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, *du* shall count the size of the file or file hierarchy referenced by the link.

–s Instead of the default output, report only the total sum for each of the specified files.

–x When evaluating file sizes, evaluate only those files that have the same device as the file specified by the *file* operand.

Specifying more than one of the mutually-exclusive options **–H** and **–L** shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS

The following operand shall be supported:

file The pathname of a file whose size is to be written. If no *file* is specified, the current directory shall be used.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *du*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The output from *du* shall consist of the amount of space allocated to a file and the name of the file, in the following format:

```
"%d %s\n", <size>, <pathname>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

None.

RATIONALE

The use of 512-byte units is historical practice and maintains compatibility with *ls* and other utilities in this volume of POSIX.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The **–k** option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (*versus* the mixed 512/1 024-byte usage on BSD systems), and that a **–k** option to switch to 1 024-byte units was a good compromise. Users who prefer the

84249 1 024-byte quantity can easily alias *du* to *du* **–k** without breaking the many historical scripts
84250 relying on the 512-byte units.

84251 The **–b** option was added to an early proposal to provide a resolution to the situation where
84252 System V and BSD systems give figures for file sizes in *blocks*, which is an implementation-
84253 defined concept. (In common usage, the block size is 512 bytes for System V and 1 024 bytes for
84254 BSD systems.) However, **–b** was later deleted, since the default was eventually decided as
84255 512-byte units.

84256 Historical file systems provided no way to obtain exact figures for the space allocation given to
84257 files. There are two known areas of inaccuracies in historical file systems: cases of *indirect blocks*
84258 being used by the file system or *sparse* files yielding incorrectly high values. An indirect block is
84259 space used by the file system in the storage of the file, but that need not be counted in the space
84260 allocated to the file. A *sparse* file is one in which an *lseek*( ) call has been made to a position
84261 beyond the end of the file and data has subsequently been written at that point. A file system
84262 need not allocate all the intervening zero-filled blocks to such a file. It is up to the
84263 implementation to define exactly how accurate its methods are.

84264 The **–a** and **–s** options were mutually-exclusive in the original version of *du*. The POSIX Shell
84265 and Utilities description is implied by the language in the SVID where **–s** is described as causing
84266 "only the grand total" to be reported. Some systems may produce output for **–sa**, but a Strictly
84267 Conforming POSIX Shell and Utilities Application cannot use that combination.

84268 The **–a** and **–s** options were adopted from the SVID except that the System V behavior of not
84269 listing non-directories explicitly given as operands, unless the **–a** option is specified, was
84270 considered a bug; the BSD-based behavior (report for all operands) is mandated. The default
84271 behavior of *du* in the SVID with regard to reporting the failure to read files (it produces no
84272 messages) was considered counter-intuitive, and thus it was specified that the POSIX Shell and
84273 Utilities default behavior shall be to produce such messages. These messages can be turned off
84274 with shell redirection to achieve the System V behavior.

84275 The **–x** option is historical practice on recent BSD systems. It has been adopted by this volume of
84276 POSIX.1-200x because there was no other historical method of limiting the *du* search to a single
84277 file hierarchy. This limitation of the search is necessary to make it possible to obtain file space
84278 usage information about a file system on which other file systems are mounted, without having
84279 to resort to a lengthy *find* and *awk* script.

84280 **FUTURE DIRECTIONS**

84281 None.

84286 **CHANGE HISTORY**

84287 First released in Issue 2.

84288 **Issue 6**

84289 This utility is marked as part of the User Portability Utilities option.

84290 The APPLICATION USAGE section is added.

84291 The obsolescent **–r** option is removed.

84292 The Open Group Corrigendum U025/3 is applied. The *du* utility is reinstated, as it had
84293 incorrectly been marked LEGACY in Issue 5.

The **–H** and **–L** options for symbolic links are added as described in the IEEE P1003.2b draft standard.

Issue 7

The *du* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

echo — write arguments to standard output

SYNOPSIS

```
echo [string...]
```

DESCRIPTION

The *echo* utility writes its arguments to standard output, followed by a <newline>. If there are no arguments, only the <newline> is written.

OPTIONS

The *echo* utility shall not recognize the "−−" argument in the manner specified by Guideline 10 of XBD Section 12.2 (on page 215); "−−" shall be recognized as a string operand.

Implementations shall not support any options.

OPERANDS

The following operands shall be supported:

string A string to be written to standard output. If the first operand is **−n**, or if any of the operands contain a <backslash> character, the results are implementation-defined.

XSI On XSI-conformant systems, if the first operand is **−n**, it shall be treated as a string, not an option. The following character sequences shall be recognized on XSI-conformant systems within any of the arguments:

`\a` Write an <alert>.

`\b` Write a <backspace>.

`\c` Suppress the <newline> that otherwise follows the final argument in the output. All characters following the `'\c'` in the arguments shall be ignored.

`\f` Write a <form-feed>.

`\n` Write a <newline>.

`\r` Write a <carriage-return>.

`\t` Write a <tab>.

`\v` Write a <vertical-tab>.

`\\` Write a <backslash> character.

`\0`*num* Write an 8-bit value that is the zero, one, two, or three-digit octal number *num*.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *echo*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

XSI *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *echo* utility arguments shall be separated by single <space> characters and a <newline> XSI character shall follow the last argument. Output transformations shall occur based on the escape sequences in the input. See the OPERANDS section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

It is not possible to use *echo* portably across all POSIX systems unless both **–n** (as the first argument) and escape sequences are omitted.

The *printf* utility can be used portably to emulate any of the traditional behaviors of the *echo* utility as follows (assuming that *IFS* has its standard value or is unset):

- The historic System V *echo* and the requirements on XSI implementations in this volume of POSIX.1-200x are equivalent to:

```
printf "%b\n" "$*"
```

- The BSD *echo* is equivalent to:

```
if [ "X$1" = "X–n" ]
then
    shift
    printf "%s" "$*"
else
    printf "%s\n" "$*"
fi
```

New applications are encouraged to use *printf* instead of *echo*.

EXAMPLES

None.

RATIONALE

The *echo* utility has not been made obsolescent because of its extremely widespread use in historical applications. Conforming applications that wish to do prompting without <newline> characters or that could possibly be expecting to echo a **–n**, should use the *printf* utility derived from the Ninth Edition system.

As specified, *echo* writes its arguments in the simplest of ways. The two different historical versions of *echo* vary in fatally incompatible ways.

The BSD *echo* checks the first argument for the string **–n** which causes it to suppress the <newline> that would otherwise follow the final argument in the output.

The System V *echo* does not support any options, but allows escape sequences within its operands, as described for XSI implementations in the OPERANDS section.

The *echo* utility does not support Utility Syntax Guideline 10 because historical applications depend on *echo* to echo *all* of its arguments, except for the **–n** option in the BSD version.

FUTURE DIRECTIONS

None.

SEE ALSO

printf

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the OPTIONS section, the last sentence is changed to indicate that implementations "do not" support any options; in the previous issue this said "need not".

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- A set of character sequences is defined as *string* operands.
- *LC_CTYPE* is added to the list of environment variables affecting *echo*.
- In the OPTIONS section, implementations shall not support any options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/21 is applied, so that the *echo* utility can accommodate historical BSD behavior.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ed — edit text

SYNOPSIS

```
ed [-p string] [-s] [file]
```

DESCRIPTION

The *ed* utility is a line-oriented text editor that uses two modes: *command mode* and *input mode*. In command mode the input characters shall be interpreted as commands, and in input mode they shall be interpreted as text. See the EXTENDED DESCRIPTION section.

If an operand is '-', the results are unspecified.

OPTIONS

The *ed* utility shall conform to XBD Section 12.2 (on page 215), except for the unspecified usage of '-'.

The following options shall be supported:

-p *string* Use *string* as the prompt string when in command mode. By default, there shall be no prompt string.

-s Suppress the writing of byte counts by **e**, **E**, **r**, and **w** commands and of the '!' prompt after a !*command*.

OPERANDS

The following operand shall be supported:

file If the *file* argument is given, *ed* shall simulate an **e** command on the file named by the pathname, *file*, before accepting commands from the standard input.

STDIN

The standard input shall be a text file consisting of commands, as described in the EXTENDED DESCRIPTION section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ed*:

HOME Determine the pathname of the user's home directory.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

The *ed* utility shall take the standard action for all signals (see the ASYNCHRONOUS EVENTS section in Section 1.4, on page 2288) with the following exceptions:

SIGINT The *ed* utility shall interrupt its current activity, write the string `"?\n"` to standard output, and return to command mode (see the EXTENDED DESCRIPTION section).

SIGHUP If the buffer is not empty and has changed since the last write, the *ed* utility shall attempt to write a copy of the buffer in a file. First, the file named **ed.hup** in the current directory shall be used; if that fails, the file named **ed.hup** in the directory named by the *HOME* environment variable shall be used. In any case, the *ed* utility shall exit without writing the file to the currently remembered pathname and without returning to command mode.

SIGQUIT The *ed* utility shall ignore this event.

STDOUT

Various editing commands and the prompting feature (see **−p**) write to standard output, as described in the EXTENDED DESCRIPTION section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files shall be text files whose formats are dependent on the editing commands given.

EXTENDED DESCRIPTION

The *ed* utility shall operate on a copy of the file it is editing; changes made to the copy shall have no effect on the file until a **w** (write) command is given. The copy of the text is called the *buffer*.

Commands to *ed* have a simple and regular structure: zero, one, or two *addresses* followed by a single-character *command*, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses very often can be omitted. If the **−p** option is specified, the prompt string shall be written to standard output before each command is read.

In general, only one command can appear on a line. Certain commands allow text to be input. This text is placed in the appropriate place in the buffer. While *ed* is accepting text, it is said to be in *input mode*. In this mode, no commands shall be recognized; all input is merely collected. Input mode is terminated by entering a line consisting of two characters: a <period> (`'.'`) followed by a <newline>. This line is not considered part of the input text.

Regular Expressions in ed

The *ed* utility shall support basic regular expressions, as described in XBD Section 9.3 (on page 183). Since regular expressions in *ed* are always matched against single lines (excluding the terminating <newline> characters), never against any larger section of text, there is no way for a regular expression to match a <newline>.

A null RE shall be equivalent to the last RE encountered.

Regular expressions are used in addresses to specify lines, and in some commands (for example, the **s** substitute command) to specify portions of a line to be substituted.

Addresses in ed

Addressing in *ed* relates to the current line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. If the edit buffer is not empty, the initial value for the current line shall be the last line in the edit buffer; otherwise, zero.

Addresses shall be constructed as follows:

1. The <period> character (`'.'`) shall address the current line.
2. The <dollar-sign> character (`'$'`) shall address the last line of the edit buffer.
3. The positive decimal number *n* shall address the *n*th line of the edit buffer.
4. The <apostrophe>-x character pair (`"'x"`) shall address the line marked with the mark name character *x*, which shall be a lowercase letter from the portable character set. It shall be an error if the character has not been set to mark a line or if the line that was marked is not currently present in the edit buffer.
5. A BRE enclosed by <slash> characters (`'/'`) shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of <slash> characters shall address the next line for which the line excluding the terminating <newline> matches the last BRE encountered. In addition, the second <slash> can be omitted at the end of a command line. Within the BRE, a <backslash>-<slash> pair (`"\/"`) shall represent a literal <slash> instead of the BRE delimiter. If necessary, the search shall wrap around to the beginning of the buffer and continue up to and including the current line, so that the entire buffer is searched.
6. A BRE enclosed by <question-mark> characters (`'?'`) shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of <question-mark> characters (`"??"`) shall address the previous line for which the line excluding the terminating <newline> matches the last BRE encountered. In addition, the second <question-mark> can be omitted at the end of a command line. Within the BRE, a <backslash>-<question-mark> pair (`"\?"`) shall represent a literal <question-mark> instead of the BRE delimiter. If necessary, the search shall wrap around to the end of the buffer and continue up to and including the current line, so that the entire buffer is searched.
7. A <plus-sign> (`'+'`) or <hyphen> character (`'-'`) followed by a decimal number shall address the current line plus or minus the number. A <plus-sign> or <hyphen> character not followed by a decimal number shall address the current line plus or minus 1.

Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:

- A <plus-sign> or <hyphen> character followed by a decimal number shall add or subtract, respectively, the indicated number of lines to or from the address. A <plus-sign> or <hyphen> character not followed by a decimal number shall add or subtract 1 to or from the address.
- A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer. It shall be an error if a search for a BRE fails to find a matching line.

Commands accept zero, one, or two addresses. If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain, for the specified command.

Addresses shall be separated from each other by a <comma> (`','`) or <semicolon> character (`';'`). In the case of a <semicolon> separator, the current line (`'.'`) shall be set to the first address, and only then will the second address be calculated. This feature can be used to determine the starting line for forwards and backwards searches; see rules 5. and 6.

Addresses can be omitted on either side of the <comma> or <semicolon> separator, in which case the resulting address pairs shall be as follows:

Specified	Resulting
`,`	`1 , $`
`, addr`	`1 , addr`
`addr ,`	`addr , addr`
`;`	`. ; $`
`; addr`	`. ; addr`
`addr ;`	`addr ; addr`

Any <blank> characters included between addresses, address separators, or address offsets shall be ignored.

Commands in ed

In the following list of *ed* commands, the default addresses are shown in parentheses. The number of addresses shown in the default shall be the number expected by the command. The parentheses are not part of the address; they show that the given addresses are the default.

It is generally invalid for more than one command to appear on a line. However, any command (except **e**, **E**, **f**, **q**, **Q**, **r**, **w**, and **!**) can be suffixed by the letter **l**, **n**, or **p**; in which case, except for the **l**, **n**, and **p** commands, the command shall be executed and then the new current line shall be written as described below under the **l**, **n**, and **p** commands. When an **l**, **n**, or **p** suffix is used with an **l**, **n**, or **p** command, the command shall write to standard output as described below, but it is unspecified whether the suffix writes the current line again in the requested format or whether the suffix has no effect. For example, the **pl** command (base **p** command with an **l** suffix) shall either write just the current line or write it twice—once as specified for **p** and once as specified for **l**. Also, the **g**, **G**, **v**, and **V** commands shall take a command as a parameter.

Each address component can be preceded by zero or more <blank> characters. The command

letter can be preceded by zero or more <blank> characters. If a suffix letter (**l**, **n**, or **p**) is given, the application shall ensure that it immediately follows the command.

The **e**, **E**, **f**, **r**, and **w** commands shall take an optional *file* parameter, separated from the command letter by one or more <blank> characters.

If changes have been made in the buffer since the last **w** command that wrote the entire buffer, *ed* shall warn the user if an attempt is made to destroy the editor buffer via the **e** or **q** commands. The *ed* utility shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged. If the **e** or **q** command is repeated with no intervening command, it shall take effect.

If a terminal disconnect (see XBD Chapter 11 (on page 199), Modem Disconnect and Closing a Device Terminal), is detected:

- If accompanied by a SIGHUP signal, the *ed* utility shall operate as described in the ASYNCHRONOUS EVENTS section for a SIGHUP signal.
- If not accompanied by a SIGHUP signal, the *ed* utility shall act as if an end-of-file had been detected on standard input.

If an end-of-file is detected on standard input:

- If the *ed* utility is in input mode, *ed* shall terminate input mode and return to command mode. It is unspecified if any partially entered lines (that is, input text without a terminating <newline>) are discarded from the input text.
- If the *ed* utility is in command mode, it shall act as if a **q** command had been entered.

If the closing delimiter of an RE or of a replacement string (for example, `'/'`) in a **g**, **G**, **s**, **v**, or **V** command would be the last character before a <newline>, that delimiter can be omitted, in which case the addressed line shall be written. For example, the following pairs of commands are equivalent:

```
s/s1/s2     s/s1/s2/p
g/s1        g/s1/p
?s1         ?s1?
```

If an invalid command is entered, *ed* shall write the string:

```
"?\n"
```

(followed by an explanatory message if *help mode* has been enabled via the **H** command) to standard output and shall continue in command mode with the current line number unchanged.

Append Command

Synopsis:

```
(.)a
<text>
.
```

The **a** command shall read the given text and append it after the addressed line; the current line number shall become the address of the last inserted line or, if there were none, the addressed line. Address 0 shall be valid for this command; it shall cause the appended text to be placed at the beginning of the buffer.

Change Command

Synopsis:
```
(.,.)c
<text>
.
```

The **c** command shall delete the addressed lines, then accept input text that replaces these lines; the current line shall be set to the address of the last line input; or, if there were none, at the line after the last line deleted; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

Delete Command

Synopsis: `(.,.)d`

The **d** command shall delete the addressed lines from the buffer. The address of the line after the last line deleted shall become the current line number; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero.

Edit Command

Synopsis: `e [file]`

The **e** command shall delete the entire contents of the buffer and then read in the file named by the pathname *file*. The current line number shall be set to the address of the last line of the buffer. If no pathname is given, the currently remembered pathname, if any, shall be used (see the **f** command). The number of bytes read shall be written to standard output, unless the **–s** option was specified, in the following format:

`"%d\n", <number of bytes read>`

The name *file* shall be remembered for possible use as a default pathname in subsequent **e**, **E**, **r**, and **w** commands. If *file* is replaced by `'!'`, the rest of the line shall be taken to be a shell command line whose output is to be read. Such a shell command line shall not be remembered as the current *file*. All marks shall be discarded upon the completion of a successful **e** command. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

Edit Without Checking Command

Synopsis: `E [file]`

The **E** command shall possess all properties and restrictions of the **e** command except that the editor shall not check to see whether any changes have been made to the buffer since the last **w** command.

84663 **Filename Command**

84664 *Synopsis*: `f [file]`

84665 If *file* is given, the **f** command shall change the currently remembered pathname to *file*; whether
84666 the name is changed or not, it shall then write the (possibly new) currently remembered
84667 pathname to the standard output in the following format:

84668 `"%s\n", <pathname>`

84669 The current line number shall be unchanged.

84670 **Global Command**

84671 *Synopsis*: `(1,$)g/RE/command list`

84672 In the **g** command, the first step shall be to mark every line for which the line excluding the
84673 terminating <newline> matches the given RE. Then, going sequentially from the beginning of
84674 the file to the end of the file, the given *command list* shall be executed for each marked line, with
84675 the current line number set to the address of that line. Any line modified by the *command list*
84676 shall be unmarked. When the **g** command completes, the current line number shall have the
84677 value assigned by the last command in the *command list*. If there were no matching lines, the
84678 current line number shall not be changed. A single command or the first of a list of commands
84679 shall appear on the same line as the global command. All lines of a multi-line list except the last
84680 line shall be ended with a <backslash> preceding the terminating <newline>; the **a**, **i**, and **c**
84681 commands and associated input are permitted. The `'.'` terminating input mode can be omitted
84682 if it would be the last line of the *command list*. An empty *command list* shall be equivalent to the **p**
84683 command. The use of the **g**, **G**, **v**, **V**, and **!** commands in the *command list* produces undefined
84684 results. Any character other than <space> or <newline> can be used instead of a <slash> to
84685 delimit the RE. Within the RE, the RE delimiter itself can be used as a literal character if it is
84686 preceded by a <backslash>.

84687 **Interactive Global Command**

84688 *Synopsis*: `(1,$)G/RE/`

84689 In the **G** command, the first step shall be to mark every line for which the line excluding the
84690 terminating <newline> matches the given RE. Then, for every such line, that line shall be
84691 written, the current line number shall be set to the address of that line, and any one command
84692 (other than one of the **a**, **c**, **i**, **g**, **G**, **v**, and **V** commands) shall be read and executed. A <newline>
84693 shall act as a null command (causing no action to be taken on the current line); an `'&'` shall
84694 cause the re-execution of the most recent non-null command executed within the current
84695 invocation of **G**. Note that the commands input as part of the execution of the **G** command can
84696 address and affect any lines in the buffer. Any line modified by the command shall be
84697 unmarked. The final value of the current line number shall be the value set by the last command
84698 successfully executed. (Note that the last command successfully executed shall be the **G**
84699 command itself if a command fails or the null command is specified.) If there were no matching
84700 lines, the current line number shall not be changed. The **G** command can be terminated by a
84701 SIGINT signal. Any character other than <space> or <newline> can be used instead of a <slash>
84702 to delimit the RE and the replacement. Within the RE, the RE delimiter itself can be used as a
84703 literal character if it is preceded by a <backslash>.

84704 **Help Command**

84705 *Synopsis*: `h`

84706 The **h** command shall write a short message to standard output that explains the reason for the
84707 most recent `'?'` notification. The current line number shall be unchanged.

84708 **Help-Mode Command**

84709 *Synopsis*: `H`

84710 The **H** command shall cause *ed* to enter a mode in which help messages (see the **h** command)
84711 shall be written to standard output for all subsequent `'?'` notifications. The **H** command
84712 alternately shall turn this mode on and off; it is initially off. If the help-mode is being turned on,
84713 the **H** command also explains the previous `'?'` notification, if there was one. The current line
84714 number shall be unchanged.

84715 **Insert Command**

84716 *Synopsis*: `(.)i`
84717 `<text>`
84718 `.`

84719 The **i** command shall insert the given text before the addressed line; the current line is set to the
84720 last inserted line or, if there was none, to the addressed line. This command differs from the **a**
84721 command only in the placement of the input text. Address 0 shall be valid for this command; it
84722 shall be interpreted as if address 1 were specified.

84723 **Join Command**

84724 *Synopsis*: `(.,.+1)j`

84725 The **j** command shall join contiguous lines by removing the appropriate <newline> characters. If
84726 exactly one address is given, this command shall do nothing. If lines are joined, the current line
84727 number shall be set to the address of the joined line; otherwise, the current line number shall be
84728 unchanged.

84729 **Mark Command**

84730 *Synopsis*: `(.)k`*x*

84731 The **k** command shall mark the addressed line with name *x*, which the application shall ensure
84732 is a lowercase letter from the portable character set. The address `"'x"` shall then refer to this
84733 line; the current line number shall be unchanged.

84734 **List Command**

84735 *Synopsis*: `(.,.)l`

84736 The **l** command shall write to standard output the addressed lines in a visually unambiguous
84737 form. The characters listed in XBD Table 5-1 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\r'`,
84738 `'\t'`, `'\v'`) shall be written as the corresponding escape sequence; the `'\n'` in that table is not
84739 applicable. Non-printable characters not in the table shall be written as one three-digit octal
84740 number (with a preceding <backslash> character) for each byte in the character (most significant
84741 byte first).

84742 Long lines shall be folded, with the point of folding indicated by <newline> preceded by a
84743 <backslash>; the length at which folding occurs is unspecified, but should be appropriate for the

output device. The end of each line shall be marked with a `'$'`, and `'$'` characters within the text shall be written with a preceding <backslash>. An **l** command can be appended to any other command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**. The current line number shall be set to the address of the last line written.

Move Command

Synopsis: `(.,.)m`*address*

The **m** command shall reposition the addressed lines after the line addressed by *address*. Address 0 shall be valid for *address* and cause the addressed lines to be moved to the beginning of the buffer. It shall be an error if address *address* falls within the range of moved lines. The current line number shall be set to the address of the last line moved.

Number Command

Synopsis: `(.,.)n`

The **n** command shall write to standard output the addressed lines, preceding each line by its line number and a <tab>; the current line number shall be set to the address of the last line written. The **n** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

Print Command

Synopsis: `(.,.)p`

The **p** command shall write to standard output the addressed lines; the current line number shall be set to the address of the last line written. The **p** command can be appended to any command other than **e**, **E**, **f**, **q**, **Q**, **r**, **w**, or **!**.

Prompt Command

Synopsis: `P`

The **P** command shall cause *ed* to prompt with an <asterisk> (`'*'`) (or *string*, if **–p** is specified) for all subsequent commands. The **P** command alternatively shall turn this mode on and off; it shall be initially on if the **–p** option is specified; otherwise, off. The current line number shall be unchanged.

Quit Command

Synopsis: `q`

The **q** command shall cause *ed* to exit. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

Quit Without Checking Command

Synopsis: `Q`

The **Q** command shall cause *ed* to exit without checking whether changes have been made in the buffer since the last **w** command.

84778 **Read Command**

84779 *Synopsis*: `($)r [file]`

84780 The **r** command shall read in the file named by the pathname *file* and append it after the
84781 addressed line. If no *file* argument is given, the currently remembered pathname, if any, shall be
84782 used (see the **e** and **f** commands). The currently remembered pathname shall not be changed
84783 unless there is no remembered pathname. Address 0 shall be valid for **r** and shall cause the file
84784 to be read at the beginning of the buffer. If the read is successful, and **–s** was not specified, the
84785 number of bytes read shall be written to standard output in the following format:

84786 `"%d\n", <number of bytes read>`

84787 The current line number shall be set to the address of the last line read in. If *file* is replaced by
84788 `'!'`, the rest of the line shall be taken to be a shell command line whose output is to be read.
84789 Such a shell command line shall not be remembered as the current pathname.

84790 **Substitute Command**

84791 *Synopsis*: `(.,.)s/RE/replacement/flags`

84792 The **s** command shall search each addressed line for an occurrence of the specified RE and
84793 replace either the first or all (non-overlapped) matched strings with the *replacement*; see the
84794 following description of the **g** suffix. It is an error if the substitution fails on every addressed
84795 line. Any character other than <space> or <newline> can be used instead of a <slash> to delimit
84796 the RE and the replacement. Within the RE, the RE delimiter itself can be used as a literal
84797 character if it is preceded by a <backslash>. The current line shall be set to the address of the
84798 last line on which a substitution occurred.

84799 An <ampersand> (`'&'`) appearing in the *replacement* shall be replaced by the string matching the
84800 RE on the current line. The special meaning of `'&'` in this context can be suppressed by
84801 preceding it by <backslash>. As a more general feature, the characters `'\n'`, where *n* is a digit,
84802 shall be replaced by the text matched by the corresponding back-reference expression. If the
84803 corresponding back-reference expression does not match, then the characters `'\n'` shall be
84804 replaced by the empty string. When the character `'%'` is the only character in the *replacement*, the
84805 *replacement* used in the most recent substitute command shall be used as the *replacement* in the
84806 current substitute command; if there was no previous substitute command, the use of `'%'` in this
84807 manner shall be an error. The `'%'` shall lose its special meaning when it is in a replacement
84808 string of more than one character or is preceded by a <backslash>. For each <backslash>
84809 encountered in scanning *replacement* from beginning to end, the following character shall lose its
84810 special meaning (if any). It is unspecified what special meaning is given to any character other
84811 than <backslash>, `'&'`, `'%'`, or digits.

84812 A line can be split by substituting a <newline> into it. The application shall ensure it escapes the
84813 <newline> in the *replacement* by preceding it by <backslash>. Such substitution cannot be done
84814 as part of a **g** or **v** *command list*. The current line number shall be set to the address of the last
84815 line on which a substitution is performed. If no substitution is performed, the current line
84816 number shall be unchanged. If a line is split, a substitution shall be considered to have been
84817 performed on each of the new lines for the purpose of determining the new current line number.
84818 A substitution shall be considered to have been performed even if the replacement string is
84819 identical to the string that it replaces.

84820 The application shall ensure that the value of *flags* is zero or more of:

84821 *count* Substitute for the *count*th occurrence only of the RE found on each addressed line.

84822 **g** Globally substitute for all non-overlapping instances of the RE rather than just the first
84823 one. If both **g** and *count* are specified, the results are unspecified.

84824 **l** Write to standard output the final line in which a substitution was made. The line shall
84825 be written in the format specified for the **l** command.

84826 **n** Write to standard output the final line in which a substitution was made. The line shall
84827 be written in the format specified for the **n** command.

84828 **p** Write to standard output the final line in which a substitution was made. The line shall
84829 be written in the format specified for the **p** command.

84830 **Copy Command**

84831 *Synopsis*: `(.,.)t`*`address`*

84832 The **t** command shall be equivalent to the **m** command, except that a copy of the addressed lines
84833 shall be placed after address *address* (which can be 0); the current line number shall be set to the
84834 address of the last line added.

84835 **Undo Command**

84836 *Synopsis*: `u`

84837 The **u** command shall nullify the effect of the most recent command that modified anything in
84838 the buffer, namely the most recent **a**, **c**, **d**, **g**, **i**, **j**, **m**, **r**, **s**, **t**, **u**, **v**, **G**, or **V** command. All changes
84839 made to the buffer by a **g**, **G**, **v**, or **V** global command shall be undone as a single change; if no
84840 changes were made by the global command (such as with **g**/RE/**p**), the **u** command shall have
84841 no effect. The current line number shall be set to the value it had immediately before the
84842 command being undone started.

84843 **Global Non-Matched Command**

84844 *Synopsis*: `(1,$)v/`*`RE/command list`*

84845 This command shall be equivalent to the global command **g** except that the lines that are marked
84846 during the first step shall be those for which the line excluding the terminating <newline> does
84847 not match the RE.

84848 **Interactive Global Not-Matched Command**

84849 *Synopsis*: `(1,$)V/`*`RE/`*

84850 This command shall be equivalent to the interactive global command **G** except that the lines that
84851 are marked during the first step shall be those for which the line excluding the terminating
84852 <newline> does not match the RE.

84853 **Write Command**

84854 *Synopsis*: `(1,$)w [`*`file`*`]`

84855 The **w** command shall write the addressed lines into the file named by the pathname *file*. The
84856 command shall create the file, if it does not exist, or shall replace the contents of the existing file.
84857 The currently remembered pathname shall not be changed unless there is no remembered
84858 pathname. If no pathname is given, the currently remembered pathname, if any, shall be used
84859 (see the **e** and **f** commands); the current line number shall be unchanged. If the command is
84860 successful, the number of bytes written shall be written to standard output, unless the **–s** option
84861 was specified, in the following format:

84862 `"%d\n", <number of bytes written>`

84863 If *file* begins with `'!'`, the rest of the line shall be taken to be a shell command line whose
84864 standard input shall be the addressed lines. Such a shell command line shall not be remembered
84865 as the current pathname. This usage of the write command with `'!'` shall not be considered as a
84866 "last **w** command that wrote the entire buffer", as described previously; thus, this alone shall
84867 not prevent the warning to the user if an attempt is made to destroy the editor buffer via the **e** or
84868 **q** commands.

84869 **Line Number Command**

84870 *Synopsis*: `($)=`

84871 The line number of the addressed line shall be written to standard output in the following
84872 format:

84873 `"%d\n", <line number>`

84874 The current line number shall be unchanged by this command.

84875 **Shell Escape Command**

84876 *Synopsis*: `!command`

84877 The remainder of the line after the `'!'` shall be sent to the command interpreter to be
84878 interpreted as a shell command line. Within the text of that shell command line, the unescaped
84879 character `'%'` shall be replaced with the remembered pathname; if a `'!'` appears as the first
84880 character of the command, it shall be replaced with the text of the previous shell command
84881 executed via `'!'`. Thus, `"!!"` shall repeat the previous !*command*. If any replacements of `'%'` or
84882 `'!'` are performed, the modified line shall be written to the standard output before *command* is
84883 executed. The **!** command shall write:

84884 `"!\n"`

84885 to standard output upon completion, unless the **–s** option is specified. The current line number
84886 shall be unchanged.

84887 **Null Command**

84888 *Synopsis*: `(.+1)`

84889 An address alone on a line shall cause the addressed line to be written. A <newline> alone shall
84890 be equivalent to `"+1p"`. The current line number shall be set to the address of the written line.

84891 **EXIT STATUS**

84892 The following exit values shall be returned:

84893 0 Successful completion without any file or command errors.

84894 >0 An error occurred.

84895 **CONSEQUENCES OF ERRORS**

84896 When an error in the input script is encountered, or when an error is detected that is a
84897 consequence of the data (not) present in the file or due to an external condition such as a read or
84898 write error:

84899 • If the standard input is a terminal device file, all input shall be flushed, and a new
84900 command read.

- If the standard input is a regular file, *ed* shall terminate with a non-zero exit status.

APPLICATION USAGE

Because of the extremely terse nature of the default error messages, the prudent script writer begins the *ed* input commands with an **H** command, so that if any errors do occur at least some clue as to the cause is made available.

In earlier versions of this standard, an obsolescent – option was described. This is no longer specified. Applications should use the –**s** option. Using – as a *file* operand now produces unspecified results. This allows implementations to continue to support the former required behavior.

EXAMPLES

None.

RATIONALE

The initial description of this utility was adapted from the SVID. It contains some features not found in Version 7 or BSD-derived systems. Some of the differences between the POSIX and BSD *ed* utilities include, but need not be limited to:

- The BSD – option does not suppress the `'!'` prompt after a **!** command.
- BSD does not support the special meanings of the `'%'` and `'!'` characters within a **!** command.
- BSD does not support the *addresses* `';'` and `','`.
- BSD allows the command/suffix pairs **pp**, **ll**, and so on, which are unspecified in this volume of POSIX.1-200x.
- BSD does not support the `'!'` character part of the **e**, **r**, or **w** commands.
- A failed **g** command in BSD sets the line number to the last line searched if there are no matches.
- BSD does not default the *command list* to the **p** command.
- BSD does not support the **G**, **h**, **H**, **n**, or **V** commands.
- On BSD, if there is no inserted text, the insert command changes the current line to the referenced line –1; that is, the line before the specified line.
- On BSD, the *join* command with only a single address changes the current line to that address.
- BSD does not support the **P** command; moreover, in BSD it is synonymous with the **p** command.
- BSD does not support the *undo* of the commands **j**, **m**, **r**, **s**, or **t**.
- The Version 7 *ed* command **W**, and the BSD *ed* commands **W**, **wq**, and **z** are not present in this volume of POSIX.1-200x.

The –**s** option was added to allow the functionality of the removed – option in a manner compatible with the Utility Syntax Guidelines.

In early proposals there was a limit, {ED_FILE_MAX}, that described the historical limitations of some *ed* utilities in their handling of large files; some of these have had problems with files larger than 100 000 bytes. It was this limitation that prompted much of the desire to include a *split* command in this volume of POSIX.1-200x. Since this limit was removed, this volume of POSIX.1-200x requires that implementations document the file size limits imposed by *ed* in the

conformance document. The limit {ED_LINE_MAX} was also removed; therefore, the global limit {LINE_MAX} is used for input and output lines.

The manner in which the **l** command writes non-printable characters was changed to avoid the historical backspace-overstrike method. On video display terminals, the overstrike is ambiguous because most terminals simply replace overstruck characters, making the **l** format not useful for its intended purpose of unambiguously understanding the content of the line. The historical <backslash>-escapes were also ambiguous. (The string `"a\0011"` could represent a line containing those six characters or a line containing the three characters `'a'`, a byte with a binary value of 1, and a 1.) In the format required here, a <backslash> appearing in the line is written as `"\\"` so that the output is truly unambiguous. The method of marking the ends of lines was adopted from the *ex* editor and is required for any line ending in <space> characters; the `'$'` is placed on all lines so that a real `'$'` at the end of a line cannot be misinterpreted.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

The description of how a NUL is written was removed. The NUL character cannot be in text files, and this volume of POSIX.1-200x should not dictate behavior in the case of undefined, erroneous input.

Unlike some of the other editing utilities, the filenames accepted by the **E**, **e**, **R**, and **r** commands are not patterns.

Early proposals stated that the **–p** option worked only when standard input was associated with a terminal device. This has been changed to conform to historical implementations, thereby allowing applications to interpose themselves between a user and the *ed* utility.

The form of the substitute command that uses the **n** suffix was limited in some historical documentation (where this was described incorrectly as "backreferencing"). This limit has been omitted because there is no reason why an editor processing lines of {LINE_MAX} length should have this restriction. The command **s/x/X/2047** should be able to substitute the 2 047th occurrence of `'x'` on a line.

The use of printing commands with printing suffixes (such as **pn**, **lp**, and so on) was made unspecified because BSD-based systems allow this, whereas System V does not.

Some BSD-based systems exit immediately upon receipt of end-of-file if all of the lines in the file have been deleted. Since this volume of POSIX.1-200x refers to the **q** command in this instance, such behavior is not allowed.

Some historical implementations returned exit status zero even if command errors had occurred; this is not allowed by this volume of POSIX.1-200x.

Some historical implementations contained a bug that allowed a single <period> to be entered in input mode as <backslash> <period> <newline>. This is not allowed by *ed* because there is no description of escaping any of the characters in input mode; <backslash> characters are entered into the buffer exactly as typed. The typical method of entering a single <period> has been to precede it with another character and then use the substitute command to delete that character.

It is difficult under some modes of some versions of historical operating system terminal drivers to distinguish between an end-of-file condition and terminal disconnect. POSIX.1-200x does not require implementations to distinguish between the two situations, which permits historical implementations of the *ed* utility on historical platforms to conform. Implementations are encouraged to distinguish between the two, if possible, and take appropriate action on terminal disconnect.

Historically, *ed* accepted a zero address for the **a** and **r** commands in order to insert text at the

start of the edit buffer. When the buffer was empty the command **.=** returned zero. POSIX.1-200x requires conformance to historical practice.

For consistency with the **a** and **r** commands and better user functionality, the **i** and **c** commands must also accept an address of 0, in which case 0*i* is treated as 1*i* and likewise for the **c** command.

All of the following are valid addresses:

`+++`	Three lines after the current line.
`/pattern/–`	One line before the next occurrence of pattern.
`–2`	Two lines before the current line.
`3 ---- 2`	Line one (note the intermediate negative address).
`1 2 3`	Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the <semicolon> delimiter, permits users to create commands based on ordered patterns in the file. For example, the command `"3;/foo/;+2p"` will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address `"3;"` must still be evaluated before being discarded, because the search origin for the `"/foo/"` command depends on this.

Historically, *ed* disallowed address chains, as discussed above, consisting solely of <comma> or <semicolon> separators; for example, `",,,"` or `";;;"` were considered an error. For consistency of address specification, this restriction is removed. The following table lists some of the address forms now possible:

Address	Addr1	Addr2	Status	Comment
`7,`	`7`	`7`	Historical	
`7,5,`	`5`	`5`	Historical	
`7,5,9`	`5`	`9`	Historical	
`7,9`	`7`	`9`	Historical	
`7,+`	`7`	`8`	Historical	
`,`	`1`	`$`	Historical	
`,7`	`1`	`7`	Extension	
`,,`	`$`	`$`	Extension	
`,;`	`$`	`$`	Extension	
`7;`	`7`	`7`	Historical	
`7;5;`	`5`	`5`	Historical	
`7;5;9`	`5`	`9`	Historical	
`7;5,9`	`5`	`9`	Historical	
`7;$;4`	`$`	`4`	Historical	Valid, but erroneous.
`7;9`	`7`	`9`	Historical	
`7;+`	`7`	`8`	Historical	
`;`	`.`	`$`	Historical	
`;7`	`.`	`7`	Extension	
`;;`	`$`	`$`	Extension	
`;,`	`$`	`$`	Extension	

Historically, *ed* accepted the `'^'` character as an address, in which case it was identical to the <hyphen> character. POSIX.1-200x does not require or prohibit this behavior.

FUTURE DIRECTIONS

None.

XBD Table 5-1 (on page 121), Chapter 8 (on page 173), Section 9.3 (on page 183), Chapter 11 (on page 199), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the OPTIONS section, the meaning of **–s** and – is clarified.

A second FUTURE DIRECTION is added.

Issue 6

The obsolescent single-minus form is removed.

A second APPLICATION USAGE note is added.

The Open Group Corrigendum U025/2 is applied, correcting the description of the Edit section.

The *ed* utility is updated to align with the IEEE P1003.2b draft standard. This includes addition of the treatment of the SIGQUIT signal, changes to *ed* addressing, and changes to processing when end-of-file is detected and when terminal disconnect is detected.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/22 is applied, adding the text: "Any line modified by the *command list* shall be unmarked." to the **G** command. This change corresponds to a similar change made to the **g** command in the first version of this standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/7 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if an operand is '–'.

Austin Group Interpretation 1003.1-2001 #036 is applied, clarifying the behavior for BREs.

SD5-XCU-ERN-94 is applied, updating text in the EXTENDED DESCRIPTION where a terminal disconnect is detected (in Commands in *ed*).

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-135 is applied, removing some RATIONALE text that is no longer applicable.

85066 **NAME**

85067 env — set the environment for command invocation

85068 **SYNOPSIS**

85069 `env [–i] [name=value]... [utility [argument...]]`

85070 **DESCRIPTION**

85071 The *env* utility shall obtain the current environment, modify it according to its arguments, then
85072 invoke the utility named by the *utility* operand with the modified environment.

85073 Optional arguments shall be passed to *utility*.

85074 If no *utility* operand is specified, the resulting environment shall be written to the standard
85075 output, with one *name=value* pair per line.

85076 If the first argument is `'–'`, the results are unspecified.

85077 **OPTIONS**

85078 The *env* utility shall conform to XBD Section 12.2 (on page 215), except for the unspecified usage
85079 of `'–'`.

85080 The following options shall be supported:

85081 **–i** Invoke *utility* with exactly the environment specified by the arguments; the
85082 inherited environment shall be ignored completely.

85083 **OPERANDS**

85084 The following operands shall be supported:

85085 *name=value* Arguments of the form *name=value* shall modify the execution environment, and
85086 shall be placed into the inherited environment before the *utility* is invoked.

85087 *utility* The name of the utility to be invoked. If the *utility* operand names any of the
85088 special built-in utilities in Section 2.14 (on page 2334), the results are undefined.

85089 *argument* A string to pass as an argument for the invoked utility.

85090 **STDIN**

85091 Not used.

85092 **INPUT FILES**

85093 None.

85094 **ENVIRONMENT VARIABLES**

85095 The following environment variables shall affect the execution of *env*:

85096 *LANG* Provide a default value for the internationalization variables that are unset or null.
85097 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
85098 variables used to determine the values of locale categories.)

85099 *LC_ALL* If set to a non-empty string value, override the values of all the other
85100 internationalization variables.

85101 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
85102 characters (for example, single-byte as opposed to multi-byte characters in
85103 arguments).

85104 *LC_MESSAGES*

85105 Determine the locale that should be used to affect the format and contents of
85106 diagnostic messages written to standard error.

85107 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

85108 *PATH* Determine the location of the *utility*, as described in XBD Chapter 8 (on page 173).
85109 If *PATH* is specified as a *name=value* operand to *env*, the *value* given shall be used in
85110 the search for *utility*.

85111 **ASYNCHRONOUS EVENTS**

85112 Default.

85113 **STDOUT**

85114 If no *utility* operand is specified, each *name=value* pair in the resulting environment shall be
85115 written in the form:

85116 `"%s=%s\n", <name>, <value>`

85117 If the *utility* operand is specified, the *env* utility shall not write to standard output.

85118 **STDERR**

85119 The standard error shall be used only for diagnostic messages.

85120 **OUTPUT FILES**

85121 None.

85122 **EXTENDED DESCRIPTION**

85123 None.

85124 **EXIT STATUS**

85125 If *utility* is invoked, the exit status of *env* shall be the exit status of *utility*; otherwise, the *env*
85126 utility shall exit with one of the following values:

85127 0 The *env* utility completed successfully.

85128 1–125 An error occurred in the *env* utility.

85129 126 The utility specified by *utility* was found but could not be invoked.

85130 127 The utility specified by *utility* could not be found.

85131 **CONSEQUENCES OF ERRORS**

85132 Default.

85133 **APPLICATION USAGE**

85134 The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if
85135 an error occurs so that applications can distinguish "failure to find a utility" from "invoked
85136 utility exited with an error indication". The value 127 was chosen because it is not commonly
85137 used for other meanings; most utilities use small values for "normal error conditions" and the
85138 values above 128 can be confused with termination due to receipt of a signal. The value 126 was
85139 chosen in a similar manner to indicate that the utility could be found, but not invoked. Some
85140 scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction
85141 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to
85142 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for
85143 any other reason.

85144 Historical implementations of the *env* utility use the *execvp*( ) or *execlp*( ) functions defined in the
85145 System Interfaces volume of POSIX.1-200x to invoke the specified utility; this provides better
85146 performance and keeps users from having to escape characters with special meaning to the shell.
85147 Therefore, shell functions, special built-ins, and built-ins that are only provided by the shell are
85148 not found.

EXAMPLES

The following command:

```
env –i PATH=/mybin:"$PATH" $(getconf V7_ENV) mygrep xyz myfile
```

invokes the command *mygrep* with a new *PATH* value as the only entry in its environment other than any variables required by the implementation for conformance. In this case, *PATH* is used to locate *mygrep*, which is expected to reside in **/mybin**.

RATIONALE

As with all other utilities that invoke other utilities, this volume of POSIX.1-200x only specifies what *env* does with standard input, standard output, standard error, input files, and output files. If a utility is executed, it is not constrained by the specification of input and output by *env*.

The **–i** option was added to allow the functionality of the removed – option in a manner compatible with the Utility Syntax Guidelines. It is possible to create a non-conforming environment using the **–i** option, as it may remove environment variables required by the implementation for conformance. The following will preserve these environment variables as well as preserve the *PATH* for conforming utilities:

```
IFS='
'
# The preceding value should be <space><tab><newline>.
# Set IFS to its default value.

set –f
# disable pathname expansion

\unalias –a
# Unset all possible aliases.
# Note that unalias is escaped to prevent an alias
# being used for unalias.
# This step is not strictly necessary, since aliases are not inherited,
# and the ENV environment variable is only used by interactive shells,
# the only way any aliases can exist in a script is if it defines them
# itself.

unset –f env getconf
# Ensure env and getconf are not user functions.

env –i $(getconf V7_ENV) PATH="$(getconf PATH)" command
```

Some have suggested that *env* is redundant since the same effect is achieved by:

```
name=value ... utility [ argument ... ]
```

The example is equivalent to *env* when an environment variable is being added to the environment of the command, but not when the environment is being set to the given value. The *env* utility also writes out the current environment if invoked without arguments. There is sufficient functionality beyond what the example provides to justify inclusion of *env*.

FUTURE DIRECTIONS

None.

Section 2.14 (on page 2334), Section 2.5 (on page 2301)

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first argument is '–'.

Austin Group Interpretation 1003.1-2001 #047 is applied, providing RATIONALE on how to use the *env* utility to preserve a conforming environment.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The EXAMPLES section is revised to change the use of *env* **–i**.

85201 **NAME**

85202 ex — text editor

85203 **SYNOPSIS**

85204 UP `ex [-rR] [-s|-v] [-c command] [-t tagstring] [-w size] [file...]`

85205 **DESCRIPTION**

85206 The *ex* utility is a line-oriented text editor. There are two other modes of the editor—open and
85207 visual—in which screen-oriented editing is available. This is described more fully by the *ex* **open**
85208 and **visual** commands and in *vi*.

85209 If an operand is `'-'`, the results are unspecified.

85210 This section uses the term *edit buffer* to describe the current working text. No specific
85211 implementation is implied by this term. All editing changes are performed on the edit buffer,
85212 and no changes to it shall affect any file until an editor command writes the file.

85213 Certain terminals do not have all the capabilities necessary to support the complete *ex* definition,
85214 such as the full-screen editing commands (*visual mode* or *open mode*). When these commands
85215 cannot be supported on such terminals, this condition shall not produce an error message such
85216 as "not an editor command" or report a syntax error. The implementation may either accept the
85217 commands and produce results on the screen that are the result of an unsuccessful attempt to
85218 meet the requirements of this volume of POSIX.1-200x or report an error describing the terminal-
85219 related deficiency.

85220 **OPTIONS**

85221 The *ex* utility shall conform to XBD Section 12.2 (on page 215), except for the unspecified usage
85222 of `'-'`, and that `'+'` may be recognized as an option delimiter as well as `'-'`.

85223 The following options shall be supported:

85224 **-c** *command* Specify an initial command to be executed in the first edit buffer loaded from an
85225 existing file (see the EXTENDED DESCRIPTION section). Implementations may
85226 support more than a single **-c** option. In such implementations, the specified
85227 commands shall be executed in the order specified on the command line.

85228 **-r** Recover the named files (see the EXTENDED DESCRIPTION section). Recovery
85229 information for a file shall be saved during an editor or system crash (for example,
85230 when the editor is terminated by a signal which the editor can catch), or after the
85231 use of an *ex* **preserve** command.

85232 A *crash* in this context is an unexpected failure of the system or utility that requires
85233 restarting the failed system or utility. A system crash implies that any utilities
85234 running at the time also crash. In the case of an editor or system crash, the number
85235 of changes to the edit buffer (since the most recent **preserve** command) that will be
85236 recovered is unspecified.

85237 If no *file* operands are given and the **-t** option is not specified, all other options, the
85238 *EXINIT* variable, and any **.exrc** files shall be ignored; a list of all recoverable files
85239 available to the invoking user shall be written, and the editor shall exit normally
85240 without further action.

85241 **-R** Set **readonly** edit option.

85242 **-s** Prepare *ex* for batch use by taking the following actions:

- Suppress writing prompts and informational (but not diagnostic) messages.
- Ignore the value of *TERM* and any implementation default terminal type and assume the terminal is a type incapable of supporting open or visual modes; see the **visual** command and the description of *vi*.
- Suppress the use of the *EXINIT* environment variable and the reading of any **.exrc** file; see the EXTENDED DESCRIPTION section.
- Suppress autoindentation, ignoring the value of the **autoindent** edit option.

−t *tagstring* Edit the file containing the specified *tagstring*; see *ctags*. The tags feature represented by **−t** *tagstring* and the **tag** command is optional. It shall be provided on any system that also provides a conforming implementation of *ctags*; otherwise, the use of **−t** produces undefined results. On any system, it shall be an error to specify more than a single **−t** option.

−v Begin in visual mode (see *vi*).

−w *size* Set the value of the *window* editor option to *size*.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be edited.

STDIN

The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section. The implementation may limit each line of standard input to a length of {LINE_MAX}.

If the standard input is not a terminal device, it shall be as if the **−s** option had been specified.

If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

INPUT FILES

Input files shall be text files or files that would be text files except for an incomplete last line that is not longer than {LINE_MAX}−1 bytes in length and contains no NUL characters. By default, any incomplete last line shall be treated as if it had a trailing <newline>. The editing of other forms of files may optionally be allowed by *ex* implementations.

The **.exrc** files and source files shall be text files consisting of *ex* commands; see the EXTENDED DESCRIPTION section.

By default, the editor shall read lines from the files to be edited without interpreting any of those lines as any form of editor command.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ex*:

COLUMNS Override the system-selected horizontal screen size. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null.

EXINIT Determine a list of *ex* commands that are executed on editor start-up. See the EXTENDED DESCRIPTION section for more details of the initialization phase.

HOME Determine a pathname of a directory that shall be searched for an editor start-up file named **.exrc**; see the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the classification of characters as uppercase or lowercase letters, the case conversion of letters, and the detection of word boundaries.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful and the vertical screen size in visual mode. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path for the shell command specified in the *ex* editor commands **!**, **shell**, **read**, and **write**, and the open and visual mode command **!**; see the description of command search and execution in Section 2.9.1.1 (on page 2317).

SHELL Determine the preferred command line interpreter for use as the default value of the **shell** edit option.

TERM Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

ASYNCHRONOUS EVENTS

The following term is used in this and following sections to specify command and asynchronous event actions:

complete write
A complete write is a write of the entire contents of the edit buffer to a file of a type other than a terminal device, or the saving of the edit buffer caused by the user executing the *ex* **preserve** command. Writing the contents of the edit buffer to a temporary file that will be removed when the editor exits shall not be considered a complete write.

The following actions shall be taken upon receipt of signals:

SIGINT If the standard input is not a terminal device, *ex* shall not write the file or return to command or text input mode, and shall exit with a non-zero exit status.

Otherwise, if executing an open or visual text input mode command, *ex* in receipt of SIGINT shall behave identically to its receipt of the <ESC> character.

Otherwise:

1. If executing an *ex* text input mode command, all input lines that have been completely entered shall be resolved into the edit buffer, and any partially entered line shall be discarded.
2. If there is a currently executing command, it shall be aborted and a message displayed. Unless otherwise specified by the *ex* or *vi* command descriptions, it is unspecified whether any lines modified by the executing command appear modified, or as they were before being modified by the executing command, in the buffer.

   If the currently executing command was a motion command, its associated command shall be discarded.
3. If in open or visual command mode, the terminal shall be alerted.
4. The editor shall then return to command mode.

SIGCONT The screen shall be refreshed if in open or visual mode.

SIGHUP If the edit buffer has been modified since the last complete write, *ex* shall attempt to save the edit buffer so that it can be recovered later using the **–r** option or the *ex* **recover** command. The editor shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

SIGTERM Refer to SIGHUP.

The action taken for all other signals is unspecified.

STDOUT

The standard output shall be used only for writing prompts to the user, for informational messages, and for writing lines from the file.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output from *ex* shall be text files.

EXTENDED DESCRIPTION

Only the *ex* mode of the editor is described in this section. See *vi* for additional editing capabilities available in *ex*.

When an error occurs, *ex* shall write a message. If the terminal supports a standout mode (such as inverse video), the message shall be written in standout mode. If the terminal does not support a standout mode, and the edit option **errorbells** is set, an alert action shall precede the error message.

By default, *ex* shall start in command mode, which shall be indicated by a **:** prompt; see the **prompt** command. Text input mode can be entered by the **append**, **insert**, or **change** commands; it can be exited (and command mode re-entered) by typing a <period> (`'.'`) alone at the beginning of a line.

85363 **Initialization in ex and vi**

85364 The following symbols are used in this and following sections to specify locations in the edit
85365 buffer:

85366 *alternate and current pathnames*
85367 Two pathnames, named *current* and *alternate*, are maintained by the editor. Any *ex*
85368 commands that take filenames as arguments shall set them as follows:

85369 1. If a *file* argument is specified to the *ex* **edit**, **ex**, or **recover** commands, or if an *ex* **tag**
85370 command replaces the contents of the edit buffer.

85371 a. If the command replaces the contents of the edit buffer, the current pathname
85372 shall be set to the *file* argument or the file indicated by the tag, and the
85373 alternate pathname shall be set to the previous value of the current pathname.

85374 b. Otherwise, the alternate pathname shall be set to the *file* argument.

85375 2. If a *file* argument is specified to the *ex* **next** command:

85376 a. If the command replaces the contents of the edit buffer, the current pathname
85377 shall be set to the first *file* argument, and the alternate pathname shall be set to
85378 the previous value of the current pathname.

85379 3. If a *file* argument is specified to the *ex* **file** command, the current pathname shall be
85380 set to the *file* argument, and the alternate pathname shall be set to the previous value
85381 of the current pathname.

85382 4. If a *file* argument is specified to the *ex* **read** and **write** commands (that is, when
85383 reading or writing a file, and not to the program named by the **shell** edit option), or a
85384 *file* argument is specified to the *ex* **xit** command:

85385 a. If the current pathname has no value, the current pathname shall be set to the
85386 *file* argument.

85387 b. Otherwise, the alternate pathname shall be set to the *file* argument.

85388 If the alternate pathname is set to the previous value of the current pathname when the
85389 current pathname had no previous value, then the alternate pathname shall have no value
85390 as a result.

85391 *current line*
85392 The line of the edit buffer referenced by the cursor. Each command description specifies the
85393 current line after the command has been executed, as the *current line value*. When the edit
85394 buffer contains no lines, the current line shall be zero; see Addressing in ex (on page 2644).

85395 *current column*
85396 The current display line column occupied by the cursor. (The columns shall be numbered
85397 beginning at 1.) Each command description specifies the current column after the command
85398 has been executed, as the *current column* value. This column is an *ideal* column that is
85399 remembered over the lifetime of the editor. The actual display line column upon which the
85400 cursor rests may be different from the current column; see the cursor positioning discussion
85401 in Command Descriptions in vi (on page 3310).

85402 *set to non-<blank>*
85403 A description for a current column value, meaning that the current column shall be set to
85404 the last display line column on which is displayed any part of the first non-<blank> of the
85405 line. If the line has no non-<blank> non-<newline> characters, the current column shall be
85406 set to the last display line column on which is displayed any part of the last non-<newline>

85407 character in the line. If the line is empty, the current column shall be set to column position
85408 1.

85409 The length of lines in the edit buffer may be limited to {LINE_MAX} bytes. In open and visual
85410 mode, the length of lines in the edit buffer may be limited to the number of characters that will
85411 fit in the display. If either limit is exceeded during editing, an error message shall be written. If
85412 either limit is exceeded by a line read in from a file, an error message shall be written and the
85413 edit session may be terminated.

85414 If the editor stops running due to any reason other than a user command, and the edit buffer has
85415 been modified since the last complete write, it shall be equivalent to a SIGHUP asynchronous
85416 event. If the system crashes, it shall be equivalent to a SIGHUP asynchronous event.

85417 During initialization (before the first file is copied into the edit buffer or any user commands
85418 from the terminal are processed) the following shall occur:

85419 1. If the environment variable *EXINIT* is set, the editor shall execute the *ex* commands
85420 contained in that variable.

85421 2. If the *EXINIT* variable is not set, and all of the following are true:

85422 a. The *HOME* environment variable is not null and not empty.

85423 b. The file **.exrc** in the directory referred to by the *HOME* environment variable:

85424 i. Exists

85425 ii. Is owned by the same user ID as the real user ID of the process or the
85426 process has appropriate privileges

85427 iii. Is not writable by anyone other than the owner

85428 the editor shall execute the *ex* commands contained in that file.

85429 3. If and only if all of the following are true:

85430 a. The current directory is not referred to by the *HOME* environment variable.

85431 b. A command in the *EXINIT* environment variable or a command in the **.exrc** file in
85432 the directory referred to by the *HOME* environment variable sets the editor option
85433 **exrc**.

85434 c. The **.exrc** file in the current directory:

85435 i. Exists

85436 ii. Is owned by the same user ID as the real user ID of the process, or by one of
85437 a set of implementation-defined user IDs

85438 iii. Is not writable by anyone other than the owner

85439 the editor shall attempt to execute the *ex* commands contained in that file.

85440 Lines in any **.exrc** file that are blank lines shall be ignored. If any **.exrc** file exists, but is not read
85441 for ownership or permission reasons, it shall be an error.

85442 After the *EXINIT* variable and any **.exrc** files are processed, the first file specified by the user
85443 shall be edited, as follows:

85444 1. If the user specified the **−t** option, the effect shall be as if the *ex* **tag** command was entered
85445 with the specified argument, with the exception that if tag processing does not result in a
85446 file to edit, the effect shall be as described in step 3. below.

2. Otherwise, if the user specified any command line *file* arguments, the effect shall be as if the *ex* **edit** command was entered with the first of those arguments as its *file* argument.

3. Otherwise, the effect shall be as if the *ex* **edit** command was entered with a nonexistent filename as its *file* argument. It is unspecified whether this action shall set the current pathname. In an implementation where this action does not set the current pathname, any editor command using the current pathname shall fail until an editor command sets the current pathname.

If the −**r** option was specified, the first time a file in the initial argument list or a file specified by the −**t** option is edited, if recovery information has previously been saved about it, that information shall be recovered and the editor shall behave as if the contents of the edit buffer have already been modified. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. If no recovery information about a file is available, an informational message to this effect shall be written, and the edit shall proceed as usual.

If the −**c** option was specified, the first time a file that already exists (including a file that might not exist but for which recovery information is available, when the −**r** option is specified) replaces or initializes the contents of the edit buffer, the current line shall be set to the last line of the edit buffer, the current column shall be set to non-<blank>, and the *ex* commands specified with the −**c** option shall be executed. In this case, the current line and current column shall not be set as described for the command associated with the replacement or initialization of the edit buffer contents. However, if the −**t** option or a **tag** command is associated with this action, the −**c** option commands shall be executed and then the movement to the tag shall be performed.

The current argument list shall initially be set to the filenames specified by the user on the command line. If no filenames are specified by the user, the current argument list shall be empty. If the −**t** option was specified, it is unspecified whether any filename resulting from tag processing shall be prepended to the current argument list. In the case where the filename is added as a prefix to the current argument list, the current argument list reference shall be set to that filename. In the case where the filename is not added as a prefix to the current argument list, the current argument list reference shall logically be located before the first of the filenames specified on the command line (for example, a subsequent *ex* **next** command shall edit the first filename from the command line). If the −**t** option was not specified, the current argument list reference shall be to the first of the filenames on the command line.

Addressing in ex

Addressing in *ex* relates to the current line and the current column; the address of a line is its 1-based line number, the address of a column is its 1-based count from the beginning of the line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. In each command description, the effect of the command on the current line number and the current column is described.

Addresses are constructed as follows:

1. The character `'.'` (period) shall address the current line.

2. The character `'$'` shall address the last line of the edit buffer.

3. The positive decimal number *n* shall address the *n*th line of the edit buffer.

4. The address `"'x"` refers to the line marked with the mark name character `'x'`, which shall be a lowercase letter from the portable character set, the backquote character, or the single-quote character. It shall be an error if the line that was marked is not currently

present in the edit buffer or the mark has not been set. Lines can be marked with the *ex* **mark** or **k** commands, or the *vi* **m** command.

5. A regular expression enclosed by <slash> characters (`'/'`) shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. As stated in Regular Expressions in ex (on page 2675), an address consisting of a null regular expression delimited by <slash> characters (`"//"`) shall address the next line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second <slash> can be omitted at the end of a command line. If the **wrapscan** edit option is set, the search shall wrap around to the beginning of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence `"\/"` shall represent a literal <slash> instead of the regular expression delimiter.

6. A regular expression enclosed in <question-mark> characters (`'?'`) shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. An address consisting of a null regular expression delimited by <question-mark> characters (`"??"`) shall address the previous line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second <question-mark> can be omitted at the end of a command line. If the **wrapscan** edit option is set, the search shall wrap around from the beginning of the edit buffer to the end of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence `"\?"` shall represent a literal <question-mark> instead of the RE delimiter.

7. A <plus-sign> (`'+'`) or a minus-sign (`'-'`) followed by a decimal number shall address the current line plus or minus the number. A `'+'` or `'-'` not followed by a decimal number shall address the current line plus or minus 1.

Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:

1. A `'+'` or `'-'` immediately followed by a decimal number shall add (subtract) the indicated number of lines to (from) the address. A `'+'` or `'-'` not followed by a decimal number shall add (subtract) 1 to (from) the address.

2. A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer.

Commands take zero, one, or two addresses; see the descriptions of *1addr* and *2addr* in Command Descriptions in ex (on page 2651). If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain.

Addresses shall be separated from each other by a <comma> (`','`) or a <semicolon> (`';'`). If no address is specified before or after a <comma> or <semicolon> separator, it shall be as if the address of the current line was specified before or after the separator. In the case of a <semicolon> separator, the current line (`'.'`) shall be set to the first address, and only then will

the next address be calculated. This feature can be used to determine the starting line for forwards and backwards searches (see rules 5. and 6.).

A <percent-sign> (`'%'`) shall be equivalent to entering the two addresses `"1,$"`.

Any delimiting <blank> characters between addresses, address separators, or address offsets shall be discarded.

Command Line Parsing in ex

The following symbol is used in this and following sections to describe parsing behavior:

escape If a character is referred to as "<backslash>-escaped" or "<control>-V-escaped", it shall mean that the character acquired or lost a special meaning by virtue of being preceded, respectively, by a <backslash> or <control>-V character. Unless otherwise specified, the escaping character shall be discarded at that time and shall not be further considered for any purpose.

Command-line parsing shall be done in the following steps. For each step, characters already evaluated shall be ignored; that is, the phrase "leading character" refers to the next character that has not yet been evaluated.

1. Leading <colon> characters shall be skipped.
2. Leading <blank> characters shall be skipped.
3. If the leading character is a double-quote character, the characters up to and including the next non-<backslash>-escaped <newline> shall be discarded, and any subsequent characters shall be parsed as a separate command.
4. Leading characters that can be interpreted as addresses shall be evaluated; see Addressing in ex (on page 2644).
5. Leading <blank> characters shall be skipped.
6. If the next character is a <vertical-line> character or a <newline>:
   a. If the next character is a <newline>:
      i. If *ex* is in open or visual mode, the current line shall be set to the last address specified, if any.
      ii. Otherwise, if the last command was terminated by a <vertical-line> character, no action shall be taken; for example, the command `"||<newline>"` shall execute two implied commands, not three.
      iii. Otherwise, step 6.b. shall apply.
   b. Otherwise, the implied command shall be the **print** command. The last **#**, **p**, and **l** flags specified to any *ex* command shall be remembered and shall apply to this implied command. Executing the *ex* **number**, **print**, or **list** command shall set the remembered flags to **#**, nothing, and **l**, respectively, plus any other flags specified for that execution of the **number**, **print**, or **list** command.

      If *ex* is not currently performing a **global** or **v** command, and no address or count is specified, the current line shall be incremented by 1 before the command is executed. If incrementing the current line would result in an address past the last line in the edit buffer, the command shall fail, and the increment shall not happen.

c. The <newline> or <vertical-line> character shall be discarded and any subsequent characters shall be parsed as a separate command.

7. The command name shall be comprised of the next character (if the character is not alphabetic), or the next character and any subsequent alphabetic characters (if the character is alphabetic), with the following exceptions:

   a. Commands that consist of any prefix of the characters in the command name **delete**, followed immediately by any of the characters `'l'`, `'p'`, `'+'`, `'-'`, or `'#'` shall be interpreted as a **delete** command, followed by a <blank>, followed by the characters that were not part of the prefix of the **delete** command. The maximum number of characters shall be matched to the command name **delete**; for example, `"del"` shall not be treated as `"de"` followed by the flag **l**.

   b. Commands that consist of the character `'k'`, followed by a character that can be used as the name of a mark, shall be equivalent to the mark command followed by a <blank>, followed by the character that followed the `'k'`.

   c. Commands that consist of the character `'s'`, followed by characters that could be interpreted as valid options to the **s** command, shall be the equivalent of the **s** command, without any pattern or replacement values, followed by a <blank>, followed by the characters after the `'s'`.

8. The command name shall be matched against the possible command names, and a command name that contains a prefix matching the characters specified by the user shall be the executed command. In the case of commands where the characters specified by the user could be ambiguous, the executed command shall be as follows:

a	**append**	**n**	**next**	**t**	**t**
c	**change**	**p**	**print**	**u**	**undo**
ch	**change**	**pr**	**print**	**un**	**undo**
e	**edit**	**r**	**read**	**v**	**v**
m	**move**	**re**	**read**	**w**	**write**
ma	**mark**	**s**	**s**		

   Implementation extensions with names causing similar ambiguities shall not be checked for a match until all possible matches for commands specified by POSIX.1-200x have been checked.

9. If the command is a **!** command, or if the command is a **read** command followed by zero or more <blank> characters and a **!**, or if the command is a **write** command followed by one or more <blank> characters and a **!**, the rest of the command shall include all characters up to a non-<backslash>-escaped <newline>. The <newline> shall be discarded and any subsequent characters shall be parsed as a separate *ex* command.

10. Otherwise, if the command is an **edit**, **ex**, or **next** command, or a **visual** command while in open or visual mode, the next part of the command shall be parsed as follows:

    a. Any `'!'` character immediately following the command shall be skipped and be part of the command.

    b. Any leading <blank> characters shall be skipped and be part of the command.

    c. If the next character is a `'+'`, characters up to the first non-<backslash>-escaped <newline> or non-<backslash>-escaped <blank> shall be skipped and be part of the command.

d. The rest of the command shall be determined by the steps specified in paragraph 12.

11. Otherwise, if the command is a **global**, **open**, **s**, or **v** command, the next part of the command shall be parsed as follows:

    a. Any leading <blank> characters shall be skipped and be part of the command.

    b. If the next character is not an alphanumeric, double-quote, <newline>, <backslash>, or <vertical-line> character:

        i. The next character shall be used as a command delimiter.

        ii. If the command is a **global**, **open**, or **v** command, characters up to the first non-<backslash>-escaped <newline>, or first non-<backslash>-escaped delimiter character, shall be skipped and be part of the command.

        iii. If the command is an **s** command, characters up to the first non-<backslash>-escaped <newline>, or second non-<backslash>-escaped delimiter character, shall be skipped and be part of the command.

    c. If the command is a **global** or **v** command, characters up to the first non-<backslash>-escaped <newline> shall be skipped and be part of the command.

    d. Otherwise, the rest of the command shall be determined by the steps specified in paragraph 12.

12. Otherwise:

    a. If the command was a **map**, **unmap**, **abbreviate**, or **unabbreviate** command, characters up to the first non-<control>-V-escaped <newline>, <vertical-line>, or double-quote character shall be skipped and be part of the command.

    b. Otherwise, characters up to the first non-<backslash>-escaped <newline>, <vertical-line>, or double-quote character shall be skipped and be part of the command.

    c. If the command was an **append**, **change**, or **insert** command, and the step 12.b. ended at a <vertical-line> character, any subsequent characters, up to the next non-<backslash>-escaped <newline> shall be used as input text to the command.

    d. If the command was ended by a double-quote character, all subsequent characters, up to the next non-<backslash>-escaped <newline>, shall be discarded.

    e. The terminating <newline> or <vertical-line> character shall be discarded and any subsequent characters shall be parsed as a separate *ex* command.

Command arguments shall be parsed as described by the Synopsis and Description of each individual *ex* command. This parsing shall not be <blank>-sensitive, except for the **!** argument, which must follow the command name without intervening <blank> characters, and where it would otherwise be ambiguous. For example, *count* and *flag* arguments need not be <blank>-separated because `"d22p"` is not ambiguous, but *file* arguments to the *ex* **next** command must be separated by one or more <blank> characters. Any <blank> in command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands can be <control>-V-escaped, in which case the <blank> shall not be used as an argument delimiter. Any <blank> in the command argument for any other command can be <backslash>-escaped, in which case that <blank> shall not be used as an argument delimiter.

Within command arguments for the **abbreviate**, **unabbreviate**, **map**, and **unmap** commands,

any character can be <control>-V-escaped. All such escaped characters shall be treated literally and shall have no special meaning. Within command arguments for all other *ex* commands that are not regular expressions or replacement strings, any character that would otherwise have a special meaning can be <backslash>-escaped. Escaped characters shall be treated literally, without special meaning as shell expansion characters or `'!'`, `'%'`, and `'#'` expansion characters. See Regular Expressions in ex (on page 2675) and Replacement Strings in ex (on page 2676) for descriptions of command arguments that are regular expressions or replacement strings.

Non-<backslash>-escaped `'%'` characters appearing in *file* arguments to any *ex* command shall be replaced by the current pathname; unescaped `'#'` characters shall be replaced by the alternate pathname. It shall be an error if `'%'` or `'#'` characters appear unescaped in an argument and their corresponding values are not set.

Non-<backslash>-escaped `'!'` characters in the arguments to either the *ex* **!** command or the open and visual mode **!** command, or in the arguments to the *ex* **read** command, where the first non-<blank> after the command name is a `'!'` character, or in the arguments to the *ex* **write** command where the command name is followed by one or more <blank> characters and the first non-<blank> after the command name is a `'!'` character, shall be replaced with the arguments to the last of those three commands as they appeared after all unescaped `'%'`, `'#'`, and `'!'` characters were replaced. It shall be an error if `'!'` characters appear unescaped in one of these commands and there has been no previous execution of one of these commands.

If an error occurs during the parsing or execution of an *ex* command:

- An informational message to this effect shall be written. Execution of the *ex* command shall stop, and the cursor (for example, the current line and column) shall not be further modified.
- If the *ex* command resulted from a map expansion, all characters from that map expansion shall be discarded, except as otherwise specified by the **map** command.
- Otherwise, if the *ex* command resulted from the processing of an *EXINIT* environment variable, a **.exrc** file, a **:source** command, a **–c** option, or a **+***command* specified to an *ex* **edit**, **ex**, **next**, or **visual** command, no further commands from the source of the commands shall be executed.
- Otherwise, if the *ex* command resulted from the execution of a buffer or a **global** or **v** command, no further commands caused by the execution of the buffer or the **global** or **v** command shall be executed.
- Otherwise, if the *ex* command was not terminated by a <newline>, all characters up to and including the next non-<backslash>-escaped <newline> shall be discarded.

Input Editing in ex

The following symbol is used in this and the following sections to specify command actions:

word In the POSIX locale, a word consists of a maximal sequence of letters, digits, and underscores, delimited at both ends by characters other than letters, digits, or underscores, or by the beginning or end of a line or the edit buffer.

When accepting input characters from the user, in either *ex* command mode or *ex* text input mode, *ex* shall enable canonical mode input processing, as defined in the System Interfaces volume of POSIX.1-200x.

If in *ex* text input mode:

1. If the **number** edit option is set, *ex* shall prompt for input using the line number that would be assigned to the line if it is entered, in the format specified for the *ex* **number** command.
2. If the **autoindent** edit option is set, *ex* shall prompt for input using **autoindent** characters, as described by the **autoindent** edit option. **autoindent** characters shall follow the line number, if any.

If in *ex* command mode:

1. If the **prompt** edit option is set, input shall be prompted for using a single `':'` character; otherwise, there shall be no prompt.

The input characters in the following sections shall have the following effects on the input line.

Scroll

Synopsis: `eof`

See the description of the *stty eof* character in *stty*.

If in *ex* command mode:

If the *eof* character is the first character entered on the line, the line shall be evaluated as if it contained two characters: a <control>-D and a <newline>.

Otherwise, the *eof* character shall have no special meaning.

If in *ex* text input mode:

If the cursor follows an **autoindent** character, the **autoindent** characters in the line shall be modified so that a part of the next text input character will be displayed on the first column in the line after the previous **shiftwidth** edit option column boundary, and the user shall be prompted again for input for the same line.

Otherwise, if the cursor follows a `'0'`, which follows an **autoindent** character, and the `'0'` was the previous text input character, the `'0'` and all **autoindent** characters in the line shall be discarded, and the user shall be prompted again for input for the same line.

Otherwise, if the cursor follows a `'^'`, which follows an **autoindent** character, and the `'^'` was the previous text input character, the `'^'` and all **autoindent** characters in the line shall be discarded, and the user shall be prompted again for input for the same line. In addition, the **autoindent** level for the next input line shall be derived from the same line from which the **autoindent** level for the current input line was derived.

Otherwise, if there are no **autoindent** or text input characters in the line, the *eof* character shall be discarded.

Otherwise, the *eof* character shall have no special meaning.

85745 **<newline>**

85746 *Synopsis*: `<newline>`
85747 `<control>-J`

85748 If in *ex* command mode:

85749 Cause the command line to be parsed; <control>-J shall be mapped to the <newline> for
85750 this purpose.

85751 If in *ex* text input mode:

85752 Terminate the current line. If there are no characters other than **autoindent** characters on
85753 the line, all characters on the line shall be discarded.

85754 Prompt for text input on a new line after the current line. If the **autoindent** edit option is
85755 set, an appropriate number of **autoindent** characters shall be added as a prefix to the line
85756 as described by the *ex* **autoindent** edit option.

85757 **<backslash>**

85758 *Synopsis*: `<backslash>`

85759 Allow the entry of a subsequent <newline> or <control>-J as a literal character, removing any
85760 special meaning that it may have to the editor during text input mode. The <backslash>
85761 character shall be retained and evaluated when the command line is parsed, or retained and
85762 included when the input text becomes part of the edit buffer.

85763 **<control>-V**

85764 *Synopsis*: `<control>-V`

85765 Allow the entry of any subsequent character as a literal character, removing any special meaning
85766 that it may have to the editor during text input mode. The <control>-V character shall be
85767 discarded before the command line is parsed or the input text becomes part of the edit buffer.

85768 If the "literal next" functionality is performed by the underlying system, it is implementation-
85769 defined whether a character other than <control>-V performs this function.

85770 **<control>-W**

85771 *Synopsis*: `<control>-W`

85772 Discard the <control>-W, and the word previous to it in the input line, including any <blank>
85773 characters following the word and preceding the <control>-W. If the "word erase" functionality
85774 is performed by the underlying system, it is implementation-defined whether a character other
85775 than <control>-W performs this function.

85776 **Command Descriptions in ex**

85777 The following symbols are used in this section to represent command modifiers. Some of these
85778 modifiers can be omitted, in which case the specified defaults shall be used.

85779 *1addr* A single line address, given in any of the forms described in Addressing in ex (on
85780 page 2644); the default shall be the current line (`'.'`), unless otherwise specified.

85781 If the line address is zero, it shall be an error, unless otherwise specified in the
85782 following command descriptions.

If the edit buffer is empty, and the address is specified with a command other than **=**, **append**, **insert**, **open**, **put**, **read**, or **visual**, or the address is not zero, it shall be an error.

2addr Two addresses specifying an inclusive range of lines. If no addresses are specified, the default for *2addr* shall be the current line only (`".,."`), unless otherwise specified in the following command descriptions. If one address is specified, *2addr* shall specify that line only, unless otherwise specified in the following command descriptions.

It shall be an error if the first address is greater than the second address.

If the edit buffer is empty, and the two addresses are specified with a command other than the **!**, **write**, **wq**, or **xit** commands, or either address is not zero, it shall be an error.

count A positive decimal number. If *count* is specified, it shall be equivalent to specifying an additional address to the command, unless otherwise specified by the following command descriptions. The additional address shall be equal to the last address specified to the command (either explicitly or by default) plus *count*−1.

If this would result in an address greater than the last line of the edit buffer, it shall be corrected to equal the last line of the edit buffer.

flags One or more of the characters `'+'`, `'−'`, `'#'`, `'p'`, or `'l'` (ell). The flag characters can be <blank>-separated, and in any order or combination. The characters `'#'`, `'p'`, and `'l'` shall cause lines to be written in the format specified by the **print** command with the specified *flags*.

The lines to be written are as follows:

1. All edit buffer lines written during the execution of the *ex* **&**, **~**, **list**, **number**, **open**, **print**, **s**, **visual**, and **z** commands shall be written as specified by *flags*.
2. After the completion of an *ex* command with a flag as an argument, the current line shall be written as specified by *flags*, unless the current line was the last line written by the command.

The characters `'+'` and `'−'` cause the value of the current line after the execution of the *ex* command to be adjusted by the offset address as described in Addressing in ex (on page 2644). This adjustment shall occur before the current line is written as described in 2. above.

The default for *flags* shall be none.

buffer One of a number of named areas for holding text. The named buffers are specified by the alphanumeric characters of the POSIX locale. There shall also be one "unnamed" buffer. When no buffer is specified for editor commands that use a buffer, the unnamed buffer shall be used. Commands that store text into buffers shall store the text as it was before the command took effect, and shall store text occurring earlier in the file before text occurring later in the file, regardless of how the text region was specified. Commands that store text into buffers shall store the text into the unnamed buffer as well as any specified buffer.

In *ex* commands, buffer names are specified as the name by itself. In open or visual mode commands the name is preceded by a double-quote (`'"'`) character.

If the specified buffer name is an uppercase character, and the buffer contents are to be modified, the buffer shall be appended to rather than being overwritten. If

the buffer is not being modified, specifying the buffer name in lowercase and uppercase shall have identical results.

There shall also be buffers named by the numbers 1 through 9. In open and visual mode, if a region of text including characters from more than a single line is being modified by the *vi* **c** or **d** commands, the motion character associated with the **c** or **d** commands specifies that the buffer text shall be in line mode, or the commands **%**, **'**, **/**, **?**, **(**, **)**, **N**, **n**, {, or } are used to define a region of text for the **c** or **d** commands, the contents of buffers 1 through 8 shall be moved into the buffer named by the next numerically greater value, the contents of buffer 9 shall be discarded, and the region of text shall be copied into buffer 1. This shall be in addition to copying the text into a user-specified buffer or unnamed buffer, or both. Numeric buffers can be specified as a source buffer for open and visual mode commands; however, specifying a numeric buffer as the write target of an open or visual mode command shall have unspecified results.

The text of each buffer shall have the characteristic of being in either line or character mode. Appending text to a non-empty buffer shall set the mode to match the characteristic of the text being appended. Appending text to a buffer shall cause the creation of at least one additional line in the buffer. All text stored into buffers by *ex* commands shall be in line mode. The *ex* commands that use buffers as the source of text specify individually how buffers of different modes are handled. Each open or visual mode command that uses buffers for any purpose specifies individually the mode of the text stored into the buffer and how buffers of different modes are handled.

file Command text used to derive a pathname. The default shall be the current pathname, as defined previously, in which case, if no current pathname has yet been established it shall be an error, except where specifically noted in the individual command descriptions that follow. If the command text contains any of the characters `'~'`, `'{'`, `'['`, `'*'`, `'?'`, `'$'`, `'"'`, backquote, single-quote, and <backslash>, it shall be subjected to the process of "shell expansions", as described below; if more than a single pathname results and the command expects only one, it shall be an error.

The process of shell expansions in the editor shall be done as follows. The *ex* utility shall pass two arguments to the program named by the shell edit option; the first shall be **–c**, and the second shall be the string `"echo"` and the command text as a single argument. The standard output and standard error of that command shall replace the command text.

! A character that can be appended to the command name to modify its operation, as detailed in the individual command descriptions. With the exception of the *ex* **read**, **write**, and **!** commands, the `'!'` character shall only act as a modifier if there are no <blank> characters between it and the command name.

remembered search direction

The *vi* commands **N** and **n** begin searching in a forwards or backwards direction in the edit buffer based on a remembered search direction, which is initially unset, and is set by the *ex* **global**, **v**, **s**, and **tag** commands, and the *vi* **/** and **?** commands.

85872 **Abbreviate**

85873 *Synopsis*: `ab[breviate][lhs rhs]`

85874 If *lhs* and *rhs* are not specified, write the current list of abbreviations and do nothing more.

85875 Implementations may restrict the set of characters accepted in *lhs* or *rhs*, except that printable
85876 characters and <blank> characters shall not be restricted. Additional restrictions shall be
85877 implementation-defined.

85878 In both *lhs* and *rhs*, any character may be escaped with a <control>-V, in which case the character
85879 shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

85880 In open and visual text input mode, if a non-word or <ESC> character that is not escaped by a
85881 <control>-V character is entered after a word character, a check shall be made for a set of
85882 characters matching *lhs*, in the text input entered during this command. If it is found, the effect
85883 shall be as if *rhs* was entered instead of *lhs*.

85884 The set of characters that are checked is defined as follows:

85885 1. If there are no characters inserted before the word and non-word or <ESC> characters
85886 that triggered the check, the set of characters shall consist of the word character.

85887 2. If the character inserted before the word and non-word or <ESC> characters that
85888 triggered the check is a word character, the set of characters shall consist of the characters
85889 inserted immediately before the triggering characters that are word characters, plus the
85890 triggering word character.

85891 3. If the character inserted before the word and non-word or <ESC> characters that
85892 triggered the check is not a word character, the set of characters shall consist of the
85893 characters that were inserted before the triggering characters that are neither <blank>
85894 characters nor word characters, plus the triggering word character.

85895 It is unspecified whether the *lhs* argument entered for the *ex* **abbreviate** and **unabbreviate**
85896 commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the
85897 effect of the command shall be as if the replacement had not occurred.

85898 *Current line*: Unchanged.

85899 *Current column*: Unchanged.

85900 **Append**

85901 *Synopsis*: `[1addr] a[ppend][!]`

85902 Enter *ex* text input mode; the input text shall be placed after the specified line. If line zero is
85903 specified, the text shall be placed at the beginning of the edit buffer.

85904 This command shall be affected by the **number** and **autoindent** edit options; following the
85905 command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the
85906 duration of this command only.

85907 *Current line*: Set to the last input line; if no lines were input, set to the specified line, or to the first
85908 line of the edit buffer if a line of zero was specified, or zero if the edit buffer is empty.

85909 *Current column*: Set to non-<blank>.

85910 **Arguments**

85911 *Synopsis*: `ar[gs]`

85912 Write the current argument list, with the current argument-list entry, if any, between `'['` and
85913 `']'` characters.

85914 *Current line*: Unchanged.

85915 *Current column*: Unchanged.

85916 **Change**

85917 *Synopsis*: `[2addr] c[hange][!][count]`

85918 Enter *ex* text input mode; the input text shall replace the specified lines. The specified lines shall
85919 be copied into the unnamed buffer, which shall become a line mode buffer.

85920 This command shall be affected by the **number** and **autoindent** edit options; following the
85921 command name with `'!'` shall cause the **autoindent** edit option setting to be toggled for the
85922 duration of this command only.

85923 *Current line*: Set to the last input line; if no lines were input, set to the line before the first
85924 address, or to the first line of the edit buffer if there are no lines preceding the first address, or to
85925 zero if the edit buffer is empty.

85926 *Current column*: Set to non-<blank>.

85927 **Change Directory**

85928 *Synopsis*: `chd[ir][!][directory]`
85929 `cd[!][directory]`

85930 Change the current working directory to *directory*.

85931 If no *directory* argument is specified, and the *HOME* environment variable is set to a non-null
85932 and non-empty value, *directory* shall default to the value named in the *HOME* environment
85933 variable. If the *HOME* environment variable is empty or is undefined, the default value of
85934 *directory* is implementation-defined.

85935 If no `'!'` is appended to the command name, and the edit buffer has been modified since the
85936 last complete write, and the current pathname does not begin with a `'/'`, it shall be an error.

85937 *Current line*: Unchanged.

85938 *Current column*: Unchanged.

85939 **Copy**

85940 *Synopsis*: `[2addr] co[py] 1addr [flags]`
85941 `[2addr] t 1addr [flags]`

85942 Copy the specified lines after the specified destination line; line zero specifies that the lines shall
85943 be placed at the beginning of the edit buffer.

85944 *Current line*: Set to the last line copied.

85945 *Current column*: Set to non-<blank>.

85946 **Delete**

85947 *Synopsis*: **[***2addr***] d[elete][***buffer***][***count***][***flags***]**

85948 Delete the specified lines into a buffer (defaulting to the unnamed buffer), which shall become a
85949 line-mode buffer.

85950 Flags can immediately follow the command name; see Command Line Parsing in ex (on page
85951 2646).

85952 *Current line*: Set to the line following the deleted lines, or to the last line in the edit buffer if that
85953 line is past the end of the edit buffer, or to zero if the edit buffer is empty.

85954 *Current column*: Set to non-<blank>.

85955 **Edit**

85956 *Synopsis*: **e[dit][!][+***command***][***file***]**
85957 **ex[!][+***command***][***file***]**

85958 If no **'!'** is appended to the command name, and the edit buffer has been modified since the
85959 last complete write, it shall be an error.

85960 If *file* is specified, replace the current contents of the edit buffer with the current contents of *file*,
85961 and set the current pathname to *file*. If *file* is not specified, replace the current contents of the
85962 edit buffer with the current contents of the file named by the current pathname. If for any reason
85963 the current contents of the file cannot be accessed, the edit buffer shall be empty.

85964 The **+***command* option shall be <blank>-delimited; <blank> characters within the **+***command* can
85965 be escaped by preceding them with a <backslash> character. The **+***command* shall be interpreted
85966 as an *ex* command immediately after the contents of the edit buffer have been replaced and the
85967 current line and column have been set.

85968 If the edit buffer is empty:

85969 *Current line*: Set to 0.

85970 *Current column*: Set to 1.

85971 Otherwise, if executed while in *ex* command mode or if the **+***command* argument is specified:

85972 *Current line*: Set to the last line of the edit buffer.

85973 *Current column*: Set to non-<blank>.

85974 Otherwise, if *file* is omitted or results in the current pathname:

85975 *Current line*: Set to the first line of the edit buffer.

85976 *Current column*: Set to non-<blank>.

85977 Otherwise, if *file* is the same as the last file edited, the line and column shall be set as follows; if
85978 the file was previously edited, the line and column may be set as follows:

85979 *Current line*: Set to the last value held when that file was last edited. If this value is not a valid
85980 line in the new edit buffer, set to the first line of the edit buffer.

85981 *Current column*: If the current line was set to the last value held when the file was last edited, set
85982 to the last value held when the file was last edited. Otherwise, or if the last value is not a valid
85983 column in the new edit buffer, set to non-<blank>.

Otherwise:

Current line: Set to the first line of the edit buffer.

Current column: Set to non-<blank>.

File

Synopsis: **f[ile][***file***]**

If a *file* argument is specified, the alternate pathname shall be set to the current pathname, and the current pathname shall be set to *file*.

Write an informational message. If the file has a current pathname, it shall be included in this message; otherwise, the message shall indicate that there is no current pathname. If the edit buffer contains lines, the current line number and the number of lines in the edit buffer shall be included in this message; otherwise, the message shall indicate that the edit buffer is empty. If the edit buffer has been modified since the last complete write, this fact shall be included in this message. If the **readonly** edit option is set, this fact shall be included in this message. The message may contain other unspecified information.

Current line: Unchanged.

Current column: Unchanged.

Global

Synopsis: **[***2addr***] g[lobal] /***pattern***/ [***commands***]**
[*2addr***] v /***pattern***/ [***commands***]**

The optional '!' character after the **global** command shall be the same as executing the **v** command.

If *pattern* is empty (for example, "//") or not specified, the last regular expression used in the editor command shall be used as the *pattern*. The *pattern* can be delimited by <slash> characters (shown in the Synopsis), as well as any non-alphanumeric or non-<blank> other than <backslash>, <vertical-line>, <newline>, or double-quote.

If no lines are specified, the lines shall default to the entire file.

The **global** and **v** commands are logically two-pass operations. First, mark the lines within the specified lines for which the line excluding the terminating <newline> matches (**global**) or does not match (**v** or **global!**) the specified pattern. Second, execute the *ex* commands given by *commands*, with the current line ('.') set to each marked line. If an error occurs during this process, or the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error message shall be written and no more commands resulting from the execution of this command shall be processed.

Multiple *ex* commands can be specified by entering multiple commands on a single line using a <vertical-line> to delimit them, or one per line, by escaping each <newline> with a <backslash>.

If no commands are specified:

1. If in *ex* command mode, it shall be as if the **print** command were specified.
2. Otherwise, no command shall be executed.

For the **append**, **change**, and **insert** commands, the input text shall be included as part of the command, and the terminating <period> can be omitted if the command ends the list of commands. The **open** and **visual** commands can be specified as one of the commands, in which

case each marked line shall cause the editor to enter open or visual mode. If open or visual mode is exited using the *vi* **Q** command, the current line shall be set to the next marked line, and open or visual mode reentered, until the list of marked lines is exhausted.

The **global**, **v**, and **undo** commands cannot be used in *commands*. Marked lines may be deleted by commands executed for lines occurring earlier in the file than the marked lines. In this case, no commands shall be executed for the deleted lines.

If the remembered search direction is not set, the **global** and **v** commands shall set it to forward.

The **autoprint** and **autoindent** edit options shall be inhibited for the duration of the **g** or **v** command.

Current line: If no commands executed, set to the last marked line. Otherwise, as specified for the executed *ex* commands.

Current column: If no commands are executed, set to non-<blank>; otherwise, as specified for the individual *ex* commands.

Insert

Synopsis: **[***1addr***] i[nsert][!]**

Enter *ex* text input mode; the input text shall be placed before the specified line. If the line is zero or 1, the text shall be placed at the beginning of the edit buffer.

This command shall be affected by the **number** and **autoindent** edit options; following the command name with '**!**' shall cause the **autoindent** edit option setting to be toggled for the duration of this command only.

Current line: Set to the last input line; if no lines were input, set to the line before the specified line, or to the first line of the edit buffer if there are no lines preceding the specified line, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.

Join

Synopsis: **[***2addr***] j[oin][!][***count***][***flags***]**

If *count* is specified:

> If no address was specified, the **join** command shall behave as if *2addr* were the current line and the current line plus *count* (*.*,*.* + *count*).
>
> If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the specified address plus *count* (*addr*,*addr* + *count*).
>
> If two addresses were specified, the **join** command shall behave as if an additional address, equal to the last address plus *count* −1 (*addr1*,*addr2*,*addr2* + *count* −1), was specified.
>
> If this would result in a second address greater than the last line of the edit buffer, it shall be corrected to be equal to the last line of the edit buffer.

If no *count* is specified:

If no address was specified, the **join** command shall behave as if *2addr* were the current line and the next line (.,. +1).

If one address was specified, the **join** command shall behave as if *2addr* were the specified address and the next line (*addr*,*addr* +1).

Join the text from the specified lines together into a single line, which shall replace the specified lines.

If a '!' character is appended to the command name, the **join** shall be without modification of any line, independent of the current locale.

Otherwise, in the POSIX locale, set the current line to the first of the specified lines, and then, for each subsequent line, proceed as follows:

1. Discard leading <space> characters from the line to be joined.
2. If the line to be joined is now empty, delete it, and skip steps 3 through 5.
3. If the current line ends in a <blank>, or the first character of the line to be joined is a ')' character, join the lines without further modification.
4. If the last character of the current line is a '.', join the lines with two <space> characters between them.
5. Otherwise, join the lines with a single <space> between them.

Current line: Set to the first line specified.

Current column: Set to non-<blank>.

List

Synopsis: **[***2addr***] l[ist][***count***][***flags***]**

This command shall be equivalent to the *ex* command:

[*2addr***] p[rint][***count***] l[***flags***]**

See Print (on page 2663).

Map

Synopsis: **map[!][***lhs rhs***]**

If *lhs* and *rhs* are not specified:

1. If '!' is specified, write the current list of text input mode maps.
2. Otherwise, write the current list of command mode maps.
3. Do nothing more.

Implementations may restrict the set of characters accepted in *lhs* or *rhs*, except that printable characters and <blank> characters shall not be restricted. Additional restrictions shall be implementation-defined. In both *lhs* and *rhs*, any character can be escaped with a <control>-V, in which case the character shall not be used to delimit *lhs* from *rhs*, and the escaping <control>-V shall be discarded.

If the character '!' is appended to the **map** command name, the mapping shall be effective during open or visual text input mode rather than **open** or **visual** command mode. This allows *lhs* to have two different **map** definitions at the same time: one for command mode and one for

text input mode.

For command mode mappings:

When the *lhs* is entered as any part of a *vi* command in open or visual mode (but not as part of the arguments to the command), the action shall be as if the corresponding *rhs* had been entered.

If any character in the command, other than the first, is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.

It is unspecified whether implementations shall support **map** commands where the *lhs* is more than a single character in length, where the first character of the *lhs* is printable.

If *lhs* contains more than one character and the first character is `'#'`, followed by a sequence of digits corresponding to a numbered function key, then when this function key is typed it shall be mapped to *rhs*. Characters other than digits following a `'#'` character also represent the function key named by the characters in the *lhs* following the `'#'` and may be mapped to *rhs*. It is unspecified how function keys are named or what function keys are supported.

For text input mode mappings:

When the *lhs* is entered as any part of text entered in open or visual text input modes, the action shall be as if the corresponding *rhs* had been entered.

If any character in the input text is escaped using a <control>-V character, that character shall not be part of a match to an *lhs*.

It is unspecified whether the *lhs* text entered for subsequent **map** or **unmap** commands is replaced with the *rhs* text for the purposes of the screen display; regardless of whether or not the display appears as if the corresponding *rhs* text was entered, the effect of the command shall be as if the *lhs* text was entered.

If only part of the *lhs* is entered, it is unspecified how long the editor will wait for additional, possibly matching characters before treating the already entered characters as not matching the *lhs*.

The *rhs* characters shall themselves be subject to remapping, unless otherwise specified by the **remap** edit option, except that if the characters in *lhs* occur as prefix characters in *rhs*, those characters shall not be remapped.

On block-mode terminals, the mapping need not occur immediately (for example, it may occur after the terminal transmits a group of characters to the system), but it shall achieve the same results as if it occurred immediately.

Current line: Unchanged.

Current column: Unchanged.

86135 **Mark**

86136 *Synopsis*: `[`*1addr*`] ma[rk]` *character*
86137 `[`*1addr*`] k` *character*

86138 Implementations shall support *character* values of a single lowercase letter of the POSIX locale
86139 and the backquote and single-quote characters; support of other characters is implementation-
86140 defined.

86141 If executing the *vi* **m** command, set the specified mark to the current line and 1-based numbered
86142 character referenced by the current column, if any; otherwise, column position 1.

86143 Otherwise, set the specified mark to the specified line and 1-based numbered first non-<blank>
86144 non-<newline> in the line, if any; otherwise, the last non-<newline> in the line, if any;
86145 otherwise, column position 1.

86146 The mark shall remain associated with the line until the mark is reset or the line is deleted. If a
86147 deleted line is restored by a subsequent **undo** command, any marks previously associated with
86148 the line, which have not been reset, shall be restored as well. Any use of a mark not associated
86149 with a current line in the edit buffer shall be an error.

86150 The marks ‘ and ’ shall be set as described previously, immediately before the following events
86151 occur in the editor:

86152 1. The use of `'$'` as an *ex* address
86153 2. The use of a positive decimal number as an *ex* address
86154 3. The use of a search command as an *ex* address
86155 4. The use of a mark reference as an *ex* address
86156 5. The use of the following open and visual mode commands: <control>-], %, **(**, **)**, [,], {, }
86157 6. The use of the following open and visual mode commands: **’**, **G**, **H**, **L**, **M**, **z** if the current
86158 line will change as a result of the command
86159 7. The use of the open and visual mode commands: **/**, **?**, **N**, **‘**, **n** if the current line or column
86160 will change as a result of the command
86161 8. The use of the *ex* mode commands: **z**, **undo**, **global**, **v**

86162 For rules 1., 2., 3., and 4., the ‘ and ’ marks shall not be set if the *ex* command is parsed as
86163 specified by rule 6.a. in Command Line Parsing in ex (on page 2646).

86164 For rules 5., 6., and 7., the ‘ and ’ marks shall not be set if the commands are used as motion
86165 commands in open and visual mode.

86166 For rules 1., 2., 3., 4., 5., 6., 7., and 8., the ‘ and ’ marks shall not be set if the command fails.

86167 The ‘ and ’ marks shall be set as described previously, each time the contents of the edit buffer
86168 are replaced (including the editing of the initial buffer), if in open or visual mode, or if in **ex**
86169 mode and the edit buffer is not empty, before any commands or movements (including
86170 commands or movements specified by the **−c** or **−t** options or the **+***command* argument) are
86171 executed on the edit buffer. If in open or visual mode, the marks shall be set as if executing the *vi*
86172 **m** command; otherwise, as if executing the *ex* **mark** command.

86173 When changing from **ex** mode to open or visual mode, if the ‘ and ’ marks are not already set,
86174 the ‘ and ’ marks shall be set as described previously.

86175 *Current line*: Unchanged.

Current column: Unchanged.

Move

Synopsis: `[`*2addr*`] m[ove] `*1addr*` [`*flags*`]`

Move the specified lines after the specified destination line. A destination of line zero specifies that the lines shall be placed at the beginning of the edit buffer. It shall be an error if the destination line is within the range of lines to be moved.

Current line: Set to the last of the moved lines.

Current column: Set to non-<blank>.

Next

Synopsis: `n[ext][!][+`*command*`][`*file ...*`]`

If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If one or more files is specified:

1. Set the argument list to the specified filenames.
2. Set the current argument list reference to be the first entry in the argument list.
3. Set the current pathname to the first filename specified.

Otherwise:

1. It shall be an error if there are no more filenames in the argument list after the filename currently referenced.
2. Set the current pathname and the current argument list reference to the filename after the filename currently referenced in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

The +*command* option shall be <blank>-delimited; <blank> characters can be escaped by preceding them with a <backslash> character. The +*command* shall be interpreted as an *ex* command immediately after the contents of the edit buffer have been replaced and the current line and column have been set.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

86208 **Number**

86209 *Synopsis*: **[***2addr***]** nu**[**mber**][***count***][***flags***]**
86210 **[***2addr***]** #**[***count***][***flags***]**

86211 These commands shall be equivalent to the *ex* command:

86212 **[***2addr***]** p**[**rint**][***count***]** #**[***flags***]**

86213 See Print.

86214 **Open**

86215 *Synopsis*: **[***1addr***]** o**[**pen**]** */pattern/* **[***flags***]**

86216 This command need not be supported on block-mode terminals or terminals with insufficient
86217 capabilities. If standard input, standard output, or standard error are not terminal devices, the
86218 results are unspecified.

86219 Enter open mode.

86220 The trailing delimiter can be omitted from *pattern* at the end of the command line. If *pattern* is
86221 empty (for example, "//") or not specified, the last regular expression used in the editor shall
86222 be used as the pattern. The pattern can be delimited by <slash> characters (shown in the
86223 Synopsis), as well as any alphanumeric, or non-<blank> other than <backslash>, <vertical-line>,
86224 <newline>, or double-quote.

86225 *Current line*: Set to the specified line.

86226 *Current column*: Set to non-<blank>.

86227 **Preserve**

86228 *Synopsis*: pre**[**serve**]**

86229 Save the edit buffer in a form that can later be recovered by using the **–r** option or by using the
86230 *ex* **recover** command. After the file has been preserved, a mail message shall be sent to the user.
86231 This message shall be readable by invoking the *mailx* utility. The message shall contain the name
86232 of the file, the time of preservation, and an *ex* command that could be used to recover the file.
86233 Additional information may be included in the mail message.

86234 *Current line*: Unchanged.

86235 *Current column*: Unchanged.

86236 **Print**

86237 *Synopsis*: **[***2addr***]** p**[**rint**][***count***][***flags***]**

86238 Write the addressed lines. The behavior is unspecified if the number of columns on the display is
86239 less than the number of columns required to write any single character in the lines being written.

86240 Non-printable characters, except for the <tab>, shall be written as implementation-defined
86241 multi-character sequences.

86242 If the **#** flag is specified or the **number** edit option is set, each line shall be preceded by its line
86243 number in the following format:

86244 "%6dΔΔ", <*line number*>

86245 If the **l** flag is specified or the **list** edit option is set:

1. The characters listed in XBD Table 5-1 (on page 121) shall be written as the corresponding escape sequence.
2. Non-printable characters not in XBD Table 5-1 (on page 121) shall be written as one three-digit octal number (with a preceding <backslash>) for each byte in the character (most significant byte first).
3. The end of each line shall be marked with a `'$'`, and literal `'$'` characters within the line shall be written with a preceding <backslash>.

Long lines shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output terminal, considering the number of columns of the terminal.

If a line is folded, and the **l** flag is not specified and the **list** edit option is not set, it is unspecified whether a multi-column character at the folding position is separated; it shall not be discarded.

Current line: Set to the last written line.

Current column: Unchanged if the current line is unchanged; otherwise, set to non-<blank>.

Put

Synopsis: **[***1addr***] pu[t][***buffer***]**

Append text from the specified buffer (by default, the unnamed buffer) to the specified line; line zero specifies that the text shall be placed at the beginning of the edit buffer. Each portion of a line in the buffer shall become a new line in the edit buffer, regardless of the mode of the buffer.

Current line: Set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Quit

Synopsis: **q[uit][!]**

If no `'!'` is appended to the command name:

1. If the edit buffer has been modified since the last complete write, it shall be an error.
2. If there are filenames in the argument list after the filename currently referenced, and the last command was not a **quit**, **wq**, **xit**, or **ZZ** (see Exit, on page 3344) command, it shall be an error.

Otherwise, terminate the editing session.

Read

Synopsis: **[***1addr***] r[ead][!][***file***]**

If `'!'` is not the first non-<blank> to follow the command name, a copy of the specified file shall be appended into the edit buffer after the specified line; line zero specifies that the copy shall be placed at the beginning of the edit buffer. The number of lines and bytes read shall be written. If no *file* is named, the current pathname shall be the default. If there is no current pathname, then *file* shall become the current pathname. If there is no current pathname or *file* operand, it shall be an error. Specifying a *file* that is not of type regular shall have unspecified results.

Otherwise, if *file* is preceded by `'!'`, the rest of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as described in Command Line Parsing in ex (on page 2646).

The *ex* utility shall then pass two arguments to the program named by the shell edit option; the

first shall be **−c** and the second shall be the expanded arguments to the **read** command as a single argument. The standard input of the program shall be set to the standard input of the *ex* program when it was invoked. The standard error and standard output of the program shall be appended into the edit buffer after the specified line.

Each line in the copied file or program output (as delimited by <newline> characters or the end of the file or output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline> characters.

The special meaning of the `'!'` following the **read** command can be overridden by escaping it with a <backslash> character.

Current line: If no lines are added to the edit buffer, unchanged. Otherwise, if in open or visual mode, set to the first line entered into the edit buffer. Otherwise, set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Recover

Synopsis: `rec[over][!]` *`file`*

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.

If no *file* operand is specified, then the current pathname shall be used. If there is no current pathname or *file* operand, it shall be an error.

If no recovery information has previously been saved about *file*, the **recover** command shall behave identically to the **edit** command, and an informational message to this effect shall be written.

Otherwise, set the current pathname to *file*, and replace the current contents of the edit buffer with the recovered contents of *file*. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. The editor shall behave as if the contents of the edit buffer have already been modified.

Current file: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Rewind

Synopsis: `rew[ind][!]`

If no `'!'` is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the **autowrite** option.

If the argument list is empty, it shall be an error.

The current argument list reference and the current pathname shall be set to the first filename in the argument list.

Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.

This command shall be affected by the **autowrite** and **writeany** edit options.

Current line: Set as described for the **edit** command.

Current column: Set as described for the **edit** command.

Set

Synopsis: `se[t][`*`option`*`[=[`*`value`*`]] ...][no`*`option`* `...][`*`option`*`? ...][all]`

When no arguments are specified, write the value of the **term** edit option and those options whose values have been changed from the default settings; when the argument *all* is specified, write all of the option values.

Giving an option name followed by the character `'?'` shall cause the current value of that option to be written. The `'?'` can be separated from the option name by zero or more <blank> characters. The `'?'` shall be necessary only for Boolean valued options. Boolean options can be given values by the form **set** *option* to turn them on or **set no***option* to turn them off; string and numeric options can be assigned by the form **set** *option*=*value*. Any <blank> characters in strings can be included as is by preceding each <blank> with an escaping <backslash>. More than one option can be set or listed by a single set command by specifying multiple arguments, each separated from the next by one or more <blank> characters.

See Edit Options in ex (on page 2676) for details about specific options.

Current line: Unchanged.

Current column: Unchanged.

Shell

Synopsis: `sh[ell]`

Invoke the program named in the **shell** edit option with the single argument **–i** (interactive mode). Editing shall be resumed when the program exits.

Current line: Unchanged.

Current column: Unchanged.

Source

Synopsis: `so[urce]` *`file`*

Read and execute *ex* commands from *file*. Lines in the file that are blank lines shall be ignored.

Current line: As specified for the individual *ex* commands.

Current column: As specified for the individual *ex* commands.

Substitute

Synopsis:
```
[2addr] s[ubstitute][/pattern/repl/[options][count][flags]]
[2addr] &[options][count][flags]]
[2addr] ~[options][count][flags]]
```

Replace the first instance of the pattern *pattern* by the string *repl* on each specified line. (See Regular Expressions in ex (on page 2675) and Replacement Strings in ex (on page 2676).) Any non-alphabetic, non-<blank> delimiter other than <backslash>, `'|'`, <newline>, or double-quote can be used instead of `'/'`. <backslash> characters can be used to escape delimiters, <backslash> characters, and other special characters.

The trailing delimiter can be omitted from *pattern* or from *repl* at the end of the command line. If both *pattern* and *repl* are not specified or are empty (for example, `"//"`), the last **s** command shall be repeated. If only *pattern* is not specified or is empty, the last regular expression used in the editor shall be used as the pattern. If only *repl* is not specified or is empty, the pattern shall be replaced by nothing. If the entire replacement pattern is `'%'`, the last replacement pattern to an **s** command shall be used.

Entering a <carriage-return> in *repl* (which requires an escaping <backslash> in *ex* mode and an escaping <control>-V in open or *vi* mode) shall split the line at that point, creating a new line in the edit buffer. The <carriage-return> shall be discarded.

If *options* includes the letter `'g'` (**global**), all non-overlapping instances of the pattern in the line shall be replaced.

If *options* includes the letter `'c'` (**confirm**), then before each substitution the line shall be written; the written line shall reflect all previous substitutions. On the following line, <space> characters shall be written beneath the characters from the line that are before the *pattern* to be replaced, and `'^'` characters written beneath the characters included in the *pattern* to be replaced. The *ex* utility shall then wait for a response from the user. An affirmative response shall cause the substitution to be done, while any other input shall not make the substitution. An affirmative response shall consist of a line with the affirmative response (as defined by the current locale) at the beginning of the line. This line shall be subject to editing in the same way as the *ex* command line.

If interrupted (see the ASYNCHRONOUS EVENTS section), any modifications confirmed by the user shall be preserved in the edit buffer after the interrupt.

If the remembered search direction is not set, the **s** command shall set it to forward.

In the second Synopsis, the **&** command shall repeat the previous substitution, as if the **&** command were replaced by:

`s/`*`pattern`*`/`*`repl`*`/`

where *pattern* and *repl* are as specified in the previous **s**, **&**, or ~ command.

In the third Synopsis, the ~ command shall repeat the previous substitution, as if the `'~'` were replaced by:

`s/`*`pattern`*`/`*`repl`*`/`

where *pattern* shall be the last regular expression specified to the editor, and *repl* shall be from the previous substitution (including **&** and ~) command.

These commands shall be affected by the *LC_MESSAGES* environment variable.

Current line: Set to the last line in which a substitution occurred, or, unchanged if no substitution occurred.

Current column: Set to non-<blank>.

86401 **Suspend**

86402 *Synopsis*: `su[spend][!]`
86403 `st[op][!]`

86404 Allow control to return to the invoking process; *ex* shall suspend itself as if it had received the
86405 SIGTSTP signal. The suspension shall occur only if job control is enabled in the invoking shell
86406 (see the description of *set* –**m**).

86407 These commands shall be affected by the **autowrite** and **writeany** edit options.

86408 The current **susp** character (see *stty*) shall be equivalent to the **suspend** command.

86409 **Tag**

86410 *Synopsis*: `ta[g][!]` *`tagstring`*

86411 The results are unspecified if the format of a tags file is not as specified by the *ctags* utility (see
86412 *ctags*) description.

86413 The **tag** command shall search for *tagstring* in the tag files referred to by the **tag** edit option, in
86414 the order they are specified, until a reference to *tagstring* is found. Files shall be searched from
86415 beginning to end. If no reference is found, it shall be an error and an error message to this effect
86416 shall be written. If the reference is not found, or if an error occurs while processing a file referred
86417 to in the **tag** edit option, it shall be an error, and an error message shall be written at the first
86418 occurrence of such an error.

86419 Otherwise, if the tags file contained a pattern, the pattern shall be treated as a regular expression
86420 used in the editor; for example, for the purposes of the **s** command.

86421 If the *tagstring* is in a file with a different name than the current pathname, set the current
86422 pathname to the name of that file, and replace the contents of the edit buffer with the contents of
86423 that file. In this case, if no `'!'` is appended to the command name, and the edit buffer has been
86424 modified since the last complete write, it shall be an error, unless the file is successfully written
86425 as specified by the **autowrite** option.

86426 This command shall be affected by the **autowrite**, **tag**, **taglength**, and **writeany** edit options.

86427 *Current line*: If the tags file contained a line number, set to that line number. If the line number is
86428 larger than the last line in the edit buffer, an error message shall be written and the current line
86429 shall be set as specified for the **edit** command.

86430 If the tags file contained a pattern, set to the first occurrence of the pattern in the file. If no
86431 matching pattern is found, an error message shall be written and the current line shall be set as
86432 specified for the **edit** command.

86433 *Current column*: If the tags file contained a line-number reference and that line-number was not
86434 larger than the last line in the edit buffer, or if the tags file contained a pattern and that pattern
86435 was found, set to non-<blank>. Otherwise, set as specified for the **edit** command.

86436 **Unabbreviate**

86437 *Synopsis*: `una[bbrev] lhs`

86438 If *lhs* is not an entry in the current list of abbreviations (see Abbreviate, on page 2654), it shall be
86439 an error. Otherwise, delete *lhs* from the list of abbreviations.

86440 *Current line*: Unchanged.

86441 *Current column*: Unchanged.

86442 **Undo**

86443 *Synopsis*: `u[ndo]`

86444 Reverse the changes made by the last command that modified the contents of the edit buffer,
86445 including **undo**. For this purpose, the **global**, **v**, **open**, and **visual** commands, and commands
86446 resulting from buffer executions and mapped character expansions, are considered single
86447 commands.

86448 If no action that can be undone preceded the **undo** command, it shall be an error.

86449 If the **undo** command restores lines that were marked, the mark shall also be restored unless it
86450 was reset subsequent to the deletion of the lines.

86451 *Current line*:

86452 1. If lines are added or changed in the file, set to the first line added or changed.
86453 2. Set to the line before the first line deleted, if it exists.
86454 3. Set to 1 if the edit buffer is not empty.
86455 4. Set to zero.

86456 *Current column*: Set to non-<blank>.

86457 **Unmap**

86458 *Synopsis*: `unm[ap][!] lhs`

86459 If `'!'` is appended to the command name, and if *lhs* is not an entry in the list of text input mode
86460 map definitions, it shall be an error. Otherwise, delete *lhs* from the list of text input mode map
86461 definitions.

86462 If no `'!'` is appended to the command name, and if *lhs* is not an entry in the list of command
86463 mode map definitions, it shall be an error. Otherwise, delete *lhs* from the list of command mode
86464 map definitions.

86465 *Current line*: Unchanged.

86466 *Current column*: Unchanged.

86467 **Version**

86468 *Synopsis*: `ve[rsion]`

86469 Write a message containing version information for the editor. The format of the message is
86470 unspecified.

86471 *Current line*: Unchanged.

86472 *Current column*: Unchanged.

86473 **Visual**

86474 *Synopsis*: `[`*`1addr`*`] vi[sual][`*`type`*`][`*`count`*`][`*`flags`*`]`

86475 If *ex* is currently in open or visual mode, the Synopsis and behavior of the visual command shall
86476 be the same as the **edit** command, as specified by Edit (on page 2656).

86477 Otherwise, this command need not be supported on block-mode terminals or terminals with
86478 insufficient capabilities. If standard input, standard output, or standard error are not terminal
86479 devices, the results are unspecified.

86480 If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in
86481 window, on page 2683). If the `'^'` type character was also specified, the **window** edit option
86482 shall be set before being used by the type character.

86483 Enter visual mode. If *type* is not specified, it shall be as if a *type* of `'+'` was specified. The *type*
86484 shall cause the following effects:

86485 `+` Place the beginning of the specified line at the top of the display.

86486 `-` Place the end of the specified line at the bottom of the display.

86487 `.` Place the beginning of the specified line in the middle of the display.

86488 `^` If the specified line is less than or equal to the value of the **window** edit option, set the line
86489 to 1; otherwise, decrement the line by the value of the **window** edit option minus 1. Place
86490 the beginning of this line as close to the bottom of the displayed lines as possible, while still
86491 displaying the value of the **window** edit option number of lines.

86492 *Current line*: Set to the specified line.

86493 *Current column*: Set to non-<blank>.

86494 **Write**

86495 *Synopsis*: `[`*`2addr`*`] w[rite][!][>>][`*`file`*`]`
86496 `[`*`2addr`*`] w[rite][!][`*`file`*`]`
86497 `[`*`2addr`*`] wq[!][>>][`*`file`*`]`

86498 If no lines are specified, the lines shall default to the entire file.

86499 The command **wq** shall be equivalent to a **write** command followed by a **quit** command; **wq!**
86500 shall be equivalent to **write!** followed by **quit**. In both cases, if the **write** command fails, the
86501 **quit** shall not be attempted.

86502 If the command name is not followed by one or more <blank> characters, or *file* is not preceded
86503 by a `'!'` character, the **write** shall be to a file.

86504 1. If the **>>** argument is specified, and the file already exists, the lines shall be appended to
86505 the file instead of replacing its contents. If the **>>** argument is specified, and the file does
86506 not already exist, it is unspecified whether the write shall proceed as if the **>>** argument

had not been specified or if the write shall fail.

2. If the **readonly** edit option is set (see readonly, on page 2680), the **write** shall fail.
3. If *file* is specified, and is not the current pathname, and the file exists, the **write** shall fail.
4. If *file* is not specified, the current pathname shall be used. If there is no current pathname, the **write** command shall fail.
5. If the current pathname is used, and the current pathname has been changed by the **file** or **read** commands, and the file exists, the **write** shall fail. If the **write** is successful, subsequent **write**s shall not fail for this reason (unless the current pathname is changed again).
6. If the whole edit buffer is not being written, and the file to be written exists, the **write** shall fail.

For rules 1., 2., 3., and 5., the **write** can be forced by appending the character `'!'` to the command name.

For rules 2., 3., and 5., the **write** can be forced by setting the **writeany** edit option.

Additional, implementation-defined tests may cause the **write** to fail.

If the edit buffer is empty, a file without any contents shall be written.

An informational message shall be written noting the number of lines and bytes written.

Otherwise, if the command is followed by one or more <blank> characters, and the file is preceded by `'!'`, the rest of the line after the `'!'` shall have `'%'`, `'#'`, and `'!'` characters expanded as described in Command Line Parsing in ex (on page 2646).

The *ex* utility shall then pass two arguments to the program named by the **shell** edit option; the first shall be **−c** and the second shall be the expanded arguments to the **write** command as a single argument. The specified lines shall be written to the standard input of the command. The standard error and standard output of the program, if any, shall be written as described for the **print** command. If the last character in that output is not a <newline>, a <newline> shall be written at the end of the output.

The special meaning of the `'!'` following the **write** command can be overridden by escaping it with a <backslash> character.

Current line: Unchanged.

Current column: Unchanged.

Write and Exit

Synopsis: `[`*2addr*`] x[it][!][`*file*`]`

If the edit buffer has not been modified since the last complete **write**, **xit** shall be equivalent to the **quit** command, or if a `'!'` is appended to the command name, to **quit!**.

Otherwise, **xit** shall be equivalent to the **wq** command, or if a `'!'` is appended to the command name, to **wq!**.

Current line: Unchanged.

Current column: Unchanged.

Yank

Synopsis: `[2addr] ya[nk][buffer][count]`

Copy the specified lines to the specified buffer (by default, the unnamed buffer), which shall become a line-mode buffer.

Current line: Unchanged.

Current column: Unchanged.

Adjust Window

Synopsis: `[1addr] z[!][type ...][count][flags]`

If no line is specified, the current line shall be the default; if *type* is omitted as well, the current line value shall first be incremented by 1. If incrementing the current line would cause it to be greater than the last line in the edit buffer, it shall be an error.

If there are <blank> characters between the *type* argument and the preceding **z** command name or optional `'!'` character, it shall be an error.

If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in window, on page 2683). If *count* is omitted, it shall default to 2 times the value of the **scroll** edit option, or if **!** was specified, the number of lines in the display minus 1.

If *type* is omitted, then *count* lines starting with the specified line shall be written. Otherwise, *count* lines starting with the line specified by the *type* argument shall be written.

The *type* argument shall change the lines to be written. The possible values of *type* are as follows:

– The specified line shall be decremented by the following value:

  `(((number of ''–'' characters) x count) –1)`

  If the calculation would result in a number less than 1, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

+ The specified line shall be incremented by the following value:

  `(((number of ''+'' characters) –1) x count) +1`

  If the calculation would result in a number greater than the last line in the edit buffer, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

=,. If more than a single `'.'` or `'='` is specified, it shall be an error. The following steps shall be taken:

1. If *count* is zero, nothing shall be written.
2. Write as many of the *N* lines before the current line in the edit buffer as exist. If *count* or `'!'` was specified, *N* shall be:

   `(count –1) /2`

   Otherwise, *N* shall be:

   `(count –3) /2`

   If *N* is a number less than 3, no lines shall be written.

3. If '=' was specified as the type character, write a line consisting of the smaller of the number of columns in the display divided by two, or 40 '–' characters.
4. Write the current line.
5. Repeat step 3.
6. Write as many of the *N* lines after the current line in the edit buffer as exist. *N* shall be defined as in step 2. If *N* is a number less than 3, no lines shall be written. If *count* is less than 3, no lines shall be written.

^ The specified line shall be decremented by the following value:

(((number of ''^'' characters) +1) x *count*) –1

If the calculation would result in a number less than 1, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until *count* lines or the last line in the edit buffer has been written.

Current line: Set to the last line written, unless the type is **=**, in which case, set to the specified line.

Current column: Set to non-<blank>.

Escape

Synopsis: ! *command*
[*addr*]! *command*

The contents of the line after the '!' shall have '%', '#', and '!' characters expanded as described in Command Line Parsing in ex (on page 2646). If the expansion causes the text of the line to change, it shall be redisplayed, preceded by a single '!' character.

The *ex* utility shall execute the program named by the **shell** edit option. It shall pass two arguments to the program; the first shall be **–c**, and the second shall be the expanded arguments to the **!** command as a single argument.

If no lines are specified, the standard input, standard output, and standard error of the program shall be set to the standard input, standard output, and standard error of the *ex* program when it was invoked. In addition, a warning message shall be written if the edit buffer has been modified since the last complete write, and the **warn** edit option is set.

If lines are specified, they shall be passed to the program as standard input, and the standard output and standard error of the program shall replace those lines in the edit buffer. Each line in the program output (as delimited by <newline> characters or the end of the output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline> characters. The specified lines shall be copied into the unnamed buffer before they are replaced, and the unnamed buffer shall become a line-mode buffer.

If in *ex* mode, a single '!' character shall be written when the program completes.

This command shall be affected by the **shell** and **warn** edit options. If no lines are specified, this command shall be affected by the **autowrite** and **writeany** edit options. If lines are specified, this command shall be affected by the **autoprint** edit option.

Current line:

1. If no lines are specified, unchanged.
2. Otherwise, set to the last line read in, if any lines are read in.
3. Otherwise, set to the line before the first line of the lines specified, if that line exists.
4. Otherwise, set to the first line of the edit buffer if the edit buffer is not empty.
5. Otherwise, set to zero.

Current column: If no lines are specified, unchanged. Otherwise, set to non-<blank>.

Shift Left

Synopsis: **[***2addr***] <[<** ...**][***count***][***flags***]**

Shift the specified lines to the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. Only leading <blank> characters shall be deleted or changed into other <blank> characters in shifting; other characters shall not be affected.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

Shift Right

Synopsis: **[***2addr***] >[>** ...**][***count***][***flags***]**

Shift the specified lines away from the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the **shiftwidth** edit option. The shift shall be accomplished by adding <blank> characters as a prefix to the line or changing leading <blank> characters into other <blank> characters. Empty lines shall not be changed.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the **autoprint** edit option.

Current line: Set to the last line in the lines specified.

Current column: Set to non-<blank>.

<control>-D

Synopsis: **<control>-D**

Write the next *n* lines, where *n* is the minimum of the values of the **scroll** edit option and the number of lines after the current line in the edit buffer. If the current line is the last line of the edit buffer it shall be an error.

Current line: Set to the last line written.

Current column: Set to non-<blank>.

Write Line Number

Synopsis: **[***1addr***] = [***flags***]**

If *line* is not specified, it shall default to the last line in the edit buffer. Write the line number of the specified line.

Current line: Unchanged.

Current column: Unchanged.

Execute

Synopsis: **[***2addr***] @ *buffer***
[*2addr***] * *buffer***

If no buffer is specified or is specified as '@' or '*', the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

For each line specified by the addresses, set the current line ('.') to the specified line, and execute the contents of the named *buffer* (as they were at the time the @ command was executed) as *ex* commands. For each line of a line-mode buffer, and all but the last line of a character-mode buffer, the *ex* command parser shall behave as if the line was terminated by a <newline>.

If an error occurs during this process, or a line specified by the addresses does not exist when the current line would be set to it, or more than a single line was specified by the addresses, and the contents of the edit buffer are replaced (for example, by the *ex* **:edit** command) an error message shall be written, and no more commands resulting from the execution of this command shall be processed.

Current line: As specified for the individual *ex* commands.

Current column: As specified for the individual *ex* commands.

Regular Expressions in ex

The *ex* utility shall support regular expressions that are a superset of the basic regular expressions described in XBD Section 9.3 (on page 183). A null regular expression ("//") shall be equivalent to the last regular expression encountered.

Regular expressions can be used in addresses to specify lines and, in some commands (for example, the **substitute** command), to specify portions of a line to be substituted.

The following constructs can be used to enhance the basic regular expressions:

\< Match the beginning of a *word*. (See the definition of *word* at the beginning of Command Descriptions in ex (on page 2651).)

\> Match the end of a *word*.

~ Match the replacement part of the last **substitute** command. The <tilde> ('~') character can be escaped in a regular expression to become a normal character with no special meaning. The <backslash> shall be discarded.

When the editor option **magic** is not set, the only characters with special meanings shall be '^' at the beginning of a pattern, '$' at the end of a pattern, and <backslash>. The characters '.', '*', '[', and '~' shall be treated as ordinary characters unless preceded by a <backslash>; when preceded by a <backslash> they shall regain their special meaning, or in the case of <backslash>, be handled as a single <backslash>. <backslash> characters used to escape other characters shall be discarded.

86700 **Replacement Strings in ex**

86701 The character '&' ('\&' if the editor option **magic** is not set) in the replacement string shall
86702 stand for the text matched by the pattern to be replaced. The character '~' ('\~' if **magic** is not
86703 set) shall be replaced by the replacement part of the previous **substitute** command. The
86704 sequence '\n', where *n* is an integer, shall be replaced by the text matched by the
86705 corresponding back-reference expression. If the corresponding back-reference expression does
86706 not match, then the characters '\n' shall be replaced by the empty string.

86707 The strings '\l', '\u', '\L', and '\U' can be used to modify the case of elements in the
86708 replacement string (using the '\&' or "\"digit) notation. The string '\l' ('\u') shall cause
86709 the character that follows to be converted to lowercase (uppercase). The string '\L' ('\U') shall
86710 cause all characters subsequent to it to be converted to lowercase (uppercase) as they are
86711 inserted by the substitution until the string '\e' or '\E', or the end of the replacement string,
86712 is encountered.

86713 Otherwise, any character following a <backslash> shall be treated as that literal character, and
86714 the escaping <backslash> shall be discarded.

86715 An example of case conversion with the **s** command is as follows:

```
86716 :p
86717 The cat sat on the mat.
86718 :s/\<.at\>/\u&/gp
86719 The Cat Sat on the Mat.
86720 :s/S\(.*\)M/S\U\1\eM/p
86721 The Cat SAT ON THE Mat.
```

86722 **Edit Options in ex**

86723 The *ex* utility has a number of options that modify its behavior. These options have default
86724 settings, which can be changed using the **set** command.

86725 Options are Boolean unless otherwise specified.

86726 **autoindent, ai**

86727 [Default *unset*]

86728 If **autoindent** is set, each line in input mode shall be indented (using first as many <tab>
86729 characters as possible, as determined by the editor option **tabstop**, and then using <space>
86730 characters) to align with another line, as follows:

86731 1. If in open or visual mode and the text input is part of a line-oriented command (see the
86732 EXTENDED DESCRIPTION in *vi*), align to the first column.

86733 2. Otherwise, if in open or visual mode, indentation for each line shall be set as follows:

86734 a. If a line was previously inserted as part of this command, it shall be set to the
86735 indentation of the last inserted line by default, or as otherwise specified for the
86736 <control>-D character in Input Mode Commands in vi (on page 3344).

86737 b. Otherwise, it shall be set to the indentation of the previous current line, if any;
86738 otherwise, to the first column.

86739 3. For the *ex* **a**, **i**, and **c** commands, indentation for each line shall be set as follows:

a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the *eof* character in Scroll (on page 2650).

b. Otherwise, if the command is the *ex* **a** command, it shall be set to the line appended after, if any; otherwise to the first column.

c. Otherwise, if the command is the *ex* **i** command, it shall be set to the line inserted before, if any; otherwise to the first column.

d. Otherwise, if the command is the *ex* **c** command, it shall be set to the indentation of the line replaced.

autoprint, ap

[Default *set*]

If **autoprint** is set, the current line shall be written after each *ex* command that modifies the contents of the current edit buffer, and after each **tag** command for which the tag search pattern was found or tag line number was valid, unless:

1. The command was executed while in open or visual mode.
2. The command was executed as part of a **global** or **v** command or @ buffer execution.
3. The command was the form of the **read** command that reads a file into the edit buffer.
4. The command was the **append**, **change**, or **insert** command.
5. The command was not terminated by a <newline>.
6. The current line shall be written by a flag specified to the command; for example, **delete #** shall write the current line as specified for the flag modifier to the **delete** command, and not as specified by the **autoprint** edit option.

autowrite, aw

[Default *unset*]

If **autowrite** is set, and the edit buffer has been modified since it was last completely written to any file, the contents of the edit buffer shall be written as if the *ex* **write** command had been specified without arguments, before each command affected by the **autowrite** edit option is executed. Appending the character '!' to the command name of any of the *ex* commands except '!' shall prevent the write. If the write fails, it shall be an error and the command shall not be executed.

beautify, bf

XSI [Default *unset*]

If **beautify** is set, all non-printable characters, other than <tab>, <newline>, and <form-feed> characters, shall be discarded from text read in from files.

directory, dir

[Default *implementation-defined*]

The value of this option specifies the directory in which the editor buffer is to be placed. If this directory is not writable by the user, the editor shall quit.

edcompatible, ed

[Default *unset*]

Causes the presence of **g** and **c** suffixes on substitute commands to be remembered, and toggled by repeating the suffixes.

errorbells, eb

[Default *unset*]

If the editor is in *ex* mode, and the terminal does not support a standout mode (such as inverse video), and **errorbells** is set, error messages shall be preceded by alerting the terminal.

exrc

[Default *unset*]

If **exrc** is set, *ex* shall access any **.exrc** file in the current directory, as described in Initialization in ex and vi (on page 2642). If **exrc** is not set, *ex* shall ignore any **.exrc** file in the current directory during initialization, unless the current directory is that named by the *HOME* environment variable.

ignorecase, ic

[Default *unset*]

If **ignorecase** is set, characters that have uppercase and lowercase representations shall have those representations considered as equivalent for purposes of regular expression comparison.

The **ignorecase** edit option shall affect all remembered regular expressions; for example, unsetting the **ignorecase** edit option shall cause a subsequent *vi* **n** command to search for the last basic regular expression in a case-sensitive fashion.

list

[Default *unset*]

If **list** is set, edit buffer lines written while in *ex* command mode shall be written as specified for the **print** command with the **l** flag specified. In open or visual mode, each edit buffer line shall be displayed as specified for the *ex* **print** command with the **l** flag specified. In open or visual text input mode, when the cursor does not rest on any character in the line, it shall rest on the `'$'` marking the end of the line.

magic

[Default *set*]

If **magic** is set, modify the interpretation of characters in regular expressions and substitution replacement strings (see Regular Expressions in ex (on page 2675) and Replacement Strings in ex, on page 2676).

mesg

[Default *set*]

If **mesg** is set, the permission for others to use the **write** or **talk** commands to write to the terminal shall be turned on while in open or visual mode. The shell-level command *mesg* **n** shall take precedence over any setting of the *ex* **mesg** option; that is, if **mesg y** was issued before the editor started (or in a shell escape), such as:

```
:!mesg y
```

the **mesg** option in *ex* shall suppress incoming messages, but the **mesg** option shall not enable incoming messages if **mesg n** was issued.

number, nu

[Default *unset*]

If **number** is set, edit buffer lines written while in *ex* command mode shall be written with line numbers, in the format specified by the **print** command with the **#** flag specified. In *ex* text input mode, each line shall be preceded by the line number it will have in the file.

In open or visual mode, each edit buffer line shall be displayed with a preceding line number, in the format specified by the *ex* **print** command with the **#** flag specified. This line number shall not be considered part of the line for the purposes of evaluating the current column; that is, column position 1 shall be the first column position after the format specified by the **print** command.

paragraphs, para

[Default in the POSIX locale `IPLPPPQPP LIpplpipbp`]

The **paragraphs** edit option shall define additional paragraph boundaries for the open and visual mode commands. The **paragraphs** edit option can be set to a character string consisting of zero or more character pairs. It shall be an error to set it to an odd number of characters.

prompt

[Default *set*]

If **prompt** is set, *ex* command mode input shall be prompted for with a <colon> (`':'`); when unset, no prompt shall be written.

readonly

[Default *see text*]

If the **readonly** edit option is set, read-only mode shall be enabled (see Write, on page 2670). The **readonly** edit option shall be initialized to set if either of the following conditions are true:

- The command-line option –R was specified.
- Performing actions equivalent to the *access*( ) function called with the following arguments indicates that the file lacks write permission:
  1. The current pathname is used as the *path* argument.
  2. The constant **W_OK** is used as the *amode* argument.

The **readonly** edit option may be initialized to set for other, implementation-defined reasons. The **readonly** edit option shall not be initialized to unset based on any special privileges of the user or process. The **readonly** edit option shall be reinitialized each time that the contents of the edit buffer are replaced (for example, by an **edit** or **next** command) unless the user has explicitly set it, in which case it shall remain set until the user explicitly unsets it. Once unset, it shall again be reinitialized each time that the contents of the edit buffer are replaced.

redraw

[Default *unset*]

The editor simulates an intelligent terminal on a dumb terminal. (Since this is likely to require a large amount of output to the terminal, it is useful only at high transmission speeds.)

remap

[Default *set*]

If **remap** is set, map translation shall allow for maps defined in terms of other maps; translation shall continue until a final product is obtained. If unset, only a one-step translation shall be done.

report

[Default 5]

The value of this **report** edit option specifies what number of lines being added, copied, deleted, or modified in the edit buffer will cause an informational message to be written to the user. The following conditions shall cause an informational message. The message shall contain the number of lines added, copied, deleted, or modified, but is otherwise unspecified.

- An *ex* or *vi* editor command, other than **open**, **undo**, or **visual**, that modifies at least the value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.
- An *ex* **yank** or *vi* **y** or **Y** command, that copies at least the value of the **report** edit option plus 1 number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written.
- An *ex* **global**, **v**, **open**, **undo**, or **visual** command or *ex* or *vi* buffer execution, that adds or deletes a total of at least the value of the **report** edit option number of lines, and which is not part of an *ex* **global** or **v** command, or *ex* or *vi* buffer execution, shall cause an informational message to be written. (For example, if 3 lines were added and 8 lines deleted during an *ex* **visual** command, 5 would be the number compared against the

86880 **report** edit option after the command completed.)

86881 **scroll, scr**

86882 [Default (number of lines in the display –1)/2]

86883 The value of the **scroll** edit option shall determine the number of lines scrolled by the *ex*
86884 <control>-D and **z** commands. For the *vi* <control>-D and <control>-U commands, it shall be the
86885 initial number of lines to scroll when no previous <control>-D or <control>-U command has
86886 been executed.

86887 **sections**

86888 [Default in the POSIX locale `NHSHH HUnhsh`]

86889 The **sections** edit option shall define additional section boundaries for the open and visual mode
86890 commands. The **sections** edit option can be set to a character string consisting of zero or more
86891 character pairs; it shall be an error to set it to an odd number of characters.

86892 **shell, sh**

86893 [Default from the environment variable *SHELL*]

86894 The value of this option shall be a string. The default shall be taken from the *SHELL*
86895 environment variable. If the *SHELL* environment variable is null or empty, the *sh* (see *sh*) utility
86896 shall be the default.

86897 **shiftwidth, sw**

86898 [Default 8]

86899 The value of this option shall give the width in columns of an indentation level used during
86900 autoindentation and by the shift commands (**<** and **>**).

86901 **showmatch, sm**

86902 [Default *unset*]

86903 The functionality described for the **showmatch** edit option need not be supported on block-
86904 mode terminals or terminals with insufficient capabilities.

86905 If **showmatch** is set, in open or visual mode, when a `')'` or `'}'` is typed, if the matching `'('` or
86906 `'{'` is currently visible on the display, the matching `'('` or `'{'` shall be flagged moving the
86907 cursor to its location for an unspecified amount of time.

86908 **showmode**

86909 [Default *unset*]

86910 If **showmode** is set, in open or visual mode, the current mode that the editor is in shall be
86911 displayed on the last line of the display. Command mode and text input mode shall be
86912 differentiated; other unspecified modes and implementation-defined information may be
86913 displayed.

slowopen

[Default *unset*]

If **slowopen** is set during open and visual text input modes, the editor shall not update portions of the display other than those display line columns that display the characters entered by the user (see Input Mode Commands in vi, on page 3344).

tabstop, ts

[Default 8]

The value of this edit option shall specify the column boundary used by a <tab> in the display (see autoprint, ap (on page 2677) and Input Mode Commands in vi, on page 3344).

taglength, tl

[Default zero]

The value of this edit option shall specify the maximum number of characters that are considered significant in the user-specified tag name and in the tag name from the tags file. If the value is zero, all characters in both tag names shall be significant.

tags

[Default *see text*]

The value of this edit option shall be a string of <blank>-delimited pathnames of files used by the **tag** command. The default value is unspecified.

term

[Default from the environment variable *TERM*]

The value of this edit option shall be a string. The default shall be taken from the *TERM* variable in the environment. If the *TERM* environment variable is empty or null, the default is unspecified. The editor shall use the value of this edit option to determine the type of the display device.

The results are unspecified if the user changes the value of the term edit option after editor initialization.

terse

[Default *unset*]

If **terse** is set, error messages may be less verbose. However, except for this caveat, error messages are unspecified. Furthermore, not all error messages need change for different settings of this option.

warn

[Default *set*]

If **warn** is set, and the contents of the edit buffer have been modified since they were last completely written, the editor shall write a warning message before certain **!** commands (see Escape, on page 2673).

window

[Default *see text*]

A value used in open and visual mode, by the <control>-B and <control>-F commands, and, in visual mode, to specify the number of lines displayed when the screen is repainted.

If the **−w** command-line option is not specified, the default value shall be set to the value of the *LINES* environment variable. If the *LINES* environment variable is empty or null, the default shall be the number of lines in the display minus 1.

Setting the **window** edit option to zero or to a value greater than the number of lines in the display minus 1 (either explicitly or based on the **−w** option or the *LINES* environment variable) shall cause the **window** edit option to be set to the number of lines in the display minus 1.

The baud rate of the terminal line may change the default in an implementation-defined manner.

wrapmargin, wm

[Default 0]

If the value of this edit option is zero, it shall have no effect.

If not in the POSIX locale, the effect of this edit option is implementation-defined.

Otherwise, it shall specify a number of columns from the ending margin of the terminal.

During open and visual text input modes, for each character for which any part of the character is displayed in a column that is less than **wrapmargin** columns from the ending margin of the display line, the editor shall behave as follows:

1. If the character triggering this event is a <blank>, it, and all immediately preceding <blank> characters on the current line entered during the execution of the current text input command, shall be discarded, and the editor shall behave as if the user had entered a single <newline> instead. In addition, if the next user-entered character is a <space>, it shall be discarded as well.

2. Otherwise, if there are one or more <blank> characters on the current line immediately preceding the last group of inserted non-<blank> characters which was entered during the execution of the current text input command, the <blank> characters shall be replaced as if the user had entered a single <newline> instead.

If the **autoindent** edit option is set, and the events described in 1. or 2. are performed, any <blank> characters at or after the cursor in the current line shall be discarded.

The ending margin shall be determined by the system or overridden by the user, as described for *COLUMNS* in the ENVIRONMENT VARIABLES section and XBD Chapter 8 (on page 173).

wrapscan, ws

[Default *set*]

If **wrapscan** is set, searches (the *ex* **/** or **?** addresses, or open and visual mode **/**, **?**, **N**, and **n** commands) shall wrap around the beginning or end of the edit buffer; when unset, searches shall stop at the beginning or end of the edit buffer.

writeany, wa

[Default *unset*]

If **writeany** is set, some of the checks performed when executing the *ex* **write** commands shall be inhibited, as described in editor option **autowrite**.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, *ex* shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered, it shall be equivalent to a SIGHUP asynchronous event.

Otherwise, when an error is encountered, the editor shall behave as specified in Command Line Parsing in ex (on page 2646).

APPLICATION USAGE

If a SIGSEGV signal is received while *ex* is saving a file, the file might not be successfully saved.

The **next** command can accept more than one file, so usage such as:

```
next 'ls [abc]*'
```

is valid; it would not be valid for the **edit** or **read** commands, for example, because they expect only one file and unspecified results occur.

EXAMPLES

None.

RATIONALE

The *ex*/*vi* specification is based on the historical practice found in the 4 BSD and System V implementations of *ex* and *vi*.

A *restricted editor* (both the historical *red* utility and modifications to *ex*) were considered and rejected for inclusion. Neither option provided the level of security that users might expect.

It is recognized that *ex* visual mode and related features would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing; thus, it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that an *ex* implementation should provide the full set of capabilities on all terminals capable of supporting them.

87021 **Options**

87022 The **−c** replacement for **+***command* was inspired by the **−e** option of *sed*. Historically, all such
87023 commands (see **edit** and **next** as well) were executed from the last line of the edit buffer. This
87024 meant, for example, that `"+/pattern"` would fail unless the **wrapscan** option was set.
87025 POSIX.1-200x requires conformance to historical practice. The +*command* option is no longer
87026 specified by POSIX.1-200x but may be present in some implementations. Historically, some
87027 implementations restricted the *ex* commands that could be listed as part of the command line
87028 arguments. For consistency, POSIX.1-200x does not permit these restrictions.

87029 In historical implementations of the editor, the **−R** option (and the **readonly** edit option) only
87030 prevented overwriting of files; appending to files was still permitted, mapping loosely into the
87031 *csh* **noclobber** variable. Some implementations, however, have not followed this semantic, and
87032 **readonly** does not permit appending either. POSIX.1-200x follows the latter practice, believing
87033 that it is a more obvious and intuitive meaning of **readonly**.

87034 The **−s** option suppresses all interactive user feedback and is useful for editing scripts in batch
87035 jobs. The list of specific effects is historical practice. The terminal type "incapable of supporting
87036 open and visual modes" has historically been named "dumb".

87037 The **−t** option was required because the *ctags* utility appears in POSIX.1-200x and the option is
87038 available in all historical implementations of *ex*.

87039 Historically, the *ex* and *vi* utilities accepted a **−x** option, which did encryption based on the
87040 algorithm found in the historical *crypt* utility. The **−x** option for encryption, and the associated
87041 *crypt* utility, were omitted because the algorithm used was not specifiable and the export control
87042 laws of some nations make it difficult to export cryptographic technology. In addition, it did not
87043 historically provide the level of security that users might expect.

87044 **Standard Input**

87045 An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file
87046 character, <control>-D, is historically an *ex* command.

87047 There was no maximum line length in historical implementations of *ex*. Specifically, as it was
87048 parsed in chunks, the addresses had a different maximum length than the filenames. Further, the
87049 maximum line buffer size was declared as BUFSIZ, which was different lengths on different
87050 systems. This version selected the value of {LINE_MAX} to impose a reasonable restriction on
87051 portable usage of *ex* and to aid test suite writers in their development of realistic tests that
87052 exercise this limit.

87053 **Input Files**

87054 It was an explicit decision by the standard developers that a <newline> be added to any file
87055 lacking one. It was believed that this feature of *ex* and *vi* was relied on by users in order to make
87056 text files lacking a trailing <newline> more portable. It is recognized that this will require a user-
87057 specified option or extension for implementations that permit *ex* and *vi* to edit files of type other
87058 than text if such files are not otherwise identified by the system. It was agreed that the ability to
87059 edit files of arbitrary type can be useful, but it was not considered necessary to mandate that an
87060 *ex* or *vi* implementation be required to handle files other than text files.

87061 The paragraph in the INPUT FILES section, "By default, ...", is intended to close a long-
87062 standing security problem in *ex* and *vi*; that of the "modeline" or "modelines" edit option. This
87063 feature allows any line in the first or last five lines of the file containing the strings `"ex:"` or
87064 `"vi:"` (and, apparently, `"ei:"` or `"vx:"`) to be a line containing editor commands, and *ex*
87065 interprets all the text up to the next `':'` or <newline> as a command. Consider the

consequences, for example, of an unsuspecting user using *ex* or *vi* as the editor when replying to a mail message in which a line such as:

```
ex:! rm –rf :
```

appeared in the signature lines. The standard developers believed strongly that an editor should not by default interpret any lines of a file. Vendors are strongly urged to delete this feature from their implementations of *ex* and *vi*.

Asynchronous Events

The intention of the phrase "complete write" is that the entire edit buffer be written to stable storage. The note regarding temporary files is intended for implementations that use temporary files to back edit buffers unnamed by the user.

Historically, SIGQUIT was ignored by *ex*, but was the equivalent of the **Q** command in visual mode; that is, it exited visual mode and entered *ex* mode. POSIX.1-200x permits, but does not require, this behavior. Historically, SIGINT was often used by *vi* users to terminate text input mode (<control>-C is often easier to enter than <ESC>). Some implementations of *vi* alerted the terminal on this event, and some did not. POSIX.1-200x requires that SIGINT behave identically to <ESC>, and that the terminal not be alerted.

Historically, suspending the *ex* editor during text input mode was similar to SIGINT, as completed lines were retained, but any partial line discarded, and the editor returned to command mode. POSIX.1-200x is silent on this issue; implementations are encouraged to follow historical practice, where possible.

Historically, the *vi* editor did not treat SIGTSTP as an asynchronous event, and it was therefore impossible to suspend the editor in visual text input mode. There are two major reasons for this. The first is that SIGTSTP is a broadcast signal on UNIX systems, and the chain of events where the shell *exec*s an application that then *exec*s *vi* usually caused confusion for the terminal state if SIGTSTP was delivered to the process group in the default manner. The second was that most implementations of the UNIX *curses* package did not handle SIGTSTP safely, and the receipt of SIGTSTP at the wrong time would cause them to crash. POSIX.1-200x is silent on this issue; implementations are encouraged to treat suspension as an asynchronous event if possible.

Historically, modifications to the edit buffer made before SIGINT interrupted an operation were retained; that is, anywhere from zero to all of the lines to be modified might have been modified by the time the SIGINT arrived. These changes were not discarded by the arrival of SIGINT. POSIX.1-200x permits this behavior, noting that the **undo** command is required to be able to undo these partially completed commands.

The action taken for signals other than SIGINT, SIGCONT, SIGHUP, and SIGTERM is unspecified because some implementations attempt to save the edit buffer in a useful state when other signals are received.

Standard Error

For *ex*/*vi*, diagnostic messages are those messages reported as a result of a failed attempt to invoke *ex* or *vi*, such as invalid options or insufficient resources, or an abnormal termination condition. Diagnostic messages should not be confused with the error messages generated by inappropriate or illegal user commands.

87107 **Initialization in ex and vi**

87108 If an *ex* command (other than **cd**, **chdir**, or **source**) has a filename argument, one or both of the
87109 alternate and current pathnames will be set. Informally, they are set as follows:

87110 1. If the *ex* command is one that replaces the contents of the edit buffer, and it succeeds, the
87111 current pathname will be set to the filename argument (the first filename argument in the
87112 case of the **next** command) and the alternate pathname will be set to the previous current
87113 pathname, if there was one.

87114 2. In the case of the file read/write forms of the **read** and **write** commands, if there is no
87115 current pathname, the current pathname will be set to the filename argument.

87116 3. Otherwise, the alternate pathname will be set to the filename argument.

87117 For example, **:edit foo** and **:recover foo**, when successful, set the current pathname, and, if there
87118 was a previous current pathname, the alternate pathname. The commands **:write**, **!command**,
87119 and **:edit** set neither the current or alternate pathnames. If the **:edit foo** command were to fail for
87120 some reason, the alternate pathname would be set. The **read** and **write** commands set the
87121 alternate pathname to their *file* argument, unless the current pathname is not set, in which case
87122 they set the current pathname to their *file* arguments. The alternate pathname was not
87123 historically set by the **:source** command. POSIX.1-200x requires conformance to historical
87124 practice. Implementations adding commands that take filenames as arguments are encouraged
87125 to set the alternate pathname as described here.

87126 Historically, *ex* and *vi* read the **.exrc** file in the *$HOME* directory twice, if the editor was executed
87127 in the *$HOME* directory. POSIX.1-200x prohibits this behavior.

87128 Historically, the 4 BSD *ex* and *vi* read the *$HOME* and local **.exrc** files if they were owned by the
87129 real ID of the user, or the **sourceany** option was set, regardless of other considerations. This was
87130 a security problem because it is possible to put normal UNIX system commands inside a **.exrc**
87131 file. POSIX.1-200x does not specify the **sourceany** option, and historical implementations are
87132 encouraged to delete it.

87133 The **.exrc** files must be owned by the real ID of the user, and not writable by anyone other than
87134 the owner. The appropriate privileges exception is intended to permit users to acquire special
87135 privileges, but continue to use the **.exrc** files in their home directories.

87136 System V Release 3.2 and later *vi* implementations added the option **[no]exrc**. The behavior is
87137 that local **.exrc** files are read-only if the **exrc** option is set. The default for the **exrc** option was off,
87138 so by default, local **.exrc** files were not read. The problem this was intended to solve was that
87139 System V permitted users to give away files, so there is no possible ownership or writeability
87140 test to ensure that the file is safe. This is still a security problem on systems where users can give
87141 away files, but there is nothing additional that POSIX.1-200x can do. The implementation-
87142 defined exception is intended to permit groups to have local **.exrc** files that are shared by users,
87143 by creating pseudo-users to own the shared files.

87144 POSIX.1-200x does not mention system-wide *ex* and *vi* start-up files. While they exist in several
87145 implementations of *ex* and *vi*, they are not present in any implementations considered historical
87146 practice by POSIX.1-200x. Implementations that have such files should use them only if they are
87147 owned by the real user ID or an appropriate user (for example, root on UNIX systems) and if
87148 they are not writable by any user other than their owner. System-wide start-up files should be
87149 read before the *EXINIT* variable, **$HOME/.exrc**, or local **.exrc** files are evaluated.

87150 Historically, any *ex* command could be entered in the *EXINIT* variable or the **.exrc** file, although
87151 ones requiring that the edit buffer already contain lines of text generally caused historical
87152 implementations of the editor to drop **core**. POSIX.1-200x requires that any *ex* command be

permitted in the *EXINIT* variable and **.exrc** files, for simplicity of specification and consistency, although many of them will obviously fail under many circumstances.

The initialization of the contents of the edit buffer uses the phrase "the effect shall be" with regard to various *ex* commands. The intent of this phrase is that edit buffer contents loaded during the initialization phase not be lost; that is, loading the edit buffer should fail if the **.exrc** file read in the contents of a file and did not subsequently write the edit buffer. An additional intent of this phrase is to specify that the initial current line and column is set as specified for the individual *ex* commands.

Historically, the **−t** option behaved as if the tag search were a **+***command*; that is, it was executed from the last line of the file specified by the tag. This resulted in the search failing if the pattern was a forward search pattern and the **wrapscan** edit option was not set. POSIX.1-200x does not permit this behavior, requiring that the search for the tag pattern be performed on the entire file, and, if not found, that the current line be set to a more reasonable location in the file.

Historically, the empty edit buffer presented for editing when a file was not specified by the user was unnamed. This is permitted by POSIX.1-200x; however, implementations are encouraged to provide users a temporary filename for this buffer because it permits them the use of *ex* commands that use the current pathname during temporary edit sessions.

Historically, the file specified using the **−t** option was not part of the current argument list. This practice is permitted by POSIX.1-200x; however, implementations are encouraged to include its name in the current argument list for consistency.

Historically, the **−c** command was generally not executed until a file that already exists was edited. POSIX.1-200x requires conformance to this historical practice. Commands that could cause the **−c** command to be executed include the *ex* commands **edit**, **next**, **recover**, **rewind**, and **tag**, and the *vi* commands <control>-^ and <control>-]. Historically, reading a file into an edit buffer did not cause the **−c** command to be executed (even though it might set the current pathname) with the exception that it did cause the **−c** command to be executed if: the editor was in *ex* mode, the edit buffer had no current pathname, the edit buffer was empty, and no read commands had yet been attempted. For consistency and simplicity of specification, POSIX.1-200x does not permit this behavior.

Historically, the **−r** option was the same as a normal edit session if there was no recovery information available for the file. This allowed users to enter:

```
vi −r *.c
```

and recover whatever files were recoverable. In some implementations, recovery was attempted only on the first file named, and the file was not entered into the argument list; in others, recovery was attempted for each file named. In addition, some historical implementations ignored **−r** if **−t** was specified or did not support command line *file* arguments with the **−t** option. For consistency and simplicity of specification, POSIX.1-200x disallows these special cases, and requires that recovery be attempted the first time each file is edited.

Historically, *vi* initialized the ‘ and ’ marks, but *ex* did not. This meant that if the first command in *ex* mode was **visual** or if an *ex* command was executed first (for example, *vi* +10 *file*), *vi* was entered without the marks being initialized. Because the standard developers believed the marks to be generally useful, and for consistency and simplicity of specification, POSIX.1-200x requires that they always be initialized if in open or visual mode, or if in *ex* mode and the edit buffer is not empty. Not initializing it in *ex* mode if the edit buffer is empty is historical practice; however, it has always been possible to set (and use) marks in empty edit buffers in open and visual mode edit sessions.

Addressing

Historically, *ex* and *vi* accepted the additional addressing forms `'\/'` and `'\?'`. They were equivalent to `"//"` and `"??"`, respectively. They are not required by POSIX.1-200x, mostly because nobody can remember whether they ever did anything different historically.

Historically, *ex* and *vi* permitted an address of zero for several commands, and permitted the % address in empty files for others. For consistency, POSIX.1-200x requires support for the former in the few commands where it makes sense, and disallows it otherwise. In addition, because POSIX.1-200x requires that **%** be logically equivalent to `"1,$"`, it is also supported where it makes sense and disallowed otherwise.

Historically, the % address could not be followed by further addresses. For consistency and simplicity of specification, POSIX.1-200x requires that additional addresses be supported.

All of the following are valid *addresses*:

`+++` Three lines after the current line.

`/re/-` One line before the next occurrence of *re*.

`-2` Two lines before the current line.

`3 ---- 2` Line one (note intermediate negative address).

`1 2 3` Line six.

Any number of addresses can be provided to commands taking addresses; for example, `"1,2,3,4,5p"` prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the **print** command. This, in combination with the <semicolon> delimiter, permits users to create commands based on ordered patterns in the file. For example, the command **3;/foo/;+2print** will display the first line after line 3 that contains the pattern *foo*, plus the next two lines. Note that the address **3;** must be evaluated before being discarded because the search origin for the **/foo/** command depends on this.

Historically, values could be added to addresses by including them after one or more <blank> characters; for example, **3 - 5p** wrote the seventh line of the file, and **/foo/ 5** was the same as **/foo/+5**. However, only absolute values could be added; for example, **5 /foo/** was an error. POSIX.1-200x requires conformance to historical practice. Address offsets are separately specified from addresses because they could historically be provided to visual mode search commands.

Historically, any missing addresses defaulted to the current line. This was true for leading and trailing <comma>-delimited addresses, and for trailing <semicolon>-delimited addresses. For consistency, POSIX.1-200x requires it for leading <semicolon> addresses as well.

Historically, *ex* and *vi* accepted the `'^'` character as both an address and as a flag offset for commands. In both cases it was identical to the `'-'` character. POSIX.1-200x does not require or prohibit this behavior.

Historically, the enhancements to basic regular expressions could be used in addressing; for example, `'~'`, `'\<'`, and `'\>'`. POSIX.1-200x requires conformance to historical practice; that is, that regular expression usage be consistent, and that regular expression enhancements be supported wherever regular expressions are used.

Command Line Parsing in ex

Historical *ex* command parsing was even more complex than that described here. POSIX.1-200x requires the subset of the command parsing that the standard developers believed was documented and that users could reasonably be expected to use in a portable fashion, and that was historically consistent between implementations. (The discarded functionality is obscure, at best.) Historical implementations will require changes in order to comply with POSIX.1-200x; however, users are not expected to notice any of these changes. Most of the complexity in *ex* parsing is to handle three special termination cases:

1. The **!**, **global**, **v**, and the filter versions of the **read** and **write** commands are delimited by <newline> characters (they can contain <vertical-line> characters that are usually shell pipes).
2. The **ex**, **edit**, **next**, and **visual** in open and visual mode commands all take *ex* commands, optionally containing <vertical-line> characters, as their first arguments.
3. The **s** command takes a regular expression as its first argument, and uses the delimiting characters to delimit the command.

Historically, <vertical-line> characters in the **+***command* argument of the **ex**, **edit**, **next**, **vi**, and **visual** commands, and in the *pattern* and *replacement* parts of the **s** command, did not delimit the command, and in the filter cases for **read** and **write**, and the **!**, **global**, and **v** commands, they did not delimit the command at all. For example, the following commands are all valid:

```
:edit +25 | s/abc/ABC/ file.c
:s/ | /PIPE/
:read !spell % | columnate
:global/pattern/p | l
:s/a/b/ | s/c/d | set
```

Historically, empty or <blank> filled lines in **.exrc** files and **source**d files (as well as *EXINIT* variables and *ex* command scripts) were treated as default commands; that is, **print** commands. POSIX.1-200x specifically requires that they be ignored when encountered in **.exrc** and **source**d files to eliminate a common source of new user error.

Historically, *ex* commands with multiple adjacent (or <blank>-separated) vertical lines were handled oddly when executed from *ex* mode. For example, the command **|||** <carriage-return>, when the cursor was on line 1, displayed lines 2, 3, and 5 of the file. In addition, the command **|** would only display the line after the next line, instead of the next two lines. The former worked more logically when executed from *vi* mode, and displayed lines 2, 3, and 4. POSIX.1-200x requires the *vi* behavior; that is, a single default command and line number increment for each command separator, and trailing <newline> characters after <vertical-line> separators are discarded.

Historically, *ex* permitted a single extra <colon> as a leading command character; for example, **:g/pattern/:p** was a valid command. POSIX.1-200x generalizes this to require that any number of leading <colon> characters be stripped.

Historically, any prefix of the **delete** command could be followed without intervening <blank> characters by a flag character because in the command **d p**, *p* is interpreted as the buffer *p*. POSIX.1-200x requires conformance to historical practice.

Historically, the **k** command could be followed by the mark name without intervening <blank> characters. POSIX.1-200x requires conformance to historical practice.

Historically, the **s** command could be immediately followed by flag and option characters; for example, **s/e/E/|s|sgc3p** was a valid command. However, flag characters could not stand alone;

for example, the commands **sp** and **s l** would fail, while the command **sgp** and **s gl** would succeed. (Obviously, the '#' flag character was used as a delimiter character if it followed the command.) Another issue was that option characters had to precede flag characters even when the command was fully specified; for example, the command **s/e/E/pg** would fail, while the command **s/e/E/gp** would succeed. POSIX.1-200x requires conformance to historical practice.

Historically, the first command name that had a prefix matching the input from the user was the executed command; for example, **ve**, **ver**, and **vers** all executed the **version** command. Commands were in a specific order, however, so that **a** matched **append**, not **abbreviate**. POSIX.1-200x requires conformance to historical practice. The restriction on command search order for implementations with extensions is to avoid the addition of commands such that the historical prefixes would fail to work portably.

Historical implementations of *ex* and *vi* did not correctly handle multiple *ex* commands, separated by <vertical-line> characters, that entered or exited visual mode or the editor. Because implementations of *vi* exist that do not exhibit this failure mode, POSIX.1-200x does not permit it.

The requirement that alphabetic command names consist of all following alphabetic characters up to the next non-alphabetic character means that alphabetic command names must be separated from their arguments by one or more non-alphabetic characters, normally a <blank> or '!' character, except as specified for the exceptions, the **delete**, **k**, and **s** commands.

Historically, the repeated execution of the *ex* default **print** commands (<control>-D, *eof*, <newline>, <carriage-return>) erased any prompting character and displayed the next lines without scrolling the terminal; that is, immediately below any previously displayed lines. This provided a cleaner presentation of the lines in the file for the user. POSIX.1-200x does not require this behavior because it may be impossible in some situations; however, implementations are strongly encouraged to provide this semantic if possible.

Historically, it was possible to change files in the middle of a command, and have the rest of the command executed in the new file; for example:

```
:edit +25 file.c | s/abc/ABC/ | 1
```

was a valid command, and the substitution was attempted in the newly edited file. POSIX.1-200x requires conformance to historical practice. The following commands are examples that exercise the *ex* parser:

```
echo 'foo | bar' > file1; echo 'foo/bar' > file2;
vi
:edit +1 | s/|/PIPE/ | w file1 | e file2 | 1 | s/\//SLASH/ | wq
```

Historically, there was no protection in editor implementations to avoid *ex* **global**, **v**, **@**, or * commands changing edit buffers during execution of their associated commands. Because this would almost invariably result in catastrophic failure of the editor, and implementations exist that do exhibit these problems, POSIX.1-200x requires that changing the edit buffer during a **global** or **v** command, or during a **@** or * command for which there will be more than a single execution, be an error. Implementations supporting multiple edit buffers simultaneously are strongly encouraged to apply the same semantics to switching between buffers as well.

The *ex* command quoting required by POSIX.1-200x is a superset of the quoting in historical implementations of the editor. For example, it was not historically possible to escape a <blank> in a filename; for example, **:edit foo\\\ bar** would report that too many filenames had been entered for the edit command, and there was no method of escaping a <blank> in the first argument of an **edit**, **ex**, **next**, or **visual** command at all. POSIX.1-200x extends historical practice, requiring that quoting behavior be made consistent across all *ex* commands, except for

the **map**, **unmap**, **abbreviate**, and **unabbreviate** commands, which historically used <control>-V instead of <backslash> characters for quoting. For those four commands, POSIX.1-200x requires conformance to historical practice.

Backslash quoting in *ex* is non-intuitive. <backslash>-escapes are ignored unless they escape a special character; for example, when performing *file* argument expansion, the string `"\\%"` is equivalent to `'\%'`, not "`\<current pathname>`". This can be confusing for users because <backslash> is usually one of the characters that causes shell expansion to be performed, and therefore shell quoting rules must be taken into consideration. Generally, quoting characters are only considered if they escape a special character, and a quoting character must be provided for each layer of parsing for which the character is special. As another example, only a single <backslash> is necessary for the `'\l'` sequence in substitute replacement patterns, because the character `'l'` is not special to any parsing layer above it.

<control>-V quoting in *ex* is slightly different from backslash quoting. In the four commands where <control>-V quoting applies (**abbreviate**, **unabbreviate**, **map**, and **unmap**), any character may be escaped by a <control>-V whether it would have a special meaning or not. POSIX.1-200x requires conformance to historical practice.

Historical implementations of the editor did not require delimiters within character classes to be escaped; for example, the command **:s/[/]//** on the string `"xxx/yyy"` would delete the `'//'` from the string. POSIX.1-200x disallows this historical practice for consistency and because it places a large burden on implementations by requiring that knowledge of regular expressions be built into the editor parser.

Historically, quoting <newline> characters in *ex* commands was handled inconsistently. In most cases, the <newline> character always terminated the command, regardless of any preceding escape character, because <backslash> characters did not escape <newline> characters for most *ex* commands. However, some *ex* commands (for example, **s**, **map**, and **abbreviation**) permitted <newline> characters to be escaped (although in the case of **map** and **abbreviation**, <control>-V characters escaped them instead of <backslash> characters). This was true in not only the command line, but also **.exrc** and **source**d files. For example, the command:

```
map = foo<control-V><newline>bar
```

would succeed, although it was sometimes difficult to get the <control>-V and the inserted <newline> passed to the *ex* parser. For consistency and simplicity of specification, POSIX.1-200x requires that it be possible to escape <newline> characters in *ex* commands at all times, using <backslash> characters for most *ex* commands, and using <control>-V characters for the **map** and **abbreviation** commands. For example, the command **print**<newline>**list** is required to be parsed as the single command **print**<newline>**list**. While this differs from historical practice, POSIX.1-200x developers believed it unlikely that any script or user depended on the historical behavior.

Historically, an error in a command specified using the **–c** option did not cause the rest of the **–c** commands to be discarded. POSIX.1-200x disallows this for consistency with mapped keys, the **@**, **global**, **source**, and **v** commands, the *EXINIT* environment variable, and the **.exrc** files.

Input Editing in ex

One of the common uses of the historical *ex* editor is over slow network connections. Editors that run in canonical mode can require far less traffic to and from, and far less processing on, the host machine, as well as more easily supporting block-mode terminals. For these reasons, POSIX.1-200x requires that *ex* be implemented using canonical mode input processing, as was done historically.

POSIX.1-200x does not require the historical 4 BSD input editing characters "word erase" or "literal next". For this reason, it is unspecified how they are handled by *ex*, although they must have the required effect. Implementations that resolve them after the line has been ended using a <newline> or <control>-M character, and implementations that rely on the underlying system terminal support for this processing, are both conforming. Implementations are strongly urged to use the underlying system functionality, if at all possible, for compatibility with other system text input interfaces.

Historically, when the *eof* character was used to decrement the **autoindent** level, the cursor moved to display the new end of the **autoindent** characters, but did not move the cursor to a new line, nor did it erase the <control>-D character from the line. POSIX.1-200x does not specify that the cursor remain on the same line or that the rest of the line is erased; however, implementations are strongly encouraged to provide the best possible user interface; that is, the cursor should remain on the same line, and any <control>-D character on the line should be erased.

POSIX.1-200x does not require the historical 4 BSD input editing character "reprint", traditionally <control>-R, which redisplayed the current input from the user. For this reason, and because the functionality cannot be implemented after the line has been terminated by the user, POSIX.1-200x makes no requirements about this functionality. Implementations are strongly urged to make this historical functionality available, if possible.

Historically, <control>-Q did not perform a literal next function in *ex*, as it did in *vi*. POSIX.1-200x requires conformance to historical practice to avoid breaking historical *ex* scripts and **.exrc** files.

eof

Whether the *eof* character immediately modifies the **autoindent** characters in the prompt is left unspecified so that implementations can conform in the presence of systems that do not support this functionality. Implementations are encouraged to modify the line and redisplay it immediately, if possible.

The specification of the handling of the *eof* character differs from historical practice only in that *eof* characters are not discarded if they follow normal characters in the text input. Historically, they were always discarded.

Command Descriptions in ex

Historically, several commands (for example, **global**, **v**, **visual**, **s**, **write**, **wq**, **yank**, **!**, **<**, **>**, **&**, and **~**) were executable in empty files (that is, the default address(es) were 0), or permitted explicit addresses of 0 (for example, 0 was a valid address, or 0,0 was a valid range). Addresses of 0, or command execution in an empty file, make sense only for commands that add new text to the edit buffer or write commands (because users may wish to write empty files). POSIX.1-200x requires this behavior for such commands and disallows it otherwise, for consistency and simplicity of specification.

A count to an *ex* command has been historically corrected to be no greater than the last line in a

file; for example, in a five-line file, the command **1,6print** would fail, but the command **1print300** would succeed. POSIX.1-200x requires conformance to historical practice.

Historically, the use of flags in *ex* commands could be obscure. General historical practice was as described by POSIX.1-200x, but there were some special cases. For instance, the **list**, **number**, and **print** commands ignored trailing address offsets; for example, **3p +++#** would display line 3, and 3 would be the current line after the execution of the command. The **open** and **visual** commands ignored both the trailing offsets and the trailing flags. Also, flags specified to the **open** and **visual** commands interacted badly with the **list** edit option, and setting and then unsetting it during the open/visual session would cause *vi* to stop displaying lines in the specified format. For consistency and simplicity of specification, POSIX.1-200x does not permit any of these exceptions to the general rule.

POSIX.1-200x uses the word *copy* in several places when discussing buffers. This is not intended to imply implementation.

Historically, *ex* users could not specify numeric buffers because of the ambiguity this would cause; for example, in the command **3 delete 2**, it is unclear whether 2 is a buffer name or a *count*. POSIX.1-200x requires conformance to historical practice by default, but does not preclude extensions.

Historically, the contents of the unnamed buffer were frequently discarded after commands that did not explicitly affect it; for example, when using the **edit** command to switch files. For consistency and simplicity of specification, POSIX.1-200x does not permit this behavior.

The *ex* utility did not historically have access to the numeric buffers, and, furthermore, deleting lines in *ex* did not modify their contents. For example, if, after doing a delete in *vi*, the user switched to *ex*, did another delete, and then switched back to *vi*, the contents of the numeric buffers would not have changed. POSIX.1-200x requires conformance to historical practice. Numeric buffers are described in the *ex* utility in order to confine the description of buffers to a single location in POSIX.1-200x.

The metacharacters that trigger shell expansion in *file* arguments match historical practice, as does the method for doing shell expansion. Implementations wishing to provide users with the flexibility to alter the set of metacharacters are encouraged to provide a **shellmeta** string edit option.

Historically, *ex* commands executed from *vi* refreshed the screen when it did not strictly need to do so; for example, **:!date > /dev/null** does not require a screen refresh because the output of the UNIX *date* command requires only a single line of the screen. POSIX.1-200x requires that the screen be refreshed if it has been overwritten, but makes no requirements as to how an implementation should make that determination. Implementations may prompt and refresh the screen regardless.

Abbreviate

Historical practice was that characters that were entered as part of an abbreviation replacement were subject to **map** expansions, the **showmatch** edit option, further abbreviation expansions, and so on; that is, they were logically pushed onto the terminal input queue, and were not a simple replacement. POSIX.1-200x requires conformance to historical practice. Historical practice was that whenever a non-word character (that had not been escaped by a <control>-V) was entered after a word character, *vi* would check for abbreviations. The check was based on the type of the character entered before the word character of the word/non-word pair that triggered the check. The word character of the word/non-word pair that triggered the check and all characters entered before the trigger pair that were of that type were included in the check, with the exception of <blank> characters, which always delimited the abbreviation.

This means that, for the abbreviation to work, the *lhs* must end with a word character, there can be no transitions from word to non-word characters (or *vice versa*) other than between the last and next-to-last characters in the *lhs*, and there can be no <blank> characters in the *lhs*. In addition, because of the historical quoting rules, it was impossible to enter a literal <control>-V in the *lhs*. POSIX.1-200x requires conformance to historical practice. Historical implementations did not inform users when abbreviations that could never be used were entered; implementations are strongly encouraged to do so.

For example, the following abbreviations will work:

```
:ab (p  REPLACE
:ab p   REPLACE
:ab ((p REPLACE
```

The following abbreviations will not work:

```
:ab (   REPLACE
:ab (pp REPLACE
```

Historical practice is that words on the *vi* colon command line were subject to abbreviation expansion, including the arguments to the **abbrev** (and more interestingly) the **unabbrev** command. Because there are implementations that do not do abbreviation expansion for the first argument to those commands, this is permitted, but not required, by POSIX.1-200x. However, the following sequence:

```
:ab foo bar
:ab foo baz
```

resulted in the addition of an abbreviation of `"baz"` for the string `"bar"` in historical *ex*/*vi*, and the sequence:

```
:ab foo1 bar
:ab foo2 bar
:unabbreviate foo2
```

deleted the abbreviation `"foo1"`, not `"foo2"`. These behaviors are not permitted by POSIX.1-200x because they clearly violate the expectations of the user.

It was historical practice that <control>-V, not <backslash>, characters be interpreted as escaping subsequent characters in the **abbreviate** command. POSIX.1-200x requires conformance to historical practice; however, it should be noted that an abbreviation containing a <blank> will never work.

Append

Historically, any text following a <vertical-line> command separator after an **append**, **change**, or **insert** command became part of the insert text. For example, in the command:

```
:g/pattern/append|stuff1
```

a line containing the text `"stuff1"` would be appended to each line matching pattern. It was also historically valid to enter:

```
:append|stuff1
stuff2
.
```

and the text on the *ex* command line would be appended along with the text inserted after it. There was an historical bug, however, that the user had to enter two terminating lines (the `'.'`

lines) to terminate text input mode in this case. POSIX.1-200x requires conformance to historical practice, but disallows the historical need for multiple terminating lines.

Change

See the RATIONALE for the **append** command. Historical practice for cursor positioning after the change command when no text is input, is as described in POSIX.1-200x. However, one System V implementation is known to have been modified such that the cursor is positioned on the first address specified, and not on the line before the first address. POSIX.1-200x disallows this modification for consistency.

Historically, the **change** command did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by POSIX.1-200x.

Change Directory

A common extension in *ex* implementations is to use the elements of a **cdpath** edit option as prefix directories for *path* arguments to **chdir** that are relative pathnames and that do not have `'.'` or `".."` as their first component. Elements in the **cdpath** edit option are <colon>-separated. The initial value of the **cdpath** edit option is the value of the shell *CDPATH* environment variable. This feature was not included in POSIX.1-200x because it does not exist in any of the implementations considered historical practice.

Copy

Historical implementations of *ex* permitted copies to lines inside of the specified range; for example, **:2,5copy3** was a valid command. POSIX.1-200x requires conformance to historical practice.

Delete

POSIX.1-200x requires support for the historical parsing of a **delete** command followed by flags, without any intervening <blank> characters. For example:

1dp Deletes the first line and prints the line that was second.

1delep As for **1dp**.

1d Deletes the first line, saving it in buffer *p*.

1d p1l (Pee-one-ell.) Deletes the first line, saving it in buffer *p*, and listing the line that was second.

Edit

Historically, any *ex* command could be entered as a **+***command* argument to the **edit** command, although some (for example, **insert** and **append**) were known to confuse historical implementations. For consistency and simplicity of specification, POSIX.1-200x requires that any command be supported as an argument to the **edit** command.

Historically, the command argument was executed with the current line set to the last line of the file, regardless of whether the **edit** command was executed from visual mode or not. POSIX.1-200x requires conformance to historical practice.

Historically, the **+***command* specified to the **edit** and **next** commands was delimited by the first <blank>, and there was no way to quote them. For consistency, POSIX.1-200x requires that the usual *ex* backslash quoting be provided.

Historically, specifying the **+***command* argument to the edit command required a filename to be specified as well; for example, **:edit +100** would always fail. For consistency and simplicity of specification, POSIX.1-200x does not permit this usage to fail for that reason.

Historically, only the cursor position of the last file edited was remembered by the editor. POSIX.1-200x requires that this be supported; however, implementations are permitted to remember and restore the cursor position for any file previously edited.

File

Historical versions of the *ex* editor **file** command displayed a current line and number of lines in the edit buffer of 0 when the file was empty, while the *vi* <control>-G command displayed a current line and number of lines in the edit buffer of 1 in the same situation. POSIX.1-200x does not permit this discrepancy, instead requiring that a message be displayed indicating that the file is empty.

Global

The two-pass operation of the **global** and **v** commands is not intended to imply implementation, only the required result of the operation.

The current line and column are set as specified for the individual *ex* commands. This requirement is cumulative; that is, the current line and column must track across all the commands executed by the **global** or **v** commands.

Insert

See the RATIONALE for the **append** command.

Historically, **insert** could not be used with an address of zero; that is, not when the edit buffer was empty. POSIX.1-200x requires that this command behave consistently with the **append** command.

Join

The action of the **join** command in relation to the special characters is only defined for the POSIX locale because the correct amount of white space after a period varies; in Japanese none is required, in French only a single space, and so on.

List

The historical output of the **list** command was potentially ambiguous. The standard developers believed correcting this to be more important than adhering to historical practice, and POSIX.1-200x requires unambiguous output.

Map

Historically, command mode maps only applied to command names; for example, if the character `'x'` was mapped to `'y'`, the command **fx** searched for the `'x'` character, not the `'y'` character. POSIX.1-200x requires this behavior. Historically, entering <control>-V as the first character of a *vi* command was an error. Several implementations have extended the semantics of *vi* such that <control>-V means that the subsequent command character is not mapped. This is permitted, but not required, by POSIX.1-200x. Regardless, using <control>-V to escape the second or later character in a sequence of characters that might match a **map** command, or any character in text input mode, is historical practice, and stops the entered keys from matching a map. POSIX.1-200x requires conformance to historical practice.

Historical implementations permitted digits to be used as a **map** command *lhs*, but then ignored the map. POSIX.1-200x requires that the mapped digits not be ignored.

The historical implementation of the **map** command did not permit **map** commands that were more than a single character in length if the first character was printable. This behavior is permitted, but not required, by POSIX.1-200x.

Historically, mapped characters were remapped unless the **remap** edit option was not set, or the prefix of the mapped characters matched the mapping characters; for example, in the **map**:

```
:map ab abcd
```

the characters `"ab"` were used as is and were not remapped, but the characters `"cd"` were mapped if appropriate. This can cause infinite loops in the *vi* mapping mechanisms. POSIX.1-200x requires conformance to historical practice, and that such loops be interruptible.

Text input maps had the same problems with expanding the *lhs* for the *ex* **map!** and **unmap!** command as did the *ex* **abbreviate** and **unabbreviate** commands. See the RATIONALE for the *ex* **abbreviate** command. POSIX.1-200x requires similar modification of some historical practice for the **map** and **unmap** commands, as described for the **abbreviate** and **unabbreviate** commands.

Historically, **map**s that were subsets of other **map**s behaved differently depending on the order in which they were defined. For example:

```
:map! ab     short
:map! abc    long
```

would always translate the characters `"ab"` to `"short"`, regardless of how fast the characters `"abc"` were entered. If the entry order was reversed:

```
:map! abc    long
:map! ab     short
```

the characters `"ab"` would cause the editor to pause, waiting for the completing `'c'` character, and the characters might never be mapped to `"short"`. For consistency and simplicity of specification, POSIX.1-200x requires that the shortest match be used at all times.

The length of time the editor spends waiting for the characters to complete the *lhs* is unspecified because the timing capabilities of systems are often inexact and variable, and it may depend on other factors such as the speed of the connection. The time should be long enough for the user to be able to complete the sequence, but not long enough for the user to have to wait. Some implementations of *vi* have added a **keytime** option, which permits users to set the number of 0,1 seconds the editor waits for the completing characters. Because mapped terminal function and cursor keys tend to start with an <ESC> character, and <ESC> is the key ending *vi* text input mode, **map**s starting with <ESC> characters are generally exempted from this timeout period, or, at least timed out differently.

Mark

Historically, users were able to set the ''previous context'' marks explicitly. In addition, the *ex* commands **''** and **``** and the *vi* commands **''**, **``**, **``**, and **''** all referred to the same mark. In addition, the previous context marks were not set if the command, with which the address setting the mark was associated, failed. POSIX.1-200x requires conformance to historical practice. Historically, if marked lines were deleted, the mark was also deleted, but would reappear if the change was undone. POSIX.1-200x requires conformance to historical practice.

The description of the special events that set the **`** and **'** marks matches historical practice. For example, historically the command **/a/,/b/** did not set the **`** and **'** marks, but the command

87633 **/a/,/b/delete** did.

87634 **Next**

87635 Historically, any *ex* command could be entered as a **+***command* argument to the **next** command,
87636 although some (for example, **insert** and **append**) were known to confuse historical
87637 implementations. POSIX.1-200x requires that any command be permitted and that it behave as
87638 specified. The **next** command can accept more than one file, so usage such as:

87639 `next 'ls [abc] '`

87640 is valid; it need not be valid for the **edit** or **read** commands, for example, because they expect
87641 only one filename.

87642 Historically, the **next** command behaved differently from the **:rewind** command in that it
87643 ignored the force flag if the **autowrite** flag was set. For consistency, POSIX.1-200x does not
87644 permit this behavior.

87645 Historically, the **next** command positioned the cursor as if the file had never been edited before,
87646 regardless. POSIX.1-200x does not permit this behavior, for consistency with the **edit** command.

87647 Implementations wanting to provide a counterpart to the **next** command that edited the
87648 previous file have used the command **prev[ious],** which takes no *file* argument. POSIX.1-200x
87649 does not require this command.

87650 **Open**

87651 Historically, the **open** command would fail if the **open** edit option was not set. POSIX.1-200x
87652 does not mention the **open** edit option and does not require this behavior. Some historical
87653 implementations do not permit entering open mode from open or visual mode, only from *ex*
87654 mode. For consistency, POSIX.1-200x does not permit this behavior.

87655 Historically, entering open mode from the command line (that is, *vi* **+open**) resulted in
87656 anomalous behaviors; for example, the *ex* file and *set* commands, and the *vi* command
87657 <control>-G did not work. For consistency, POSIX.1-200x does not permit this behavior.

87658 Historically, the **open** command only permitted `'/'` characters to be used as the search pattern
87659 delimiter. For consistency, POSIX.1-200x requires that the search delimiters used by the **s**, **global**,
87660 and **v** commands be accepted as well.

87661 **Preserve**

87662 The **preserve** command does not historically cause the file to be considered unmodified for the
87663 purposes of future commands that may exit the editor. POSIX.1-200x requires conformance to
87664 historical practice.

87665 Historical documentation stated that mail was not sent to the user when preserve was executed;
87666 however, historical implementations did send mail in this case. POSIX.1-200x requires
87667 conformance to the historical implementations.

87668 **Print**

87669 The writing of NUL by the **print** command is not specified as a special case because the standard
87670 developers did not want to require *ex* to support NUL characters. Historically, characters were
87671 displayed using the ARPA standard mappings, which are as follows:

87672 1. Printable characters are left alone.

87673 2. Control characters less than \177 are represented as `'^'` followed by the character offset
87674 from the `'@'` character in the ASCII map; for example, \007 is represented as `'^G'`.

87675 3. \177 is represented as `'^'` followed by `'?'`.

87676 The display of characters having their eighth bit set was less standard. Existing implementations
87677 use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed bytes that had their
87678 eighth bit set as the two characters `"M-"` followed by the seven-bit display as described above.)
87679 The latter probably has the best claim to historical practice because it was used for the **–v** option
87680 of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

87681 No specific display format is required by POSIX.1-200x.

87682 Explicit dependence on the ASCII character set has been avoided where possible, hence the use
87683 of the phrase an "implementation-defined multi-character sequence" for the display of non-
87684 printable characters in preference to the historical usage of, for instance, `"^I"` for the <tab>.
87685 Implementations are encouraged to conform to historical practice in the absence of any strong
87686 reason to diverge.

87687 Historically, all *ex* commands beginning with the letter `'p'` could be entered using capitalized
87688 versions of the commands; for example, **P[rint]**, **Pre[serve]**, and **Pu[t]** were all valid command
87689 names. POSIX.1-200x permits, but does not require, this historical practice because capital forms
87690 of the commands are used by some implementations for other purposes.

87691 **Put**

87692 Historically, an *ex* **put** command, executed from open or visual mode, was the same as the open
87693 or visual mode **P** command, if the buffer was named and was cut in character mode, and the
87694 same as the **p** command if the buffer was named and cut in line mode. If the unnamed buffer
87695 was the source of the text, the entire line from which the text was taken was usually **put**, and the
87696 buffer was handled as if in line mode, but it was possible to get extremely anomalous behavior.
87697 In addition, using the **Q** command to switch into *ex* mode, and then doing a **put** often resulted in
87698 errors as well, such as appending text that was unrelated to the (supposed) contents of the
87699 buffer. For consistency and simplicity of specification, POSIX.1-200x does not permit these
87700 behaviors. All *ex* **put** commands are required to operate in line mode, and the contents of the
87701 buffers are not altered by changing the mode of the editor.

87702 **Read**

87703 Historically, an *ex* **read** command executed from open or visual mode, executed in an empty file,
87704 left an empty line as the first line of the file. For consistency and simplicity of specification,
87705 POSIX.1-200x does not permit this behavior. Historically, a **read** in open or visual mode from a
87706 program left the cursor at the last line read in, not the first. For consistency, POSIX.1-200x does
87707 not permit this behavior.

87708 Historical implementations of *ex* were unable to undo **read** commands that read from the output
87709 of a program. For consistency, POSIX.1-200x does not permit this behavior.

87710 Historically, the *ex* and *vi* message after a successful **read** or **write** command specified
87711 "characters", not "bytes". POSIX.1-200x requires that the number of bytes be displayed, not the

number of characters, because it may be difficult in multi-byte implementations to determine the number of characters read. Implementations are encouraged to clarify the message displayed to the user.

Historically, reads were not permitted on files other than type regular, except that FIFO files could be read (probably only because they did not exist when *ex* and *vi* were originally written). Because the historical *ex* evaluated **read!** and **read !** equivalently, there can be no optional way to force the read. POSIX.1-200x permits, but does not require, this behavior.

Recover

Some historical implementations of the editor permitted users to recover the edit buffer contents from a previous edit session, and then exit without saving those contents (or explicitly discarding them). The intent of POSIX.1-200x in requiring that the edit buffer be treated as already modified is to prevent this user error.

Rewind

Historical implementations supported the **rewind** command when the user was editing the first file in the list; that is, the file that the **rewind** command would edit. POSIX.1-200x requires conformance to historical practice.

Substitute

Historically, *ex* accepted an **r** option to the **s** command. The effect of the **r** option was to use the last regular expression used in any command as the pattern, the same as the ~ command. The **r** option is not required by POSIX.1-200x. Historically, the **c** and **g** options were toggled; for example, the command **:s/abc/def/** was the same as **s/abc/def/ccccgggg**. For simplicity of specification, POSIX.1-200x does not permit this behavior.

The tilde command is often used to replace the last search RE. For example, in the sequence:

```
s/red/blue/
/green
~
```

the ~ command is equivalent to:

```
s/green/blue/
```

Historically, *ex* accepted all of the following forms:

```
s/abc/def/
s/abc/def
s/abc/
s/abc
```

POSIX.1-200x requires conformance to this historical practice.

The **s** command presumes that the `'^'` character only occupies a single column in the display. Much of the *ex* and *vi* specification presumes that the <space> only occupies a single column in the display. There are no known character sets for which this is not true.

Historically, the final column position for the substitute commands was based on previous column movements; a search for a pattern followed by a substitution would leave the column position unchanged, while a 0 command followed by a substitution would change the column position to the first non-<blank>. For consistency and simplicity of specification, POSIX.1-200x requires that the final column position always be set to the first non-<blank>.

87754 **Set**

87755 Historical implementations redisplayed all of the options for each occurrence of the **all** keyword.
87756 POSIX.1-200x permits, but does not require, this behavior.

87757 **Tag**

87758 No requirement is made as to where *ex* and *vi* shall look for the file referenced by the tag entry.
87759 Historical practice has been to look for the path found in the **tags** file, based on the current
87760 directory. A useful extension found in some implementations is to look based on the directory
87761 containing the tags file that held the entry, as well. No requirement is made as to which reference
87762 for the tag in the tags file is used. This is deliberate, in order to permit extensions such as
87763 multiple entries in a tags file for a tag.

87764 Because users often specify many different tags files, some of which need not be relevant or exist
87765 at any particular time, POSIX.1-200x requires that error messages about problem tags files be
87766 displayed only if the requested tag is not found, and then, only once for each time that the **tag**
87767 edit option is changed.

87768 The requirement that the current edit buffer be unmodified is only necessary if the file indicated
87769 by the tag entry is not the same as the current file (as defined by the current pathname).
87770 Historically, the file would be reloaded if the filename had changed, as well as if the filename
87771 was different from the current pathname. For consistency and simplicity of specification,
87772 POSIX.1-200x does not permit this behavior, requiring that the name be the only factor in the
87773 decision.

87774 Historically, *vi* only searched for tags in the current file from the current cursor to the end of the
87775 file, and therefore, if the **wrapscan** option was not set, tags occurring before the current cursor
87776 were not found. POSIX.1-200x considers this a bug, and implementations are required to search
87777 for the first occurrence in the file, regardless.

87778 **Undo**

87779 The **undo** description deliberately uses the word "modified". The **undo** command is not
87780 intended to undo commands that replace the contents of the edit buffer, such as **edit**, **next**, **tag**,
87781 or **recover**.

87782 Cursor positioning after the **undo** command was inconsistent in the historical *vi*, sometimes
87783 attempting to restore the original cursor position (**global**, **undo**, and **v** commands), and
87784 sometimes, in the presence of maps, placing the cursor on the last line added or changed instead
87785 of the first. POSIX.1-200x requires a simplified behavior for consistency and simplicity of
87786 specification.

87787 **Version**

87788 The **version** command cannot be exactly specified since there is no widely-accepted definition of
87789 what the version information should contain. Implementations are encouraged to do something
87790 reasonably intelligent.

87791 **Write**

87792 Historically, the *ex* and *vi* message after a successful **read** or **write** command specified
87793 "characters", not "bytes". POSIX.1-200x requires that the number of bytes be displayed, not the
87794 number of characters because it may be difficult in multi-byte implementations to determine the
87795 number of characters written. Implementations are encouraged to clarify the message displayed
87796 to the user.

87797 Implementation-defined tests are permitted so that implementations can make additional
87798 checks; for example, for locks or file modification times.

87799 Historically, attempting to append to a nonexistent file caused an error. It has been left
87800 unspecified in POSIX.1-200x to permit implementations to let the **write** succeed, so that the
87801 append semantics are similar to those of the historical *csh*.

87802 Historical *vi* permitted empty edit buffers to be written. However, since the way *vi* got around
87803 dealing with "empty" files was to always have a line in the edit buffer, no matter what, it wrote
87804 them as files of a single, empty line. POSIX.1-200x does not permit this behavior.

87805 Historically, *ex* restored standard output and standard error to their values as of when *ex* was
87806 invoked, before writes to programs were performed. This could disturb the terminal
87807 configuration as well as be a security issue for some terminals. POSIX.1-200x does not permit
87808 this, requiring that the program output be captured and displayed as if by the *ex* **print**
87809 command.

87810 **Adjust Window**

87811 Historically, the line count was set to the value of the **scroll** option if the type character was end-
87812 of-file. This feature was broken on most historical implementations long ago, however, and is
87813 not documented anywhere. For this reason, POSIX.1-200x is resolutely silent.

87814 Historically, the **z** command was <blank>-sensitive and **z +** and **z −** did different things than **z+**
87815 and **z−** because the type could not be distinguished from a flag. (The commands **z .** and **z =**
87816 were historically invalid.) POSIX.1-200x requires conformance to this historical practice.

87817 Historically, the **z** command was further <blank>-sensitive in that the *count* could not be
87818 <blank>-delimited; for example, the commands **z= 5** and **z− 5** were also invalid. Because the
87819 *count* is not ambiguous with respect to either the type character or the flags, this is not permitted
87820 by POSIX.1-200x.

87821 **Escape**

87822 Historically, *ex* filter commands only read the standard output of the commands, letting
87823 standard error appear on the terminal as usual. The *vi* utility, however, read both standard
87824 output and standard error. POSIX.1-200x requires the latter behavior for both *ex* and *vi*, for
87825 consistency.

87826 **Shift Left and Shift Right**

87827 Historically, it was possible to add shift characters to increase the effect of the command; for
87828 example, **<<<** outdented (or **>>>** indented) the lines 3 levels of indentation instead of the default
87829 1. POSIX.1-200x requires conformance to historical practice.

87830 **<control>-D**

87831 Historically, the <control>-D command erased the prompt, providing the user with an unbroken
87832 presentation of lines from the edit buffer. This is not required by POSIX.1-200x; implementations
87833 are encouraged to provide it if possible. Historically, the <control>-D command took, and then
87834 ignored, a *count*. POSIX.1-200x does not permit this behavior.

87835 **Write Line Number**

87836 Historically, the *ex* **=** command, when executed in *ex* mode in an empty edit buffer, reported 0,
87837 and from open or visual mode, reported 1. For consistency and simplicity of specification,
87838 POSIX.1-200x does not permit this behavior.

87839 **Execute**

87840 Historically, *ex* did not correctly handle the inclusion of text input commands (that is, **append**,
87841 **insert**, and **change**) in executed buffers. POSIX.1-200x does not permit this exclusion for
87842 consistency.

87843 Historically, the logical contents of the buffer being executed did not change if the buffer itself
87844 were modified by the commands being executed; that is, buffer execution did not support self-
87845 modifying code. POSIX.1-200x requires conformance to historical practice.

87846 Historically, the @ command took a range of lines, and the @ buffer was executed once per line,
87847 with the current line (`'.'`) set to each specified line. POSIX.1-200x requires conformance to
87848 historical practice.

87849 Some historical implementations did not notice if errors occurred during buffer execution. This,
87850 coupled with the ability to specify a range of lines for the *ex* @ command, makes it trivial to
87851 cause them to drop **core**. POSIX.1-200x requires that implementations stop buffer execution if
87852 any error occurs, if the specified line doesn't exist, or if the contents of the edit buffer itself are
87853 replaced (for example, the buffer executes the *ex* **:edit** command).

87854 **Regular Expressions in ex**

87855 Historical practice is that the characters in the replacement part of the last **s** command—that is,
87856 those matched by entering a `'~'` in the regular expression—were not further expanded by the
87857 regular expression engine. So, if the characters contained the string `"a.,"` they would match
87858 `'a'` followed by `".,"` and not `'a'` followed by any character. POSIX.1-200x requires
87859 conformance to historical practice.

87860 **Edit Options in ex**

87861 The following paragraphs describe the historical behavior of some edit options that were not, for
87862 whatever reason, included in POSIX.1-200x. Implementations are strongly encouraged to only
87863 use these names if the functionality described here is fully supported.

87864 **extended** The **extended** edit option has been used in some implementations of *vi* to provide
87865 extended regular expressions instead of basic regular expressions This option was
87866 omitted from POSIX.1-200x because it is not widespread historical practice.

87867 **flash** The **flash** edit option historically caused the screen to flash instead of beeping on
87868 error. This option was omitted from POSIX.1-200x because it is not found in some
87869 historical implementations.

hardtabs The **hardtabs** edit option historically defined the number of columns between hardware tab settings. This option was omitted from POSIX.1-200x because it was believed to no longer be generally useful.

modeline The **modeline** (sometimes named **modelines**) edit option historically caused *ex* or *vi* to read the five first and last lines of the file for editor commands. This option is a security problem, and vendors are strongly encouraged to delete it from historical implementations.

open The **open** edit option historically disallowed the *ex* **open** and **visual** commands. This edit option was omitted because these commands are required by POSIX.1-200x.

optimize The **optimize** edit option historically expedited text throughput by setting the terminal to not do automatic <carriage-return> characters when printing more than one logical line of output. This option was omitted from POSIX.1-200x because it was intended for terminals without addressable cursors, which are rarely, if ever, still used.

ruler The **ruler** edit option has been used in some implementations of *vi* to present a current row/column ruler for the user. This option was omitted from POSIX.1-200x because it is not widespread historical practice.

sourceany The **sourceany** edit option historically caused *ex* or *vi* to source start-up files that were owned by users other than the user running the editor. This option is a security problem, and vendors are strongly encouraged to remove it from their implementations.

timeout The **timeout** edit option historically enabled the (now standard) feature of only waiting for a short period before returning keys that could be part of a macro. This feature was omitted from POSIX.1-200x because its behavior is now standard, it is not widely useful, and it was rarely documented.

verbose The **verbose** edit option has been used in some implementations of *vi* to cause *vi* to output error messages for common errors; for example, attempting to move the cursor past the beginning or end of the line instead of only alerting the screen. (The historical *vi* only alerted the terminal and presented no message for such errors. The historical editor option **terse** did not select when to present error messages, it only made existing error messages more or less verbose.) This option was omitted from POSIX.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they wish to provide error messages for naive users.

wraplen The **wraplen** edit option has been used in some implementations of *vi* to specify an automatic margin measured from the left margin instead of from the right margin. This is useful when multiple screen sizes are being used to edit a single file. This option was omitted from POSIX.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they add this functionality.

87911 **autoindent, ai**

87912 Historically, the command **0a** did not do any autoindentation, regardless of the current
87913 indentation of line 1. POSIX.1-200x requires that any indentation present in line 1 be used.

87914 **autoprint, ap**

87915 Historically, the **autoprint** edit option was not completely consistent or based solely on
87916 modifications to the edit buffer. Exceptions were the **read** command (when reading from a file,
87917 but not from a filter), the **append**, **change**, **insert**, **global**, and **v** commands, all of which were not
87918 affected by **autoprint**, and the **tag** command, which was affected by **autoprint**. POSIX.1-200x
87919 requires conformance to historical practice.

87920 Historically, the **autoprint** option only applied to the last of multiple commands entered using
87921 <vertical-line> delimiters; for example, **delete** <newline> was affected by **autoprint**, but
87922 **delete | version** <newline> was not. POSIX.1-200x requires conformance to historical practice.

87923 **autowrite, aw**

87924 Appending the `'!'` character to the *ex* **next** command to avoid performing an automatic write
87925 was not supported in historical implementations. POSIX.1-200x requires that the behavior match
87926 the other *ex* commands for consistency.

87927 **ignorecase, ic**

87928 Historical implementations of case-insensitive matching (the **ignorecase** edit option) lead to
87929 counter-intuitive situations when uppercase characters were used in range expressions.
87930 Historically, the process was as follows:

87931 1. Take a line of text from the edit buffer.
87932 2. Convert uppercase to lowercase in text line.
87933 3. Convert uppercase to lowercase in regular expressions, except in character class
87934 specifications.
87935 4. Match regular expressions against text.

87936 This would mean that, with **ignorecase** in effect, the text:

87937 `The cat sat on the mat`

87938 would be matched by

87939 `/^the/`

87940 but not by:

87941 `/^[A–Z]he/`

87942 For consistency with other commands implementing regular expressions, POSIX.1-200x does not
87943 permit this behavior.

87944 **paragraphs, para**

87945 The ISO POSIX-2:1993 standard made the default **paragraphs** and **sections** edit options
87946 implementation-defined, arguing they were historically oriented to the UNIX system *troff* text
87947 formatter, and a "portable user" could use the {, }, [[,]], **(**, and **)** commands in open or visual
87948 mode and have the cursor stop in unexpected places. POSIX.1-200x specifies their values in the
87949 POSIX locale because the unusual grouping (they only work when grouped into two characters
87950 at a time) means that they cannot be used for general-purpose movement, regardless.

87951 **readonly**

87952 Implementations are encouraged to provide the best possible information to the user as to the
87953 read-only status of the file, with the exception that they should not consider the current special
87954 privileges of the process. This provides users with a safety net because they must force the
87955 overwrite of read-only files, even when running with additional privileges.

87956 The **readonly** edit option specification largely conforms to historical practice. The only
87957 difference is that historical implementations did not notice that the user had set the **readonly**
87958 edit option in cases where the file was already marked read-only for some reason, and would
87959 therefore reinitialize the **readonly** edit option the next time the contents of the edit buffer were
87960 replaced. This behavior is disallowed by POSIX.1-200x.

87961 **report**

87962 The requirement that lines copied to a buffer interact differently than deleted lines is historical
87963 practice. For example, if the **report** edit option is set to 3, deleting 3 lines will cause a report to be
87964 written, but 4 lines must be copied before a report is written.

87965 The requirement that the *ex* **global**, **v**, **open**, **undo**, and **visual** commands present reports based
87966 on the total number of lines added or deleted during the command execution, and that
87967 commands executed by the **global** and **v** commands not present reports, is historical practice.
87968 POSIX.1-200x extends historical practice by requiring that buffer execution be treated similarly.
87969 The reasons for this are two-fold. Historically, only the report by the last command executed
87970 from the buffer would be seen by the user, as each new report would overwrite the last. In
87971 addition, the standard developers believed that buffer execution had more in common with
87972 **global** and **v** commands than it did with other *ex* commands, and should behave similarly, for
87973 consistency and simplicity of specification.

87974 **showmatch, sm**

87975 The length of time the cursor spends on the matching character is unspecified because the
87976 timing capabilities of systems are often inexact and variable. The time should be long enough for
87977 the user to notice, but not long enough for the user to become annoyed. Some implementations
87978 of *vi* have added a **matchtime** option that permits users to set the number of 0,1 second intervals
87979 the cursor pauses on the matching character.

87980 **showmode**

87981 The **showmode** option has been used in some historical implementations of *ex* and *vi* to display
87982 the current editing mode when in open or visual mode. The editing modes have generally
87983 included "command" and "input", and sometimes other modes such as "replace" and
87984 "change". The string was usually displayed on the bottom line of the screen at the far right-hand
87985 corner. In addition, a preceding '*' character often denoted whether the contents of the edit
87986 buffer had been modified. The latter display has sometimes been part of the **showmode** option,
87987 and sometimes based on another option. This option was not available in the 4 BSD historical

implementation of *vi*, but was viewed as generally useful, particularly to novice users, and is required by POSIX.1-200x.

The **smd** shorthand for the **showmode** option was not present in all historical implementations of the editor. POSIX.1-200x requires it, for consistency.

Not all historical implementations of the editor displayed a mode string for command mode, differentiating command mode from text input mode by the absence of a mode string. POSIX.1-200x permits this behavior for consistency with historical practice, but implementations are encouraged to provide a display string for both modes.

slowopen

Historically, the **slowopen** option was automatically set if the terminal baud rate was less than 1 200 baud, or if the baud rate was 1 200 baud and the **redraw** option was not set. The **slowopen** option had two effects. First, when inserting characters in the middle of a line, characters after the cursor would not be pushed ahead, but would appear to be overwritten. Second, when creating a new line of text, lines after the current line would not be scrolled down, but would appear to be overwritten. In both cases, ending text input mode would cause the screen to be refreshed to match the actual contents of the edit buffer. Finally, terminals that were sufficiently intelligent caused the editor to ignore the **slowopen** option. POSIX.1-200x permits most historical behavior, extending historical practice to require **slowopen** behaviors if the edit option is set by the user.

tags

The default path for tags files is left unspecified as implementations may have their own **tags** implementations that do not correspond to the historical ones. The default **tags** option value should probably at least include the file **./tags**.

term

Historical implementations of *ex* and *vi* ignored changes to the **term** edit option after the initial terminal information was loaded. This is permitted by POSIX.1-200x; however, implementations are encouraged to permit the user to modify their terminal type at any time.

terse

Historically, the **terse** edit option optionally provided a shorter, less descriptive error message, for some error messages. This is permitted, but not required, by POSIX.1-200x. Historically, most common visual mode errors (for example, trying to move the cursor past the end of a line) did not result in an error message, but simply alerted the terminal. Implementations wishing to provide messages for novice users are urged to do so based on the **edit** option **verbose**, and not **terse**.

window

In historical implementations, the default for the **window** edit option was based on the baud rate as follows:

1. If the baud rate was less than 1 200, the **edit** option **w300** set the window value; for example, the line:

   ```
   set w300=12
   ```

   would set the window option to 12 if the baud rate was less than 1 200.

2. If the baud rate was equal to 1 200, the **edit** option **w1200** set the window value.
3. If the baud rate was greater than 1 200, the **edit** option **w9600** set the window value.

The **w300**, **w1200**, and **w9600** options do not appear in POSIX.1-200x because of their dependence on specific baud rates.

In historical implementations, the size of the window displayed by various commands was related to, but not necessarily the same as, the **window** edit option. For example, the size of the window was set by the *ex* command **visual 10**, but it did not change the value of the **window** edit option. However, changing the value of the **window** edit option did change the number of lines that were displayed when the screen was repainted. POSIX.1-200x does not permit this behavior in the interests of consistency and simplicity of specification, and requires that all commands that change the number of lines that are displayed do it by setting the value of the **window** edit option.

wrapmargin, wm

Historically, the **wrapmargin** option did not affect maps inserting characters that also had associated *count*s; for example **:map K 5aABC DEF**. Unfortunately, there are widely used maps that depend on this behavior. For consistency and simplicity of specification, POSIX.1-200x does not permit this behavior.

Historically, **wrapmargin** was calculated using the column display width of all characters on the screen. For example, an implementation using `"^I"` to represent <tab> characters when the **list** edit option was set, where `'^'` and `'I'` each took up a single column on the screen, would calculate the **wrapmargin** based on a value of 2 for each <tab>. The **number** edit option similarly changed the effective length of the line as well. POSIX.1-200x requires conformance to historical practice.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed, removing the +*command* and – options.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the **map** command description, the sequence **#***digit* is added.
- The **directory**, **edcompatible**, **redraw**, and **slowopen** edit options are added.

The *ex* utility is extensively changed for alignment with the IEEE P1003.2b draft standard. This includes changes as a result of the IEEE PASC Interpretations 1003.2 #31, #38, #49, #50, #51, #52, #55, #56, #57, #61, #62, #63, #64, #65, and #78.

The **–l** option is removed.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/23 is applied, correcting a URL.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/8 is applied, making an editorial correction in the EXTENDED DESCRIPTION.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/9 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if an operand is '–'.

Austin Group Interpretation 1003.1-2001 #036 is applied, clarifying the behavior for BREs.

Austin Group Interpretation 1003.1-2001 #121 is applied, clarifying the *ex* **write** command.

Austin Group Interpretation 1003.1-2001 #156 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

expand — convert tabs to spaces

SYNOPSIS

```
expand [–t tablist] [file...]
```

DESCRIPTION

The *expand* utility shall write files or the standard input to the standard output with <tab> characters replaced with one or more <space> characters needed to pad to the next tab stop. Any <backspace> characters shall be copied to the output and cause the column position count for tab stop calculations to be decremented; the column position count shall not be decremented below zero.

OPTIONS

The *expand* utility shall conform to XBD Section 12.2 (on page 215).

The following option shall be supported:

–t *tablist* Specify the tab stops. The application shall ensure that the argument *tablist* consists of either a single positive decimal integer or a list of tabstops. If a single number is given, tabs shall be set that number of column positions apart instead of the default 8.

If a list of tabstops is given, the application shall ensure that it consists of a list of two or more positive decimal integers, separated by <blank> or <comma> characters, in ascending order. The <tab> characters shall be set at those specific column positions. Each tab stop *N* shall be an integer value greater than zero, and the list is in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* shall cause the next character output to be in the (*N*+1)th column position on that line.

In the event of *expand* having to process a <tab> at a position beyond the last of those specified in a multiple tab-stop list, the <tab> shall be replaced by a single <space> in the output.

OPERANDS

The following operand shall be supported:

file The pathname of a text file to be used as input.

STDIN

See the INPUT FILES section.

INPUT FILES

Input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *expand*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab> and <space> characters, and for the determination of the width in column positions each character would

88133 occupy on an output device.

88134 *LC_MESSAGES*

88135 Determine the locale that should be used to affect the format and contents of
88136 diagnostic messages written to standard error.

88137 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

88138 **ASYNCHRONOUS EVENTS**

88139 Default.

88140 **STDOUT**

88141 The standard output shall be equivalent to the input files with <tab> characters converted into
88142 the appropriate number of <space> characters.

88143 **STDERR**

88144 The standard error shall be used only for diagnostic messages.

88145 **OUTPUT FILES**

88146 None.

88147 **EXTENDED DESCRIPTION**

88148 None.

88149 **EXIT STATUS**

88150 The following exit values shall be returned:

88151 0 Successful completion

88152 >0 An error occurred.

88153 **CONSEQUENCES OF ERRORS**

88154 The *expand* utility shall terminate with an error message and non-zero exit status upon
88155 encountering difficulties accessing one of the *file* operands.

88156 **APPLICATION USAGE**

88157 None.

88158 **EXAMPLES**

88159 None.

88160 **RATIONALE**

88161 The *expand* utility is useful for preprocessing text files (before sorting, looking at specific
88162 columns, and so on) that contain <tab> characters.

88163 See XBD Section 3.103 (on page 50).

88164 The *tablist* option-argument consists of integers in ascending order. Utility Syntax Guideline 8
88165 mandates that *expand* shall accept the integers (within the single argument) separated using
88166 either <comma> or <blank> characters.

88167 Earlier versions of this standard allowed the following form in the SYNOPSIS:

88168 `expand [–tabstop][–tab1,tab2,...,tabn][`*`file ...`*`]`

88169 This form is no longer specified by POSIX.1-200x but may be present in some implementations.

88170 **FUTURE DIRECTIONS**

88171 None.

SEE ALSO

tabs, *unexpand*

XBD Section 3.103 (on page 50), Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

The *LC_CTYPE* environment variable description is updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *expand* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

88189 **NAME**

88190 expr — evaluate arguments as an expression

88191 **SYNOPSIS**

88192 `expr` *operand...*

88193 **DESCRIPTION**

88194 The *expr* utility shall evaluate an expression and write the result to standard output.

88195 **OPTIONS**

88196 None.

88197 **OPERANDS**

88198 The single expression evaluated by *expr* shall be formed from the *operand* operands, as described
88199 in the EXTENDED DESCRIPTION section. The application shall ensure that each of the
88200 expression operator symbols:

88201 `( ) | & = > >= < <= != + - * / % :`

88202 and the symbols *integer* and *string* in the table are provided as separate arguments to *expr*.

88203 **STDIN**

88204 Not used.

88205 **INPUT FILES**

88206 None.

88207 **ENVIRONMENT VARIABLES**

88208 The following environment variables shall affect the execution of *expr*:

88209 *LANG* Provide a default value for the internationalization variables that are unset or null.
88210 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
88211 variables used to determine the values of locale categories.)

88212 *LC_ALL* If set to a non-empty string value, override the values of all the other
88213 internationalization variables.

88214 *LC_COLLATE*

88215 Determine the locale for the behavior of ranges, equivalence classes, and multi-
88216 character collating elements within regular expressions and by the string
88217 comparison operators.

88218 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
88219 characters (for example, single-byte as opposed to multi-byte characters in
88220 arguments) and the behavior of character classes within regular expressions.

88221 *LC_MESSAGES*

88222 Determine the locale that should be used to affect the format and contents of
88223 diagnostic messages written to standard error.

88224 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

88225 **ASYNCHRONOUS EVENTS**

88226 Default.

88227 **STDOUT**

88228 The *expr* utility shall evaluate the expression and write the result, followed by a <newline>, to
88229 standard output.

88230 **STDERR**

88231 The standard error shall be used only for diagnostic messages.

88232 **OUTPUT FILES**

88233 None.

88234 **EXTENDED DESCRIPTION**

88235 The formation of the expression to be evaluated is shown in the following table. The symbols
88236 *expr*, *expr1*, and *expr2* represent expressions formed from *integer* and *string* symbols and the
88237 expression operator symbols (all separate arguments) by recursive application of the constructs
88238 described in the table. The expressions are listed in order of increasing precedence, with equal-
88239 precedence operators grouped between horizontal lines. All of the operators shall be left-
88240 associative.

88241

Expression	Description
88242 *expr1* | *expr2*	88243 Returns the evaluation of *expr1* if it is neither null nor zero; 88244 otherwise, returns the evaluation of *expr2* if it is not null; otherwise, zero.
88245 *expr1* & *expr2*	88246 Returns the evaluation of *expr1* if neither expression evaluates to null or zero; otherwise, returns zero.
88247 *expr1* = *expr2* 88252 *expr1* > *expr2* 88253 *expr1* >= *expr2* 88254 *expr1* < *expr2* 88255 *expr1* <= *expr2* 88256 *expr1* != *expr2* 88257	88248 Returns the result of a decimal integer comparison if both 88249 arguments are integers; otherwise, returns the result of a string 88250 comparison using the locale-specific collation sequence. The 88251 result of each comparison is 1 if the specified relationship is true, or 0 if the relationship is false. Equal. Greater than. Greater than or equal. Less than. Less than or equal. Not equal.
88258 *expr1* + *expr2* 88259 *expr1* – *expr2*	Addition of decimal integer-valued arguments. Subtraction of decimal integer-valued arguments.
88260 *expr1* * *expr2* 88261 *expr1* / *expr2* 88262 88263 *expr1* % *expr2* 88264	Multiplication of decimal integer-valued arguments. Integer division of decimal integer-valued arguments, producing an integer result. Remainder of integer division of decimal integer-valued arguments.
88265 *expr1* : *expr2*	Matching expression; see below.
88266 (*expr*)	88267 Grouping symbols. Any expression can be placed within 88268 parentheses. Parentheses can be nested to a depth of {EXPR_NEST_MAX}.
88269 *integer* 88270 88271 *string*	An argument consisting only of an (optional) unary minus followed by digits. A string argument; see below.

88272 **Matching Expression**

88273 The `':'` matching operator shall compare the string resulting from the evaluation of *expr1* with
88274 the regular expression pattern resulting from the evaluation of *expr2*. Regular expression syntax
88275 shall be that defined in XBD Section 9.3 (on page 183), except that all patterns are anchored to
88276 the beginning of the string (that is, only sequences starting at the first character of a string are
88277 matched by the regular expression) and, therefore, it is unspecified whether `'^'` is a special
88278 character in that context. Usually, the matching operator shall return a string representing the
88279 number of characters matched (`'0'` on failure). Alternatively, if the pattern contains at least one
88280 regular expression subexpression `"[\(...\)]"`, the string matched by the back-reference
88281 expression `"\1"` shall be returned. If the back-reference expression `"\1"` does not match, then
88282 the null string shall be returned.

88283 **String Operand**

88284 A string argument is an argument that cannot be identified as an *integer* argument or as one of
88285 the expression operator symbols shown in the OPERANDS section.

88286 The use of string arguments **length**, **substr**, **index**, or **match** produces unspecified results.

88287 **EXIT STATUS**

88288 The following exit values shall be returned:

88289 0 The *expression* evaluates to neither null nor zero.

88290 1 The *expression* evaluates to null or zero.

88291 2 Invalid *expression*.

88292 >2 An error occurred.

88293 **CONSEQUENCES OF ERRORS**

88294 Default.

88295 **APPLICATION USAGE**

88296 After argument processing by the shell, *expr* is not required to be able to tell the difference
88297 between an operator and an operand except by the value. If `"$a"` is `'='`, the command:

88298 ```
expr $a = '='
```

88299 looks like:

88300 ```
expr = = =
```

88301 as the arguments are passed to *expr* (and they all may be taken as the `'='` operator). The
88302 following works reliably:

88303 ```
expr X$a = X=
```

88304 Also note that this volume of POSIX.1-200x permits implementations to extend utilities. The *expr*
88305 utility permits the integer arguments to be preceded with a unary minus. This means that an
88306 integer argument could look like an option. Therefore, the conforming application must employ
88307 the `"--"` construct of Guideline 10 of XBD Section 12.2 (on page 215) to protect its operands if
88308 there is any chance the first operand might be a negative integer (or any string with a leading
88309 minus).

 
```

EXAMPLES

The *expr* utility has a rather difficult syntax:

- Many of the operators are also shell control operators or reserved words, so they have to be escaped on the command line.
- Each part of the expression is composed of separate arguments, so liberal usage of <blank> characters is required. For example:

Invalid	Valid
`expr 1+2`	`expr 1 + 2`
`expr "1 + 2"`	`expr 1 + 2`
`expr 1 + (2 * 3)`	`expr 1 + \( 2 \* 3 \)`

In many cases, the arithmetic and string features provided as part of the shell command language are easier to use than their equivalents in *expr*. Newly written scripts should avoid *expr* in favor of the new features within the shell; see Section 2.5 (on page 2301) and Section 2.6.4 (on page 2310).

The following command:

```
a=$(expr $a + 1)
```

adds 1 to the variable *a*.

The following command, for `"$a"` equal to either **/usr/abc/file** or just **file**:

```
expr $a : '.*/\(.*\)' \| $a
```

returns the last segment of a pathname (that is, **file**). Applications should avoid the character `'/'` used alone as an argument; *expr* may interpret it as the division operator.

The following command:

```
expr "//$a" : '.*/\(.*\)'
```

is a better representation of the previous example. The addition of the `"//"` characters eliminates any ambiguity about the division operator and simplifies the whole expression. Also note that pathnames may contain characters contained in the *IFS* variable and should be quoted to avoid having `"$a"` expand into multiple arguments.

The following command:

```
expr "$VAR" : '.*'
```

returns the number of characters in *VAR*.

RATIONALE

In an early proposal, EREs were used in the matching expression syntax. This was changed to BREs to avoid breaking historical applications.

The use of a leading <circumflex> in the BRE is unspecified because many historical implementations have treated it as a special character, despite their system documentation. For example:

```
expr foo : ^foo     expr ^foo : ^foo
```

return 3 and 0, respectively, on those systems; their documentation would imply the reverse. Thus, the anchoring condition is left unspecified to avoid breaking historical scripts relying on this undocumented feature.

88350 **FUTURE DIRECTIONS**

88351 None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/24 is applied, changing the STDERR section from "None." to "Not used." for alignment with Section 1.4 (on page 2288).

88412 **NAME**

88413 fc — process the command history list

88414 **SYNOPSIS**

88415 UP
```
fc [–r] [–e editor] [first [last]]
```
88416
```
fc –l [–nr] [first [last]]
```
88417
```
fc –s [old=new] [first]
```

88418 **DESCRIPTION**

88419 The *fc* utility shall list, or shall edit and re-execute, commands previously entered to an
88420 interactive *sh*.

88421 The command history list shall reference commands by number. The first number in the list is
88422 selected arbitrarily. The relationship of a number to its command shall not change except when
88423 the user logs in and no other process is accessing the list, at which time the system may reset the
88424 numbering to start the oldest retained command at another number (usually 1). When the
88425 number reaches an implementation-defined upper limit, which shall be no smaller than the
88426 value in *HISTSIZE* or 32 767 (whichever is greater), the shell may wrap the numbers, starting the
88427 next command with a lower number (usually 1). However, despite this optional wrapping of
88428 numbers, *fc* shall maintain the time-ordering sequence of the commands. For example, if four
88429 commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are
88430 executed, command 32 767 is considered the command previous to 1, even though its number is
88431 higher.

88432 When commands are edited (when the **–l** option is not specified), the resulting lines shall be
88433 entered at the end of the history list and then re-executed by *sh*. The *fc* command that caused the
88434 editing shall not be entered into the history list. If the editor returns a non-zero exit status, this
88435 shall suppress the entry into the history list and the command re-execution. Any command line
88436 variable assignments or redirection operators used with *fc* shall affect both the *fc* command itself
88437 as well as the command that results; for example:

88438
```
fc –s –– –1 2>/dev/null
```

88439 reinvokes the previous command, suppressing standard error for both *fc* and the previous
88440 command.

88441 **OPTIONS**

88442 The *fc* utility shall conform to XBD Section 12.2 (on page 215).

88443 The following options shall be supported:

88444 **–e** *editor* Use the editor named by *editor* to edit the commands. The *editor* string is a utility
88445 name, subject to search via the *PATH* variable (see XBD Chapter 8, on page 173).
88446 The value in the *FCEDIT* variable shall be used as a default when **–e** is not
88447 specified. If *FCEDIT* is null or unset, *ed* shall be used as the editor.

88448 **–l** (The letter ell.) List the commands rather than invoking an editor on them. The
88449 commands shall be written in the sequence indicated by the *first* and *last* operands,
88450 as affected by **–r**, with each command preceded by the command number.

88451 **–n** Suppress command numbers when listing with **–l**.

88452 **–r** Reverse the order of the commands listed (with **–l**) or edited (with neither **–l** nor
88453 **–s**).

88454 **–s** Re-execute the command without invoking an editor.

88455 **OPERANDS**

88456 The following operands shall be supported:

88457 *first*, *last* Select the commands to list or edit. The number of previous commands that can be
88458 accessed shall be determined by the value of the *HISTSIZE* variable. The value of
88459 *first* or *last* or both shall be one of the following:

88460 **[+]***number* A positive number representing a command number; command
88461 numbers can be displayed with the **–l** option.

88462 *–number* A negative decimal number representing the command that was
88463 executed *number* of commands previously. For example, –1 is the
88464 immediately previous command.

88465 *string* A string indicating the most recently entered command that begins
88466 with that string. If the *old=new* operand is not also specified with **–s**,
88467 the string form of the *first* operand cannot contain an embedded
88468 <equals-sign>.

88469 When the synopsis form with **–s** is used:

88470 • If *first* is omitted, the previous command shall be used.

88471 For the synopsis forms without **–s**:

88472 • If *last* is omitted, *last* shall default to the previous command when **–l** is
88473 specified; otherwise, it shall default to *first*.

88474 • If *first* and *last* are both omitted, the previous 16 commands shall be listed or
88475 the previous single command shall be edited (based on the **–l** option).

88476 • If *first* and *last* are both present, all of the commands from *first* to *last* shall be
88477 edited (without **–l**) or listed (with **–l**). Editing multiple commands shall be
88478 accomplished by presenting to the editor all of the commands at one time,
88479 each command starting on a new line. If *first* represents a newer command
88480 than *last*, the commands shall be listed or edited in reverse sequence,
88481 equivalent to using **–r**. For example, the following commands on the first
88482 line are equivalent to the corresponding commands on the second:

88483 `fc –r 10 20  fc  30 40`
88484 `fc  20 10  fc –r 40 30`

88485 • When a range of commands is used, it shall not be an error to specify *first* or
88486 *last* values that are not in the history list; *fc* shall substitute the value
88487 representing the oldest or newest command in the list, as appropriate. For
88488 example, if there are only ten commands in the history list, numbered 1 to 10:

88489 `fc –l`
88490 `fc 1 99`

88491 shall list and edit, respectively, all ten commands.

88492 *old=new* Replace the first occurrence of string *old* in the commands to be re-executed by the
88493 string *new*.

88494 **STDIN**

88495 Not used.

88496 **INPUT FILES**

88497 None.

88498 **ENVIRONMENT VARIABLES**

88499 The following environment variables shall affect the execution of *fc*:

88500 *FCEDIT* This variable, when expanded by the shell, shall determine the default value for
88501 the **−e** *editor* option's *editor* option-argument. If *FCEDIT* is null or unset, *ed* shall be
88502 used as the editor.

88503 *HISTFILE* Determine a pathname naming a command history file. If the *HISTFILE* variable is
88504 not set, the shell may attempt to access or create a file **.sh_history** in the directory
88505 referred to by the *HOME* environment variable. If the shell cannot obtain both read
88506 and write access to, or create, the history file, it shall use an unspecified
88507 mechanism that allows the history to operate properly. (References to history "file"
88508 in this section shall be understood to mean this unspecified mechanism in such
88509 cases.) An implementation may choose to access this variable only when
88510 initializing the history file; this initialization shall occur when *fc* or *sh* first attempt
88511 to retrieve entries from, or add entries to, the file, as the result of commands issued
88512 by the user, the file named by the *ENV* variable, or implementation-defined system
88513 start-up files. In some historical shells, the history file is initialized just after the
88514 *ENV* file has been processed. Therefore, it is implementation-defined whether
88515 changes made to *HISTFILE* after the history file has been initialized are effective.
88516 Implementations may choose to disable the history list mechanism for users with
88517 appropriate privileges who do not set *HISTFILE*; the specific circumstances under
88518 which this occurs are implementation-defined. If more than one instance of the
88519 shell is using the same history file, it is unspecified how updates to the history file
88520 from those shells interact. As entries are deleted from the history file, they shall be
88521 deleted oldest first. It is unspecified when history file entries are physically
88522 removed from the history file.

88523 *HISTSIZE* Determine a decimal number representing the limit to the number of previous
88524 commands that are accessible. If this variable is unset, an unspecified default
88525 greater than or equal to 128 shall be used. The maximum number of commands in
88526 the history list is unspecified, but shall be at least 128. An implementation may
88527 choose to access this variable only when initializing the history file, as described
88528 under *HISTFILE*. Therefore, it is unspecified whether changes made to *HISTSIZE*
88529 after the history file has been initialized are effective.

88530 *LANG* Provide a default value for the internationalization variables that are unset or null.
88531 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
88532 variables used to determine the values of locale categories.)

88533 *LC_ALL* If set to a non-empty string value, override the values of all the other
88534 internationalization variables.

88535 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
88536 characters (for example, single-byte as opposed to multi-byte characters in
88537 arguments and input files).

88538 *LC_MESSAGES*

88539 Determine the locale that should be used to affect the format and contents of
88540 diagnostic messages written to standard error.

88541 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

88542 **ASYNCHRONOUS EVENTS**

88543 Default.

88544 **STDOUT**

88545 When the **–l** option is used to list commands, the format of each command in the list shall be as
88546 follows:

88547 `"%d\t%s\n", <line number>, <command>`

88548 If both the **–l** and **–n** options are specified, the format of each command shall be:

88549 `"\t%s\n", <command>`

88550 If the <*command*> consists of more than one line, the lines after the first shall be displayed as:

88551 `"\t%s\n", <continued-command>`

88552 **STDERR**

88553 The standard error shall be used only for diagnostic messages.

88554 **OUTPUT FILES**

88555 None.

88556 **EXTENDED DESCRIPTION**

88557 None.

88558 **EXIT STATUS**

88559 The following exit values shall be returned:

88560 0 Successful completion of the listing.

88561 >0 An error occurred.

88562 Otherwise, the exit status shall be that of the commands executed by *fc*.

88563 **CONSEQUENCES OF ERRORS**

88564 Default.

88565 **APPLICATION USAGE**

88566 Since editors sometimes use file descriptors as integral parts of their editing, redirecting their file
88567 descriptors as part of the *fc* command can produce unexpected results. For example, if *vi* is the
88568 *FCEDIT* editor, the command:

88569 `fc –s | more`

88570 does not work correctly on many systems.

88571 Users on windowing systems may want to have separate history files for each window by
88572 setting *HISTFILE* as follows:

88573 `HISTFILE=$HOME/.sh_hist$$`

88574 **EXAMPLES**

88575 None.

88576 **RATIONALE**

88577 This utility is based on the *fc* built-in of the KornShell.

88578 An early proposal specified the **–e** option as **[–e** *editor* **[***old***=** *new* **]]**, which is not historical
88579 practice. Historical practice in *fc* of either **[–e** *editor***]** or **[–e** – **[** *old***=** *new* **]]** is acceptable, but not
88580 both together. To clarify this, a new option **–s** was introduced replacing the **[–e** –**]**. This resolves

the conflict and makes *fc* conform to the Utility Syntax Guidelines.

HISTFILE Some implementations of the KornShell check for the superuser and do not create a history file unless *HISTFILE* is set. This is done primarily to avoid creating unlinked files in the root file system when logging in during single-user mode. *HISTFILE* must be set for the superuser to have history.

HISTSIZE Needed to limit the size of history files. It is the intent of the standard developers that when two shells share the same history file, commands that are entered in one shell shall be accessible by the other shell. Because of the difficulties of synchronization over a network, the exact nature of the interaction is unspecified.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the settings the user has for *HISTFILE* and *HISTSIZE*. For example, function definition commands are recorded in the history file. If the system administrator includes function definitions in some system start-up file called before the *ENV* file, the history file is initialized before the user can influence its characteristics. In some historical shells, the history file is initialized just after the *ENV* file has been processed. Because of these situations, the text requires the initialization process to be implementation-defined.

Consideration was given to omitting the *fc* utility in favor of the command line editing feature in *sh*. For example, in *vi* editing mode, typing "<ESC> v" is equivalent to:

```
EDITOR=vi fc
```

However, the *fc* utility allows the user the flexibility to edit multiple commands simultaneously (such as *fc* 10 20) and to use editors other than those supported by *sh* for command line editing.

In the KornShell, the alias **r** ("re-do") is preset to *fc* **–e** – (equivalent to the POSIX *fc* **–s**). This is probably an easier command name to remember than *fc* ("fix command"), but it does not meet the Utility Syntax Guidelines. Renaming *fc* to *hist* or *redo* was considered, but since this description closely matches historical KornShell practice already, such a renaming was seen as gratuitous. Users are free to create aliases whenever odd historical names such as *fc*, *awk*, *cat*, *grep*, or *yacc* are standardized by POSIX.

Command numbers have no ordering effects; they are like serial numbers. The **–r** option and *–number* operand address the sequence of command execution, regardless of serial numbers. So, for example, if the command number wrapped back to 1 at some arbitrary point, there would be no ambiguity associated with traversing the wrap point. For example, if the command history were:

```
32766: echo 1
32767: echo 2
1: echo 3
```

the number –2 refers to command 32 767 because it is the second previous command, regardless of serial number.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

In the ENVIRONMENT VARIABLES section, the text "user's home directory" is updated to "directory referred to by the *HOME* environment variable".

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

88633 **NAME**

88634 fg — run jobs in the foreground

88635 **SYNOPSIS**

88636 UP

```
fg [job_id]
```

88637 **DESCRIPTION**

88638 If job control is enabled (see the description of *set* **–m**), the *fg* utility shall move a background job
88639 from the current environment (see Section 2.12, on page 2331) into the foreground.

88640 Using *fg* to place a job into the foreground shall remove its process ID from the list of those
88641 "known in the current shell execution environment"; see Section 2.9.3.1 (on page 2319).

88642 **OPTIONS**

88643 None.

88644 **OPERANDS**

88645 The following operand shall be supported:

88646 *job_id* Specify the job to be run as a foreground job. If no *job_id* operand is given, the
88647 *job_id* for the job that was most recently suspended, placed in the background, or
88648 run as a background job shall be used. The format of *job_id* is described in XBD
88649 Section 3.203 (on page 65).

88650 **STDIN**

88651 Not used.

88652 **INPUT FILES**

88653 None.

88654 **ENVIRONMENT VARIABLES**

88655 The following environment variables shall affect the execution of *fg*:

88656 *LANG* Provide a default value for the internationalization variables that are unset or null.
88657 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
88658 variables used to determine the values of locale categories.)

88659 *LC_ALL* If set to a non-empty string value, override the values of all the other
88660 internationalization variables.

88661 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
88662 characters (for example, single-byte as opposed to multi-byte characters in
88663 arguments).

88664 *LC_MESSAGES*

88665 Determine the locale that should be used to affect the format and contents of
88666 diagnostic messages written to standard error.

88667 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

88668 **ASYNCHRONOUS EVENTS**

88669 Default.

88670 **STDOUT**

88671 The *fg* utility shall write the command line of the job to standard output in the following format:

88672 `"%s\n", <command>`

88673 **STDERR**

88674 The standard error shall be used only for diagnostic messages.

88675 **OUTPUT FILES**

88676 None.

88677 **EXTENDED DESCRIPTION**

88678 None.

88679 **EXIT STATUS**

88680 The following exit values shall be returned:

88681 0 Successful completion.

88682 >0 An error occurred.

88683 **CONSEQUENCES OF ERRORS**

88684 If job control is disabled, the *fg* utility shall exit with an error and no job shall be placed in the
88685 foreground.

88686 **APPLICATION USAGE**

88687 The *fg* utility does not work as expected when it is operating in its own utility execution
88688 environment because that environment has no applicable jobs to manipulate. See the
88689 APPLICATION USAGE section for *bg*. For this reason, *fg* is generally implemented as a shell
88690 regular built-in.

88691 **EXAMPLES**

88692 None.

88693 **RATIONALE**

88694 The extensions to the shell specified in this volume of POSIX.1-200x have mostly been based on
88695 features provided by the KornShell. The job control features provided by *bg*, *fg*, and *jobs* are also
88696 based on the KornShell. The standard developers examined the characteristics of the C shell
88697 versions of these utilities and found that differences exist. Despite widespread use of the C shell,
88698 the KornShell versions were selected for this volume of POSIX.1-200x to maintain a degree of
88699 uniformity with the rest of the KornShell features selected (such as the very popular command
88700 line editing features).

88701 **FUTURE DIRECTIONS**

88702 None.

88703 **SEE ALSO**

88704 Section 2.9.3.1 (on page 2319), Section 2.12 (on page 2331), *bg*, *kill*, *jobs*, *wait*

88705 XBD Section 3.203 (on page 65), Chapter 8 (on page 173)

88706 **CHANGE HISTORY**

88707 First released in Issue 4.

88708 **Issue 6**

88709 This utility is marked as part of the User Portability Utilities option.

88710 The APPLICATION USAGE section is added.

88711 The JC marking is removed from the SYNOPSIS since job control is mandatory is this version.

88712 **NAME**

88713 file — determine file type

88714 **SYNOPSIS**

88715 `file [–dh] [–M` *file*`] [–m` *file*`]` *file*`...`

88716 `file –i [–h]` *file*`...`

88717 **DESCRIPTION**

88718 The *file* utility shall perform a series of tests in sequence on each specified *file* in an attempt to
88719 classify it:

88720 1. If *file* does not exist, cannot be read, or its file status could not be determined, the output
88721 shall indicate that the file was processed, but that its type could not be determined.

88722 2. If the file is not a regular file, its file type shall be identified. The file types directory,
88723 FIFO, socket, block special, and character special shall be identified as such. Other
88724 implementation-defined file types may also be identified. If *file* is a symbolic link, by
88725 default the link shall be resolved and *file* shall test the type of file referenced by the
88726 symbolic link. (See the **–h** and **–i** options below.)

88727 3. If the length of *file* is zero, it shall be identified as an empty file.

88728 4. The *file* utility shall examine an initial segment of *file* and shall make a guess at
88729 identifying its contents based on position-sensitive tests. (The answer is not guaranteed to
88730 be correct; see the **–d**, **–M**, and **–m** options below.)

88731 5. The *file* utility shall examine *file* and make a guess at identifying its contents based on
88732 context-sensitive default system tests. (The answer is not guaranteed to be correct.)

88733 6. The file shall be identified as a data file.

88734 If *file* does not exist, cannot be read, or its file status could not be determined, the output shall
88735 indicate that the file was processed, but that its type could not be determined.

88736 If *file* is a symbolic link, by default the link shall be resolved and *file* shall test the type of file
88737 referenced by the symbolic link.

88738 **OPTIONS**

88739 The *file* utility shall conform to XBD Section 12.2 (on page 215), except that the order of the **–m**,
88740 **–d**, and **–M** options shall be significant.

88741 The following options shall be supported by the implementation:

88742 **–d** Apply any position-sensitive default system tests and context-sensitive default
88743 system tests to the file. This is the default if no **–M** or **–m** option is specified.

88744 **–h** When a symbolic link is encountered, identify the file as a symbolic link. If **–h** is
88745 not specified and *file* is a symbolic link that refers to a nonexistent file, *file* shall
88746 identify the file as a symbolic link, as if **–h** had been specified.

88747 **–i** If a file is a regular file, do not attempt to classify the type of the file further, but
88748 identify the file as specified in the STDOUT section.

88749 **–M** *file* Specify the name of a file containing position-sensitive tests that shall be applied to
88750 a file in order to classify it (see the EXTENDED DESCRIPTION). No position-
88751 sensitive default system tests nor context-sensitive default system tests shall be
88752 applied unless the **–d** option is also specified.

88753 **–m** *file* Specify the name of a file containing position-sensitive tests that shall be applied to
88754 a file in order to classify it (see the EXTENDED DESCRIPTION).

88755 If the **–m** option is specified without specifying the **–d** option or the **–M** option, position-
88756 sensitive default system tests shall be applied after the position-sensitive tests specified by the
88757 **–m** option. If the **–M** option is specified with the **–d** option, the **–m** option, or both, or the **–m**
88758 option is specified with the **–d** option, the concatenation of the position-sensitive tests specified
88759 by these options shall be applied in the order specified by the appearance of these options. If a
88760 **–M** or **–m** *file* option-argument is –, the results are unspecified.

88761 **OPERANDS**

88762 The following operand shall be supported:

88763 *file* A pathname of a file to be tested.

88764 **STDIN**

88765 The standard input shall be used if a *file* operand is `'-'` and the implementation treats the `'-'`
88766 as meaning standard input. Otherwise, the standard input shall not be used.

88767 **INPUT FILES**

88768 The *file* can be any file type.

88769 **ENVIRONMENT VARIABLES**

88770 The following environment variables shall affect the execution of *file*:

88771 *LANG* Provide a default value for the internationalization variables that are unset or null.
88772 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
88773 variables used to determine the values of locale categories.)

88774 *LC_ALL* If set to a non-empty string value, override the values of all the other
88775 internationalization variables.

88776 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
88777 characters (for example, single-byte as opposed to multi-byte characters in
88778 arguments and input files).

88779 *LC_MESSAGES*
88780 Determine the locale that should be used to affect the format and contents of
88781 diagnostic messages written to standard error and informative messages written to
88782 standard output.

88783 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

88784 **ASYNCHRONOUS EVENTS**

88785 Default.

88786 **STDOUT**

88787 In the POSIX locale, the following format shall be used to identify each operand, *file* specified:

88788 `"%s: %s\n", <file>, <type>`

88789 The values for <*type*> are unspecified, except that in the POSIX locale, if *file* is identified as one
88790 of the types listed in the following table, <*type*> shall contain (but is not limited to) the
88791 corresponding string, unless the file is identified by a position-sensitive test specified by a **–M** or
88792 **–m** option. Each <space> shown in the strings shall be exactly one <space>.

88793 **Table 4-9** File Utility Output Strings

88794 If *file* is:	<*type*> shall contain the string:	Notes
88795 Nonexistent	cannot open	
88796 Block special	block special	1
88797 Character special	character special	1
88798 Directory	directory	1
88799 FIFO	fifo	1
88800 Socket	socket	1
88801 Symbolic link	symbolic link to	1
88802 Regular file	regular file	1,2
88803 Empty regular file	empty	3
88804 Regular file that cannot be read	cannot open	3
88805 Executable binary	executable	3,4,6
88806 *ar* archive library (see *ar*)	archive	3,4,6
88807 Extended *cpio* format (see *pax*)	cpio archive	3,4,6
88808 Extended *tar* format (see **ustar** in *pax*)	tar archive	3,4,6
88809 Shell script	commands text	3,5,6
88810 C-language source	c program text	3,5,6
88811 FORTRAN source	fortran program text	3,5,6
88812 Regular file whose type cannot be determined	data	3

88813 **Notes:**

88814 1. This is a file type test.

88815 2. This test is applied only if the **–i** option is specified.

88816 3. This test is applied only if the **–i** option is not specified.

88817 4. This is a position-sensitive default system test.

88818 5. This is a context-sensitive default system test.

88819 88820 6. Position-sensitive default system tests and context-sensitive default system tests are not applied if the **–M** option is specified unless the **–d** option is also specified.

88821 88822 In the POSIX locale, if *file* is identified as a symbolic link (see the **–h** option), the following alternative output format shall be used:

88823 `"%s: %s %s\n", <file>, <type>, <contents of link>"`

88824 88825 88826 If the file named by the *file* operand does not exist, cannot be read, or the type of the file named by the *file* operand cannot be determined, this shall not be considered an error that affects the exit status.

88827 **STDERR**

88828 The standard error shall be used only for diagnostic messages.

88829 **OUTPUT FILES**

88830 None.

88831 **EXTENDED DESCRIPTION**

88832 A file specified as an option-argument to the **–m** or **–M** options shall contain one position-
88833 sensitive test per line, which shall be applied to the file. If the test succeeds, the message field of
88834 the line shall be printed and no further tests shall be applied, with the exception that tests on
88835 immediately following lines beginning with a single `'>'` character shall be applied.

88836 Each line shall be composed of the following four <tab>-separated fields. (Implementations may
88837 allow any combination of one or more white-space characters other than <newline> to act as
88838 field separators.)

88839 *offset* An unsigned number (optionally preceded by a single `'>'` character) specifying
88840 the *offset*, in bytes, of the value in the file that is to be compared against the *value*
88841 field of the line. If the file is shorter than the specified offset, the test shall fail.

88842 If the *offset* begins with the character `'>'`, the test contained in the line shall not be
88843 applied to the file unless the test on the last line for which the *offset* did not begin
88844 with a `'>'` was successful. By default, the *offset* shall be interpreted as an unsigned
88845 decimal number. With a leading 0x or 0X, the *offset* shall be interpreted as a
88846 hexadecimal number; otherwise, with a leading 0, the *offset* shall be interpreted as
88847 an octal number.

88848 *type* The type of the value in the file to be tested. The type shall consist of the type
88849 specification characters `d`, `s`, and `u`, specifying signed decimal, string, and
88850 unsigned decimal, respectively.

88851 The *type* string shall be interpreted as the bytes from the file starting at the
88852 specified *offset* and including the same number of bytes specified by the *value* field.
88853 If insufficient bytes remain in the file past the *offset* to match the *value* field, the test
88854 shall fail.

88855 The type specification characters `d` and `u` can be followed by an optional unsigned
88856 decimal integer that specifies the number of bytes represented by the type. The
88857 type specification characters `d` and `u` can be followed by an optional `C`, `S`, `I`, or `L`,
88858 indicating that the value is of type **char**, **short**, **int**, or **long**, respectively.

88859 The default number of bytes represented by the type specifiers `d`, `f`, and `u` shall
88860 correspond to their respective C-language types as follows. If the system claims
88861 conformance to the C-Language Development Utilities option, those specifiers
88862 shall correspond to the default sizes used in the *c99* utility. Otherwise, the default
88863 sizes shall be implementation-defined.

88864 For the type specifier characters `d` and `u`, the default number of bytes shall
88865 correspond to the size of a basic integer type of the implementation. For these
88866 specifier characters, the implementation shall support values of the optional
88867 number of bytes to be converted corresponding to the number of bytes in the C-
88868 language types **char**, **short**, **int**, or **long**. These numbers can also be specified by an
88869 application as the characters `C`, `S`, `I`, and `L`, respectively. The byte order used when
88870 interpreting numeric values is implementation-defined, but shall correspond to the
88871 order in which a constant of the corresponding type is stored in memory on the
88872 system.

88873 All type specifiers, except for `s`, can be followed by a mask specifier of the form
88874 &*number*. The mask value shall be AND'ed with the value of the input file before
88875 the comparison with the *value* field of the line is made. By default, the mask shall
88876 be interpreted as an unsigned decimal number. With a leading 0x or 0X, the mask
88877 shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading

0, the mask shall be interpreted as an unsigned octal number.

The strings **byte**, **short**, **long**, and **string** shall also be supported as type fields, being interpreted as `dC`, `dS`, `dL`, and `s`, respectively.

value The *value* to be compared with the value from the file.

If the specifier from the type field is `s` or **string**, then interpret the value as a string. Otherwise, interpret it as a number. If the value is a string, then the test shall succeed only when a string value exactly matches the bytes from the file.

If the *value* is a string, it can contain the following sequences:

character The <backslash>-escape sequences as specified in XBD Table 5-1 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequence `'\ '` (the <backslash> character followed by a <space> character) shall be recognized to represent a <space> character. The results of using any other character, other than an octal digit, following the <backslash> are unspecified.

octal Octal sequences that can be used to represent characters with specific coded values. An octal sequence shall consist of a <backslash> followed by the longest sequence of one, two, or three octal-digit characters (01234567).

By default, any value that is not a string shall be interpreted as a signed decimal number. Any such value, with a leading 0x or 0X, shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading zero, the value shall be interpreted as an unsigned octal number.

If the value is not a string, it can be preceded by a character indicating the comparison to be performed. Permissible characters and the comparisons they specify are as follows:

`=` The test shall succeed if the value from the file equals the *value* field.

`<` The test shall succeed if the value from the file is less than the *value* field.

`>` The test shall succeed if the value from the file is greater than the *value* field.

`&` The test shall succeed if all of the set bits in the *value* field are set in the value from the file.

`^` The test shall succeed if at least one of the set bits in the *value* field is not set in the value from the file.

`x` The test shall succeed if the file is large enough to contain a value of the type specified starting at the offset specified.

message The *message* to be printed if the test succeeds. The *message* shall be interpreted using the notation for the *printf* formatting specification; see *printf*. If the *value* field was a string, then the value from the file shall be the argument for the *printf* formatting specification; otherwise, the value from the file shall be the argument.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *file* utility can only be required to guess at many of the file types because only exhaustive testing can determine some types with certainty. For example, binary data on some implementations might match the initial segment of an executable or a *tar* archive.

Note that the table indicates that the output contains the stated string. Systems may add text before or after the string. For executables, as an example, the machine architecture and various facts about how the file was link-edited may be included. Note also that on systems that recognize shell script files starting with "#!" as executable files, these may be identified as executable binary files rather than as shell scripts.

EXAMPLES

Determine whether an argument is a binary executable file:

```
file -- "$1" | grep -q ':.*executable' &&
    printf "%s is executable.\n" "$1"
```

RATIONALE

The **-f** option was omitted because the same effect can (and should) be obtained using the *xargs* utility.

Historical versions of the *file* utility attempt to identify the following types of files: symbolic link, directory, character special, block special, socket, *tar* archive, *cpio* archive, SCCS archive, archive library, empty, *compress* output, *pack* output, binary data, C source, FORTRAN source, assembler source, *nroff*/*troff*/*eqn*/*tbl* source *troff* output, shell script, C shell script, English text, ASCII text, various executables, APL workspace, compiled terminfo entries, and CURSES screen images. Only those types that are reasonably well specified in POSIX or are directly related to POSIX utilities are listed in the table.

Historical systems have used a "magic file" named **/etc/magic** to help identify file types. Because it is generally useful for users and scripts to be able to identify special file types, the **-m** flag and a portable format for user-created magic files has been specified. No requirement is made that an implementation of *file* use this method of identifying files, only that users be permitted to add their own classifying tests.

In addition, three options have been added to historical practice. The **-d** flag has been added to permit users to cause their tests to follow any default system tests. The **-i** flag has been added to permit users to test portably for regular files in shell scripts. The **-M** flag has been added to permit users to ignore any default system tests.

The POSIX.1-200x description of default system tests and the interaction between the **-d**, **-M**, and **-m** options did not clearly indicate that there were two types of "default system tests". The "position-sensitive tests" determine file types by looking for certain string or binary values at specific offsets in the file being examined. These position-sensitive tests were implemented in historical systems using the magic file described above. Some of these tests are now built into the *file* utility itself on some implementations so the output can provide more detail than can be provided by magic files. For example, a magic file can easily identify a **core** file on most implementations, but cannot name the program file that dropped the core. A magic file could

produce output such as:

```
/home/dwc/core: ELF 32-bit MSB core file SPARC Version 1
```

but by building the test into the *file* utility, you could get output such as:

```
/home/dwc/core: ELF 32-bit MSB core file SPARC Version 1, from 'testprog'
```

These extended built-in tests are still to be treated as position-sensitive default system tests even if they are not listed in **/etc/magic** or any other magic file.

The context-sensitive default system tests were always built into the *file* utility. These tests looked for language constructs in text files trying to identify shell scripts, C, FORTRAN, and other computer language source files, and even plain text files. With the addition of the –**m** and –**M** options the distinction between position-sensitive and context-sensitive default system tests became important because the order of testing is important. The context-sensitive system default tests should never be applied before any position-sensitive tests even if the –**d** option is specified before a –**m** option or –**M** option due to the high probability that the context-sensitive system default tests will incorrectly identify arbitrary text files as text files before position-sensitive tests specified by the –**m** or –**M** option would be applied to give a more accurate identification.

Leaving the meaning of –**M** – and –**m** – unspecified allows an existing prototype of these options to continue to work in a backwards-compatible manner. (In that implementation, –**M** – was roughly equivalent to –**d** in POSIX.1-200x.)

The historical –**c** option was omitted as not particularly useful to users or portable shell scripts. In addition, a reasonable implementation of the *file* utility would report any errors found each time the magic file is read.

The historical format of the magic file was the same as that specified by the Rationale in the ISO POSIX-2: 1993 standard for the *offset*, *value*, and *message* fields; however, it used less precise type fields than the format specified by the current normative text. The new type field values are a superset of the historical ones.

The following is an example magic file:

```
0  short     070707              cpio archive
0  short     0143561             Byte-swapped cpio archive
0  string    070707              ASCII cpio archive
0  long      0177555             Very old archive
0  short     0177545             Old archive
0  short     017437              Old packed data
0  string    \037\036            Packed data
0  string    \377\037            Compacted data
0  string    \037\235            Compressed data
>2 byte&0x80 >0                  Block compressed
>2 byte&0x1f x                   %d bits
0  string    \032\001            Compiled Terminfo Entry
0  short     0433                Curses screen image
0  short     0434                Curses screen image
0  string    <ar>                System V Release 1 archive
0  string    !<arch>\n__.SYMDEF  Archive random library
0  string    !<arch>             Archive
0  string    ARF_BEGARF          PHIGS clear text archive
0  long      0x137A2950          Scalable OpenFont binary
0  long      0x137A2951          Encrypted scalable OpenFont binary
```

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Options and an EXTENDED DESCRIPTION are added as specified in the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 #192 and #178 are applied.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/25 is applied, making major changes to address ambiguities raised in defect reports.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/26 is applied, making it clear in the OPTIONS section that the **−m**, **−d**, and **−M** options do not comply with Guideline 11 of the Utility Syntax Guidelines.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/10 is applied, clarifying the specification characters.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/11 is applied, allowing application developers to create portable magic files that can match characters in strings, and allowing common extensions found in existing implementations.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/12 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-4 is applied, adding further entries in the Notes column in Table 4-9.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *file* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

The EXAMPLES section is revised to correct an error with the pathname `"$1"`.

NAME

find — find files

SYNOPSIS

```
find [–H|–L] path... [operand_expression...]
```

DESCRIPTION

The *find* utility shall recursively descend the directory hierarchy from each file specified by *path*, evaluating a Boolean expression composed of the primaries described in the OPERANDS section for each file encountered. Each *path* operand shall be evaluated unaltered as it was provided, including all trailing <slash> characters; all pathnames for other files encountered in the hierarchy shall consist of the concatenation of the current *path* operand, a <slash> if the current *path* operand did not end in one, and the filename relative to the *path* operand. The relative portion shall contain no dot or dot-dot components, no trailing <slash> characters, and only single <slash> characters between pathname components.

The *find* utility shall be able to descend to arbitrary depths in a file hierarchy and shall not fail due to path length limitations (unless a *path* operand specified by the application exceeds {PATH_MAX} requirements).

The *find* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *find* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

OPTIONS

The *find* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported by the implementation:

–H Cause the file information and file type evaluated for each symbolic link encountered as a *path* operand on the command line to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself. File information and type for symbolic links encountered during the traversal of a file hierarchy shall be that of the link itself.

–L Cause the file information and file type evaluated for each symbolic link encountered as a *path* operand on the command line or encountered during the traversal of a file hierarchy to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself.

Specifying more than one of the mutually-exclusive options **–H** and **–L** shall not be considered an error. The last option specified shall determine the behavior of the utility. If neither the **–H** nor the **–L** option is specified, then the file information and type for symbolic links encountered as a *path* operand on the command line or encountered during the traversal of a file hierarchy shall be that of the link itself.

OPERANDS

The following operands shall be supported:

The first operand and subsequent operands up to but not including the first operand that starts with a `'–'`, or is a `'!'` or a `'('`, shall be interpreted as *path* operands. If the first operand starts with a `'–'`, or is a `'!'` or a `'('`, the behavior is unspecified. Each *path* operand is a pathname of a starting point in the file hierarchy.

The first operand that starts with a `'–'`, or is a `'!'` or a `'('`, and all subsequent arguments shall

be interpreted as an *expression* made up of the following primaries and operators. In the descriptions, wherever *n* is used as a primary argument, it shall be interpreted as a decimal integer optionally preceded by a plus ('+') or minus-sign ('−') sign, as follows:

+n More than *n*.

n Exactly *n*.

−n Less than *n*.

The following primaries shall be supported:

−name *pattern*
The primary shall evaluate as true if the basename of the current pathname matches *pattern* using the pattern matching notation described in Section 2.13 (on page 2332). The additional rules in Section 2.13.3 (on page 2333) do not apply as this is a matching operation, not an expansion.

−path *pattern*
The primary shall evaluate as true if the current pathname matches *pattern* using the pattern matching notation described in Section 2.13 (on page 2332). The additional rules in Section 2.13.3 (on page 2333) do not apply as this is a matching operation, not an expansion.

−nouser The primary shall evaluate as true if the file belongs to a user ID for which the *getpwuid*() function defined in the System Interfaces volume of POSIX.1-200x (or equivalent) returns NULL.

−nogroup The primary shall evaluate as true if the file belongs to a group ID for which the *getgrgid*() function defined in the System Interfaces volume of POSIX.1-200x (or equivalent) returns NULL.

−xdev The primary shall always evaluate as true; it shall cause *find* not to continue descending past directories that have a different device ID (*st_dev*, see the *stat*() function defined in the System Interfaces volume of POSIX.1-200x). If any **−xdev** primary is specified, it shall apply to the entire expression even if the **−xdev** primary would not normally be evaluated.

−prune The primary shall always evaluate as true; it shall cause *find* not to descend the current pathname if it is a directory. If the **−depth** primary is specified, the **−prune** primary shall have no effect.

−perm [−]*mode*
The *mode* argument is used to represent file mode bits. It shall be identical in format to the *symbolic_mode* operand described in *chmod*, and shall be interpreted as follows. To start, a template shall be assumed with all file mode bits cleared. An *op* symbol of '+' shall set the appropriate mode bits in the template; '−' shall clear the appropriate bits; '=' shall set the appropriate mode bits, without regard to the contents of the file mode creation mask of the process. The *op* symbol of '−' cannot be the first character of *mode*; this avoids ambiguity with the optional leading <hyphen>. Since the initial mode is all bits off, there are not any symbolic modes that need to use '−' as the first character.

If the <hyphen> is omitted, the primary shall evaluate as true when the file permission bits exactly match the value of the resulting template.

Otherwise, if *mode* is prefixed by a <hyphen>, the primary shall evaluate as true if at least all the bits in the resulting template are set in the file permission bits.

89135 –**perm** [–]*onum*

89136 If the <hyphen> is omitted, the primary shall evaluate as true when the file mode
89137 bits exactly match the value of the octal number *onum* (see the description of the
89138 octal *mode* in *chmod*). Otherwise, if *onum* is prefixed by a <hyphen>, the primary
89139 shall evaluate as true if at least all of the bits specified in *onum* are set. In both
89140 cases, the behavior is unspecified when *onum* exceeds 07777.

89141 –**type** *c* The primary shall evaluate as true if the type of the file is *c*, where *c* is `'b'`, `'c'`,
89142 `'d'`, `'l'`, `'p'`, `'f'`, or `'s'` for block special file, character special file, directory,
89143 symbolic link, FIFO, regular file, or socket, respectively.

89144 –**links** *n* The primary shall evaluate as true if the file has *n* links.

89145 –**user** *uname* The primary shall evaluate as true if the file belongs to the user *uname*. If *uname* is
89146 a decimal integer and the *getpwnam*() (or equivalent) function does not return a
89147 valid user name, *uname* shall be interpreted as a user ID.

89148 –**group** *gname*

89149 The primary shall evaluate as true if the file belongs to the group *gname*. If *gname*
89150 is a decimal integer and the *getgrnam*() (or equivalent) function does not return a
89151 valid group name, *gname* shall be interpreted as a group ID.

89152 –**size** *n*[**c**] The primary shall evaluate as true if the file size in bytes, divided by 512 and
89153 rounded up to the next integer, is *n*. If *n* is followed by the character `'c'`, the size
89154 shall be in bytes.

89155 –**atime** *n* The primary shall evaluate as true if the file access time subtracted from the
89156 initialization time, divided by 86 400 (with any remainder discarded), is *n*.

89157 –**ctime** *n* The primary shall evaluate as true if the time of last change of file status
89158 information subtracted from the initialization time, divided by 86 400 (with any
89159 remainder discarded), is *n*.

89160 –**mtime** *n* The primary shall evaluate as true if the file modification time subtracted from the
89161 initialization time, divided by 86 400 (with any remainder discarded), is *n*.

89162 –**exec** *utility_name* [*argument* ...] **;**
89163 –**exec** *utility_name* [*argument* ...] `{}` +

89164 The end of the primary expression shall be punctuated by a <semicolon> or by a
89165 <plus-sign>. Only a <plus-sign> that immediately follows an argument
89166 containing the two characters `"{}"` shall punctuate the end of the primary
89167 expression. Other uses of the <plus-sign> shall not be treated as special.

89168 If the primary expression is punctuated by a <semicolon>, the utility *utility_name*
89169 shall be invoked once for each pathname and the primary shall evaluate as true if
89170 the utility returns a zero value as exit status. A *utility_name* or *argument* containing
89171 only the two characters `"{}"` shall be replaced by the current pathname.

89172 If the primary expression is punctuated by a <plus-sign>, the primary shall always
89173 evaluate as true, and the pathnames for which the primary is evaluated shall be
89174 aggregated into sets. The utility *utility_name* shall be invoked once for each set of
89175 aggregated pathnames. Each invocation shall begin after the last pathname in the
89176 set is aggregated, and shall be completed before the *find* utility exits and before the
89177 first pathname in the next set (if any) is aggregated for this primary, but it is
89178 otherwise unspecified whether the invocation occurs before, during, or after the
89179 evaluations of other primaries. If any invocation returns a non-zero value as exit
89180 status, the *find* utility shall return a non-zero exit status. An argument containing

only the two characters "{}" shall be replaced by the set of aggregated pathnames, with each pathname passed as a separate argument to the invoked utility in the same order that it was aggregated. The size of any set of two or more pathnames shall be limited such that execution of the utility does not cause the system's {ARG_MAX} limit to be exceeded. If more than one argument containing only the two characters "{}" is present, the behavior is unspecified.

If a *utility_name* or *argument* string contains the two characters "{}", but not just the two characters "{}", it is implementation-defined whether *find* replaces those two characters or uses the string without change. The current directory for the invocation of *utility_name* shall be the same as the current directory when the *find* utility was started. If the *utility_name* names any of the special built-in utilities (see Section 2.14, on page 2334), the results are undefined.

–ok *utility_name* **[***argument* ...**] ;**
The **–ok** primary shall be equivalent to **–exec**, except that the use of a <plus-sign> to punctuate the end of the primary expression need not be supported, and *find* shall request affirmation of the invocation of *utility_name* using the current file as an argument by writing to standard error as described in the STDERR section. If the response on standard input is affirmative, the utility shall be invoked. Otherwise, the command shall not be invoked and the value of the **–ok** operand shall be false.

–print The primary shall always evaluate as true; it shall cause the current pathname to be written to standard output.

–newer *file* The primary shall evaluate as true if the modification time of the current file is more recent than the modification time of the file named by the pathname *file*.

–depth The primary shall always evaluate as true; it shall cause descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. If a **–depth** primary is not specified, all entries in a directory shall be acted on after the directory itself. If any **–depth** primary is specified, it shall apply to the entire expression even if the **–depth** primary would not normally be evaluated.

The primaries can be combined using the following operators (in order of decreasing precedence):

(*expression*) True if *expression* is true.

! *expression* Negation of a primary; the unary NOT operator.

expression **[–a]** *expression*
Conjunction of primaries; the AND operator is implied by the juxtaposition of two primaries or made explicit by the optional **–a** operator. The second expression shall not be evaluated if the first expression is false.

expression **–o** *expression*
Alternation of primaries; the OR operator. The second expression shall not be evaluated if the first expression is true.

If no *expression* is present, **–print** shall be used as the expression. Otherwise, if the given expression does not contain any of the primaries **–exec**, **–ok**, or **–print**, the given expression shall be effectively replaced by:

```
( given_expression ) –print
```

The **–user**, **–group**, and **–newer** primaries each shall evaluate their respective arguments only once.

When the file type evaluated for the current file is a symbolic link, the results of evaluating the **–perm** primary are implementation-defined.

STDIN

If the **–ok** primary is used, the response shall be read from the standard input. An entire line shall be read as the response. Otherwise, the standard input shall not be used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *find*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the pattern matching notation for the **–n** option and in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE This variable determines the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments), the behavior of character classes within the pattern matching notation used for the **–n** option, and the behavior of character classes within regular expressions used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages and prompts written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the location of the *utility_name* for the **–exec** and **–ok** primaries, as described in XBD Chapter 8 (on page 173).

ASYNCHRONOUS EVENTS

Default.

STDOUT

The **–print** primary shall cause the current pathnames to be written to standard output. The format shall be:

```
"%s\n", <path>
```

89266 **STDERR**

89267 The **–ok** primary shall write a prompt to standard error containing at least the *utility_name* to be
89268 invoked and the current pathname. In the POSIX locale, the last non-<blank> in the prompt shall
89269 be `'?'`. The exact format used is unspecified.

89270 Otherwise, the standard error shall be used only for diagnostic messages.

89271 **OUTPUT FILES**

89272 None.

89273 **EXTENDED DESCRIPTION**

89274 None.

89275 **EXIT STATUS**

89276 The following exit values shall be returned:

89277 0 All *path* operands were traversed successfully.

89278 >0 An error occurred.

89279 **CONSEQUENCES OF ERRORS**

89280 Default.

89281 **APPLICATION USAGE**

89282 When used in operands, pattern matching notation, <semicolon>, <left-parenthesis>, and
89283 <right-parenthesis> characters are special to the shell and must be quoted (see Section 2.2, on
89284 page 2298).

89285 The bit that is traditionally used for sticky (historically 01000) is specified in the **–perm** primary
89286 using the octal number argument form. Since this bit is not defined by this volume of
89287 POSIX.1-200x, applications must not assume that it actually refers to the traditional sticky bit.

89288 **EXAMPLES**

89289 1. The following commands are equivalent:

89290 ```
find .
```
89291 ```
find . –print
```

89292 They both write out the entire directory hierarchy from the current directory.

89293 2. The following command:

89294 ```
find / \(–name tmp –o –name '*.xx' \) –atime +7 –exec rm {} \;
```

89295 removes all files named **tmp** or ending in **.xx** that have not been accessed for seven or
89296 more 24-hour periods.

89297 3. The following command:

89298 ```
find . –perm –o+w,+s
```

89299 prints (**–print** is assumed) the names of all files in or below the current directory, with all
89300 of the file permission bits S_ISUID, S_ISGID, and S_IWOTH set.

89301 4. The following command:

89302 ```
find . –name SCCS –prune –o –print
```

89303 recursively prints pathnames of all files in the current directory and below, but skips
89304 directories named SCCS and files in them.
```

5. The following command:

```
find . –print –name SCCS –prune
```

behaves as in the previous example, but prints the names of the SCCS directories.

6. The following command is roughly equivalent to the –**nt** extension to *test*:

```
if [ –n "$(find file1 –prune –newer file2)" ]; then
    printf %s\\n "file1 is newer than file2"
fi
```

7. The descriptions of –**atime**, –**ctime**, and –**mtime** use the terminology *n* "86 400 second periods (days)". For example, a file accessed at 23:59 is selected by:

```
find . –atime –1 –print
```

at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.

8. The following command:

```
find . ! –name . –prune –name '*.old' –exec \
    sh –c 'mv "$@" ../old/' sh {} +
```

performs the same task as:

```
mv ./*.old ./.*.old ../old/
```

while avoiding an "Argument list too long" error if there are a large number of files ending with **.old** (and avoiding "No such file or directory" errors if no files match **./*.old** or **./.*.old**).

The alternative:

```
find . ! –name . –prune –name '*.old' –exec mv {} ../old/ \;
```

is less efficient if there are many files to move because it executes one *mv* command per file.

9. On systems configured to mount removable media on directories under **/media**, the following command searches the file hierarchy for files larger than 100 000 KB without searching any mounted removable media:

```
find / –path /media –prune –o –size +200000 –print
```

10. Except for the root directory, and `"//"` on implementations where `"//"` does not refer to the root directory, no pattern given to –**name** will match a <slash>, because trailing <slash> characters are ignored when computing the basename of the file under evaluation. Given two empty directories named **foo** and **bar**, the following command:

```
find foo/// bar/// –name foo –o –name 'bar?*'
```

prints only the line `"foo///"`.

RATIONALE

The –**a** operator was retained as an optional operator for compatibility with historical shell scripts, even though it is redundant with expression concatenation.

The descriptions of the `'–'` modifier on the *mode* and *onum* arguments to the –**perm** primary agree with historical practice on BSD and System V implementations. System V and BSD documentation both describe it in terms of checking additional bits; in fact, it uses the same bits, but checks for having at least all of the matching bits set instead of having exactly the matching

bits set.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because:

- Implementations may desire more descriptive prompts than those used on historical implementations.
- Since the historical prompt strings do not terminate with <newline> characters, there is no portable way for another program to interact with the prompts of this utility via pipes.

Therefore, an application using this prompting option relies on the system to provide the most suitable dialog directly with the user, based on the general guidelines specified.

The **–name** *file* operand was changed to use the shell pattern matching notation so that *find* is consistent with other utilities using pattern matching.

The **–size** operand refers to the size of a file, rather than the number of blocks it may occupy in the file system. The intent is that the *st_size* field defined in the System Interfaces volume of POSIX.1-200x should be used, not the *st_blocks* found in historical implementations. There are at least two reasons for this:

1. In both System V and BSD, *find* only uses *st_size* in size calculations for the operands specified by this volume of POSIX.1-200x. (BSD uses *st_blocks* only when processing the **–ls** primary.)
2. Users usually think of file size in terms of bytes, which is also the unit used by the *ls* utility for the output from the **–l** option. (In both System V and BSD, *ls* uses *st_size* for the **–l** option size field and uses *st_blocks* for the *ls* **–s** calculations. This volume of POSIX.1-200x does not specify *ls* **–s**.)

The descriptions of **–atime**, **–ctime**, and **–mtime** were changed from the SVID description of *n* "days" to *n* being the result of the integer division of the time difference in seconds by 86 400. The description is also different in terms of the exact timeframe for the *n* case (*versus* the +*n* or –*n*), but it matches all known historical implementations. It refers to one 86 400 second period in the past, not any time from the beginning of that period to the current time. For example, **–atime** 2 is true if the file was accessed any time in the period from 72 hours to 48 hours ago.

Historical implementations do not modify `"{}"` when it appears as a substring of an **–exec** or **–ok** *utility_name* or argument string. There have been numerous user requests for this extension, so this volume of POSIX.1-200x allows the desired behavior. At least one recent implementation does support this feature, but encountered several problems in managing memory allocation and dealing with multiple occurrences of `"{}"` in a string while it was being developed, so it is not yet required behavior.

Assuming the presence of **–print** was added to correct a historical pitfall that plagues novice users, it is entirely upwards-compatible from the historical System V *find* utility. In its simplest form (*find directory*), it could be confused with the historical BSD fast *find*. The BSD developers agreed that adding **–print** as a default expression was the correct decision and have added the fast *find* functionality within a new utility called *locate*.

Historically, the **–L** option was implemented using the primary **–follow**. The **–H** and **–L** options were added for two reasons. First, they offer a finer granularity of control and consistency with other programs that walk file hierarchies. Second, the **–follow** primary always evaluated to true. As they were historically really global variables that took effect before the traversal began, some valid expressions had unexpected results. An example is the expression **–print –o –follow**. Because **–print** always evaluates to true, the standard order of evaluation implies that **–follow** would never be evaluated. This was never the case. Historical practice for the **–follow** primary,

however, is not consistent. Some implementations always follow symbolic links on the command line whether **–follow** is specified or not. Others follow symbolic links on the command line only if **–follow** is specified. Both behaviors are provided by the **–H** and **–L** options, but scripts using the current **–follow** primary would be broken if the **–follow** option is specified to work either way.

Since the **–L** option resolves all symbolic links and the **–type** *l* primary is true for symbolic links that still exist after symbolic links have been resolved, the command:

```
find –L . –type l
```

prints a list of symbolic links reachable from the current directory that do not resolve to accessible files.

A feature of SVR4's *find* utility was the **–exec** primary's **+** terminator. This allowed filenames containing special characters (especially <newline> characters) to be grouped together without the problems that occur if such filenames are piped to *xargs*. Other implementations have added other ways to get around this problem, notably a **–print0** primary that wrote filenames with a null byte terminator. This was considered here, but not adopted. Using a null terminator meant that any utility that was going to process *find*'s **–print0** output had to add a new option to parse the null terminators it would now be reading.

The "`–exec ... {} +`" syntax adopted was a result of IEEE PASC Interpretation 1003.2 #210. It should be noted that this is an incompatible change to the ISO/IEC 9899:1999 standard. For example, the following command prints all files with a `'–'` after their name if they are regular files, and a `'+'` otherwise:

```
find / –type f –exec echo {} – ';' –o –exec echo {} + ';'
```

The change invalidates usage like this. Even though the previous standard stated that this usage would work, in practice many did not support it and the standard developers felt it better to now state that this was not allowable.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–perm** [–]*onum* primary is supported.

The *find* utility is aligned with the IEEE P1003.2b draft standard, to include processing of symbolic links and changes to the description of the **atime**, **ctime**, and **mtime** operands.

IEEE PASC Interpretation 1003.2 #210 is applied, extending the **–exec** operand.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/13 is applied, updating the RATIONALE section to be consistent with the normative text.

Issue 7

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

Austin Group Interpretation 1003.1-2001 #127 is applied, rephrasing the description of the –**exec** primary to be "immediately follows".

Austin Group Interpretation 1003.1-2001 #185 is applied, clarifying the requirements for the –**H** and –**L** options.

Austin Group Interpretation 1003.1-2001 #186 is applied, clarifying the requirements for the evaluation of *path* operands.

Austin Group Interpretation 1003.1-2001 #195 is applied, clarifying the interpretation of the first operand.

SD5-XCU-ERN-48 is applied, clarifying the –**L** option in the case that the referenced file does not exist.

SD5-XCU-ERN-89 is applied, updating the OPERANDS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-117 is applied, clarifying the –**perm** operand.

SD5-XCU-ERN-122 is applied, adding a new EXAMPLE.

The description of the –**name** primary is revised and the –**path** primary is added (with a new example).

NAME

fold — filter for folding lines

SYNOPSIS

```
fold [–bs] [–w width] [file...]
```

DESCRIPTION

The *fold* utility is a filter that shall fold lines from its input files, breaking the lines to have a maximum of *width* column positions (or bytes, if the **–b** option is specified). Lines shall be broken by the insertion of a <newline> such that each output line (referred to later in this section as a *segment*) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line shall not be broken in the middle of a character. The behavior is undefined if *width* is less than the number of columns any single character in the input would occupy.

If the <carriage-return>, <backspace>, or <tab> characters are encountered in the input, and the **–b** option is not specified, they shall be treated specially:

<backspace> The current count of line width shall be decremented by one, although the count never shall become negative. The *fold* utility shall not insert a <newline> immediately before or after any <backspace>, unless the following character has a width greater than 1 and would cause the line width to exceed *width*.

<carriage-return>
The current count of line width shall be set to zero. The *fold* utility shall not insert a <newline> immediately before or after any <carriage-return>.

<tab> Each <tab> encountered shall advance the column position pointer to the next tab stop. Tab stops shall be at each column position *n* such that *n* modulo 8 equals 1.

OPTIONS

The *fold* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–b Count *width* in bytes rather than column positions.

–s If a segment of a line contains a <blank> within the first *width* column positions (or bytes), break the line after the last such <blank> meeting the width constraints. If there is no <blank> meeting the requirements, the **–s** option shall have no effect for that output segment of the input line.

–w *width* Specify the maximum line length, in column positions (or bytes if **–b** is specified). The results are unspecified if *width* is not a positive decimal number. The default value shall be 80.

OPERANDS

The following operand shall be supported:

file A pathname of a text file to be folded. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'–'` and the implementation treats the `'–'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

89498 **INPUT FILES**

89499 If the **–b** option is specified, the input files shall be text files except that the lines are not limited
89500 to {LINE_MAX} bytes in length. If the **–b** option is not specified, the input files shall be text files.

89501 **ENVIRONMENT VARIABLES**

89502 The following environment variables shall affect the execution of *fold*:

89503 *LANG* Provide a default value for the internationalization variables that are unset or null.
89504 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
89505 variables used to determine the values of locale categories.)

89506 *LC_ALL* If set to a non-empty string value, override the values of all the other
89507 internationalization variables.

89508 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
89509 characters (for example, single-byte as opposed to multi-byte characters in
89510 arguments and input files), and for the determination of the width in column
89511 positions each character would occupy on a constant-width font output device.

89512 *LC_MESSAGES*
89513 Determine the locale that should be used to affect the format and contents of
89514 diagnostic messages written to standard error.

89515 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

89516 **ASYNCHRONOUS EVENTS**

89517 Default.

89518 **STDOUT**

89519 The standard output shall be a file containing a sequence of characters whose order shall be
89520 preserved from the input files, possibly with inserted <newline> characters.

89521 **STDERR**

89522 The standard error shall be used only for diagnostic messages.

89523 **OUTPUT FILES**

89524 None.

89525 **EXTENDED DESCRIPTION**

89526 None.

89527 **EXIT STATUS**

89528 The following exit values shall be returned:

89529 0 All input files were processed successfully.

89530 >0 An error occurred.

89531 **CONSEQUENCES OF ERRORS**

89532 Default.

APPLICATION USAGE

The *cut* and *fold* utilities can be used to create text files out of files with arbitrary line lengths. The *cut* utility should be used when the number of lines (or records) needs to remain constant. The *fold* utility should be used when the contents of long lines need to be kept contiguous.

The *fold* utility is frequently used to send text files to printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

EXAMPLES

An example invocation that submits a file of possibly long lines to the printer (under the assumption that the user knows the line width of the printer to be assigned by *lp*):

```
fold –w 132 bigfile | lp
```

RATIONALE

Although terminal input in canonical processing mode requires the erase character (frequently set to <backspace>) to erase the previous character (not byte or column position), terminal output is not buffered and is extremely difficult, if not impossible, to parse correctly; the interpretation depends entirely on the physical device that actually displays/prints/stores the output. In all known internationalized implementations, the utilities producing output for mixed column-width output assume that a <backspace> character backs up one column position and outputs enough <backspace> characters to return to the start of the character when <backspace> is used to provide local line motions to support underlining and emboldening operations. Since *fold* without the **–b** option is dealing with these same constraints, <backspace> is always treated as backing up one column position rather than backing up one character.

Historical versions of the *fold* utility assumed 1 byte was one character and occupied one column position when written out. This is no longer always true. Since the most common usage of *fold* is believed to be folding long lines for output to limited-length output devices, this capability was preserved as the default case. The **–b** option was added so that applications could *fold* files with arbitrary length lines into text files that could then be processed by the standard utilities. Note that although the width for the **–b** option is in bytes, a line is never split in the middle of a character. (It is unspecified what happens if a width is specified that is too small to hold a single character found in the input followed by a <newline>.)

The tab stops are hardcoded to be every eighth column to meet historical practice. No new method of specifying other tab stops was invented.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

Austin Group Interpretation 1003.1-2001 #204 is applied, updating the DESCRIPTION to clarify when a <newline> can be inserted before or after a <backspace>.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

89578 **NAME**

89579 fort77 — FORTRAN compiler (**FORTRAN**)

89580 **SYNOPSIS**

89581 FD
```
fort77 [–c] [–g] [–L directory]... [–O optlevel] [–o outfile] [–s]
    [–w] operand...
```

89583 **DESCRIPTION**

89584 The *fort77* utility is the interface to the FORTRAN compilation system; it shall accept the full
89585 FORTRAN-77 language defined by the ANSI X3.9-1978 standard. The system conceptually
89586 consists of a compiler and link editor. The files referenced by *operand*s are compiled and linked
89587 to produce an executable file. It is unspecified whether the linking occurs entirely within the
89588 operation of *fort77*; some implementations may produce objects that are not fully resolved until
89589 the file is executed.

89590 If the **–c** option is present, for all pathname operands of the form *file***.f**, the files:

89591 `$(basename pathname.f).o`

89592 shall be created or overwritten as the result of successful compilation. If the **–c** option is not
89593 specified, it is unspecified whether such **.o** files are created or deleted for the *file***.f** operands.

89594 If there are no options that prevent link editing (such as **–c**) and all operands compile and link
89595 without error, the resulting executable file shall be written into the file named by the **–o** option
89596 (if present) or to the file **a.out**. The executable file shall be created as specified in the System
89597 Interfaces volume of POSIX.1-200x, except that the file permissions shall be set to:

89598 S_IRWXO | S_IRWXG | S_IRWXU

89599 and that the bits specified by the *umask* of the process shall be cleared.

89600 **OPTIONS**

89601 The *fort77* utility shall conform to XBD Section 12.2 (on page 215), except that:

89602 • The **–l** *library* operands have the format of options, but their position within a list of
89603 operands affects the order in which libraries are searched.

89604 • The order of specifying the multiple **–L** options is significant.

89605 • Conforming applications shall specify each option separately; that is, grouping option
89606 letters (for example, **–cg**) need not be recognized by all implementations.

89607 The following options shall be supported:

89608 **–c** Suppress the link-edit phase of the compilation, and do not remove any object files
89609 that are produced.

89610 **–g** Produce symbolic information in the object or executable files; the nature of this
89611 information is unspecified, and may be modified by implementation-defined
89612 interactions with other options.

89613 **–s** Produce object or executable files, or both, from which symbolic and other
89614 information not required for proper execution using the *exec* family of functions
89615 defined in the System Interfaces volume of POSIX.1-200x has been removed
89616 (stripped). If both **–g** and **–s** options are present, the action taken is unspecified.

89617 **–o** *outfile* Use the pathname *outfile*, instead of the default **a.out**, for the executable file
89618 produced. If the **–o** option is present with **–c**, the result is unspecified.

89619 –**L** *directory* Change the algorithm of searching for the libraries named in –**l** operands to look in
89620 the directory named by the *directory* pathname before looking in the usual places.
89621 Directories named in –**L** options shall be searched in the specified order. At least
89622 ten instances of this option shall be supported in a single *fort77* command
89623 invocation. If a directory specified by a –**L** option contains a file named **libf.a**, the
89624 results are unspecified.

89625 –**O** *optlevel* Specify the level of code optimization. If the *optlevel* option-argument is the digit
89626 `'0'`, all special code optimizations shall be disabled. If it is the digit `'1'`, the
89627 nature of the optimization is unspecified. If the –**O** option is omitted, the nature of
89628 the system's default optimization is unspecified. It is unspecified whether code
89629 generated in the presence of the –**O** 0 option is the same as that generated when
89630 –**O** is omitted. Other *optlevel* values may be supported.

89631 –**w** Suppress warnings.

89632 Multiple instances of –**L** options can be specified.

89633 **OPERANDS**

89634 An *operand* is either in the form of a pathname or the form –**l** *library*. At least one operand of the
89635 pathname form shall be specified. The following operands shall be supported:

89636 *file*.**f** The pathname of a FORTRAN source file to be compiled and optionally passed to
89637 the link editor. The filename operand shall be of this form if the –**c** option is used.

89638 *file*.**a** A library of object files typically produced by *ar*, and passed directly to the link
89639 editor. Implementations may recognize implementation-defined suffixes other
89640 than **.a** as denoting object file libraries.

89641 *file*.**o** An object file produced by *fort77* –**c** and passed directly to the link editor.
89642 Implementations may recognize implementation-defined suffixes other than **.o** as
89643 denoting object files.

89644 The processing of other files is implementation-defined.

89645 –**l** *library* (The letter ell.) Search the library named:

89646 `lib`*`library`*`.a`

89647 A library is searched when its name is encountered, so the placement of a –**l**
89648 operand is significant. Several standard libraries can be specified in this manner, as
89649 described in the EXTENDED DESCRIPTION section. Implementations may
89650 recognize implementation-defined suffixes other than **.a** as denoting libraries.

89651 **STDIN**

89652 Not used.

89653 **INPUT FILES**

89654 The input file shall be one of the following: a text file containing FORTRAN source code; an
89655 object file in the format produced by *fort77* –**c**; or a library of object files, in the format produced
89656 by archiving zero or more object files, using *ar*. Implementations may supply additional utilities
89657 that produce files in these formats. Additional input files are implementation-defined.

89658 A <tab> encountered within the first six characters on a line of source code shall cause the
89659 compiler to interpret the following character as if it were the seventh character on the line (that
89660 is, in column 7).

89661 **ENVIRONMENT VARIABLES**

89662 The following environment variables shall affect the execution of *fort77*:

89663 *LANG* Provide a default value for the internationalization variables that are unset or null.
89664 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
89665 variables used to determine the values of locale categories.)

89666 *LC_ALL* If set to a non-empty string value, override the values of all the other
89667 internationalization variables.

89668 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
89669 characters (for example, single-byte as opposed to multi-byte characters in
89670 arguments and input files).

89671 *LC_MESSAGES*
89672 Determine the locale that should be used to affect the format and contents of
89673 diagnostic messages written to standard error.

89674 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

89675 *TMPDIR* Determine the pathname that should override the default directory for temporary
89676 files, if any.

89677 **ASYNCHRONOUS EVENTS**

89678 Default.

89679 **STDOUT**

89680 Not used.

89681 **STDERR**

89682 The standard error shall be used only for diagnostic messages. If more than one *file* operand
89683 ending in **.f** (or possibly other unspecified suffixes) is given, for each such file:

89684 `"%s:\n", <file>`

89685 may be written to allow identification of the diagnostic message with the appropriate input file.

89686 This utility may produce warning messages about certain conditions that do not warrant
89687 returning an error (non-zero) exit value.

89688 **OUTPUT FILES**

89689 Object files, listing files, and executable files shall be produced in unspecified formats.

89690 **EXTENDED DESCRIPTION**

89691 **Standard Libraries**

89692 The *fort77* utility shall recognize the following **–l** operand for the standard library:

89693 **–l f** This library contains all functions referenced in the ANSI X3.9-1978 standard. This
89694 operand shall not be required to be present to cause a search of this library.

89695 In the absence of options that inhibit invocation of the link editor, such as **–c**, the *fort77* utility
89696 shall cause the equivalent of a **–l f** operand to be passed to the link editor as the last **–l** operand,
89697 causing it to be searched after all other object files and libraries are loaded.

89698 It is unspecified whether the library **libf.a** exists as a regular file. The implementation may
89699 accept as **–l** operands names of objects that do not exist as regular files.

89700 **External Symbols**

89701 The FORTRAN compiler and link editor shall support the significance of external symbols up to
89702 a length of at least 31 bytes; case folding is permitted. The action taken upon encountering
89703 symbols exceeding the implementation-defined maximum symbol length is unspecified.

89704 The compiler and link editor shall support a minimum of 511 external symbols per source or
89705 object file, and a minimum of 4 095 external symbols total. A diagnostic message is written to
89706 standard output if the implementation-defined limit is exceeded; other actions are unspecified.

89707 **EXIT STATUS**

89708 The following exit values shall be returned:

89709 0 Successful compilation or link edit.

89710 >0 An error occurred.

89711 **CONSEQUENCES OF ERRORS**

89712 When *fort77* encounters a compilation error, it shall write a diagnostic to standard error and
89713 continue to compile other source code operands. It shall return a non-zero exit status, but it is
89714 implementation-defined whether an object module is created. If the link edit is unsuccessful, a
89715 diagnostic message shall be written to standard error, and *fort77* shall exit with a non-zero status.

89716 **APPLICATION USAGE**

89717 None.

89718 **EXAMPLES**

89719 The following usage example compiles **xyz.f** and creates the executable file **foo**:

89720 ```
fort77 -o foo xyz.f
```

89721 The following example compiles **xyz.f** and creates the object file **xyz.o**:

89722 ```
fort77 -c xyz.f
```

89723 The following example compiles **xyz.f** and creates the executable file **a.out**:

89724 ```
fort77 xyz.f
```

89725 The following example compiles **xyz.f**, links it with **b.o**, and creates the executable **a.out**:

89726 ```
fort77 xyz.f b.o
```

89727 **RATIONALE**

89728 The name of this utility was chosen as *fort77* to parallel the renaming of the C compiler. The
89729 name *f77* was not chosen to avoid problems with historical implementations. The
89730 ANSI X3.9-1978 standard was selected as a normative reference because the ISO/IEC version of
89731 FORTRAN-77 has been superseded by the ISO/IEC 1539: 1990 standard (Fortran-90).

89732 The file inclusion and symbol definition **#define** mechanisms used by the *c99* utility were not
89733 included in this volume of POSIX.1-200x—even though they are commonly implemented—since
89734 there is no requirement that the FORTRAN compiler use the C preprocessor.

89735 The **–onetrip** option was not included in this volume of POSIX.1-200x, even though many
89736 historical compilers support it, because it is derived from FORTRAN-66; it is an anachronism
89737 that should not be perpetuated.

89738 Some implementations produce compilation listings. This aspect of FORTRAN has been left
89739 unspecified because there was controversy concerning the various methods proposed for
89740 implementing it: a **–V** option overlapped with historical vendor practice and a naming
89741 convention of creating files with **.l** suffixes collided with historical *lex* file naming practice.

There is no **–I** option in this version of this volume of POSIX.1-200x to specify a directory for file inclusion. An INCLUDE directive has been a part of the Fortran-90 discussions, but an interface supporting that standard is not in the current scope.

It is noted that many FORTRAN compilers produce an object module even when compilation errors occur; during a subsequent compilation, the compiler may patch the object module rather than recompiling all the code. Consequently, it is left to the implementor whether or not an object file is created.

A reference to MIL-STD-1753 was removed from an early proposal in response to a request from the POSIX FORTRAN-binding standard developers. It was not the intention of the standard developers to require certification of the FORTRAN compiler, and IEEE Std 1003.9-1992 does not specify the military standard or any special preprocessing requirements. Furthermore, use of that document would have been inappropriate for an international standard.

The specification of optimization has been subject to changes through early proposals. At one time, **–O** and **–N** were Booleans: optimize and do not optimize (with an unspecified default). Some historical practice led this to be changed to:

–O 0 No optimization.

–O 1 Some level of optimization.

–O *n* Other, unspecified levels of optimization.

It is not always clear whether "good code generation" is the same thing as optimization. Simple optimizations of local actions do not usually affect the semantics of a program. The **–O** 0 option has been included to accommodate the very particular nature of scientific calculations in a highly optimized environment; compilers make errors. Some degree of optimization is expected, even if it is not documented here, and the ability to shut it off completely could be important when porting an application. An implementation may treat **–O** 0 as "do less than normal" if it wishes, but this is only meaningful if any of the operations it performs can affect the semantics of a program. It is highly dependent on the implementation whether doing less than normal is logical. It is not the intent of the **–O** 0 option to ask for inefficient code generation, but rather to assure that any semantically visible optimization is suppressed.

The specification of standard library access is consistent with the C compiler specification. Implementations are not required to have **/usr/lib/libf.a**, as many historical implementations do, but if not they are required to recognize **f** as a token.

External symbol size limits are in normative text; conforming applications need to know these limits. However, the minimum maximum symbol length should be taken as a constraint on a conforming application, not on an implementation, and consequently the action taken for a symbol exceeding the limit is unspecified. The minimum size for the external symbol table was added for similar reasons.

The CONSEQUENCES OF ERRORS section clearly specifies the behavior of the compiler when compilation or link-edit errors occur. The behavior of several historical implementations was examined, and the choice was made to be silent on the status of the executable, or **a.out**, file in the face of compiler or linker errors. If a linker writes the executable file, then links it on disk with *lseek*()s and *write*()s, the partially linked executable file can be left on disk and its execute bits turned off if the link edit fails. However, if the linker links the image in memory before writing the file to disk, it need not touch the executable file (if it already exists) because the link edit fails. Since both approaches are historical practice, a conforming application shall rely on the exit status of *fort77*, rather than on the existence or mode of the executable file.

The **–g** and **–s** options are not specified as mutually-exclusive. Historically, these two options

have been mutually-exclusive, but because both are so loosely specified, it seemed appropriate to leave their interaction unspecified.

The requirement that conforming applications specify compiler options separately is to reserve the multi-character option name space for vendor-specific compiler options, which are known to exist in many historical implementations. Implementations are not required to recognize, for example, **–gc** as if it were **–g –c**; nor are they forbidden from doing so. The SYNOPSIS shows all of the options separately to highlight this requirement on applications.

Echoing filenames to standard error is considered a diagnostic message because it would otherwise be difficult to associate an error message with the erring file. They are described with "may" to allow implementations to use other methods of identifying files and to parallel the description in *c99*.

FUTURE DIRECTIONS

A compilation system based on the ISO/IEC 1539: 1990 standard (Fortran-90) may be considered for a future version; it may have a different utility name from *fort77*.

XSH *exec*

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the FORTRAN Development Utilities option.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

fuser — list process IDs of all processes that have one or more files open

SYNOPSIS

XSI

```
fuser [–cfu] file...
```

DESCRIPTION

The *fuser* utility shall write to standard output the process IDs of processes running on the local system that have one or more named files open. For block special devices, all processes using any file on that device are listed.

The *fuser* utility shall write to standard error additional information about the named files indicating how the file is being used.

Any output for processes running on remote systems that have a named file open is unspecified.

A user may need appropriate privileges to invoke the *fuser* utility.

OPTIONS

The *fuser* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–c The file is treated as a mount point and the utility shall report on any files open in the file system.

–f The report shall be only for the named files.

–u The user name, in parentheses, associated with each process ID written to standard output shall be written to standard error.

OPERANDS

The following operand shall be supported:

file A pathname on which the file or file system is to be reported.

STDIN

Not used.

INPUT FILES

The user database.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *fuser*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *fuser* utility shall write the process ID for each process using each file given as an operand to standard output in the following format:

```
"%d", <process_id>
```

STDERR

The *fuser* utility shall write diagnostic messages to standard error.

The *fuser* utility also shall write the following to standard error:

- The pathname of each named file is written followed immediately by a <colon>.
- For each process ID written to standard output, the character `'c'` shall be written to standard error if the process is using the file as its current directory and the character `'r'` shall be written to standard error if the process is using the file as its root directory. Implementations may write other alphabetic characters to indicate other uses of files.
- When the **–u** option is specified, characters indicating the use of the file shall be followed immediately by the user name, in parentheses, corresponding to the real user ID of the process. If the user name cannot be resolved from the real user ID of the process, the real user ID of the process shall be written instead of the user name.

When standard output and standard error are directed to the same file, the output shall be interleaved so that the filename appears at the start of each line, followed by the process ID and characters indicating the use of the file. Then, if the **–u** option is specified, the user name or user ID for each process using that file shall be written.

A <newline> shall be written to standard error after the last output described above for each *file* operand.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The command:

```
fuser –fu .
```

writes to standard output the process IDs of processes that are using the current directory and writes to standard error an indication of how those processes are using the directory and the user names associated with the processes that are using the current directory.

```
fuser –c <mount point>
```

writes to standard output the process IDs of processes that are using any file in the file system which is mounted on <*mount point*> and writes to standard error an indication of how those processes are using the files.

```
fuser <mount point>
```

writes to standard output the process IDs of processes that are using the file which is named by <*mount point*> and writes to standard error an indication of how those processes are using the file.

```
fuser <block device>
```

writes to standard output the process IDs of processes that are using any file which is on the device named by <*block device*> and writes to standard error an indication of how those processes are using the file.

```
fuser –-f <block device>
```

writes to standard output the process IDs of processes that are using the file <*block device*> itself and writes to standard error an indication of how those processes are using the file.

RATIONALE

The definition of the *fuser* utility follows existing practice.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 5.

Issue 7

SD5-XCU-ERN-90 is applied, updating the EXAMPLES section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

89922 **NAME**

89923 gencat — generate a formatted message catalog

89924 **SYNOPSIS**

89925 `gencat` *`catfile msgfile...`*

89926 **DESCRIPTION**

89927 The *gencat* utility shall merge the message text source file *msgfile* into a formatted message
89928 catalog *catfile*. The file *catfile* shall be created if it does not already exist. If *catfile* does exist, its
89929 messages shall be included in the new *catfile*. If set and message numbers collide, the new
89930 message text defined in *msgfile* shall replace the old message text currently contained in *catfile*.

89931 **OPTIONS**

89932 None.

89933 **OPERANDS**

89934 The following operands shall be supported:

89935 *catfile* A pathname of the formatted message catalog. If `'-'` is specified, standard output
89936 shall be used. The format of the message catalog produced is unspecified.

89937 *msgfile* A pathname of a message text source file. If `'-'` is specified for an instance of
89938 *msgfile*, standard input shall be used. The format of message text source files is
89939 defined in the EXTENDED DESCRIPTION section.

89940 **STDIN**

89941 The standard input shall not be used unless a *msgfile* operand is specified as `'-'`.

89942 **INPUT FILES**

89943 The input files shall be text files.

89944 **ENVIRONMENT VARIABLES**

89945 The following environment variables shall affect the execution of *gencat*:

89946 *LANG* Provide a default value for the internationalization variables that are unset or null.
89947 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
89948 variables used to determine the values of locale categories.)

89949 *LC_ALL* If set to a non-empty string value, override the values of all the other
89950 internationalization variables.

89951 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
89952 characters (for example, single-byte as opposed to multi-byte characters in
89953 arguments and input files).

89954 *LC_MESSAGES*
89955 Determine the locale that should be used to affect the format and contents of
89956 diagnostic messages written to standard error.

89957 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

89958 **ASYNCHRONOUS EVENTS**

89959 Default.

89960 **STDOUT**

89961 The standard output shall not be used unless the *catfile* operand is specified as `'-'`.

89962 **STDERR**

89963 The standard error shall be used only for diagnostic messages.

89964 **OUTPUT FILES**

89965 None.

89966 **EXTENDED DESCRIPTION**

89967 The content of a message text file shall be in the format defined as follows. Note that the fields of
89968 a message text source line are separated by a single <blank> character. Any other <blank>
89969 characters are considered to be part of the subsequent field.

89970 **$set** *n comment*

89971 This line specifies the set identifier of the following messages until the next **$set** or
89972 end-of-file appears. The *n* denotes the set identifier, which is defined as a number
89973 in the range [1, {NL_SETMAX}] (see the **<limits.h>** header defined in the Base
89974 Definitions volume of POSIX.1-200x). The application shall ensure that set
89975 identifiers are presented in ascending order within a single source file, but need
89976 not be contiguous. Any string following the set identifier shall be treated as a
89977 comment. If no **$set** directive is specified in a message text source file, all messages
89978 shall be located in an implementation-defined default message set NL_SETD (see
89979 the **<nl_types.h>** header defined in the Base Definitions volume of POSIX.1-200x).

89980 **$delset** *n comment*

89981 This line deletes message set *n* from an existing message catalog. The *n* denotes the
89982 set number [1, {NL_SETMAX}]. Any string following the set number shall be
89983 treated as a comment.

89984 **$** *comment* A line beginning with '$' followed by a <blank> shall be treated as a comment.

89985 *m message-text*

89986 The *m* denotes the message identifier, which is defined as a number in the range [1,
89987 {NL_MSGMAX}] (see the **<limits.h>** header). The *message-text* shall be stored in the
89988 message catalog with the set identifier specified by the last **$set** directive, and with
89989 message identifier *m*. If the *message-text* is empty, and a <blank> field separator is
89990 present, an empty string shall be stored in the message catalog. If a message source
89991 line has a message number, but neither a field separator nor *message-text*, the
89992 existing message with that number (if any) shall be deleted from the catalog. The
89993 application shall ensure that message identifiers are in ascending order within a
89994 single set, but need not be contiguous. The application shall ensure that the length
89995 of *message-text* is in the range [0, {NL_TEXTMAX}] (see the **<limits.h>** header).

89996 **$quote** *n* This line specifies an optional quote character *c*, which can be used to surround
89997 *message-text* so that trailing <space> characters or null (empty) messages are visible
89998 in a message source line. By default, or if an empty **$quote** directive is supplied, no
89999 quoting of *message-text* shall be recognized.

90000 Empty lines in a message text source file shall be ignored. The effects of lines starting with any
90001 character other than those defined above are implementation-defined.

90002 Text strings can contain the special characters and escape sequences defined in the following
90003 table:

Description	Symbol	Sequence
<newline>	NL(LF)	`\n`
Horizontal-tab	HT	`\t`
<vertical-tab>	VT	`\v`
<backspace>	BS	`\b`
<carriage-return>	CR	`\r`
<form-feed>	FF	`\f`
Backslash	\	`\\`
Bit pattern	`ddd`	`\ddd`

The escape sequence `"\ddd"` consists of <backslash> followed by one, two, or three octal digits, which shall be taken to specify the value of the desired character. If the character following a <backslash> is not one of those specified, the <backslash> shall be ignored.

A <backslash> followed by a <newline> is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

```
1 This line continues \
to the next line
```

which shall be equivalent to:

```
1 This line continues to the next line
```

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Message catalogs produced by *gencat* are binary encoded, meaning that their portability cannot be guaranteed between different types of machine. Thus, just as C programs need to be recompiled for each type of machine, so message catalogs must be recreated via *gencat*.

CHANGE HISTORY

First released in Issue 3.

Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.

90045 **Issue 7**
90046 The *gencat* utility is moved from the XSI option to the Base.

90047 **NAME**

90048 get — get a version of an SCCS file (**DEVELOPMENT**)

90049 **SYNOPSIS**

90050 XSI `get [–begkmnlLpst] [–c cutoff] [–i list] [–r SID] [–x list] file...`

90051 **DESCRIPTION**

90052 The *get* utility shall generate a text file from each named SCCS *file* according to the specifications
90053 given by its options.

90054 The generated text shall normally be written into a file called the **g-file** whose name is derived
90055 from the SCCS filename by simply removing the leading `"s."`.

90056 **OPTIONS**

90057 The *get* utility shall conform to XBD Section 12.2 (on page 215).

90058 The following options shall be supported:

90059 –**r** *SID* Indicate the SCCS Identification String (SID) of the version (delta) of an SCCS file
90060 to be retrieved. The table shows, for the most useful cases, what version of an
90061 SCCS file is retrieved (as well as the SID of the version to be eventually created by
90062 *delta* if the –**e** option is also used), as a function of the SID specified.

90063 –**c** *cutoff* Indicate the *cutoff* date-time, in the form:

90064 *YY*[*MM*[*DD*[*HH*[*MM*[*SS*]]]]]

90065 For the *YY* component, values in the range [69,99] shall refer to years 1969 to 1999
90066 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive.

90067 **Note:** It is expected that in a future version of this standard the default century inferred
90068 from a 2-digit year will change. (This would apply to all commands accepting a
90069 2-digit year as input.)

90070 No changes (deltas) to the SCCS file that were created after the specified *cutoff*
90071 date-time shall be included in the generated text file. Units omitted from the date-
90072 time default to their maximum possible values; for example, –**c** 7502 is equivalent
90073 to –**c** 750228235959.

90074 Any number of non-numeric characters may separate the various 2-digit pieces of
90075 the *cutoff* date-time. This feature allows the user to specify a *cutoff* date in the form:
90076 –**c** "77/2/2 9:22:25".

90077 –**e** Indicate that the *get* is for the purpose of editing or making a change (delta) to the
90078 SCCS file via a subsequent use of *delta*. The –**e** option used in a *get* for a particular
90079 version (SID) of the SCCS file shall prevent further *get* commands from editing on
90080 the same SID until *delta* is executed or the **j** (joint edit) flag is set in the SCCS file.
90081 Concurrent use of *get* –**e** for different SIDs is always allowed.

90082 If the **g-file** generated by *get* with a –**e** option is accidentally ruined in the process
90083 of editing, it may be regenerated by re-executing the *get* command with the –**k**
90084 option in place of the –**e** option.

90085 SCCS file protection specified via the ceiling, floor, and authorized user list stored
90086 in the SCCS file shall be enforced when the –**e** option is used.

90087 –**b** Use with the –**e** option to indicate that the new delta should have an SID in a new
90088 branch as shown in the table below. This option shall be ignored if the **b** flag is not
90089 present in the file or if the retrieved delta is not a leaf delta. (A leaf delta is one that
90090 has no successors on the SCCS file tree.)

Note: A branch delta may always be created from a non-leaf delta.

–i *list* Indicate a *list* of deltas to be included (forced to be applied) in the creation of the generated file. The *list* has the following syntax:

```
<list> ::= <range> | <list> , <range>
<range> ::= SID | SID – SID
```

SID, the SCCS Identification of a delta, may be in any form shown in the "SID Specified" column of the table in the EXTENDED DESCRIPTION section, except that the result of supplying a partial SID is unspecified. A diagnostic message shall be written if the first SID in the range is not an ancestor of the second SID in the range.

–x *list* Indicate a *list* of deltas to be excluded (forced not to be applied) in the creation of the generated file. See the **–i** option for the *list* format.

–k Suppress replacement of identification keywords (see below) in the retrieved text by their value. The **–k** option shall be implied by the **–e** option.

–l Write a delta summary into an **l-file**.

–L Write a delta summary to standard output. All informative output that normally is written to standard output shall be written to standard error instead, unless the **–s** option is used, in which case it shall be suppressed.

–p Write the text retrieved from the SCCS file to the standard output. No **g-file** shall be created. All informative output that normally goes to the standard output shall go to standard error instead, unless the **–s** option is used, in which case it shall disappear.

–s Suppress all informative output normally written to standard output. However, fatal error messages (which shall always be written to the standard error) shall remain unaffected.

–m Precede each text line retrieved from the SCCS file by the SID of the delta that inserted the text line in the SCCS file. The format shall be:

```
"%s\t%s", <SID>, <text line>
```

–n Precede each generated text line with the %**M**% identification keyword value (see below). The format shall be:

```
"%s\t%s", <%M% value>, <text line>
```

When both the **–m** and **–n** options are used, the <*text line*> shall be replaced by the **–m** option-generated format.

–g Suppress the actual retrieval of text from the SCCS file. It is primarily used to generate an **l-file**, or to verify the existence of a particular SID.

–t Use to access the most recently created (top) delta in a given release (for example, **–r 1**), or release and level (for example, **–r 1.2**).

90128 **OPERANDS**

90129 The following operands shall be supported:

90130 *file* A pathname of an existing SCCS file or a directory. If *file* is a directory, the *get*
90131 utility shall behave as though each file in the directory were specified as a named
90132 file, except that non-SCCS files (last component of the pathname does not begin
90133 with **s.**) and unreadable files shall be silently ignored.

90134 If exactly one *file* operand appears, and it is `'-'`, the standard input shall be read;
90135 each line of the standard input is taken to be the name of an SCCS file to be
90136 processed. Non-SCCS files and unreadable files shall be silently ignored.

90137 **STDIN**

90138 The standard input shall be a text file used only if the *file* operand is specified as `'-'`. Each line
90139 of the text file shall be interpreted as an SCCS pathname.

90140 **INPUT FILES**

90141 The SCCS files shall be files of an unspecified format.

90142 **ENVIRONMENT VARIABLES**

90143 The following environment variables shall affect the execution of *get*:

90144 *LANG* Provide a default value for the internationalization variables that are unset or null.
90145 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
90146 variables used to determine the values of locale categories.)

90147 *LC_ALL* If set to a non-empty string value, override the values of all the other
90148 internationalization variables.

90149 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
90150 characters (for example, single-byte as opposed to multi-byte characters in
90151 arguments and input files).

90152 *LC_MESSAGES*

90153 Determine the locale that should be used to affect the format and contents of
90154 diagnostic messages written to standard error, and informative messages written
90155 to standard output (or standard error, if the **–p** option is used).

90156 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

90157 *TZ* Determine the timezone in which the times and dates written in the SCCS file are
90158 evaluated. If the *TZ* variable is unset or NULL, an unspecified system default
90159 timezone is used.

90160 **ASYNCHRONOUS EVENTS**

90161 Default.

90162 **STDOUT**

90163 For each file processed, *get* shall write to standard output the SID being accessed and the
90164 number of lines retrieved from the SCCS file, in the following format:

90165 `"%s\n%d lines\n", <SID>, <number of lines>`

90166 If the **–e** option is used, the SID of the delta to be made shall appear after the SID accessed and
90167 before the number of lines generated, in the POSIX locale:

90168 `"%s\nnew delta %s\n%d lines\n", <SID accessed>,`
90169 `<SID to be made>, <number of lines>`

90170 If there is more than one named file or if a directory or standard input is named, each pathname

shall be written before each of the lines shown in one of the preceding formats:

`"\n%s:\n", <pathname>`

If the **–L** option is used, a delta summary shall be written following the format specified below for **l-files**.

If the **–i** option is used, included deltas shall be listed following the notation, in the POSIX locale:

`"Included:\n"`

If the **–x** option is used, excluded deltas shall be listed following the notation, in the POSIX locale:

`"Excluded:\n"`

If the **–p** or **–L** options are specified, the standard output shall consist of the text retrieved from the SCCS file.

STDERR

The standard error shall be used only for diagnostic messages, except if the **–p** or **–L** options are specified, it shall include all informative messages normally sent to standard output.

OUTPUT FILES

Several auxiliary files may be created by *get*. These files are known generically as the **g-file**, **l-file**, **p-file**, and **z-file**. The letter before the <hyphen> is called the *tag*. An auxiliary filename shall be formed from the SCCS filename: the application shall ensure that the last component of all SCCS filenames is of the form **s.***module-name*; the auxiliary files shall be named by replacing the leading **s** with the tag. The **g-file** shall be an exception to this scheme: the **g-file** is named by removing the **s.** prefix. For example, for **s.xyz.c**, the auxiliary filenames would be **xyz.c**, **l.xyz.c**, **p.xyz.c**, and **z.xyz.c**, respectively.

The **g-file**, which contains the generated text, shall be created in the current directory (unless the **–p** option is used). A **g-file** shall be created in all cases, whether or not any lines of text were generated by the *get*. It shall be owned by the real user. If the **–k** option is used or implied, the **g-file** shall be writable by the owner only (read-only for everyone else); otherwise, it shall be read-only. Only the real user need have write permission in the current directory.

The **l-file** shall contain a table showing which deltas were applied in generating the retrieved text. The **l-file** shall be created in the current directory if the **–l** option is used; it shall be read-only and it is owned by the real user. Only the real user need have write permission in the current directory.

Lines in the **l-file** shall have the following format:

`"%c%c%cΔ%s\t%sΔ%s\n", <code1>, <code2>, <code3>,`
`    <SID>, <date-time>, <login>`

where the entries are:

<code1> A <space> if the delta was applied; `'*'` otherwise.

<code2> A <space> if the delta was applied or was not applied and ignored; `'*'` if the delta was not applied and was not ignored.

<code3> A character indicating a special reason why the delta was or was not applied:

I Included.

90212 **X** Excluded.

90213 **C** Cut off (by a –**c** option).

90214 <*date-time*> Date and time (using the format of the *date* utility's `%y/%m/%d %T` conversion
90215 specification format) of creation.

90216 <*login*> Login name of person who created *delta*.

90217 The comments and MR data shall follow on subsequent lines, indented one <tab>. A blank line
90218 shall terminate each entry.

90219 The **p-file** shall be used to pass information resulting from a *get* with a –**e** option along to *delta*.
90220 Its contents shall also be used to prevent a subsequent execution of *get* with a –**e** option for the
90221 same SID until *delta* is executed or the joint edit flag, **j**, is set in the SCCS file. The **p-file** shall be
90222 created in the directory containing the SCCS file and the application shall ensure that the
90223 effective user has write permission in that directory. It shall be writable by owner only, and
90224 owned by the effective user. Each line in the **p-file** shall have the following format:

90225 `"%sΔ%sΔ%sΔ%s%s%s\n", <g-file SID>,`
90226 `<SID of new delta>, <login-name of real user>,`
90227 `<date-time>, <i-value>, <x-value>`

90228 where <*i-value*> uses the format `""` if no –**i** option was specified, and shall use the format:

90229 `"Δ–i%s", <–i option option-argument>`

90230 if a –**i** option was specified and <*x-value*> uses the format `""` if no –**x** option was specified, and
90231 shall use the format:

90232 `"Δ–x%s", <–x option option-argument>`

90233 if a –**x** option was specified. There can be an arbitrary number of lines in the **p-file** at any time;
90234 no two lines shall have the same new delta SID.

90235 The **z-file** shall serve as a lock-out mechanism against simultaneous updates. Its contents shall
90236 be the binary process ID of the command (that is, *get*) that created it. The **z-file** shall be created
90237 in the directory containing the SCCS file for the duration of *get*. The same protection restrictions
90238 as those for the **p-file** shall apply for the **z-file**. The **z-file** shall be created read-only.

EXTENDED DESCRIPTION

Determination of SCCS Identification String

SID* Specified	–b Keyletter Used†	Other Conditions	SID Retrieved	SID of Delta to be Created
none‡	no	R defaults to mR	mR.mL	mR.(mL+1)
none‡	yes	R defaults to mR	mR.mL	mR.mL.(mB+1).1
R	no	R > mR	mR.mL	R.1***
R	no	R = mR	mR.mL	mR.(mL+1)
R	yes	R > mR	mR.mL	mR.mL.(mB+1).1
R	yes	R = mR	mR.mL	mR.mL.(mB+1).1
R	–	R < mR and R does not exist	hR.mL**	hR.mL.(mB+1).1
R	–	Trunk successor in release > R and R exists	R.mL	R.mL.(mB+1).1
R.L	no	No trunk successor	R.L	R.(L+1)
R.L	yes	No trunk successor	R.L	R.L.(mB+1).1
R.L	–	Trunk successor in release ≥ R	R.L	R.L.(mB+1).1
R.L.B	no	No branch successor	R.L.B.mS	R.L.B.(mS+1)
R.L.B	yes	No branch successor	R.L.B.mS	R.L.(mB+1).1
R.L.B.S	no	No branch successor	R.L.B.S	R.L.B.(S+1)
R.L.B.S	yes	No branch successor	R.L.B.S	R.L.(mB+1).1
R.L.B.S	–	Branch successor	R.L.B.S	R.L.(mB+1).1

* R, L, B, and S are the release, level, branch, and sequence components of the SID, respectively; m means maximum. Thus, for example, R.mL means "the maximum level number within release R"; R.L.(mB+1).1 means "the first sequence number on the new branch (that is, maximum branch number plus one) of level L within release R". Note that if the SID specified is of the form R.L, R.L.B, or R.L.B.S, each of the specified components shall exist.

** hR is the highest existing release that is lower than the specified, nonexistent, release R.

*** This is used to force creation of the first delta in a new release.

† The **–b** option is effective only if the **b** flag is present in the file. An entry of '–' means "irrelevant".

‡ This case applies if the **d** (default SID) flag is not present in the file. If the **d** flag is present in the file, then the SID obtained from the **d** flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

90275 **System Date and Time**

90276 When a **g-file** is generated, the creation time of deltas in the SCCS file may be taken into
90277 account. If any of these times are apparently in the future, the behavior is unspecified.

90278 **Identification Keywords**

90279 Identifying information shall be inserted into the text retrieved from the SCCS file by replacing
90280 identification keywords with their value wherever they occur. The following keywords may be
90281 used in the text stored in an SCCS file:

90282 %**M**% Module name: either the value of the **m** flag in the file, or if absent, the name of the
90283 SCCS file with the leading **s.** removed.

90284 %**I**% SCCS identification (SID) (%**R**%.%**L**% or %**R**%.%**L**%.%**B**%.%**S**%) of the retrieved
90285 text.

90286 %**R**% Release.

90287 %**L**% Level.

90288 %**B**% Branch.

90289 %**S**% Sequence.

90290 %**D**% Current date (*YY*/*MM*/*DD*).

90291 %**H**% Current date (*MM*/*DD*/*YY*).

90292 %**T**% Current time (*HH*:*MM*:*SS*).

90293 %**E**% Date newest applied delta was created (*YY*/*MM*/*DD*).

90294 %**G**% Date newest applied delta was created (*MM*/*DD*/*YY*).

90295 %**U**% Time newest applied delta was created (*HH*:*MM*:*SS*).

90296 %**Y**% Module type: value of the **t** flag in the SCCS file.

90297 %**F**% SCCS filename.

90298 %**P**% SCCS absolute pathname.

90299 %**Q**% The value of the **q** flag in the file.

90300 %**C**% Current line number. This keyword is intended for identifying messages output by
90301 the program, such as "this should not have happened" type errors. It is not
90302 intended to be used on every line to provide sequence numbers.

90303 %**Z**% The four-character string `"@(#)"` recognizable by *what*.

90304 %**W**% A shorthand notation for constructing *what* strings:

90305 `%W%=%Z%%M%<tab>%I%`

90306 %**A**% Another shorthand notation for constructing *what* strings:

90307 `%A%=%Z%%Y%%M%%I%%Z%`

90308 **EXIT STATUS**

90309 The following exit values shall be returned:

90310 0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Problems can arise if the system date and time have been modified (for example, put forward and then back again, or unsynchronized clocks across a network) and can also arise when different values of the *TZ* environment variable are used.

Problems of a similar nature can also arise for the operation of the *delta* utility, which compares the previous file body against the working file as part of its normal operation.

EXAMPLES

None.

RATIONALE

None.

FUTURE DIRECTIONS

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

A correction is made to the first format string in STDOUT.

The interpretation of the *YY* component of the **–c** *cutoff* argument is noted.

Issue 6

The obsolescent SYNOPSIS is removed, removing the **–lp** option.

The normative text is reworded to avoid use of the term "must" for application requirements.

The Open Group Corrigendum U025/5 is applied, correcting text in the OPTIONS section.

The Open Group Corrigendum U048/1 is applied.

The Open Group Interpretation PIN4C.00014 is applied.

The Open Group Base Resolution bwg2001-007 is applied as follows:

- The EXTENDED DESCRIPTION section is updated to make partial SID handling unspecified, reflecting common usage, and to clarify SID ranges.
- New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections regarding how the system date and time may be taken into account.
- The *TZ* environment variable is added to the ENVIRONMENT VARIABLES section.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

90348 **NAME**

90349 getconf — get configuration values

90350 **SYNOPSIS**

90351 `getconf [–v specification] system_var`

90352 `getconf [–v specification] path_var pathname`

90353 **DESCRIPTION**

90354 In the first synopsis form, the *getconf* utility shall write to the standard output the value of the
90355 variable specified by the *system_var* operand.

90356 In the second synopsis form, the *getconf* utility shall write to the standard output the value of the
90357 variable specified by the *path_var* operand for the path specified by the *pathname* operand.

90358 The value of each configuration variable shall be determined as if it were obtained by calling the
90359 function from which it is defined to be available by this volume of POSIX.1-200x or by the
90360 System Interfaces volume of POSIX.1-200x (see the OPERANDS section). The value shall reflect
90361 conditions in the current operating environment.

90362 **OPTIONS**

90363 The *getconf* utility shall conform to XBD Section 12.2 (on page 215).

90364 The following option shall be supported:

90365 **–v** *specification*

90366 Indicate a specific specification and version for which configuration variables shall
90367 be determined. If this option is not specified, the values returned correspond to an
90368 implementation default conforming compilation environment.

90369 If the command:

90370 `getconf _POSIX_V7_ILP32_OFF32`

90371 does not write `"–1\n"` or `"undefined\n"` to standard output, then commands of
90372 the form:

90373 `getconf –v POSIX_V7_ILP32_OFF32 ...`

90374 determine values for configuration variables corresponding to the
90375 POSIX_V7_ILP32_OFF32 compilation environment specified in *c99*, the
90376 EXTENDED DESCRIPTION.

90377 If the command:

90378 `getconf _POSIX_V7_ILP32_OFFBIG`

90379 does not write `"–1\n"` or `"undefined\n"` to standard output, then commands of
90380 the form:

90381 `getconf –v POSIX_V7_ILP32_OFFBIG ...`

90382 determine values for configuration variables corresponding to the
90383 POSIX_V7_ILP32_OFFBIG compilation environment specified in *c99*, the
90384 EXTENDED DESCRIPTION.

90385 If the command:

90386 `getconf _POSIX_V7_LP64_OFF64`

90387 does not write `"–1\n"` or `"undefined\n"` to standard output, then commands of
90388 the form:

```
getconf –v POSIX_V7_LP64_OFF64 ...
```

determine values for configuration variables corresponding to the POSIX_V7_LP64_OFF64 compilation environment specified in *c99*, the EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V7_LPBIG_OFFBIG
```

does not write `"–1\n"` or `"undefined\n"` to standard output, then commands of the form:

```
getconf –v POSIX_V7_LPBIG_OFFBIG ...
```

determine values for configuration variables corresponding to the POSIX_V7_LPBIG_OFFBIG compilation environment specified in *c99*, the EXTENDED DESCRIPTION.

OPERANDS

The following operands shall be supported:

path_var A name of a configuration variable. All of the variables in the Variable column of the table in the DESCRIPTION of the *fpathconf*( ) function defined in the System Interfaces volume of POSIX.1-200x, without the enclosing braces, shall be supported. The implementation may add other local variables.

pathname A pathname for which the variable specified by *path_var* is to be determined.

system_var A name of a configuration variable. All of the following variables shall be supported:

- The names in the Variable column of the table in the DESCRIPTION of the *sysconf*( ) function in the System Interfaces volume of POSIX.1-200x, except for the entries corresponding to _SC_CLK_TCK, _SC_GETGR_R_SIZE_MAX, and _SC_GETPW_R_SIZE_MAX, without the enclosing braces.

  For compatibility with earlier versions, the following variable names shall also be supported:

  POSIX2_C_BIND
  POSIX2_C_DEV
  POSIX2_CHAR_TERM
  POSIX2_FORT_DEV
  POSIX2_FORT_RUN
  POSIX2_LOCALEDEF
  POSIX2_SW_DEV
  POSIX2_UPE
  POSIX2_VERSION

  and shall be equivalent to the same name prefixed with an <underscore>. This requirement may be removed in a future version.

- The names of the symbolic constants used as the *name* argument of the *confstr*( ) function in the System Interfaces volume of POSIX.1-200x, without the _CS_ prefix.

- The names of the symbolic constants listed under the headings "Maximum Values" and "Minimum Values" in the description of the **<limits.h>** header in the Base Definitions volume of POSIX.1-200x, without the enclosing braces.

  For compatibility with earlier versions, the following variable names shall also be supported:

  POSIX2_BC_BASE_MAX
  POSIX2_BC_DIM_MAX
  POSIX2_BC_SCALE_MAX
  POSIX2_BC_STRING_MAX
  POSIX2_COLL_WEIGHTS_MAX
  POSIX2_EXPR_NEST_MAX
  POSIX2_LINE_MAX
  POSIX2_RE_DUP_MAX

  and shall be equivalent to the same name prefixed with an <underscore>. This requirement may be removed in a future version.

The implementation may add other local values.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getconf*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the specified variable is defined on the system and its value is described to be available from the *confstr*() function defined in the System Interfaces volume of POSIX.1-200x, its value shall be written in the following format:

```
"%s\n", <value>
```

Otherwise, if the specified variable is defined on the system, its value shall be written in the

following format:

```
"%d\n", <value>
```

If the specified variable is valid, but is undefined on the system, *getconf* shall write using the following format:

```
"undefined\n"
```

If the variable name is invalid or an error occurs, nothing shall be written to standard output.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 The specified variable is valid and information about its current state was written successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

None.

EXAMPLES

The following example illustrates the value of {NGROUPS_MAX}:

```
getconf NGROUPS_MAX
```

The following example illustrates the value of {NAME_MAX} for a specific directory:

```
getconf NAME_MAX /usr
```

The following example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
    if [ "$value" = "undefined" ]; then
        echo PATH_MAX in /usr is indeterminate.
    else
        echo PATH_MAX in /usr is $value.
    fi
else
    echo Error in getconf.
fi
```

Note that:

```
sysconf(_SC_2_C_BIND);
```

and:

```
system("getconf _POSIX2_C_BIND");
```

in a C program could give different answers. The *sysconf*( ) call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation; the *system*( ) call to *getconf* always supplies a value corresponding to conditions when the program is executed.

RATIONALE

The original need for this utility, and for the *confstr*( ) function, was to provide a way of finding the configuration-defined default value for the *PATH* environment variable. Since *PATH* can be modified by the user to include directories that could contain utilities replacing the standard utilities, shell scripts need a way to determine the system-supplied *PATH* environment variable value that contains the correct search path for the standard utilities. It was later suggested that access to the other variables described in this volume of POSIX.1-200x could also be useful to applications.

This functionality of *getconf* would not be adequately subsumed by another command such as:

```
grep var /etc/conf
```

because such a strategy would provide correct values for neither those variables that can vary at runtime, nor those that can vary depending on the path.

Early proposal versions of *getconf* specified exit status 1 when the specified variable was valid, but not defined on the system. The output string `"undefined"` is now used to specify this case with exit code 0 because so many things depend on an exit code of zero when an invoked utility is successful.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

In the OPERANDS section:

- {NL_MAX} is changed to {NL_NMAX}.
- Entries beginning NL_ are deleted from the list of standard configuration variables.
- The list of variables previously marked UX is merged with the list marked EX.
- Operands are added to support new Option Groups.
- Operands are added so that *getconf* can determine supported programming environments.

Issue 6

The Open Group Corrigendum U029/4 is applied, correcting the example command in the last paragraph of the OPTIONS section.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Operands are added to determine supported programming environments.

This reference page is updated for alignment with the ISO/IEC 9899: 1999 standard. Specifically, new macros for *c99* programming environments are introduced.

XSI marked *system_var* (XBS5_*) values are marked LEGACY.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/27 is applied, correcting the descriptions of *path_var* and *system_var* in the OPERANDS section.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The EXAMPLES section is corrected.

NAME

getopts — parse utility options

SYNOPSIS

```
getopts optstring name [arg...]
```

DESCRIPTION

The *getopts* utility shall retrieve options and option-arguments from a list of parameters. It shall support the Utility Syntax Guidelines 3 to 10, inclusive, described in XBD Section 12.2 (on page 215).

Each time it is invoked, the *getopts* utility shall place the value of the next option in the shell variable specified by the *name* operand and the index of the next argument to be processed in the shell variable *OPTIND*. Whenever the shell is invoked, *OPTIND* shall be initialized to 1.

When the option requires an option-argument, the *getopts* utility shall place it in the shell variable *OPTARG*. If no option was found, or if the option that was found does not have an option-argument, *OPTARG* shall be unset.

If an option character not contained in the *optstring* operand is found where an option character is expected, the shell variable specified by *name* shall be set to the <question-mark> (`'?'`) character. In this case, if the first character in *optstring* is a <colon> (`':'`), the shell variable *OPTARG* shall be set to the option character found, but no output shall be written to standard error; otherwise, the shell variable *OPTARG* shall be unset and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in *getopts* processing.

If an option-argument is missing:

- If the first character of *optstring* is a <colon>, the shell variable specified by *name* shall be set to the <colon> character and the shell variable *OPTARG* shall be set to the option character found.
- Otherwise, the shell variable specified by *name* shall be set to the <question-mark> character, the shell variable *OPTARG* shall be unset, and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in *getopts* processing; a diagnostic message shall be written as stated, but the exit status shall be zero.

When the end of options is encountered, the *getopts* utility shall exit with a return value greater than zero; the shell variable *OPTIND* shall be set to the index of the first non-option-argument, where the first `"--"` argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value `"$#"+1` if there are no non-option-arguments; the *name* variable shall be set to the <question-mark> character. Any of the following shall identify the end of options: the special option `"--"`, finding an argument that does not begin with a `'-'`, or encountering an error.

The shell variables *OPTIND* and *OPTARG* shall be local to the caller of *getopts* and shall not be exported by default.

The shell variable specified by the *name* operand, *OPTIND*, and *OPTARG* shall affect the current shell execution environment; see Section 2.12 (on page 2331).

If the application sets *OPTIND* to the value 1, a new set of parameters can be used: either the current positional parameters or new *arg* values. Any other attempt to invoke *getopts* multiple times in a single shell execution environment with parameters (positional parameters or *arg*

operands) that are not the same in all invocations, or with an *OPTIND* value modified to be a value other than 1, produces unspecified results.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

optstring A string containing the option characters recognized by the utility invoking *getopts*. If a character is followed by a <colon>, the option shall be expected to have an argument, which should be supplied as a separate argument. Applications should specify an option character and its option-argument as separate arguments, but *getopts* shall interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognized if it is not supplied as a separate argument when *getopts* is invoked. (See also the *getopt*( ) function defined in the System Interfaces volume of POSIX.1-200x.) The characters <question-mark> and <colon> shall not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in *OPTARG* shall be stripped of the option character and the `'-'`. The first character in *optstring* determines how *getopts* behaves if an option character is not known or an option-argument is missing.

name The name of a shell variable that shall be set by the *getopts* utility to the option character that was found.

The *getopts* utility by default shall parse positional parameters passed to the invoking shell procedure. If *arg*s are given, they shall be parsed instead of the positional parameters.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *getopts*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

90651 *OPTIND* This variable shall be used by the *getopts* utility as the index of the next argument
90652 to be processed.

90653 **ASYNCHRONOUS EVENTS**

90654 Default.

90655 **STDOUT**

90656 Not used.

90657 **STDERR**

90658 Whenever an error is detected and the first character in the *optstring* operand is not a <colon>
90659 (':'), a diagnostic message shall be written to standard error with the following information in
90660 an unspecified format:

90661 • The invoking program name shall be identified in the message. The invoking program
90662 name shall be the value of the shell special parameter 0 (see Section 2.5.2, on page 2302) at
90663 the time the *getopts* utility is invoked. A name equivalent to:

90664 `basename "$0"`

90665 may be used.

90666 • If an option is found that was not specified in *optstring*, this error is identified and the
90667 invalid option character shall be identified in the message.

90668 • If an option requiring an option-argument is found, but an option-argument is not found,
90669 this error shall be identified and the invalid option character shall be identified in the
90670 message.

90671 **OUTPUT FILES**

90672 None.

90673 **EXTENDED DESCRIPTION**

90674 None.

90675 **EXIT STATUS**

90676 The following exit values shall be returned:

90677 0 An option, specified or unspecified by *optstring*, was found.

90678 >0 The end of options was encountered or an error occurred.

90679 **CONSEQUENCES OF ERRORS**

90680 Default.

90681 **APPLICATION USAGE**

90682 Since *getopts* affects the current shell execution environment, it is generally provided as a shell
90683 regular built-in. If it is called in a subshell or separate utility execution environment, such as one
90684 of the following:

```
90685 (getopts abc value "$@")
90686 nohup getopts ...
90687 find . –exec getopts ... \;
```

90688 it does not affect the shell variables in the caller's environment.

90689 Note that shell functions share *OPTIND* with the calling shell even though the positional
90690 parameters are changed. If the calling shell and any of its functions uses *getopts* to parse
90691 arguments, the results are unspecified.

EXAMPLES

The following example script parses and displays its arguments:

```
aflag=
bflag=
while getopts ab: name
do
    case $name in
    a)    aflag=1;;
    b)    bflag=1
          bval="$OPTARG";;
    ?)   printf "Usage: %s: [–a] [–b value] args\n" $0
          exit 2;;
    esac
done
if [ ! –z "$aflag" ]; then
    printf "Option –a specified\n"
fi
if [ ! –z "$bflag" ]; then
    printf 'Option –b "%s" specified\n' "$bval"
fi
shift $(($OPTIND – 1))
printf "Remaining arguments are: %s\n" "$*"
```

RATIONALE

The *getopts* utility was chosen in preference to the System V *getopt* utility because *getopts* handles option-arguments containing <blank> characters.

The *OPTARG* variable is not mentioned in the ENVIRONMENT VARIABLES section because it does not affect the execution of *getopts*; it is one of the few "output-only" variables used by the standard utilities.

The <colon> is not allowed as an option character because that is not historical behavior, and it violates the Utility Syntax Guidelines. The <colon> is now specified to behave as in the KornShell version of the *getopts* utility; when used as the first character in the *optstring* operand, it disables diagnostics concerning missing option-arguments and unexpected option characters. This replaces the use of the *OPTERR* variable that was specified in an early proposal.

The formats of the diagnostic messages produced by the *getopts* utility and the *getopt*() function are not fully specified because implementations with superior ("friendlier") formats objected to the formats used by some historical implementations. The standard developers considered it important that the information in the messages used be uniform between *getopts* and *getopt*(). Exact duplication of the messages might not be possible, particularly if a utility is built on another system that has a different *getopt*() function, but the messages must have specific information included so that the program name, invalid option character, and type of error can be distinguished by a user.

Only a rare application program intercepts a *getopts* standard error message and wants to parse it. Therefore, implementations are free to choose the most usable messages they can devise. The following formats are used by many historical implementations:

```
"%s: illegal option –– %c\n", <program name>, <option character>
"%s: option requires an argument –– %c\n", <program name>, \
    <option character>
```

Historical shells with built-in versions of *getopt*( ) or *getopts* have used different formats, frequently not even indicating the option character found in error.

FUTURE DIRECTIONS

CHANGE HISTORY

First released in Issue 4.

Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.

NAME

grep — search a file for a pattern

SYNOPSIS

```
grep [–E|–F] [–c|–l|–q] [–insvx] –e pattern_list
    [–e pattern_list]... [–f pattern_file]... [file...]

grep [–E|–F] [–c|–l|–q] [–insvx] [–e pattern_list]...
    –f pattern_file [–f pattern_file]... [file...]

grep [–E|–F] [–c|–l|–q] [–insvx] pattern_list [file...]
```

DESCRIPTION

The *grep* utility shall search the input files, selecting lines matching one or more patterns; the types of patterns are controlled by the options specified. The patterns are specified by the **–e** option, **–f** option, or the *pattern_list* operand. The *pattern_list*'s value shall consist of one or more patterns separated by <newline> characters; the *pattern_file*'s contents shall consist of one or more patterns terminated by a <newline> character. By default, an input line shall be selected if any pattern, treated as an entire basic regular expression (BRE) as described in XBD Section 9.3 (on page 183), matches any part of the line excluding the terminating <newline>; a null BRE shall match every line. By default, each selected input line shall be written to the standard output.

Regular expression matching shall be based on text lines. Since a <newline> separates or terminates patterns (see the **–e** and **–f** options below), regular expressions cannot contain a <newline>. Similarly, since patterns are matched against individual lines (excluding the terminating <newline> characters) of the input, there is no way for a pattern to match a <newline> found in the input.

OPTIONS

The *grep* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–E Match using extended regular expressions. Treat each pattern specified as an ERE, as described in XBD Section 9.4 (on page 188). If any entire ERE pattern matches some part of an input line excluding the terminating <newline>, the line shall be matched. A null ERE shall match every line.

–F Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line shall be matched. A null string shall match every line.

–c Write only a count of selected lines to standard output.

–e *pattern_list*
Specify one or more patterns to be used during the search for input. The application shall ensure that patterns in *pattern_list* are separated by a <newline>. A null pattern can be specified by two adjacent <newline> characters in *pattern_list*. Unless the **–E** or **–F** option is also specified, each pattern shall be treated as a BRE, as described in XBD Section 9.3 (on page 183). Multiple **–e** and **–f** options shall be accepted by the *grep* utility. All of the specified patterns shall be used when matching lines, but the order of evaluation is unspecified.

–f *pattern_file*
Read one or more patterns from the file named by the pathname *pattern_file*. Patterns in *pattern_file* shall be terminated by a <newline>. A null pattern can be specified by an empty line in *pattern_file*. Unless the **–E** or **–F** option is also

specified, each pattern shall be treated as a BRE, as described in XBD Section 9.3 (on page 183).

–i Perform pattern matching in searches without regard to case; see XBD Section 9.2 (on page 182).

–l (The letter ell.) Write only the names of files containing selected lines to standard output. Pathnames shall be written once per file searched. If the standard input is searched, a pathname of `"(standard input)"` shall be written, in the POSIX locale. In other locales, `"standard input"` may be replaced by something more appropriate in those locales.

–n Precede each output line by its relative line number in the file, each file starting at line 1. The line number counter shall be reset for each file processed.

–q Quiet. Nothing shall be written to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.

–s Suppress the error messages ordinarily written for nonexistent or unreadable files. Other error messages shall not be suppressed.

–v Select lines not matching any of the specified patterns. If the **–v** option is not specified, selected lines shall be those that match any of the specified patterns.

–x Consider only input lines that use all characters in the line excluding the terminating <newline> to match an entire fixed string or regular expression to be matching lines.

OPERANDS

The following operands shall be supported:

pattern_list Specify one or more patterns to be used during the search for input. This operand shall be treated as if it were specified as **–e** *pattern_list*.

file A pathname of a file to be searched for the patterns. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'–'` and the implementation treats the `'–'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *grep*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

90839 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
90840 characters (for example, single-byte as opposed to multi-byte characters in
90841 arguments and input files) and the behavior of character classes within regular
90842 expressions.

90843 *LC_MESSAGES*
90844 Determine the locale that should be used to affect the format and contents of
90845 diagnostic messages written to standard error.

90846 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

90847 **ASYNCHRONOUS EVENTS**
90848 Default.

90849 **STDOUT**
90850 If the **–l** option is in effect, the following shall be written for each file containing at least one
90851 selected input line:

90852 `"%s\n", <file>`

90853 Otherwise, if more than one *file* argument appears, and **–q** is not specified, the *grep* utility shall
90854 prefix each output line by:

90855 `"%s:", <file>`

90856 The remainder of each output line shall depend on the other options specified:

90857 • If the **–c** option is in effect, the remainder of each output line shall contain:

90858 `"%d\n", <count>`

90859 • Otherwise, if **–c** is not in effect and the **–n** option is in effect, the following shall be written
90860 to standard output:

90861 `"%d:", <line number>`

90862 • Finally, the following shall be written to standard output:

90863 `"%s", <selected-line contents>`

90864 **STDERR**
90865 The standard error shall be used only for diagnostic messages.

90866 **OUTPUT FILES**
90867 None.

90868 **EXTENDED DESCRIPTION**
90869 None.

90870 **EXIT STATUS**
90871 The following exit values shall be returned:

90872 0 One or more lines were selected.

90873 1 No lines were selected.

90874 >1 An error occurred.

90875 **CONSEQUENCES OF ERRORS**
90876 If the **–q** option is specified, the exit status shall be zero if an input line is selected, even if an
90877 error was detected. Otherwise, default actions shall be performed.

APPLICATION USAGE

Care should be taken when using characters in *pattern_list* that may also be meaningful to the command interpreter. It is safest to enclose the entire *pattern_list* argument in single-quotes:

```
'...'
```

The **–e** *pattern_list* option has the same effect as the *pattern_list* operand, but is useful when *pattern_list* begins with the <hyphen> delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.

Multiple **–e** and **–f** options are accepted and *grep* uses all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)

The **–q** option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it exits zero if it finds a match even if *grep* detected an access or read error on earlier *file* operands).

EXAMPLES

1. To find all uses of the word `"Posix"` (in any case) in file **text.mm** and write with line numbers:

   ```
   grep –i –n posix text.mm
   ```

2. To find all empty lines in the standard input:

   ```
   grep ^$
   ```

   or:

   ```
   grep –v .
   ```

3. Both of the following commands print all lines containing strings `"abc"` or `"def"` or both:

   ```
   grep –E 'abc|def'
   ```

   ```
   grep –F 'abc
   def'
   ```

4. Both of the following commands print all lines matching exactly `"abc"` or `"def"`:

   ```
   grep –E '^abc$|^def$'
   ```

   ```
   grep –F –x 'abc
   def'
   ```

RATIONALE

This *grep* has been enhanced in an upwards-compatible way to provide the exact functionality of the historical *egrep* and *fgrep* commands as well. It was the clear intention of the standard developers to consolidate the three *grep*s into a single command.

The old *egrep* and *fgrep* commands are likely to be supported for many years to come as implementation extensions, allowing historical applications to operate unmodified.

Historical implementations usually silently ignored all but one of multiply-specified **–e** and **–f** options, but were not consistent as to which specification was actually used.

The **–b** option was omitted from the OPTIONS section because block numbers are implementation-defined.

The System V restriction on using – to mean standard input was omitted.

A definition of action taken when given a null BRE or ERE is specified. This is an error condition in some historical implementations.

The **–l** option previously indicated that its use was undefined when no files were explicitly named. This behavior was historical and placed an unnecessary restriction on future implementations. It has been removed.

The historical BSD *grep* **–s** option practice is easily duplicated by redirecting standard output to **/dev/null**. The **–s** option required here is from System V.

The **–x** option, historically available only with *fgrep*, is available here for all of the non-obsolescent versions.

FUTURE DIRECTIONS

None.

SD5-XCU-ERN-98 is applied, updating the STDOUT section.

NAME

hash — remember or report utility locations

SYNOPSIS

```
hash [utility...]
hash -r
```

DESCRIPTION

The *hash* utility shall affect the way the current shell environment remembers the locations of utilities found as described in Section 2.9.1.1 (on page 2317). Depending on the arguments specified, it shall add utility locations to its list of remembered locations or it shall purge the contents of the list. When no arguments are specified, it shall report on the contents of the list.

Utilities provided as built-ins to the shell shall not be reported by *hash*.

OPTIONS

The *hash* utility shall conform to XBD Section 12.2 (on page 215).

The following option shall be supported:

-r Forget all previously remembered utility locations.

OPERANDS

The following operand shall be supported:

utility The name of a utility to be searched for and added to the list of remembered locations. If *utility* contains one or more <slash> characters, the results are unspecified.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *hash*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the location of *utility*, as described in XBD Chapter 8 (on page 173).

90986 **ASYNCHRONOUS EVENTS**
90987 Default.

90988 **STDOUT**
90989 The standard output of *hash* shall be used when no arguments are specified. Its format is
90990 unspecified, but includes the pathname of each utility in the list of remembered locations for the
90991 current shell environment. This list shall consist of those utilities named in previous *hash*
90992 invocations that have been invoked, and may contain those invoked and found through the
90993 normal command search process.

90994 **STDERR**
90995 The standard error shall be used only for diagnostic messages.

90996 **OUTPUT FILES**
90997 None.

90998 **EXTENDED DESCRIPTION**
90999 None.

91000 **EXIT STATUS**
91001 The following exit values shall be returned:

91002 0 Successful completion.

91003 >0 An error occurred.

91004 **CONSEQUENCES OF ERRORS**
91005 Default.

91006 **APPLICATION USAGE**
91007 Since *hash* affects the current shell execution environment, it is always provided as a shell
91008 regular built-in. If it is called in a separate utility execution environment, such as one of the
91009 following:

91010 ```
nohup hash -r
91011 find . -type f | xargs hash
```

91012 it does not affect the command search process of the caller's environment.

91013 The *hash* utility may be implemented as an alias—for example, *alias* **–t** –, in which case utilities
91014 found through normal command search are not listed by the *hash* command.

91015 The effects of *hash* **–r** can also be achieved portably by resetting the value of *PATH*; in the
91016 simplest form, this can be:

91017 ```
PATH="$PATH"
```

91018 The use of *hash* with *utility* names is unnecessary for most applications, but may provide a
91019 performance improvement on a few implementations; normally, the hashing process is included
91020 by default.

91021 **EXAMPLES**
91022 None.

91023 **RATIONALE**
91024 None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 7

The *hash* utility is moved from the XSI option to the Base.

NAME

head — copy the first part of files

SYNOPSIS

```
head [–n number] [file...]
```

DESCRIPTION

The *head* utility shall copy its input files to the standard output, ending the output for each file at a designated point.

Copying shall end at the point in each input file indicated by the **–n** *number* option. The option-argument *number* shall be counted in units of lines.

OPTIONS

The *head* utility shall conform to XBD Section 12.2 (on page 215).

The following option shall be supported:

–n *number* The first *number* lines of each input file shall be copied to standard output. The application shall ensure that the *number* option-argument is a positive decimal integer.

When a file contains less than *number* lines, it shall be copied to standard output in its entirety. This shall not be an error.

If no options are specified, *head* shall act as if **–n 10** had been specified.

OPERANDS

The following operand shall be supported:

file A pathname of an input file. If no *file* operands are specified, the standard input shall be used.

STDIN

The standard input shall be used if no *file* operands are specified, and shall be used if a *file* operand is `'–'` and the implementation treats the `'–'` as meaning standard input. Otherwise, the standard input shall not be used. See the INPUT FILES section.

INPUT FILES

Input files shall be text files, but the line length is not restricted to {LINE_MAX} bytes.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *head*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

91075 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

91076 **ASYNCHRONOUS EVENTS**
91077 Default.

91078 **STDOUT**
91079 The standard output shall contain designated portions of the input files.

91080 If multiple *file* operands are specified, *head* shall precede the output for each with the header:

91081 `"\n==> %s <==\n", <pathname>`

91082 except that the first header written shall not include the initial <newline>.

91083 **STDERR**
91084 The standard error shall be used only for diagnostic messages.

91085 **OUTPUT FILES**
91086 None.

91087 **EXTENDED DESCRIPTION**
91088 None.

91089 **EXIT STATUS**
91090 The following exit values shall be returned:

91091 0 Successful completion.

91092 >0 An error occurred.

91093 **CONSEQUENCES OF ERRORS**
91094 Default.

91095 **APPLICATION USAGE**
91096 None.

91097 **EXAMPLES**
91098 To write the first ten lines of all files (except those with a leading period) in the directory:

91099 ```
head -- *
```

91100 **RATIONALE**
91101 Although it is possible to simulate *head* with *sed* 10q for a single file, the standard developers
91102 decided that the popularity of *head* on historical BSD systems warranted its inclusion alongside
91103 *tail*.

91104 POSIX.1-200x version of *head* follows the Utility Syntax Guidelines. The **–n** option was added to
91105 this new interface so that *head* and *tail* would be more logically related. Earlier versions of this
91106 standard allowed a **–number** option. This form is no longer specified by POSIX.1-200x but may
91107 be present in some implementations.

91108 There is no **–c** option (as there is in *tail*) because it is not historical practice and because other
91109 utilities in this volume of POSIX.1-200x provide similar functionality.

91110 **FUTURE DIRECTIONS**
91111 None.

91112 **SEE ALSO**
91113 *sed*, *tail*

91114 XBD Chapter 8 (on page 173), Section 12.2 (on page 215)
```

CHANGE HISTORY

First released in Issue 4.

Issue 6

The obsolescent –**number** form is removed.

The normative text is reworded to avoid use of the term "must" for application requirements.

The DESCRIPTION is updated to clarify that when a file contains less than the number of lines requested, the entire file is copied to standard output.

Issue 7

Austin Group Interpretations 1003.1-2001 #027 and #092 are applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The APPLICATION USAGE section is removed and the EXAMPLES section is corrected.

NAME

iconv — codeset conversion

SYNOPSIS

```
iconv [–cs] –f frommap –t tomap [file...]
iconv –f fromcode [–cs] [–t tocode] [file...]
iconv –t tocode [–cs] [–f fromcode] [file...]
iconv –l
```

DESCRIPTION

The *iconv* utility shall convert the encoding of characters in *file* from one codeset to another and write the results to standard output.

When the options indicate that charmap files are used to specify the codesets (see OPTIONS), the codeset conversion shall be accomplished by performing a logical join on the symbolic character names in the two charmaps. The implementation need not support the use of charmap files for codeset conversion unless the POSIX2_LOCALEDEF symbol is defined on the system.

OPTIONS

The *iconv* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–c Omit any characters that are invalid in the codeset of the input file from the output. When **–c** is not used, the results of encountering invalid characters in the input stream (either those that are not characters in the codeset of the input file or that have no corresponding character in the codeset of the output file) shall be specified in the system documentation. The presence or absence of **–c** shall not affect the exit status of *iconv*.

–f *fromcodeset*

Identify the codeset of the input file. The implementation shall recognize the following two forms of the *fromcodeset* option-argument:

fromcode The *fromcode* option-argument must not contain a <slash> character. It shall be interpreted as the name of one of the codeset descriptions provided by the implementation in an unspecified format. Valid values of *fromcode* are implementation-defined.

frommap The *frommap* option-argument must contain a <slash> character. It shall be interpreted as the pathname of a charmap file as defined in XBD Section 6.4 (on page 129). If the pathname does not represent a valid, readable charmap file, the results are undefined.

If this option is omitted, the codeset of the current locale shall be used.

–l Write all supported *fromcode* and *tocode* values to standard output in an unspecified format.

–s Suppress any messages written to standard error concerning invalid characters. When **–s** is not used, the results of encountering invalid characters in the input stream (either those that are not valid characters in the codeset of the input file or that have no corresponding character in the codeset of the output file) shall be specified in the system documentation. The presence or absence of **–s** shall not affect the exit status of *iconv*.

91169 **–t** *tocodeset* Identify the codeset to be used for the output file. The implementation shall
91170 recognize the following two forms of the *tocodeset* option-argument:

91171 *tocode* The semantics shall be equivalent to the **–f** *fromcode* option.

91172 *tomap* The semantics shall be equivalent to the **–f** *frommap* option.

91173 If this option is omitted, the codeset of the current locale shall be used.

91174 If either **–f** or **–t** represents a charmap file, but the other does not (or is omitted), or both **–f** and
91175 **–t** are omitted, the results are undefined.

91176 **OPERANDS**

91177 The following operand shall be supported:

91178 *file* A pathname of an input file. If no *file* operands are specified, or if a *file* operand is
91179 `'–'`, the standard input shall be used.

91180 **STDIN**

91181 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

91182 **INPUT FILES**

91183 The input file shall be a text file.

91184 **ENVIRONMENT VARIABLES**

91185 The following environment variables shall affect the execution of *iconv*:

91186 *LANG* Provide a default value for the internationalization variables that are unset or null.
91187 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
91188 variables used to determine the values of locale categories.)

91189 *LC_ALL* If set to a non-empty string value, override the values of all the other
91190 internationalization variables.

91191 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
91192 characters (for example, single-byte as opposed to multi-byte characters in
91193 arguments). During translation of the file, this variable is superseded by the use of
91194 the *fromcode* option-argument.

91195 *LC_MESSAGES*
91196 Determine the locale that should be used to affect the format and contents of
91197 diagnostic messages written to standard error.

91198 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

91199 **ASYNCHRONOUS EVENTS**

91200 Default.

91201 **STDOUT**

91202 When the **–l** option is used, the standard output shall contain all supported *fromcode* and *tocode*
91203 values, written in an unspecified format.

91204 When the **–l** option is not used, the standard output shall contain the sequence of characters
91205 read from the input files, translated to the specified codeset. Nothing else shall be written to the
91206 standard output.

91207 **STDERR**

91208 The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The user must ensure that both charmap files use the same symbolic names for characters the two codesets have in common.

EXAMPLES

The following example converts the contents of file **mail.x400** from the ISO/IEC 6937:2001 standard codeset to the ISO/IEC 8859-1:1998 standard codeset, and stores the results in file **mail.local**:

```
iconv –f IS6937 –t IS8859 mail.x400 > mail.local
```

RATIONALE

The *iconv* utility can be used portably only when the user provides two charmap files as option-arguments. This is because a single charmap provided by the user cannot reliably be joined with the names in a system-provided character set description. The valid values for *fromcode* and *tocode* are implementation-defined and do not have to have any relation to the charmap mechanisms. As an aid to interactive users, the **–l** option was adopted from the Plan 9 operating system. It writes information concerning these implementation-defined values. The format is unspecified because there are many possible useful formats that could be chosen, such as a matrix of valid combinations of *fromcode* and *tocode*. The **–l** option is not intended for shell script usage; conforming applications will have to use charmaps.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 3.

Issue 6

This utility has been rewritten to align with the IEEE P1003.2b draft standard. Specifically, the ability to use charmap files for conversion has been added.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/29 is applied, making changes to address inconsistencies with the *iconv*( ) function in the System Interfaces volume of POSIX.1-200x.

Issue 7

Austin Group Interpretation 1003.1-2001 #206 is applied, correcting the *tomap* option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

id — return user identity

SYNOPSIS

```
id [user]
id -G [-n] [user]
id -g [-nr] [user]
id -u [-nr] [user]
```

DESCRIPTION

If no *user* operand is provided, the *id* utility shall write the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both shall be written. If multiple groups are supported by the underlying system (see the description of {NGROUPS_MAX} in the System Interfaces volume of POSIX.1-200x), the supplementary group affiliations of the invoking process shall also be written.

If a *user* operand is provided and the process has appropriate privileges, the user and group IDs of the selected user shall be written. In this case, effective IDs shall be assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, these shall be written in the same manner as the supplementary groups described in the preceding paragraph.

OPTIONS

The *id* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

-G Output all different group IDs (effective, real, and supplementary) only, using the format `"%u\n"`. If there is more than one distinct group affiliation, output each such affiliation, using the format `" %u"`, before the <newline> is output.

-g Output only the effective group ID, using the format `"%u\n"`.

-n Output the name in the format `"%s"` instead of the numeric ID using the format `"%u"`.

-r Output the real ID instead of the effective ID.

-u Output only the effective user ID, using the format `"%u\n"`.

OPERANDS

The following operand shall be supported:

user The login name for which information is to be written.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *id*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The following formats shall be used when the *LC_MESSAGES* locale category specifies the POSIX locale. In other locales, the strings *uid*, *gid*, *euid*, *egid*, and *groups* may be replaced with more appropriate strings corresponding to the locale.

```
"uid=%u(%s) gid=%u(%s)\n", <real user ID>, <user-name>,
    <real group ID>, <group-name>
```

If the effective and real user IDs do not match, the following shall be inserted immediately before the `'\n'` character in the previous format:

```
" euid=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<effective user ID>, <effective user-name>
```

If the effective and real group IDs do not match, the following shall be inserted directly before the `'\n'` character in the format string (and after any addition resulting from the effective and real user IDs not matching):

```
" egid=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<effective group-ID>, <effective group name>
```

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first shall be added directly before the <newline> in the format string:

```
" groups=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

and the necessary number of the following added after that for any remaining supplementary group IDs:

```
",%u(%s)"
```

and the necessary number of the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

If any of the user ID, group ID, effective user ID, effective group ID, or supplementary/multiple

group IDs cannot be mapped by the system into printable user or group names, the corresponding `"(%s)"` and *name* argument shall be omitted from the corresponding format string.

When any of the options are specified, the output format shall be as described in the OPTIONS section.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Output produced by the **–G** option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups. (On systems with user and group IDs that are 32-bit integers and with group names with a maximum of 8 bytes per name, 93 supplementary groups plus distinct effective and real group and user IDs could theoretically overflow the 2 048-byte {LINE_MAX} text file line limit on the default output case. It would take about 186 supplementary groups to overflow the 2 048-byte barrier using *id* **–G**). This is not expected to be a problem in practice, but in cases where it is a concern, applications should consider using *fold* **–s** before post-processing the output of *id*.

EXAMPLES

None.

RATIONALE

The functionality provided by the 4 BSD *groups* utility can be simulated using:

```
id –Gn [ user ]
```

The 4 BSD command *groups* was considered, but it was not included because it did not provide the functionality of the *id* utility of the SVID. Also, it was thought that it would be easier to modify *id* to provide the additional functionality necessary to systems with multiple groups than to invent another command.

The options **–u**, **–g**, **–n**, and **–r** were added to ease the use of *id* with shell commands substitution. Without these options it is necessary to use some preprocessor such as *sed* to select the desired piece of information. Since output such as that produced by:

```
id –u –n
```

is frequently wanted, it seemed desirable to add the options.

FUTURE DIRECTIONS

None.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ipcrm — remove an XSI message queue, semaphore set, or shared memory segment identifier

SYNOPSIS

XSI

```
ipcrm [–q msgid|–Q msgkey|–s semid|–S semkey|–m shmid|–M shmkey]...
```

DESCRIPTION

The *ipcrm* utility shall remove zero or more message queues, semaphore sets, or shared memory segments. The interprocess communication facilities to be removed are specified by the options.

Only a user with appropriate privileges shall be allowed to remove an interprocess communication facility that was not created by or owned by the user invoking *ipcrm*.

OPTIONS

The *ipcrm* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–q *msgid* Remove the message queue identifier *msgid* from the system and destroy the message queue and data structure associated with it.

–m *shmid* Remove the shared memory identifier *shmid* from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

–s *semid* Remove the semaphore identifier *semid* from the system and destroy the set of semaphores and data structure associated with it.

–Q *msgkey* Remove the message queue identifier, created with key *msgkey*, from the system and destroy the message queue and data structure associated with it.

–M *shmkey* Remove the shared memory identifier, created with key *shmkey*, from the system. The shared memory segment and data structure associated with it shall be destroyed after the last detach.

–S *semkey* Remove the semaphore identifier, created with key *semkey*, from the system and destroy the set of semaphores and data structure associated with it.

NAME

ipcs — report XSI interprocess communication facilities status

SYNOPSIS

XSI
```
ipcs [–qms] [–a|–bcopt]
```

DESCRIPTION

The *ipcs* utility shall write information about active interprocess communication facilities.

Without options, information shall be written in short format for message queues, shared memory segments, and semaphore sets that are currently active in the system. Otherwise, the information that is displayed is controlled by the options specified.

OPTIONS

The *ipcs* utility shall conform to XBD Section 12.2 (on page 215).

The *ipcs* utility accepts the following options:

–q Write information about active message queues.

–m Write information about active shared memory segments.

–s Write information about active semaphore sets.

If **–q**, **–m**, or **–s** are specified, only information about those facilities shall be written. If none of these three are specified, information about all three shall be written subject to the following options:

–a Use all print options. (This is a shorthand notation for **–b**, **–c**, **–o**, **–p**, and **–t**.)

–b Write information on maximum allowable size. (Maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores.)

–c Write creator's user name and group name; see below.

–o Write information on outstanding usage. (Number of messages on queue and total number of bytes in messages on queue for message queues, and number of processes attached to shared memory segments.)

–p Write process number information. (Process ID of the last process to send a message and process ID of the last process to receive a message on message queues, process ID of the creating process, and process ID of the last process to attach or detach on shared memory segments.)

–t Write time information. (Time of the last control operation that changed the access permissions for all facilities, time of the last *msgsnd*( ) and *msgrcv*( ) operations on message queues, time of the last *shmat*( ) and *shmdt*( ) operations on shared memory, and time of the last *semop*( ) operation on semaphores.)

OPERANDS

None.

STDIN

Not used.

INPUT FILES

- The group database

- The user database

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ipcs*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone for the date and time strings written by *ipcs*. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

An introductory line shall be written with the format:

`"IPC status from %s as of %s\n", <source>, <date>`

where <*source*> indicates the source used to gather the statistics and <*date*> is the information that would be produced by the *date* command when invoked in the POSIX locale.

The *ipcs* utility then shall create up to three reports depending upon the **–q**, **–m**, and **–s** options. The first report shall indicate the status of message queues, the second report shall indicate the status of shared memory segments, and the third report shall indicate the status of semaphore sets.

If the corresponding facility is not installed or has not been used since the last reboot, then the report shall be written out in the format:

`"%s facility not in system.\n", <facility>`

where <*facility*> is *Message Queue*, *Shared Memory*, or *Semaphore*, as appropriate. If the facility has been installed and has been used since the last reboot, column headings separated by one or more <space> characters and followed by a <newline> shall be written as indicated below followed by the facility name written out using the format:

`"%s:\n", <facility>`

where <*facility*> is *Message Queues*, *Shared Memory*, or *Semaphores*, as appropriate. On the second and third reports the column headings need not be written if the last column headings written already provide column headings for all information in that report.

The column headings provided in the first column below and the meaning of the information in those columns shall be given in order below; the letters in parentheses indicate the options that shall cause the corresponding column to appear; "all" means that the column shall always appear. Each column is separated by one or more <space> characters. Note that these options

only determine what information is provided for each report; they do not determine which reports are written.

T (all) Type of facility:

`q` Message queue.

`m` Shared memory segment.

`s` Semaphore.

This field is a single character written using the format `%c`.

ID (all) The identifier for the facility entry. This field shall be written using the format `%d`.

KEY (all) The key used as an argument to *msgget*(), *semget*(), or *shmget*() to create the facility entry.

Note: The key of a shared memory segment is changed to IPC_PRIVATE when the segment has been removed until all processes attached to the segment detach it.

This field shall be written using the format `0x%x`.

MODE (all) The facility access modes and flags. The mode shall consist of 11 characters that are interpreted as follows.

The first character shall be:

`S` If a process is waiting on a *msgsnd*() operation.

– If the above is not true.

The second character shall be:

`R` If a process is waiting on a *msgrcv*() operation.

`C` or – If the associated shared memory segment is to be cleared when the first attach operation is executed.

– If none of the above is true.

The next nine characters shall be interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the usergroup of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is a minus-sign (`'–'`).

The permissions shall be indicated as follows:

r If read permission is granted.

w If write permission is granted.

a If alter permission is granted.

– If the indicated permission is not granted.

The first character following the permissions specifies if there is an alternate or additional access control method associated with the facility. If there is no alternate or additional access control method associated with the facility, a single <space> shall be written; otherwise, another printable character is

written.

OWNER (all) The user name of the owner of the facility entry. If the user name of the owner is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the owner shall be written using the format `%d`.

GROUP (all) The group name of the owner of the facility entry. If the group name of the owner is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the owner shall be written using the format `%d`.

The following nine columns shall be only written out for message queues:

CREATOR (**a**,**c**) The user name of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

CBYTES (**a**,**o**) The number of bytes in messages currently outstanding on the associated message queue. This field shall be written using the format `%d`.

QNUM (**a**,**o**) The number of messages currently outstanding on the associated message queue. This field shall be written using the format `%d`.

QBYTES (**a**,**b**) The maximum number of bytes allowed in messages outstanding on the associated message queue. This field shall be written using the format `%d`.

LSPID (**a**,**p**) The process ID of the last process to send a message to the associated queue. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no message has been sent to the corresponding message queue; otherwise, <*pid*> shall be the process ID of the last process to send a message to the queue.

LRPID (**a**,**p**) The process ID of the last process to receive a message from the associated queue. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no message has been received from the corresponding message queue; otherwise, <*pid*> shall be the process ID of the last process to receive a message from the queue.

STIME (**a**,**t**) The time the last message was sent to the associated queue. If a message has been sent to the corresponding message queue, the hour, minute, and second of the last time a message was sent to the queue shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

RTIME (**a**,**t**) The time the last message was received from the associated queue. If a message has been received from the corresponding message queue, the hour, minute, and second of the last time a message was received from the queue

shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following eight columns shall be only written out for shared memory segments.

CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

NATTCH (**a**,**o**) The number of processes attached to the associated shared memory segment. This field shall be written using the format `%d`.

SEGSZ (**a**,**b**) The size of the associated shared memory segment. This field shall be written using the format `%d`.

CPID (**a**,**p**) The process ID of the creator of the shared memory entry. This field shall be written using the format `%d`.

LPID (**a**,**p**) The process ID of the last process to attach or detach the shared memory segment. This field shall be written using the format:

`"%d", <pid>`

where <*pid*> is 0 if no process has attached the corresponding shared memory segment; otherwise, <*pid*> shall be the process ID of the last process to attach or detach the segment.

ATIME (**a**,**t**) The time the last attach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been attached, the hour, minute, and second of the last time the segment was attached shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

DTIME (**a**,**t**) The time the last detach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been detached, the hour, minute, and second of the last time the segment was detached shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following four columns shall be only written out for semaphore sets:

CREATOR (**a**,**c**) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the user ID of the creator shall be written using the format `%d`.

CGROUP (**a**,**c**) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format `%s`. Otherwise, the group ID of the creator shall be written using the format `%d`.

NSEMS (**a**,**b**) The number of semaphores in the set associated with the semaphore entry. This field shall be written using the format `%d`.

OTIME (**a**,**t**) The time the last semaphore operation on the set associated with the semaphore entry was completed. If a semaphore operation has ever been performed on the corresponding semaphore set, the hour, minute, and second of the last semaphore operation on the semaphore set shall be written using the format `%d:%2.2d:%2.2d`. Otherwise, the format `" no-entry"` shall be written.

The following column shall be written for all three reports when it is requested:

CTIME (**a**,**t**) The time the associated entry was created or changed. The hour, minute, and second of the time when the associated entry was created shall be written using the format `%d:%2.2d:%2.2d`.

STDERR

The standard error shall be used only for diagnostic messages.

CHANGE HISTORY

First released in Issue 5.

Issue 6

The Open Group Corrigendum U020/1 is applied, correcting the SYNOPSIS.

The Open Group Corrigenda U032/1 and U032/2 are applied, clarifying the output format.

The Open Group Base Resolution bwg98-004 is applied.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-139 is applied, adding the *ipcrm* utility to the SEE ALSO section.

NAME

jobs — display status of jobs in the current session

SYNOPSIS

UP

```
jobs [-l|-p] [job_id...]
```

DESCRIPTION

The *jobs* utility shall display the status of jobs that were started in the current shell environment; see Section 2.12 (on page 2331).

When *jobs* reports the termination status of a job, the shell shall remove its process ID from the list of those "known in the current shell execution environment"; see Section 2.9.3.1 (on page 2319).

OPTIONS

The *jobs* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

-l (The letter ell.) Provide more information about each job listed. This information shall include the job number, current job, process group ID, state, and the command that formed the job.

-p Display only the process IDs for the process group leaders of the selected jobs.

By default, the *jobs* utility shall display the status of all stopped jobs, running background jobs and all jobs whose status has changed and have not been reported by the shell.

OPERANDS

The following operand shall be supported:

job_id Specifies the jobs for which the status is to be displayed. If no *job_id* is given, the status information for all jobs shall be displayed. The format of *job_id* is described in XBD Section 3.203 (on page 65).

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *jobs*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If the –**p** option is specified, the output shall consist of one line for each process ID:

`"%d\n", <process ID>`

Otherwise, if the –**l** option is not specified, the output shall be a series of lines of the form:

`"[%d] %c %s %s\n", <job-number>, <current>, <state>, <command>`

where the fields shall be as follows:

<*current*> The character `'+'` identifies the job that would be used as a default for the *fg* or *bg* utilities; this job can also be specified using the *job_id* %+ or `"%%"`. The character `'–'` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* %–. For other jobs, this field is a <space>. At most one job can be identified with `'+'` and at most one job can be identified with `'–'`. If there is any suspended job, then the current job shall be a suspended job. If there are at least two suspended jobs, then the previous job also shall be a suspended job.

<*job-number*> A number that can be used to identify the process group to the *wait*, *fg*, *bg*, and *kill* utilities. Using these utilities, the job can be identified by prefixing the job number with `'%'`.

<*state*> One of the following strings (in the POSIX locale):

Running Indicates that the job has not been suspended by a signal and has not exited.

Done Indicates that the job completed and returned exit status zero.

Done(*code*) Indicates that the job completed normally and that it exited with the specified non-zero exit status, *code*, expressed as a decimal number.

Stopped Indicates that the job was suspended by the SIGTSTP signal.

Stopped (**SIGTSTP**)
Indicates that the job was suspended by the SIGTSTP signal.

Stopped (**SIGSTOP**)
Indicates that the job was suspended by the SIGSTOP signal.

Stopped (**SIGTTIN**)
Indicates that the job was suspended by the SIGTTIN signal.

Stopped (**SIGTTOU**)
Indicates that the job was suspended by the SIGTTOU signal.

The implementation may substitute the string **Suspended** in place of **Stopped**. If the job was terminated by a signal, the format of <*state*> is unspecified, but it shall be visibly distinct from all of the other <*state*> formats shown here and shall indicate the name or description of the signal causing the termination.

<*command*> The associated command that was given to the shell.

If the –**l** option is specified, a field containing the process group ID shall be inserted before the <*state*> field. Also, more processes in a process group may be output on separate lines, using

only the process ID and <*command*> fields.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **−p** option is the only portable way to find out the process group of a job because different implementations have different strategies for defining the process group of the job. Usage such as $(*jobs* **−p**) provides a way of referring to the process group of the job in an implementation-independent way.

The *jobs* utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for *bg*. For this reason, *jobs* is generally implemented as a shell regular built-in.

EXAMPLES

None.

RATIONALE

Both "%%" and "%+" are used to refer to the current job. Both forms are of equal validity—the "%%" mirroring "$$" and "%+" mirroring the output of *jobs*. Both forms reflect historical practice of the KornShell and the C shell with job control.

The job control features provided by *bg*, *fg*, and *jobs* are based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of POSIX.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

The *jobs* utility is not dependent on the job control option, as are the seemingly related *bg* and *fg* utilities because *jobs* is useful for examining background jobs, regardless of the condition of job control. When the user has invoked a *set* **+m** command and job control has been turned off, *jobs* can still be used to examine the background jobs associated with that current session. Similarly, *kill* can then be used to kill background jobs with *kill* %<*background job number*>.

The output for terminated jobs is left unspecified to accommodate various historical systems. The following formats have been witnessed:

1. **Killed**(*signal name*)
2. *signal name*

3. *signal name*(**coredump**)
4. *signal description*– **core dumped**

Most users should be able to understand these formats, although it means that applications have trouble parsing them.

The calculation of job IDs was not described since this would suggest an implementation, which may impose unnecessary restrictions.

In an early proposal, a –**n** option was included to "Display the status of jobs that have changed, exited, or stopped since the last status report". It was removed because the shell always writes any changed status of jobs before each prompt.

FUTURE DIRECTIONS

None.

XBD Section 3.203 (on page 65), Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 4.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The JC shading is removed as job control is mandatory in this version.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

join — relational database operator

SYNOPSIS

```
join [–a file_number|–v file_number] [–e string] [–o list] [–t char]
    [–1 field] [–2 field] file1 file2
```

DESCRIPTION

The *join* utility shall perform an equality join on the files *file1* and *file2*. The joined files shall be written to the standard output.

The join field is a field in each file on which the files are compared. The *join* utility shall write one line in the output for each pair of lines in *file1* and *file2* that have identical join fields. The output line by default shall consist of the join field, then the remaining fields from *file1*, then the remaining fields from *file2*. This format can be changed by using the **–o** option (see below). The **–a** option can be used to add unmatched lines to the output. The **–v** option can be used to output only unmatched lines.

The files *file1* and *file2* shall be ordered in the collating sequence of *sort* **–b** on the fields on which they shall be joined, by default the first in each line. All selected output shall be written in the same collating sequence.

The default input field separators shall be <blank> characters. In this case, multiple separators shall count as one field separator, and leading separators shall be ignored. The default output field separator shall be a <space>.

The field separator and collating sequence can be changed by using the **–t** option (see below).

If the same key appears more than once in either file, all combinations of the set of remaining fields in *file1* and the set of remaining fields in *file2* are output in the order of the lines encountered.

If the input files are not in the appropriate collating sequence, the results are unspecified.

OPTIONS

The *join* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–a *file_number*
: Produce a line for each unpairable line in file *file_number*, where *file_number* is 1 or 2, in addition to the default output. If both **–a**1 and **–a**2 are specified, all unpairable lines shall be output.

–e *string*
: Replace empty output fields in the list selected by **–o** with the string *string*.

–o *list*
: Construct the output line to comprise the fields specified in *list*, each element of which shall have one of the following two forms:

  1. *file_number.field*, where *file_number* is a file number and *field* is a decimal integer field number
  2. 0 (zero), representing the join field

  The elements of *list* shall be either <comma>-separated or <blank>-separated, as specified in Guideline 8 of XBD Section 12.2 (on page 215). The fields specified by *list* shall be written for all selected output lines. Fields selected by *list* that do not appear in the input shall be treated as empty output fields. (See the **–e** option.) Only specifically requested fields shall be written. The application shall ensure that *list* is a single command line argument.

91908 **–t** *char* Use character *char* as a separator, for both input and output. Every appearance of
91909 *char* in a line shall be significant. When this option is specified, the collating
91910 sequence shall be the same as *sort* without the **–b** option.

91911 **–v** *file_number*
91912 Instead of the default output, produce a line only for each unpairable line in
91913 *file_number*, where *file_number* is 1 or 2. If both **–v**1 and **–v**2 are specified, all
91914 unpairable lines shall be output.

91915 **–1** *field* Join on the *field*th field of file 1. Fields are decimal integers starting with 1.

91916 **–2** *field* Join on the *field*th field of file 2. Fields are decimal integers starting with 1.

91917 **OPERANDS**

91918 The following operands shall be supported:

91919 *file1*, *file2* A pathname of a file to be joined. If either of the *file1* or *file2* operands is `'–'`, the
91920 standard input shall be used in its place.

91921 **STDIN**

91922 The standard input shall be used only if the *file1* or *file2* operand is `'–'`. See the INPUT FILES
91923 section.

91924 **INPUT FILES**

91925 The input files shall be text files.

91926 **ENVIRONMENT VARIABLES**

91927 The following environment variables shall affect the execution of *join*:

91928 *LANG* Provide a default value for the internationalization variables that are unset or null.
91929 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
91930 variables used to determine the values of locale categories.)

91931 *LC_ALL* If set to a non-empty string value, override the values of all the other
91932 internationalization variables.

91933 *LC_COLLATE*
91934 Determine the locale of the collating sequence *join* expects to have been used when
91935 the input files were sorted.

91936 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
91937 characters (for example, single-byte as opposed to multi-byte characters in
91938 arguments and input files).

91939 *LC_MESSAGES*
91940 Determine the locale that should be used to affect the format and contents of
91941 diagnostic messages written to standard error.

91942 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

91943 **ASYNCHRONOUS EVENTS**

91944 Default.

91945 **STDOUT**

91946 The *join* utility output shall be a concatenation of selected character fields. When the **–o** option
91947 is not specified, the output shall be:

91948 `"%s%s%s\n", <join field>, <other file1 fields>,`
91949 `<other file2 fields>`

91950 If the join field is not the first field in a file, the <*other file fields*> for that file shall be:

91951 *<fields preceding join field>, <fields following join field>*

91952 When the **–o** option is specified, the output format shall be:

91953 `"%s\n", <concatenation of fields>`

91954 where the concatenation of fields is described by the **–o** option, above.

91955 For either format, each field (except the last) shall be written with its trailing separator character.
91956 If the separator is the default (<blank> characters), a single <space> shall be written after each
91957 field (except the last).

91958 **STDERR**

91959 The standard error shall be used only for diagnostic messages.

91960 **OUTPUT FILES**

91961 None.

91962 **EXTENDED DESCRIPTION**

91963 None.

91964 **EXIT STATUS**

91965 The following exit values shall be returned:

91966 0 All input files were output successfully.

91967 >0 An error occurred.

91968 **CONSEQUENCES OF ERRORS**

91969 Default.

91970 **APPLICATION USAGE**

91971 Pathnames consisting of numeric digits or of the form *string.string* should not be specified
91972 directly following the **–o** list.

91973 **EXAMPLES**

91974 The **–o** 0 field essentially selects the union of the join fields. For example, given file **phone**:

```
91975 !Name          Phone Number
91976 Don            +1 123-456-7890
91977 Hal            +1 234-567-8901
91978 Yasushi        +2 345-678-9012
```

91979 and file **fax**:

```
91980 !Name          Fax Number
91981 Don            +1 123-456-7899
91982 Keith          +1 456-789-0122
91983 Yasushi        +2 345-678-9011
```

91984 (where the large expanses of white space are meant to each represent a single <tab>), the
91985 command:

```
91986 join –t "<tab>" –a 1 –a 2 –e '(unknown)' –o 0,1.2,2.2 phone fax
```

91987 would produce:

```
91988 !Name          Phone Number          Fax Number
91989 Don            +1 123-456-7890       +1 123-456-7899
91990 Hal            +1 234-567-8901       (unknown)
91991 Keith          (unknown)             +1 456-789-0122
91992 Yasushi        +2 345-678-9012       +2 345-678-9011
```

Multiple instances of the same key will produce combinatorial results. The following:

```
fa:
    a x
    a y
    a z
fb:
    a p
```

will produce:

```
a x p
a y p
a z p
```

And the following:

```
fa:
    a b c
    a d e
fb:
    a w x
    a y z
    a o p
```

will produce:

```
a b c w x
a b c y z
a b c o p
a d e w x
a d e y z
a d e o p
```

RATIONALE

The **–e** option is only effective when used with **–o** because, unless specific fields are identified using **–o**, *join* is not aware of what fields might be empty. The exception to this is the join field, but identifying an empty join field with the **–e** string is not historical practice and some scripts might break if this were changed.

The 0 field in the **–o** list was adopted from the Tenth Edition version of *join* to satisfy international objections that the *join* in the base documents does not support the "full join" or "outer join" described in relational database literature. Although it has been possible to include a join field in the output (by default, or by field number using **–o**), the join field could not be included for an unpaired line selected by **–a**. The **–o** 0 field essentially selects the union of the join fields.

This sort of outer join was not possible with the *join* commands in the base documents. The **–o** 0 field was chosen because it is an upwards-compatible change for applications. An alternative was considered: have the join field represent the union of the fields in the files (where they are identical for matched lines, and one or both are null for unmatched lines). This was not adopted because it would break some historical applications.

The ability to specify *file2* as – is not historical practice; it was added for completeness.

The **–v** option is not historical practice, but was considered necessary because it permitted the writing of *only* those lines that do not match on the join field, as opposed to the **–a** option, which prints both lines that do and do not match. This additional facility is parallel with the **–v** option

of *grep*.

Some historical implementations have been encountered where a blank line in one of the input files was considered to be the end of the file; the description in this volume of POSIX.1-200x does not cite this as an allowable case.

Earlier versions of this standard allowed **–j**, **–j1**, **–j2** options, and a form of the **–o** option that allowed the *list* option-argument to be multiple arguments. These forms are no longer specified by POSIX.1-200x but may be present in some implementations.

FUTURE DIRECTIONS

None.

awk, *comm*, *sort*, *uniq*

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent **–j** options and the multi-argument **–o** option are removed in this version.

The normative text is reworded to avoid use of the term "must" for application requirements.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

92059 **NAME**

92060 kill — terminate or signal processes

92061 **SYNOPSIS**

92062 `kill –s signal_name pid...`

92063 `kill –l [exit_status]`

92064 XSI `kill [–signal_name] pid...`

92065 `kill [–signal_number] pid...`

92066 **DESCRIPTION**

92067 The *kill* utility shall send a signal to the process or processes specified by each *pid* operand.

92068 For each *pid* operand, the *kill* utility shall perform actions equivalent to the *kill*() function
92069 defined in the System Interfaces volume of POSIX.1-200x called with the following arguments:

92070 • The value of the *pid* operand shall be used as the *pid* argument.

92071 • The *sig* argument is the value specified by the **–s** option, *–signal_number* option, or the
92072 *–signal_name* option, or by SIGTERM, if none of these options is specified.

92073 **OPTIONS**

92074 XSI The *kill* utility shall conform to XBD Section 12.2 (on page 215), except that in the last two
92075 SYNOPSIS forms, the *–signal_number* and *–signal_name* options are usually more than a single
92076 character.

92077 The following options shall be supported:

92078 **–l** (The letter ell.) Write all values of *signal_name* supported by the implementation, if
92079 no operand is given. If an *exit_status* operand is given and it is a value of the `'?'`
92080 shell special parameter (see Section 2.5.2 (on page 2302) and *wait*) corresponding to
92081 a process that was terminated by a signal, the *signal_name* corresponding to the
92082 signal that terminated the process shall be written. If an *exit_status* operand is
92083 given and it is the unsigned decimal integer value of a signal number, the
92084 *signal_name* (the symbolic constant name without the **SIG** prefix defined in the
92085 Base Definitions volume of POSIX.1-200x) corresponding to that signal shall be
92086 written. Otherwise, the results are unspecified.

92087 **–s** *signal_name*

92088 Specify the signal to send, using one of the symbolic names defined in the
92089 **<signal.h>** header. Values of *signal_name* shall be recognized in a case-independent
92090 fashion, without the **SIG** prefix. In addition, the symbolic name 0 shall be
92091 recognized, representing the signal value zero. The corresponding signal shall be
92092 sent instead of SIGTERM.

92093 XSI *–signal_name*

92094 Equivalent to **–s** *signal_name*.

92095 XSI *–signal_number*

92096 Specify a non-negative decimal integer, *signal_number*, representing the signal to be
92097 used instead of SIGTERM, as the *sig* argument in the effective call to *kill*(). The
92098 correspondence between integer values and the *sig* value used is shown in the
92099 following list.

92100 The effects of specifying any *signal_number* other than those listed below are
92101 undefined.

0	0
1	SIGHUP
2	SIGINT
3	SIGQUIT
6	SIGABRT
9	SIGKILL
14	SIGALRM
15	SIGTERM

If the first argument is a negative integer, it shall be interpreted as a *–signal_number* option, not as a negative *pid* operand specifying a process group.

OPERANDS

The following operands shall be supported:

pid One of the following:

1. A decimal integer specifying a process or process group to be signaled. The process or processes selected by positive, negative, and zero values of the *pid* operand shall be as described for the *kill*( ) function. If process number 0 is specified, all processes in the current process group shall be signaled. For the effects of negative *pid* numbers, see the *kill*( ) function defined in the System Interfaces volume of POSIX.1-200x. If the first *pid* operand is negative, it should be preceded by "−−" to keep it from being interpreted as an option.
2. A job control job ID (see XBD Section 3.203, on page 65) that identifies a background process group to be signaled. The job control job ID notation is applicable only for invocations of *kill* in the current shell execution environment; see Section 2.12 (on page 2331).

exit_status A decimal integer specifying a signal number or the exit status of a process terminated by a signal.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *kill*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

When the **–l** option is not specified, the standard output shall not be used.

When the **–l** option is specified, the symbolic name of each signal shall be written in the following format:

```
"%s%c", <signal_name>, <separator>
```

where the <*signal_name*> is in uppercase, without the **SIG** prefix, and the <*separator*> shall be either a <newline> or a <space>. For the last signal written, <*separator*> shall be a <newline>.

When both the **–l** option and *exit_status* operand are specified, the symbolic name of the corresponding signal shall be written in the following format:

```
"%s\n", <signal_name>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 At least one matching process was found for each *pid* operand, and the specified signal was successfully processed for at least one matching process.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Process numbers can be found by using *ps*.

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not share the shell's understanding of job numbers.

EXAMPLES

Any of the commands:

```
kill –9 100 –165
kill –s kill 100 –165
```

```
kill –s KILL 100 –165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

The System Interfaces volume of POSIX.1-200x and this volume of POSIX.1-200x do not require specific signal numbers for any *signal_names*. Even the *–signal_number* option provides symbolic (although numeric) names for signals. If a process is terminated by a signal, its exit status indicates the signal that killed it, but the exact values are not specified. The *kill* **–l** option, however, can be used to map decimal signal numbers and exit status values into the name of a signal. The following example reports the status of a terminated job:

```
job
stat=$?
if [ $stat –eq 0 ]
then
    echo job completed successfully.
elif [ $stat –gt 128 ]
then
    echo job terminated by signal SIG$(kill –l $stat).
else
    echo job terminated with error code $stat.
fi
```

To send the default signal to a process group (say 123), an application should use a command similar to one of the following:

```
kill –TERM –123
kill –– –123
```

RATIONALE

The **–l** option originated from the C shell, and is also implemented in the KornShell. The C shell output can consist of multiple output lines because the signal names do not always fit on a single line on some terminal screens. The KornShell output also included the implementation-defined signal numbers and was considered by the standard developers to be too difficult for scripts to parse conveniently. The specified output format is intended not only to accommodate the historical C shell output, but also to permit an entirely vertical or entirely horizontal listing on systems for which this is appropriate.

An early proposal invented the name SIGNULL as a *signal_name* for signal 0 (used by the System Interfaces volume of POSIX.1-200x to test for the existence of a process without sending it a signal). Since the *signal_name* 0 can be used in this case unambiguously, SIGNULL has been removed.

An early proposal also required symbolic *signal_name*s to be recognized with or without the **SIG** prefix. Historical versions of *kill* have not written the **SIG** prefix for the **–l** option and have not recognized the **SIG** prefix on *signal_name*s. Since neither applications portability nor ease-of-use would be improved by requiring this extension, it is no longer required.

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, POSIX.1-200x mandates that it is always considered the former by implementations that support the XSI option. It also requires that conforming applications always use the "––" options terminator argument when specifying a process group, unless an option is also specified.

The **–s** option was added in response to international interest in providing some form of *kill* that

meets the Utility Syntax Guidelines.

The job control job ID notation is not required to work as expected when *kill* is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the *kill* operates in a different environment and does not understand how the shell has managed its job numbers.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The obsolescent versions of the SYNOPSIS are turned into non-obsolescent features of the XSI option, corresponding to a similar change in the *trap* special built-in.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

92251 **NAME**

92252 lex — generate programs for lexical tasks (**DEVELOPMENT**)

92253 **SYNOPSIS**

92254 CD

```
lex [–t] [–n|–v] [file...]
```

92255 **DESCRIPTION**

92256 The *lex* utility shall generate C programs to be used in lexical processing of character input, and
92257 that can be used as an interface to *yacc*. The C programs shall be generated from *lex* source code
92258 and conform to the ISO C standard, without depending on any undefined, unspecified, or
92259 implementation-defined behavior, except in cases where the code is copied directly from the
92260 supplied source, or in cases that are documented by the implementation. Usually, the *lex* utility
92261 shall write the program it generates to the file **lex.yy.c**; the state of this file is unspecified if *lex*
92262 exits with a non-zero exit status. See the EXTENDED DESCRIPTION section for a complete
92263 description of the *lex* input language.

92264 **OPTIONS**

92265 The *lex* utility shall conform to XBD Section 12.2 (on page 215), except for Guideline 9.

92266 The following options shall be supported:

92267 **–n** Suppress the summary of statistics usually written with the **–v** option. If no table
92268 sizes are specified in the *lex* source code and the **–v** option is not specified, then **–n**
92269 is implied.

92270 **–t** Write the resulting program to standard output instead of **lex.yy.c**.

92271 **–v** Write a summary of *lex* statistics to the standard output. (See the discussion of *lex*
92272 table sizes in Definitions in lex (on page 2828).) If the **–t** option is specified and **–n**
92273 is not specified, this report shall be written to standard error. If table sizes are
92274 specified in the *lex* source code, and if the **–n** option is not specified, the **–v** option
92275 may be enabled.

92276 **OPERANDS**

92277 The following operand shall be supported:

92278 *file* A pathname of an input file. If more than one such *file* is specified, all files shall be
92279 concatenated to produce a single *lex* program. If no *file* operands are specified, or if
92280 a *file* operand is `'–'`, the standard input shall be used.

92281 **STDIN**

92282 The standard input shall be used if no *file* operands are specified, or if a *file* operand is `'–'`. See
92283 INPUT FILES.

92284 **INPUT FILES**

92285 The input files shall be text files containing *lex* source code, as described in the EXTENDED
92286 DESCRIPTION section.

92287 **ENVIRONMENT VARIABLES**

92288 The following environment variables shall affect the execution of *lex*:

92289 *LANG* Provide a default value for the internationalization variables that are unset or null.
92290 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
92291 variables used to determine the values of locale categories.)

92292 *LC_ALL* If set to a non-empty string value, override the values of all the other
92293 internationalization variables.

92294 *LC_COLLATE*
92295 Determine the locale for the behavior of ranges, equivalence classes, and multi-
92296 character collating elements within regular expressions. If this variable is not set to
92297 the POSIX locale, the results are unspecified.

92298 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
92299 characters (for example, single-byte as opposed to multi-byte characters in
92300 arguments and input files), and the behavior of character classes within regular
92301 expressions. If this variable is not set to the POSIX locale, the results are
92302 unspecified.

92303 *LC_MESSAGES*
92304 Determine the locale that should be used to affect the format and contents of
92305 diagnostic messages written to standard error.

92306 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92307 **ASYNCHRONOUS EVENTS**
92308 Default.

92309 **STDOUT**
92310 If the **–t** option is specified, the text file of C source code output of *lex* shall be written to
92311 standard output.

92312 If the **–t** option is not specified:

92313 • Implementation-defined informational, error, and warning messages concerning the
92314 contents of *lex* source code input shall be written to either the standard output or standard
92315 error.

92316 • If the **–v** option is specified and the **–n** option is not specified, *lex* statistics shall also be
92317 written to either the standard output or standard error, in an implementation-defined
92318 format. These statistics may also be generated if table sizes are specified with a `'%'`
92319 operator in the *Definitions* section, as long as the **–n** option is not specified.

92320 **STDERR**
92321 If the **–t** option is specified, implementation-defined informational, error, and warning messages
92322 concerning the contents of *lex* source code input shall be written to the standard error.

92323 If the **–t** option is not specified:

92324 1. Implementation-defined informational, error, and warning messages concerning the
92325 contents of *lex* source code input shall be written to either the standard output or
92326 standard error.

92327 2. If the **–v** option is specified and the **–n** option is not specified, *lex* statistics shall also be
92328 written to either the standard output or standard error, in an implementation-defined
92329 format. These statistics may also be generated if table sizes are specified with a `'%'`
92330 operator in the *Definitions* section, as long as the **–n** option is not specified.

92331 **OUTPUT FILES**
92332 A text file containing C source code shall be written to **lex.yy.c**, or to the standard output if the **–t**
92333 option is present.

92334 **EXTENDED DESCRIPTION**
92335 Each input file shall contain *lex* source code, which is a table of regular expressions with
92336 corresponding actions in the form of C program fragments.

92337 When **lex.yy.c** is compiled and linked with the *lex* library (using the **–ll** operand with *c99*), the

resulting program shall read character input from the standard input and shall partition it into strings that match the given expressions.

When an expression is matched, these actions shall occur:

- The input string that was matched shall be left in *yytext* as a null-terminated string; *yytext* shall either be an external character array or a pointer to a character string. As explained in Definitions in lex (on page 2828), the type can be explicitly selected using the **%array** or **%pointer** declarations, but the default is implementation-defined.
- The external **int** *yyleng* shall be set to the length of the matching string.
- The expression's corresponding program fragment, or action, shall be executed.

During pattern matching, *lex* shall search the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first shall be chosen.

The general format of *lex* source shall be:

Definitions
%%
Rules
%%
*User*Subroutines

The first "%%" is required to mark the beginning of the rules (regular expressions and actions); the second "%%" is required only if user subroutines follow.

Any line in the *Definitions* section beginning with a <blank> shall be assumed to be a C program fragment and shall be copied to the external definition area of the **lex.yy.c** file. Similarly, anything in the *Definitions* section included between delimiter lines containing only "%{" and "%}" shall also be copied unchanged to the external definition area of the **lex.yy.c** file.

Any such input (beginning with a <blank> or within "%{" and "%}" delimiter lines) appearing at the beginning of the *Rules* section before any rules are specified shall be written to **lex.yy.c** after the declarations of variables for the *yylex*() function and before the first line of code in *yylex*(). Thus, user variables local to *yylex*() can be declared here, as well as application code to execute upon entry to *yylex*().

The action taken by *lex* when encountering any input beginning with a <blank> or within "%{" and "%}" delimiter lines appearing in the *Rules* section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the *yylex*() function.

C-language code in the input shall not contain C-language trigraphs. The C-language code within "%{" and "%}" delimiter lines shall not contain any lines consisting only of "%}", or only of "%%".

92374 **Definitions in lex**

92375 *Definitions* appear before the first "%%" delimiter. Any line in this section not contained between
92376 "%{" and "%}" lines and not beginning with a <blank> shall be assumed to define a *lex*
92377 substitution string. The format of these lines shall be:

92378 `name substitute`

92379 If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is
92380 undefined. The string *substitute* shall replace the string {*name*} when it is used in a rule. The *name*
92381 string shall be recognized in this context only when the braces are provided and when it does
92382 not appear within a bracket expression or within double-quotes.

92383 In the *Definitions* section, any line beginning with a <percent-sign> ('%') character and followed
92384 by an alphanumeric word beginning with either 's' or 'S' shall define a set of start conditions.
92385 Any line beginning with a '%' followed by a word beginning with either 'x' or 'X' shall
92386 define a set of exclusive start conditions. When the generated scanner is in a %s state, patterns
92387 with no state specified shall be also active; in a %x state, such patterns shall not be active. The
92388 rest of the line, after the first word, shall be considered to be one or more <blank>-separated
92389 names of start conditions. Start condition names shall be constructed in the same way as
92390 definition names. Start conditions can be used to restrict the matching of regular expressions to
92391 one or more states as described in Regular Expressions in lex (on page 2829).

92392 Implementations shall accept either of the following two mutually-exclusive declarations in the
92393 *Definitions* section:

92394 **%array** Declare the type of *yytext* to be a null-terminated character array.

92395 **%pointer** Declare the type of *yytext* to be a pointer to a null-terminated character string.

92396 The default type of *yytext* is implementation-defined. If an application refers to *yytext* outside of
92397 the scanner source file (that is, via an **extern**), the application shall include the appropriate
92398 **%array** or **%pointer** declaration in the scanner source file.

92399 Implementations shall accept declarations in the *Definitions* section for setting certain internal
92400 table sizes. The declarations are shown in the following table.

92401 **Table 4-10** Table Size Declarations in *lex*

92402

Declaration	Description	Minimum Value
92403 %**p** *n*	Number of positions	2 500
92404 %**n** *n*	Number of states	500
92405 %**a** *n*	Number of transitions	2 000
92406 %**e** *n*	Number of parse tree nodes	1 000
92407 %**k** *n*	Number of packed character classes	1 000
92408 %**o** *n*	Size of the output array	3 000

92409 In the table, *n* represents a positive decimal integer, preceded by one or more <blank>
92410 characters. The exact meaning of these table size numbers is implementation-defined. The
92411 implementation shall document how these numbers affect the *lex* utility and how they are
92412 related to any output that may be generated by the implementation should limitations be
92413 encountered during the execution of *lex*. It shall be possible to determine from this output
92414 which of the table size values needs to be modified to permit *lex* to successfully generate tables
92415 for the input language. The values in the column Minimum Value represent the lowest values
92416 conforming implementations shall provide.

Rules in lex

The rules in *lex* source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

```
ERE action
ERE action
...
```

The extended regular expression (ERE) portion of a row shall be separated from *action* by one or more <blank> characters. A regular expression containing <blank> characters shall be recognized under one of the following conditions:

- The entire expression appears within double-quotes.
- The <blank> characters appear within double-quotes or square brackets.
- Each <blank> is preceded by a <backslash> character.

User Subroutines in lex

Anything in the user subroutines section shall be copied to **lex.yy.c** following *yylex*( ).

Regular Expressions in lex

The *lex* utility shall support the set of extended regular expressions (see XBD Section 9.4, on page 188), with the following additions and exceptions to the syntax:

`"..."` Any string enclosed in double-quotes shall represent the characters within the double-quotes as themselves, except that <backslash>-escapes (which appear in the following table) shall be recognized. Any <backslash>-escape sequence shall be terminated by the closing quote. For example, `"\01""1"` represents a single string: the octal value 1 followed by the character `'1'`.

<state>r, *<state1,state2,...>r*
The regular expression *r* shall be matched only when the program is in one of the start conditions indicated by *state*, *state1*, and so on; see Actions in lex (on page 2831). (As an exception to the typographical conventions of the rest of this volume of POSIX.1-200x, in this case *<state>* does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition shall be recognized as such only at the beginning of a regular expression.

r/*x* The regular expression *r* shall be matched only if it is followed by an occurrence of regular expression *x* (*x* is the instance of trailing context, further defined below). The token returned in *yytext* shall only match *r*. If the trailing portion of *r* matches the beginning of *x*, the result is unspecified. The *r* expression cannot include further trailing context or the `'$'` (match-end-of-line) operator; *x* cannot include the `'^'` (match-beginning-of-line) operator, nor trailing context, nor the `'$'` operator. That is, only one occurrence of trailing context is allowed in a *lex* regular expression, and the `'^'` operator only can be used at the beginning of such an expression.

{*name*} When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, shall be replaced by the *substitute* value. The *substitute* value shall be treated in the extended regular expression as if it were enclosed in parentheses. No substitution shall occur if {*name*} occurs within a bracket expression or within double-quotes.

Within an ERE, a <backslash> character shall be considered to begin an escape sequence as specified in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`). In addition, the escape sequences in the following table shall be recognized.

A literal <newline> cannot occur within an ERE; the escape sequence `'\n'` can be used to represent a <newline>. A <newline> shall not be matched by a period operator.

Table 4-11 Escape Sequences in *lex*

Escape Sequence	Description	Meaning
`\`*`digits`*	A <backslash> character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one, two, or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <backslash> for each byte.
`\x`*`digits`*	A <backslash> character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the hexadecimal integer.
`\c`	A <backslash> character followed by any character not described in this table or in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`).	The character `'c'`, unchanged.

Note: If a `'\x'` sequence needs to be immediately followed by a hexadecimal digit character, a sequence such as `"\x1""1"` can be used, which represents a character containing the value 1, followed by the character `'1'`.

The order of precedence given to extended regular expressions for *lex* differs from that specified in XBD Section 9.4 (on page 188). The order of precedence for *lex* shall be as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context, and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

92499 **Table 4-12** ERE Precedence in *lex*

92500

Extended Regular Expression	Precedence
collation-related bracket symbols	`[= =]  [: :]  [. .]`
escaped characters	`\<special character>`
bracket expression	`[ ]`
quoting	`"..."`
grouping	`( )`
definition	`{name}`
single-character RE duplication	`* + ?`
concatenation	
interval expression	`{m,n}`
alternation	`|`

92511 The ERE anchoring operators '^' and '$' do not appear in the table. With *lex* regular
92512 expressions, these operators are restricted in their use: the '^' operator can only be used at the
92513 beginning of an entire regular expression, and the '$' operator only at the end. The operators
92514 apply to the entire regular expression. Thus, for example, the pattern "(^abc)|(def$)" is
92515 undefined; it can instead be written as two separate rules, one with the regular expression
92516 "^abc" and one with "def$", which share a common action via the special '|' action (see
92517 below). If the pattern were written "^abc|def$", it would match either "abc" or "def" on a
92518 line by itself.

92519 Unlike the general ERE rules, embedded anchoring is not allowed by most historical *lex*
92520 implementations. An example of embedded anchoring would be for patterns such as
92521 "(^|)foo(|$)" to match "foo" when it exists as a complete word. This functionality can
92522 be obtained using existing *lex* features:

```
92523 ^foo/[ \n]      |
92524 " foo"/[ \n]    /* Found foo as a separate word. */
```

92525 Note also that '$' is a form of trailing context (it is equivalent to "/\n") and as such cannot be
92526 used with regular expressions containing another instance of the operator (see the preceding
92527 discussion of trailing context).

92528 The additional regular expressions trailing-context operator '/' can be used as an ordinary
92529 character if presented within double-quotes, "/"; preceded by a <backslash>, "\/"; or within a
92530 bracket expression, "[/]". The start-condition '<' and '>' operators shall be special only in a
92531 start condition at the beginning of a regular expression; elsewhere in the regular expression they
92532 shall be treated as ordinary characters.

92533 **Actions in lex**

92534 The action to be taken when an ERE is matched can be a C program fragment or the special
92535 actions described below; the program fragment can contain one or more C statements, and can
92536 also include special actions. The empty C statement ';' shall be a valid action; any string in the
92537 **lex.yy.c** input that matches the pattern portion of such a rule is effectively ignored or skipped.
92538 However, the absence of an action shall not be valid, and the action *lex* takes in such a condition
92539 is undefined.

92540 The specification for an action, including C statements and special actions, can extend across
92541 several lines if enclosed in braces:

```
92542 ERE <one or more blanks> { program statement
92543                             program statement }
```

The program statements shall not contain unbalanced curly brace preprocessing tokens.

The default action when a string in the input to a **lex.yy.c** program is not matched by any expression shall be to copy the string to the output. Because the default behavior of a program generated by *lex* is to read the input and copy it to the output, a minimal *lex* source program that has just `"%%"` shall generate a C program that simply copies the input to the output unchanged.

Four special actions shall be available:

`|  ECHO;  REJECT;  BEGIN`

`|` The action `'|'` means that the action for the next rule is the action for this rule. Unlike the other three actions, `'|'` cannot be enclosed in braces or be <semicolon>-terminated; the application shall ensure that it is specified alone, with no other actions.

ECHO; Write the contents of the string *yytext* on the output.

REJECT; Usually only a single expression is matched by a given string in the input. **REJECT** means "continue to the next expression that matches the current input", and shall cause whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions `"xyz"` and `"xy"` and the input `"xyz"`, usually only the regular expression `"xyz"` would match. The next attempted match would start after **z.** If the last action in the `"xyz"` rule is **REJECT**, both this rule and the `"xy"` rule would be executed. The **REJECT** action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a **goto** to another part of *yylex*(). The use of **REJECT** may result in somewhat larger and slower scanners.

BEGIN The action:

`BEGIN` *`newstate`*`;`

switches the state (start condition) to *newstate*. If the string *newstate* has not been declared previously as a start condition in the *Definitions* section, the results are unspecified. The initial state is indicated by the digit `'0'` or the token **INITIAL**.

The functions or macros described below are accessible to user code included in the *lex* input. It is unspecified whether they appear in the C code output of *lex*, or are accessible only through the **–l l** operand to *c99* (the *lex* library).

int *yylex*(**void**)
Performs lexical analysis on the input; this is the primary function generated by the *lex* utility. The function shall return zero when the end of input is reached; otherwise, it shall return non-zero values (tokens) determined by the actions that are selected.

int *yymore*(**void**)
When called, indicates that when the next input string is recognized, it is to be appended to the current value of *yytext* rather than replacing it; the value in *yyleng* shall be adjusted accordingly.

int *yyless*(**int** *n*)
Retains *n* initial characters in *yytext*, NUL-terminated, and treats the remaining characters as if they had not been read; the value in *yyleng* shall be adjusted accordingly.

92587 **int** *input*(**void**)
92588 Returns the next character from the input, or zero on end-of-file. It shall obtain input from
92589 the stream pointer *yyin*, although possibly via an intermediate buffer. Thus, once scanning
92590 has begun, the effect of altering the value of *yyin* is undefined. The character read shall be
92591 removed from the input stream of the scanner without any processing by the scanner.

92592 **int** *unput*(**int** *c*)
92593 Returns the character `'c'` to the input; *yytext* and *yyleng* are undefined until the next
92594 expression is matched. The result of using *unput*( ) for more characters than have been input
92595 is unspecified.

92596 The following functions shall appear only in the *lex* library accessible through the **–l l** operand;
92597 they can therefore be redefined by a conforming application:

92598 **int** *yywrap*(**void**)
92599 Called by *yylex*( ) at end-of-file; the default *yywrap*( ) shall always return 1. If the application
92600 requires *yylex*( ) to continue processing with another source of input, then the application
92601 can include a function *yywrap*( ), which associates another file with the external variable
92602 **FILE** * *yyin* and shall return a value of zero.

92603 **int** *main*(**int** *argc*, **char** **argv*[ ])
92604 Calls *yylex*( ) to perform lexical analysis, then exits. The user code can contain *main*( ) to
92605 perform application-specific operations, calling *yylex*( ) as applicable.

92606 Except for *input*( ), *unput*( ), and *main*( ), all external and static names generated by *lex* shall begin
92607 with the prefix **yy** or **YY**.

92608 **EXIT STATUS**
92609 The following exit values shall be returned:

92610 0 Successful completion.

92611 >0 An error occurred.

92612 **CONSEQUENCES OF ERRORS**
92613 Default.

92614 **APPLICATION USAGE**
92615 Conforming applications are warned that in the *Rules* section, an ERE without an action is not
92616 acceptable, but need not be detected as erroneous by *lex*. This may result in compilation or
92617 runtime errors.

92618 The purpose of *input*( ) is to take characters off the input stream and discard them as far as the
92619 lexical analysis is concerned. A common use is to discard the body of a comment once the
92620 beginning of a comment is recognized.

92621 The *lex* utility is not fully internationalized in its treatment of regular expressions in the *lex*
92622 source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer
92623 interpret the regular expressions given in the *lex* source according to the environment specified
92624 when the lexical analyzer is executed, but this is not possible with the current *lex* technology.
92625 Furthermore, the very nature of the lexical analyzers produced by *lex* must be closely tied to the
92626 lexical requirements of the input language being described, which is frequently locale-specific
92627 anyway. (For example, writing an analyzer that is used for French text is not automatically
92628 useful for processing other languages.)

EXAMPLES

The following is an example of a *lex* program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* Need this for the call to atof() below. */
#include <math.h>
/* Need this for printf(), fopen(), and stdin below. */
#include <stdio.h>
%}

DIGIT    [0-9]
ID       [a-z][a-z0-9]*

%%

{DIGIT}+ {
    printf("An integer: %s (%d)\n", yytext,
        atoi(yytext));
    }

{DIGIT}+"."{DIGIT}*        {
    printf("A float: %s (%g)\n", yytext,
        atof(yytext));
    }

if|then|begin|end|procedure|function        {
    printf("A keyword: %s\n", yytext);
    }

{ID}    printf("An identifier: %s\n", yytext);

"+"|"-"|"*"|"/"        printf("An operator: %s\n", yytext);

"{"[^}\n]*"}"    /* Eat up one-line comments. */

[ \t\n]+          /* Eat up white space. */

.  printf("Unrecognized character: %s\n", yytext);

%%

int main(int argc, char *argv[])
{
    ++argv, --argc;  /* Skip over program name. */
    if (argc > 0)
        yyin = fopen(argv[0], "r");
    else
        yyin = stdin;

    yylex();
}
```

RATIONALE

Even though the **-c** option and references to the C language are retained in this description, *lex* may be generalized to other languages, as was done at one time for EFL, the Extended FORTRAN Language. Since the *lex* input specification is essentially language-independent, versions of this utility could be written to produce Ada, Modula-2, or Pascal code, and there are known historical implementations that do so.

The current description of *lex* bypasses the issue of dealing with internationalized EREs in the *lex* source code or generated lexical analyzer. If it follows the model used by *awk* (the source code is assumed to be presented in the POSIX locale, but input and output are in the locale specified by the environment variables), then the tables in the lexical analyzer produced by *lex* would interpret EREs specified in the *lex* source in terms of the environment variables specified when *lex* was executed. The desired effect would be to have the lexical analyzer interpret the EREs given in the *lex* source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current *lex* technology.

The description of octal and hexadecimal-digit escape sequences agrees with the ISO C standard use of escape sequences.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

There is no detailed output format specification. The observed behavior of *lex* under four different historical implementations was that none of these implementations consistently reported the line numbers for error and warning messages. Furthermore, there was a desire that *lex* be allowed to output additional diagnostic messages. Leaving message formats unspecified avoids these formatting questions and problems with internationalization.

Although the %x specifier for *exclusive* start conditions is not historical practice, it is believed to be a minor change to historical implementations and greatly enhances the usability of *lex* programs since it permits an application to obtain the expected functionality with fewer statements.

The **%array** and **%pointer** declarations were added as a compromise between historical systems. The System V-based *lex* copies the matched text to a *yytext* array. The *flex* program, supported in BSD and GNU systems, uses a pointer. In the latter case, significant performance improvements are available for some scanners. Most historical programs should require no change in porting from one system to another because the string being referenced is null-terminated in both cases. (The method used by *flex* in its case is to null-terminate the token in place by remembering the character that used to come right after the token and replacing it before continuing on to the next scan.) Multi-file programs with external references to *yytext* outside the scanner source file should continue to operate on their historical systems, but would require one of the new declarations to be considered strictly portable.

The description of EREs avoids unnecessary duplication of ERE details because their meanings within a *lex* ERE are the same as that for the ERE in this volume of POSIX.1-200x.

The reason for the undefined condition associated with text beginning with a <blank> or within "%{" and "%}" delimiter lines appearing in the *Rules* section is historical practice. Both the BSD and System V *lex* copy the indented (or enclosed) input in the *Rules* section (except at the beginning) to unreachable areas of the *yylex*() function (the code is written directly after a *break* statement). In some cases, the System V *lex* generates an error message or a syntax error, depending on the form of indented input.

The intention in breaking the list of functions into those that may appear in **lex.yy.c** *versus* those that only appear in **libl.a** is that only those functions in **libl.a** can be reliably redefined by a conforming application.

The descriptions of standard output and standard error are somewhat complicated because historical *lex* implementations chose to issue diagnostic messages to standard output (unless **–t** was given). POSIX.1-200x allows this behavior, but leaves an opening for the more expected behavior of using standard error for diagnostics. Also, the System V behavior of writing the statistics when any table sizes are given is allowed, while BSD-derived systems can avoid it. The

programmer can always precisely obtain the desired results by using either the **–t** or **–n** options.

The OPERANDS section does not mention the use of – as a synonym for standard input; not all historical implementations support such usage for any of the *file* operands.

A description of the *translation table* was deleted from early proposals because of its relatively low usage in historical applications.

The change to the definition of the *input*() function that allows buffering of input presents the opportunity for major performance gains in some applications.

The following examples clarify the differences between *lex* regular expressions and regular expressions appearing elsewhere in this volume of POSIX.1-200x. For regular expressions of the form `"r/x"`, the string matching *r* is always returned; confusion may arise when the beginning of *x* matches the trailing portion of *r*. For example, given the regular expression `"a*b/cc"` and the input `"aaabcc"`, *yytext* would contain the string `"aaab"` on this match. But given the regular expression `"x*/xy"` and the input `"xxxy"`, the token **xxx**, not **xx**, is returned by some implementations because **xxx** matches `"x*"`.

In the rule `"ab*/bc"`, the `"b*"` at the end of *r* extends *r*'s match into the beginning of the trailing context, so the result is unspecified. If this rule were `"ab/bc"`, however, the rule matches the text `"ab"` when it is followed by the text `"bc"`. In this latter case, the matching of *r* cannot extend into the beginning of *x*, so the result is specified.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the C-Language Development Utilities option.

The obsolescent **–c** option is removed.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/14 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #190 is applied, clarifying the requirements for generated code to conform to the ISO C standard.

Austin Group Interpretation 1003.1-2001 #191 is applied, clarifying the handling of C-language trigraphs and curly brace preprocessing tokens.

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

92760 **NAME**

92761 link — call *link*( ) function

92762 **SYNOPSIS**

92763 XSI
```
link file1 file2
```

92764 **DESCRIPTION**

92765 The *link* utility shall perform the function call:

92766
```
link(file1, file2);
```

92767 A user may need appropriate privileges to invoke the *link* utility.

92768 **OPTIONS**

92769 None.

92770 **OPERANDS**

92771 The following operands shall be supported:

92772 *file1* The pathname of an existing file.

92773 *file2* The pathname of the new directory entry to be created.

92774 **STDIN**

92775 Not used.

92776 **INPUT FILES**

92777 Not used.

92778 **ENVIRONMENT VARIABLES**

92779 The following environment variables shall affect the execution of *link*:

92780 92781 92782 *LANG* Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

92783 92784 *LC_ALL* If set to a non-empty string value, override the values of all the other internationalization variables.

92785 92786 92787 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

92788 92789 92790 *LC_MESSAGES* Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

92791 *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92792 **ASYNCHRONOUS EVENTS**

92793 Default.

92794 **STDOUT**

92795 None.

92796 **STDERR**

92797 The standard error shall be used only for diagnostic messages.

92798 **OUTPUT FILES**

92799 None.

92800 **EXTENDED DESCRIPTION**

92801 None.

92802 **EXIT STATUS**

92803 The following exit values shall be returned:

92804 0 Successful completion.

92805 >0 An error occurred.

92806 **CONSEQUENCES OF ERRORS**

92807 Default.

92808 **APPLICATION USAGE**

92809 None.

92810 **EXAMPLES**

92811 None.

92812 **RATIONALE**

92813 None.

92817 *ln*, *unlink*

92818 XBD Chapter 8 (on page 173)

92819 XSH *link*( )

92820 **CHANGE HISTORY**

92821 First released in Issue 5.

92822 **NAME**

92823 ln — link files

92824 **SYNOPSIS**

92825 `ln [-fs] [-L|-P] source_file target_file`

92826 `ln [-fs] [-L|-P] source_file... target_dir`

92827 **DESCRIPTION**

92828 In the first synopsis form, the *ln* utility shall create a new directory entry (link) at the destination
92829 path specified by the *target_file* operand. If the **-s** option is specified, a symbolic link shall be
92830 created for the file specified by the *source_file* operand. This first synopsis form shall be assumed
92831 when the final operand does not name an existing directory; if more than two operands are
92832 specified and the final is not an existing directory, an error shall result.

92833 In the second synopsis form, the *ln* utility shall create a new directory entry (link), or if the **-s**
92834 option is specified a symbolic link, for each file specified by a *source_file* operand, at a
92835 destination path in the existing directory named by *target_dir*.

92836 If the last operand specifies an existing file of a type not specified by the System Interfaces
92837 volume of POSIX.1-200x, the behavior is implementation-defined.

92838 The corresponding destination path for each *source_file* shall be the concatenation of the target
92839 directory pathname, a <slash> character if the target directory pathname did not end in a
92840 <slash>, and the last pathname component of the *source_file*. The second synopsis form shall be
92841 assumed when the final operand names an existing directory.

92842 For each *source_file*:

92843 1. If the destination path exists and was created by a previous step, it is unspecified whether
92844 *ln* shall write a diagnostic message to standard error, do nothing more with the current
92845 *source_file*, and go on to any remaining *source_file*s; or will continue processing the current
92846 *source_file*. If the destination path exists:

92847 a. If the **-f** option is not specified, *ln* shall write a diagnostic message to standard
92848 error, do nothing more with the current *source_file*, and go on to any remaining
92849 *source_file*s.

92850 b. If *destination* names the same directory entry as the current *source_file* *ln* shall write
92851 a diagnostic message to standard error, do nothing more with the current
92852 *source_file*, and go on to any remaining *source_file*s.

92853 c. Actions shall be performed equivalent to the *unlink*() function defined in the
92854 System Interfaces volume of POSIX.1-200x, called using *destination* as the *path*
92855 argument. If this fails for any reason, *ln* shall write a diagnostic message to
92856 standard error, do nothing more with the current *source_file*, and go on to any
92857 remaining *source_file*s.

92858 2. If the **-s** option is specified, *ln* shall create a symbolic link named by the destination path
92859 and containing as its pathname *source_file*. The *ln* utility shall do nothing more with
92860 *source_file* and shall go on to any remaining files.

92861 3. If *source_file* is a symbolic link:

92862 a. If the **-P** option is in effect, actions shall be performed equivalent to the *linkat*()
92863 function with *source_file* as the *path1* argument, the destination path as the *path2*
92864 argument, AT_FDCWD as the *fd1* and *fd2* arguments, and zero as the *flag*
92865 argument.

b. If the **–L** option is in effect, actions shall be performed equivalent to the *linkat*() function with *source_file* as the *path1* argument, the destination path as the *path2* argument, AT_FDCWD as the *fd1* and *fd2* arguments, and AT_SYMLINK_FOLLOW as the *flag* argument.

The *ln* utility shall do nothing more with *source_file* and shall go on to any remaining files.

4. Actions shall be performed equivalent to the *link*() function defined in the System Interfaces volume of POSIX.1-200x using *source_file* as the *path1* argument, and the destination path as the *path2* argument.

OPTIONS

The *ln* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–f Force existing destination pathnames to be removed to allow the link.

–L For each *source_file* operand that names a file of type symbolic link, create a (hard) link to the file referenced by the symbolic link.

–P For each *source_file* operand that names a file of type symbolic link, create a (hard) link to the symbolic link itself.

–s Create symbolic links instead of hard links. If the **–s** option is specified, the **–L** and **–P** options shall be silently ignored.

Specifying more than one of the mutually-exclusive options **–L** and **–P** shall not be considered an error. The last option specified shall determine the behavior of the utility (unless the **–s** option causes it to be ignored).

If the **–s** option is not specified and neither a **–L** nor a **–P** option is specified, it is implementation-defined which of the **–L** and **–P** options will be used as the default.

OPERANDS

The following operands shall be supported:

source_file A pathname of a file to be linked. If the **–s** option is specified, no restrictions on the type of file or on its existence shall be made. If the **–s** option is not specified, whether a directory can be linked is implementation-defined.

target_file The pathname of the new directory entry to be created.

target_dir A pathname of an existing directory in which the new directory entries are created.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *ln*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

92907 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
92908 characters (for example, single-byte as opposed to multi-byte characters in
92909 arguments).

92910 *LC_MESSAGES*
92911 Determine the locale that should be used to affect the format and contents of
92912 diagnostic messages written to standard error.

92913 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

92914 **ASYNCHRONOUS EVENTS**
92915 Default.

92916 **STDOUT**
92917 Not used.

92918 **STDERR**
92919 The standard error shall be used only for diagnostic messages.

92920 **OUTPUT FILES**
92921 None.

92922 **EXTENDED DESCRIPTION**
92923 None.

92924 **EXIT STATUS**
92925 The following exit values shall be returned:

92926 0 All the specified files were linked successfully.

92927 >0 An error occurred.

92928 **CONSEQUENCES OF ERRORS**
92929 Default.

92930 **APPLICATION USAGE**
92931 None.

92932 **EXAMPLES**
92933 None.

92934 **RATIONALE**
92935 The CONSEQUENCES OF ERRORS section does not require *ln* **−f** *a b* to remove *b* if a
92936 subsequent link operation would fail.

92937 Some historic versions of *ln* (including the one specified by the SVID) unlink the destination file,
92938 if it exists, by default. If the mode does not permit writing, these versions prompt for
92939 confirmation before attempting the unlink. In these versions the **−f** option causes *ln* not to
92940 attempt to prompt for confirmation.

92941 This allows *ln* to succeed in creating links when the target file already exists, even if the file itself
92942 is not writable (although the directory must be). Early proposals specified this functionality.

92943 This volume of POSIX.1-200x does not allow the *ln* utility to unlink existing destination paths by
92944 default for the following reasons:

92945 • The *ln* utility has historically been used to provide locking for shell applications, a usage
92946 that is incompatible with *ln* unlinking the destination path by default. There was no
92947 corresponding technical advantage to adding this functionality.

- This functionality gave *ln* the ability to destroy the link structure of files, which changes the historical behavior of *ln*.
- This functionality is easily replicated with a combination of *rm* and *ln*.
- It is not historical practice in many systems; BSD and BSD-derived systems do not support this behavior. Unfortunately, whichever behavior is selected can cause scripts written expecting the other behavior to fail.
- It is preferable that *ln* perform in the same manner as the *link*( ) function, which does not permit the target to exist already.

This volume of POSIX.1-200x retains the **–f** option to provide support for shell scripts depending on the SVID semantics. It seems likely that shell scripts would not be written to handle prompting by *ln* and would therefore have specified the **–f** option.

The **–f** option is an undocumented feature of many historical versions of the *ln* utility, allowing linking to directories. These versions require modification.

Early proposals of this volume of POSIX.1-200x also required a **–i** option, which behaved like the **–i** options in *cp* and *mv*, prompting for confirmation before unlinking existing files. This was not historical practice for the *ln* utility and has been omitted.

The **–L** and **–P** options allow for implementing both common behaviors of the *ln* utility. Earlier versions of this standard did not specify these options and required the behavior now described for the **–L** option. Many systems by default or as an alternative provided a non-conforming *ln* utility with the behavior now described for the **–P** option. Since applications could not rely on *ln* following links in practice, the **–L** and **–P** options were added to specify the desired behavior for the application.

The **–L** and **–P** options are ignored when **–s** is specified in order to allow an alias to be created to alter the default behavior when creating hard links (for example, *alias ln='ln –L'*). They serve no purpose when **–s** is specified, since *source_file* is then just a string to be used as the contents of the created symbolic link and need not exist as a file.

The specification ensures that *ln* **a a** with or without the **–f** option will not unlink the file **a**. Earlier versions of this standard were unclear in this case.

FUTURE DIRECTIONS

None.

```

DESCRIPTION

The *locale* utility shall write information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a *public locale* is one provided by the implementation that is accessible to the application.

When *locale* is invoked without any arguments, it shall summarize the current locale environment for each locale category as determined by the settings of the environment variables defined in XBD Chapter 7 (on page 135).

When invoked with operands, it shall write values that have been assigned to the keywords in the locale categories, as follows:

- Specifying a keyword name shall select the named keyword and the category containing that keyword.
- Specifying a category name shall select the named category and all keywords in that category.

OPTIONS

The *locale* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

-a Write information about all available public locales. The available locales shall include **POSIX**, representing the POSIX locale. The manner in which the implementation determines what other locales are available is implementation-defined.

-c Write the names of selected locale categories; see the STDOUT section. The **-c** option increases readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the **-k** option.

-k Write the names and values of selected keywords. The implementation may omit values for some keywords; see the OPERANDS section.

-m Write names of available charmaps; see XBD Section 6.1 (on page 125).

OPERANDS

The following operand shall be supported:

name The name of a locale category as defined in XBD Chapter 7 (on page 135), the name of a keyword in a locale category, or the reserved name **charmap**. The named category or keyword shall be selected for output. If a single *name* represents both a locale category name and a keyword name in the current locale, the results are unspecified. Otherwise, both category and keyword names can be specified as *name* operands, in any sequence. It is implementation-defined whether any keyword values are written for the categories *LC_CTYPE* and *LC_COLLATE*.

93034 **STDIN**

93035 Not used.

93036 **INPUT FILES**

93037 None.

93038 **ENVIRONMENT VARIABLES**

93039 The following environment variables shall affect the execution of *locale*:

93040 93041 93042 *LANG* Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

93043 93044 *LC_ALL* If set to a non-empty string value, override the values of all the other internationalization variables.

93045 93046 93047 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

93048 93049 93050 *LC_MESSAGES* Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

93051 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

93052 XSI 93053 93054 The application shall ensure that the *LANG*, *LC_**, and *NLSPATH* environment variables specify the current locale environment to be written out; they shall be used if the **–a** option is not specified.

93055 **ASYNCHRONOUS EVENTS**

93056 Default.

93057 **STDOUT**

93058 The *LANG* variable shall be written first using the format:

93059 `"LANG=%s\n", <value>`

93060 If *LANG* is not set or is an empty string, the value is the empty string.

93061 93062 93063 93064 If *locale* is invoked without any options or operands, the names and values of the *LC_** environment variables described in this volume of POSIX.1-200x shall be written to the standard output, one variable per line, and each line using the following format. Only those variables set in the environment and not overridden by *LC_ALL* shall be written using this format:

93065 `"%s=%s\n", <variable_name>, <value>`

93066 93067 93068 The names of those *LC_** variables associated with locale categories defined in this volume of POSIX.1-200x that are not set in the environment or are overridden by *LC_ALL* shall be written in the following format:

93069 `"%s=\"%s\"\n", <variable_name>, <implied value>`

93070 93071 93072 The <*implied value*> shall be the name of the locale that has been selected for that category by the implementation, based on the values in *LANG* and *LC_ALL*, as described in XBD Chapter 8 (on page 173).

93073 93074 93075 The <*value*> and <*implied value*> shown above shall be properly quoted for possible later reentry to the shell. The <*value*> shall not be quoted using double-quotes (so that it can be distinguished by the user from the <*implied value*> case, which always requires double-quotes).

The *LC_ALL* variable shall be written last, using the first format shown above. If it is not set, it shall be written as:

```
"LC_ALL=\n"
```

If any arguments are specified:

1. If the **–a** option is specified, the names of all the public locales shall be written, each in the following format:

   ```
   "%s\n", <locale name>
   ```

2. If the **–c** option is specified, the names of all selected categories shall be written, each in the following format:

   ```
   "%s\n", <category name>
   ```

   If keywords are also selected for writing (see following items), the category name output shall precede the keyword output for that category.

   If the **–c** option is not specified, the names of the categories shall not be written; only the keywords, as selected by the *<name>* operand, shall be written.

3. If the **–k** option is specified, the names and values of selected keywords shall be written. If a value is non-numeric and is not a compound keyword value, it shall be written in the following format:

   ```
   "%s=\"%s\"\n", <keyword name>, <keyword value>
   ```

   If a value is a non-numeric compound keyword value, it shall either be written in the format:

   ```
   "%s=\"%s\"\n", <keyword name>, <keyword value>
   ```

   where the *<keyword value>* is a single string of values separated by <semicolon> characters, or it shall be written in the format:

   ```
   "%s=%s\n", <keyword name>, <keyword value>
   ```

   where the *<keyword value>* is encoded as a set of strings, each enclosed in double-quotation-marks, separated by <semicolon> characters.

   If the keyword was **charmap**, the name of the charmap (if any) that was specified via the *localedef* **–f** option when the locale was created shall be written, with the word **charmap** as *<keyword name>*.

   If a value is numeric, it shall be written in one of the following formats:

   ```
   "%s=%d\n", <keyword name>, <keyword value>
   ```

   ```
   "%s=%c%o\n", <keyword name>, <escape character>, <keyword value>
   ```

   ```
   "%s=%cx%x\n", <keyword name>, <escape character>, <keyword value>
   ```

   where the *<escape character>* is that identified by the **escape_char** keyword in the current locale; see XBD Section 7.3 (on page 136).

   Compound keyword values (list entries) shall be separated in the output by <semicolon> characters. When included in keyword values, the <semicolon>, <backslash>, double-quote, and any control character shall be preceded (escaped) with the escape character.

4. If the **–k** option is not specified, selected keyword values shall be written, each in the following format:

   `"%s\n", <keyword value>`

   If the keyword was **charmap**, the name of the charmap (if any) that was specified via the *localedef* **–f** option when the locale was created shall be written.

5. If the **–m** option is specified, then a list of all available charmaps shall be written, each in the format:

   `"%s\n", <charmap>`

   where <*charmap*> is in a format suitable for use as the option-argument to the *localedef* **–f** option.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All the requested information was found and output successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If the *LANG* environment variable is not set or set to an empty value, or one of the *LC_** environment variables is set to an unrecognized value, the actual locales assumed (if any) are implementation-defined as described in XBD Chapter 8 (on page 173).

Implementations are not required to write out the actual values for keywords in the categories *LC_CTYPE* and *LC_COLLATE*; however, they must write out the categories (allowing an application to determine, for example, which character classes are available).

EXAMPLES

In the following examples, the assumption is that locale environment variables are set as follows:

```
LANG=locale_x
LC_COLLATE=locale_y
```

The command *locale* would result in the following output:

```
LANG=locale_x
LC_CTYPE="locale_x"
LC_COLLATE=locale_y
LC_TIME="locale_x"
LC_NUMERIC="locale_x"
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=
```

The order of presentation of the categories is not specified by this volume of POSIX.1-200x.

The command:

```
LC_ALL=POSIX locale –ck decimal_point
```

would produce:

```
LC_NUMERIC
decimal_point="."
```

The following command shows an application of *locale* to determine whether a user-supplied response is affirmative:

```
if printf "%s\n" "$response" | grep –Eq "$(locale yesexpr)"
then
    affirmative processing goes here
else
    non-affirmative processing goes here
fi
```

RATIONALE

The output for categories *LC_CTYPE* and *LC_COLLATE* has been made implementation-defined because there is a questionable value in having a shell script receive an entire array of characters. It is also difficult to return a logical collation description, short of returning a complete *localedef* source.

The **–m** option was included to allow applications to query for the existence of charmaps. The output is a list of the charmaps (implementation-supplied and user-supplied, if any) on the system.

The **–c** option was included for readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the **–k** option.

The **charmap** keyword, which returns the name of the charmap (if any) that was used when the current locale was created, was included to allow applications needing the information to retrieve it.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/30 is applied, correcting an editorial error in the STDOUT section.

Issue 7

Austin Group Interpretations 1003.1-2001 #017, #021, and #088 are applied, clarifying the standard output for the **–k** option when *LANG* is not set or is an empty string.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

localedef — define locale environment

SYNOPSIS

```
localedef [–c] [–f charmap] [–i sourcefile] [–u code_set_name] name
```

DESCRIPTION

The *localedef* utility shall convert source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables defined in XBD Chapter 7 (on page 135). It is implementation-defined whether users have the capability to create new locales, in addition to those supplied by the implementation. If the symbolic constant POSIX2_LOCALEDEF is defined, the system supports

XSI the creation of new locales. On XSI-conformant systems, the symbolic constant POSIX2_LOCALEDEF shall be defined.

The utility shall read source definitions for one or more locale categories belonging to the same locale from the file named in the **–i** option (if specified) or from standard input.

The *name* operand identifies the target locale. The utility shall support the creation of *public*, or generally accessible locales, as well as *private*, or restricted-access locales. Implementations may restrict the capability to create or modify public locales to users with appropriate privileges.

Each category source definition shall be identified by the corresponding environment variable name and terminated by an **END** *category-name* statement. The following categories shall be supported. In addition, the input may contain source for implementation-defined categories.

LC_CTYPE Defines character classification and case conversion.

LC_COLLATE
Defines collation rules.

LC_MONETARY
Defines the format and symbols used in formatting of monetary information.

LC_NUMERIC
Defines the decimal delimiter, grouping, and grouping symbol for non-monetary numeric editing.

LC_TIME Defines the format and content of date and time information.

LC_MESSAGES
Defines the format and values of affirmative and negative responses.

OPTIONS

The *localedef* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–c Create permanent output even if warning messages have been issued.

–f *charmap* Specify the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. The format of the *charmap* is described in XBD Section 6.4 (on page 129). The application shall ensure that this option is specified if symbolic names (other than collating symbols defined in a **collating-symbol** keyword) are used. If the **–f** option is not present, an implementation-defined character mapping shall be used.

–i *inputfile* The pathname of a file containing the source definitions. If this option is not present, source definitions shall be read from standard input. The format of the *inputfile* is described in XBD Section 7.3 (on page 136).

93247 **–u** *code_set_name*

93248 Specify the name of a codeset used as the target mapping of character symbols and
93249 collating element symbols whose encoding values are defined in terms of the
93250 ISO/IEC 10646-1: 2000 standard position constant values.

93251 **OPERANDS**

93252 The following operand shall be supported:

93253 *name* Identifies the locale; see XBD Chapter 7 (on page 135) for a description of the use of
93254 this name. If the name contains one or more <slash> characters, *name* shall be
93255 interpreted as a pathname where the created locale definitions shall be stored. If
93256 *name* does not contain any <slash> characters, the interpretation of the name is
93257 implementation-defined and the locale shall be public. The ability to create public
93258 locales in this way may be restricted to users with appropriate privileges. (As a
93259 consequence of specifying one *name*, although several categories can be processed
93260 in one execution, only categories belonging to the same locale can be processed.)

93261 **STDIN**

93262 Unless the **–i** option is specified, the standard input shall be a text file containing one or more
93263 locale category source definitions, as described in XBD Section 7.3 (on page 136). When lines are
93264 continued using the escape character mechanism, there is no limit to the length of the
93265 accumulated continued line.

93266 **INPUT FILES**

93267 The character set mapping file specified as the *charmap* option-argument is described in XBD
93268 Section 6.4 (on page 129). If a locale category source definition contains a **copy** statement, as
93269 defined in XBD Chapter 7 (on page 135), and the **copy** statement names a valid, existing locale,
93270 then *localedef* shall behave as if the source definition had contained a valid category source
93271 definition for the named locale.

93272 **ENVIRONMENT VARIABLES**

93273 The following environment variables shall affect the execution of *localedef*:

93274 *LANG* Provide a default value for the internationalization variables that are unset or null.
93275 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
93276 variables used to determine the values of locale categories.)

93277 *LC_ALL* If set to a non-empty string value, override the values of all the other
93278 internationalization variables.

93279 *LC_COLLATE*

93280 (This variable has no affect on *localedef*; the POSIX locale is used for this category.)

93281 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
93282 characters (for example, single-byte as opposed to multi-byte characters in
93283 arguments and input files). This variable has no affect on the processing of *localedef*
93284 input data; the POSIX locale is used for this purpose, regardless of the value of this
93285 variable.

93286 *LC_MESSAGES*

93287 Determine the locale that should be used to affect the format and contents of
93288 diagnostic messages written to standard error.

93289 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

93290 **ASYNCHRONOUS EVENTS**
93291 Default.

93292 **STDOUT**
93293 The utility shall report all categories successfully processed, in an unspecified format.

93294 **STDERR**
93295 The standard error shall be used only for diagnostic messages.

93296 **OUTPUT FILES**
93297 The format of the created output is unspecified. If the *name* operand does not contain a <slash>,
93298 the existence of an output file for the locale is unspecified.

93299 **EXTENDED DESCRIPTION**
93300 When the **–u** option is used, the *code_set_name* option-argument shall be interpreted as an
93301 implementation-defined name of a codeset to which the ISO/IEC 10646-1:2000 standard
93302 position constant values shall be converted via an implementation-defined method. Both the
93303 ISO/IEC 10646-1:2000 standard position constant values and other formats (decimal,
93304 hexadecimal, or octal) shall be valid as encoding values within the *charmap* file. The codeset
93305 represented by the implementation-defined name can be any codeset that is supported by the
93306 implementation.

93307 When conflicts occur between the *charmap* specification of <*code_set_name*>, <*mb_cur_max*>, or
93308 <*mb_cur_min*> and the implementation-defined interpretation of these respective items for the
93309 codeset represented by the **–u** option-argument *code_set_name*, the result is unspecified.

93310 When conflicts occur between the *charmap* encoding values specified for symbolic names of
93311 characters of the portable character set and the implementation-defined assignment of character
93312 encoding values, the result is unspecified.

93313 If a non-printable character in the *charmap* has a width specified that is not **–1**, the result will be
93314 undefined.

93315 **EXIT STATUS**
93316 The following exit values shall be returned:

93317 0 No errors occurred and the locales were successfully created.

93318 1 Warnings occurred and the locales were successfully created.

93319 2 The locale specification exceeded implementation limits or the coded character set or sets
93320 used were not supported by the implementation, and no locale was created.

93321 3 The capability to create new locales is not supported by the implementation.

93322 >3 Warnings or errors occurred and no output was created.

93323 **CONSEQUENCES OF ERRORS**
93324 If an error is detected, no permanent output shall be created.

93325 If warnings occur, permanent output shall be created if the **–c** option was specified. The
93326 following conditions shall cause warning messages to be issued:

93327 • If a symbolic name not found in the *charmap* file is used for the descriptions of the
93328 *LC_CTYPE* or *LC_COLLATE* categories (for other categories, this shall be an error
93329 condition).

93330 • If the number of operands to the **order** keyword exceeds the {COLL_WEIGHTS_MAX}
93331 limit.

- If optional keywords not supported by the implementation are present in the source.

Other implementation-defined conditions may also cause warnings.

APPLICATION USAGE

The *charmap* definition is optional, and is contained outside the locale definition. This allows both completely self-defined source files, and generic sources (applicable to more than one codeset). To aid portability, all *charmap* definitions must use the same symbolic names for the portable character set. As explained in XBD Section 6.4 (on page 129), it is implementation-defined whether or not users or applications can provide additional character set description files. Therefore, the **–f** option might be operable only when an implementation-defined *charmap* is named.

EXAMPLES

None.

RATIONALE

The output produced by the *localedef* utility is implementation-defined. The *name* operand is used to identify the specific locale. (As a consequence, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 6

The **–u** option is added, as specified in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/15 is applied, rewording text in the OPERANDS section describing the ability to create public locales.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/16 is applied, making the text consistent with the descriptions of **WIDTH** and **WIDTH_DEFAULT** in the Base Definitions volume of POSIX.1-200x.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

logger — log messages

SYNOPSIS

```
logger string...
```

DESCRIPTION

The *logger* utility saves a message, in an unspecified manner and format, containing the *string* operands provided by the user. The messages are expected to be evaluated later by personnel performing system administration tasks.

It is implementation-defined whether messages written in locales other than the POSIX locale are effective.

OPTIONS

None.

OPERANDS

The following operand shall be supported:

string One of the string arguments whose contents are concatenated together, in the order specified, separated by single <space> characters.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *logger*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error. (This means diagnostics from *logger* to the user or application, not diagnostic messages that the user is sending to the system administrator.)

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

93406 **STDERR**
93407 The standard error shall be used only for diagnostic messages.

93408 **OUTPUT FILES**
93409 Unspecified.

93410 **EXTENDED DESCRIPTION**
93411 None.

93412 **EXIT STATUS**
93413 The following exit values shall be returned:

93414 0 Successful completion.

93415 >0 An error occurred.

93416 **CONSEQUENCES OF ERRORS**
93417 Default.

93418 **APPLICATION USAGE**
93419 This utility allows logging of information for later use by a system administrator or programmer
93420 in determining why non-interactive utilities have failed. The locations of the saved messages,
93421 their format, and retention period are all unspecified. There is no method for a conforming
93422 application to read messages, once written.

93423 **EXAMPLES**
93424 A batch application, running non-interactively, tries to read a configuration file and fails; it may
93425 attempt to notify the system administrator with:

93426
```
logger myname: unable to read file foo. [timestamp]
```

93427 **RATIONALE**
93428 The standard developers believed strongly that some method of alerting administrators to errors
93429 was necessary. The obvious example is a batch utility, running non-interactively, that is unable to
93430 read its configuration files or that is unable to create or write its results file. However, the
93431 standard developers did not wish to define the format or delivery mechanisms as they have
93432 historically been (and will probably continue to be) very system-specific, as well as involving
93433 functionality clearly outside the scope of this volume of POSIX.1-200x.

93434 The text with *LC_MESSAGES* about diagnostic messages means diagnostics from *logger* to the
93435 user or application, not diagnostic messages that the user is sending to the system administrator.

93436 Multiple *string* arguments are allowed, similar to *echo*, for ease-of-use.

93437 Like the utilities *mailx* and *lp*, *logger* is admittedly difficult to test. This was not deemed sufficient
93438 justification to exclude these utilities from this volume of POSIX.1-200x. It is also arguable that
93439 they are, in fact, testable, but that the tests themselves are not portable.

93440 **FUTURE DIRECTIONS**
93441 None.

93442 **SEE ALSO**
93443 *lp*, *mailx*, *write*

93444 XBD Chapter 8 (on page 173)

93445 **CHANGE HISTORY**
93446 First released in Issue 4.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

logname — return the user's login name

SYNOPSIS

```
logname
```

DESCRIPTION

The *logname* utility shall write the user's login name to standard output. The login name shall be the string that would be returned by the *getlogin*() function defined in the System Interfaces volume of POSIX.1-200x. Under the conditions where the *getlogin*() function would fail, the *logname* utility shall write a diagnostic message to standard error and exit with a non-zero exit status.

OPTIONS

None.

OPERANDS

None.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *logname*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The *logname* utility output shall be a single line consisting of the user's login name:

```
"%s\n", <login name>
```

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *logname* utility explicitly ignores the *LOGNAME* environment variable because environment changes could produce erroneous results.

EXAMPLES

None.

RATIONALE

The **passwd** file is not listed as required because the implementation may have other means of mapping login names.

FUTURE DIRECTIONS

None.

SYNOPSIS

```
lp [–c] [–d dest] [–n copies] [–msw] [–o option]... [–t title] [file...]
```

DESCRIPTION

The *lp* utility shall copy the input files to an output destination in an unspecified manner. The default output destination should be to a hardcopy device, such as a printer or microfilm recorder, that produces non-volatile, human-readable documents. If such a device is not available to the application, or if the system provides no such device, the *lp* utility shall exit with a non-zero exit status.

The actual writing to the output device may occur some time after the *lp* utility successfully exits. During the portion of the writing that corresponds to each input file, the implementation shall guarantee exclusive access to the device.

The *lp* utility shall associate a unique *request ID* with each request.

Normally, a banner page is produced to separate and identify each print job. This page may be suppressed by implementation-defined conditions, such as an operator command or one of the **–o** *option* values.

OPTIONS

The *lp* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–c Exit only after further access to any of the input files is no longer required. The application can then safely delete or modify the files without affecting the output operation. Normally, files are not copied, but are linked whenever possible. If the **–c** option is not given, then the user should be careful not to remove any of the files before the request has been printed in its entirety. It should also be noted that in the absence of the **–c** option, any changes made to the named files after the request is made but before it is printed may be reflected in the printed output. On some implementations, **–c** may be on by default.

–d *dest* Specify a string that names the destination (*dest*). If *dest* is a printer, the request shall be printed only on that specific printer. If *dest* is a class of printers, the request shall be printed on the first available printer that is a member of the class. Under certain conditions (printer unavailability, file space limitation, and so on), requests for specific destinations need not be accepted. Destination names vary between systems.

If **–d** is not specified, and neither the *LPDEST* nor *PRINTER* environment variable is set, an unspecified destination is used. The **–d** *dest* option shall take precedence over *LPDEST*, which in turn shall take precedence over *PRINTER*. Results are undefined when *dest* contains a value that is not a valid destination name.

–m Send mail (see *mailx*) after the files have been printed. By default, no mail is sent upon normal completion of the print request.

–n *copies* Write *copies* number of copies of the files, where *copies* is a positive decimal integer. The methods for producing multiple copies and for arranging the multiple copies when multiple *file* operands are used are unspecified, except that each file shall be output as an integral whole, not interleaved with portions of other files.

93558 **–o** *option* Specify printer-dependent or class-dependent *option*s. Several such *option*s may be
93559 collected by specifying the **–o** option more than once.

93560 **–s** Suppress messages from *lp*.

93561 **–t** *title* Write *title* on the banner page of the output.

93562 **–w** Write a message on the user's terminal after the files have been printed. If the user
93563 is not logged in, then mail shall be sent instead.

93564 **OPERANDS**

93565 The following operand shall be supported:

93566 *file* A pathname of a file to be output. If no *file* operands are specified, or if a *file*
93567 operand is '–', the standard input shall be used. If a *file* operand is used, but the
93568 **–c** option is not specified, the process performing the writing to the output device
93569 may have user and group permissions that differ from that of the process invoking
93570 *lp*.

93571 **STDIN**

93572 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is '–'.
93573 See the INPUT FILES section.

93574 **INPUT FILES**

93575 The input files shall be text files.

93576 **ENVIRONMENT VARIABLES**

93577 The following environment variables shall affect the execution of *lp*:

93578 *LANG* Provide a default value for the internationalization variables that are unset or null.
93579 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
93580 variables used to determine the values of locale categories.)

93581 *LC_ALL* If set to a non-empty string value, override the values of all the other
93582 internationalization variables.

93583 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
93584 characters (for example, single-byte as opposed to multi-byte characters in
93585 arguments and input files).

93586 *LC_MESSAGES*
93587 Determine the locale that should be used to affect the format and contents of
93588 diagnostic messages written to standard error and informative messages written to
93589 standard output.

93590 *LC_TIME* Determine the format and contents of date and time strings displayed in the *lp*
93591 banner page, if any.

93592 *LPDEST* Determine the destination. If the *LPDEST* environment variable is not set, the
93593 *PRINTER* environment variable shall be used. The **–d** *dest* option takes precedence
93594 over *LPDEST*. Results are undefined when **–d** is not specified and *LPDEST*
93595 contains a value that is not a valid destination name.

93596 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

93597 *PRINTER* Determine the output device or destination. If the *LPDEST* and *PRINTER*
93598 environment variables are not set, an unspecified output device is used. The **–d**
93599 *dest* option and the *LPDEST* environment variable shall take precedence over
93600 *PRINTER*. Results are undefined when **–d** is not specified, *LPDEST* is unset, and
93601 *PRINTER* contains a value that is not a valid device or destination name.

93602 *TZ* Determine the timezone used to calculate date and time strings displayed in the *lp*
93603 banner page, if any. If *TZ* is unset or null, an unspecified default timezone shall be
93604 used.

93605 **ASYNCHRONOUS EVENTS**

93606 Default.

93607 **STDOUT**

93608 The *lp* utility shall write a *request ID* to the standard output, unless **–s** is specified. The format of
93609 the message is unspecified. The request ID can be used on systems supporting the historical
93610 *cancel* and *lpstat* utilities.

93611 **STDERR**

93612 The standard error shall be used only for diagnostic messages.

93613 **OUTPUT FILES**

93614 None.

93615 **EXTENDED DESCRIPTION**

93616 None.

93617 **EXIT STATUS**

93618 The following exit values shall be returned:

93619 0 All input files were processed successfully.

93620 >0 No output device was available, or an error occurred.

93621 **CONSEQUENCES OF ERRORS**

93622 Default.

93623 **APPLICATION USAGE**

93624 The *pr* and *fold* utilities can be used to achieve reasonable formatting for the implementation's
93625 default page size.

93626 A conforming application can use one of the *file* operands only with the **–c** option or if the file is
93627 publicly readable and guaranteed to be available at the time of printing. This is because
93628 POSIX.1-200x gives the implementation the freedom to queue up the request for printing at
93629 some later time by a different process that might not be able to access the file.

93630 **EXAMPLES**

93631 1. To print file *file*:

93632 `lp –c file`

93633 2. To print multiple files with headers:

93634 `pr file1 file2 | lp`

93635 **RATIONALE**

93636 The *lp* utility was designed to be a basic version of a utility that is already available in many
93637 historical implementations. The standard developers considered that it should be implementable
93638 simply as:

93639 `cat "$@" > /dev/lp`

93640 after appropriate processing of options, if that is how the implementation chose to do it and if
93641 exclusive access could be granted (so that two users did not write to the device simultaneously).
93642 Although in the future the standard developers may add other options to this utility, it should
93643 always be able to execute with no options or operands and send the standard input to an

unspecified output device.

This volume of POSIX.1-200x makes no representations concerning the format of the printed output, except that it must be "human-readable" and "non-volatile". Thus, writing by default to a disk or tape drive or a display terminal would not qualify. (Such destinations are not prohibited when **–d** *dest*, *LPDEST*, or *PRINTER* are used, however.)

This volume of POSIX.1-200x is worded such that a "print job" consisting of multiple input files, possibly in multiple copies, is guaranteed to print so that any one file is not intermixed with another, but there is no statement that all the files or copies have to print out together.

The **–c** option may imply a spooling operation, but this is not required. The utility can be implemented to wait until the printer is ready and then wait until it is finished. Because of that, there is no attempt to define a queuing mechanism (priorities, classes of output, and so on).

On some historical systems, the request ID reported on the STDOUT can be used to later cancel or find the status of a request using utilities not defined in this volume of POSIX.1-200x.

Although the historical System V *lp* and BSD *lpr* utilities have provided similar functionality, they used different names for the environment variable specifying the destination printer. Since the name of the utility here is *lp*, *LPDEST* (used by the System V *lp* utility) was given precedence over *PRINTER* (used by the BSD *lpr* utility). Since environments of users frequently contain one or the other environment variable, the *lp* utility is required to recognize both. If this was not done, many applications would send output to unexpected output devices when users moved from system to system.

Some have commented that *lp* has far too little functionality to make it worthwhile. Requests have proposed additional options or operands or both that added functionality. The requests included:

- Wording *requiring* the output to be "hardcopy"
- A requirement for multiple printers
- Options for supporting various page-description languages

Given that a compliant system is not required to even have a printer, placing further restrictions upon the behavior of the printer is not useful. Since hardcopy format is so application-dependent, it is difficult, if not impossible, to select a reasonable subset of functionality that should be required on all compliant systems.

The term *unspecified* is used in this section in lieu of *implementation-defined* as most known implementations would not be able to make definitive statements in their conformance documents; the existence and usage of printers is very dependent on how the system administrator configures each individual system.

Since the default destination, device type, queuing mechanisms, and acceptable forms of input are all unspecified, usage guidelines for what a conforming application can do are as follows:

- Use the command in a pipeline, or with **–c**, so that there are no permission problems and the files can be safely deleted or modified.
- Limit output to text files of reasonable line lengths and printable characters and include no device-specific formatting information, such as a page description language. The meaning of "reasonable" in this context can only be answered as a quality-of-implementation issue, but it should be apparent from historical usage patterns in the industry and the locale. The *pr* and *fold* utilities can be used to achieve reasonable formatting for the default page size of the implementation.

Alternatively, the application can arrange its installation in such a way that it requires the system administrator or operator to provide the appropriate information on *lp* options and environment variable values.

At a minimum, having this utility in this volume of POSIX.1-200x tells the industry that conforming applications require a means to print output and provides at least a command name and *LPDEST* routing mechanism that can be used for discussions between vendors, application developers, and users. The use of "should" in the DESCRIPTION of *lp* clearly shows the intent of the standard developers, even if they cannot mandate that all systems (such as laptops) have printers.

This volume of POSIX.1-200x does not specify what the ownership of the process performing the writing to the output device may be. If **–c** is not used, it is unspecified whether the process performing the writing to the output device has permission to read *file* if there are any restrictions in place on who may read *file* until after it is printed. Also, if **–c** is not used, the results of deleting *file* before it is printed are unspecified.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the DESCRIPTION, the requirement to associate a unique request ID, and the normal generation of a banner page is added.
- In the OPTIONS section:
  - The **–d** *dest* description is expanded, but references to *lpstat* are removed.
  - The **–m**, **–o**, **–s**, **–t**, and **–w** options are added.
- In the ENVIRONMENT VARIABLES section, *LC_TIME* may now affect the execution.
- The STDOUT section is added.

The normative text is reworded to avoid use of the term "must" for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

ls — list directory contents

SYNOPSIS

XSI `ls [–ACFRSacdfiklmnpqrstux1] [–H|–L] [–go] [file...]`

DESCRIPTION

For each operand that names a file of a type other than directory or symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. For each operand that names a file of type directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information. Filenames beginning with a <period> (`'.'`) and any associated information shall not be written out unless explicitly referenced, the **–A** or **–a** option is supplied, or an implementation-defined condition causes them to be written. If one or more of the **–d**, **–F**, or **–l** options are specified, and neither the **–H** nor the **–L** option is specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the name of the file as well as any requested, associated information. If none of the **–d**, **–F**, or **–l** options are specified, or the **–H** or **–L** options are specified, for each operand that names a file of type symbolic link to a directory, *ls* shall write the names of files contained within the directory as well as any requested, associated information. In each case where the names of files contained within a directory are written, if the directory contains any symbolic links then *ls* shall evaluate the file information and file type to be those of the symbolic link itself, unless the **–L** option is specified.

If no operands are specified, *ls* shall behave as if a single operand of dot (`'.'`) had been specified. If more than one operand is specified, *ls* shall write non-directory operands first; it shall sort directory and non-directory operands separately according to the collating sequence in the current locale.

The *ls* utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, *ls* shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

OPTIONS

The *ls* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–A Write out all directory entries, including those whose names begin with a <period> (`'.'`) but excluding the entries dot and dot-dot (if they exist).

–C Write multi-text-column output with entries sorted down the columns, according to the collating sequence. The number of text columns and the column separator characters are unspecified, but should be adapted to the nature of the output device.

–F Do not follow symbolic links named as operands unless the **–H** or **–L** options are specified. Write a <slash> (`'/'`) immediately after each pathname that is a directory, an <asterisk> (`'*'`) after each that is executable, a <vertical-line> (`'|'`) after each that is a FIFO, and an at-sign (`'@'`) after each that is a symbolic link. For other file types, other symbols may be written.

–H Evaluate the file information and file type for symbolic links specified on the command line to be those of the file referenced by the link, and not the link itself; however, *ls* shall write the name of the link itself and not the file referenced by the link.

–L Evaluate the file information and file type for all symbolic links (whether named on the command line or encountered in a file hierarchy) to be those of the file referenced by the link, and not the link itself; however, *ls* shall write the name of the link itself and not the file referenced by the link. When **–L** is used with **–l**, write the contents of symbolic links in the long format (see the STDOUT section).

–R Recursively list subdirectories encountered. When a symbolic link to a directory is encountered, the directory shall not be recursively listed unless the **–L** option is specified.

–S Sort with the primary key being file size (in decreasing order) and the secondary key being filename in the collating sequence (in increasing order).

–a Write out all directory entries, including those whose names begin with a <period> (`'.'`).

–c Use time of last modification of the file status information (see **<sys/stat.h>** in the System Interfaces volume of POSIX.1-200x) instead of last modification of the file itself for sorting (**–t**) or writing (**–l**).

–d Do not follow symbolic links named as operands unless the **–H** or **–L** options are specified. Do not treat directories differently than other types of files. The use of **–d** with **–R** produces unspecified results.

–f List the entries in directory operands in the order they appear in the directory. The behavior for non-directory operands is unspecified. This option shall turn off **–l**, **–t**, **–S**, **–s**, and **–r**, and shall turn on **–a**.

XSI **–g** The same as **–l**, except that the owner shall not be written.

–i For each file, write the file's file serial number (see *stat*( ) in the System Interfaces volume of POSIX.1-200x).

–k XSI Set the block size for the **–s** option and the per-directory block count written for the **–l**, **–n**, **–s**, **–g**, and **–o** options (see the STDOUT section) to 1 024 bytes.

–l (The letter ell.) Do not follow symbolic links named as operands unless the **–H** or **–L** options are specified. Write out in long format (see the STDOUT section). When **–l** (ell) is specified, –1 (one) shall be assumed.

–m Stream output format; list files across the page, separated by <comma> characters.

–n The same as **–l**, except that the owner's UID and GID numbers shall be written, rather than the associated character strings.

XSI **–o** The same as **–l**, except that the group shall not be written.

–p Write a <slash> (`'/'`) after each filename if that file is a directory.

–q Force each instance of non-printable filename characters and <tab> characters to be written as the <question-mark> (`'?'`) character. Implementations may provide this option by default if the output is to a terminal device.

–r Reverse the order of the sort to get reverse collating sequence oldest first, or smallest file size first depending on the other options given.

–s Indicate the total number of file system blocks consumed by each file displayed. If the **–k** option is also specified, the block size shall be 1 024 bytes; otherwise, the block size is implementation-defined.

93810 **–t** Sort with the primary key being time modified (most recently modified first) and
93811 the secondary key being filename in the collating sequence. For a symbolic link,
93812 the time used as the sort key is that of the symbolic link itself, unless *ls* is
93813 evaluating its file information to be that of the file referenced by the link (see the
93814 **–H** and **–L** options).

93815 **–u** Use time of last access (see **<sys/stat.h>**) instead of last modification of the file for
93816 sorting (**–t**) or writing (**–l**).

93817 **–x** The same as **–C**, except that the multi-text-column output is produced with entries
93818 sorted across, rather than down, the columns.

93819 **–1** (The numeric digit one.) Force output to be one entry per line.

93820 Specifying more than one of the options in the following mutually-exclusive pairs shall not be
93821 considered an error: **–C** and **–l** (ell), **–m** and **–l** (ell), **–x** and **–l** (ell), **–C** and **–1** (one), **–H** and **–L**,
93822 **–c** and **–u**, **–t** and **–S**. The last option specified in each pair shall determine the output format.

93823 **OPERANDS**

93824 The following operand shall be supported:

93825 *file* A pathname of a file to be written. If the file specified is not found, a diagnostic
93826 message shall be output on standard error.

93827 **STDIN**

93828 Not used.

93829 **INPUT FILES**

93830 None.

93831 **ENVIRONMENT VARIABLES**

93832 The following environment variables shall affect the execution of *ls*:

93833 *COLUMNS* Determine the user's preferred column position width for writing multiple text-
93834 column output. If this variable contains a string representing a decimal integer, the
93835 *ls* utility shall calculate how many pathname text columns to write (see **–C**) based
93836 on the width provided. If *COLUMNS* is not set or invalid, an implementation-
93837 defined number of column positions shall be assumed, based on the
93838 implementation's knowledge of the output device. The column width chosen to
93839 write the names of files in any given directory shall be constant. Filenames shall
93840 not be truncated to fit into the multiple text-column output.

93841 *LANG* Provide a default value for the internationalization variables that are unset or null.
93842 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
93843 variables used to determine the values of locale categories.)

93844 *LC_ALL* If set to a non-empty string value, override the values of all the other
93845 internationalization variables.

93846 *LC_COLLATE*
93847 Determine the locale for character collation information in determining the
93848 pathname collation sequence.

93849 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
93850 characters (for example, single-byte as opposed to multi-byte characters in
93851 arguments) and which characters are defined as printable (character class **print**).

93852 *LC_MESSAGES*
93853 Determine the locale that should be used to affect the format and contents of
93854 diagnostic messages written to standard error.

93855 *LC_TIME* Determine the format and contents for date and time strings written by *ls*.

93856 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

93857 *TZ* Determine the timezone for date and time strings written by *ls*. If *TZ* is unset or
93858 null, an unspecified default timezone shall be used.

93859 **ASYNCHRONOUS EVENTS**
93860 Default.

93861 **STDOUT**
93862 The default format shall be to list one entry per line to standard output; the exceptions are to
93863 terminals or when one of the –**C**, –**m**, or –**x** options is specified. If the output is to a terminal, the
93864 format is implementation-defined.

93865 When –**m** is specified, the format used shall be:

93866 `"%s, %s, ...\n", <filename1>, <filename2>`

93867 where the largest number of filenames shall be written without exceeding the length of the line.

93868 If the –**i** option is specified, the file's file serial number (see **<sys/stat.h>**) shall be written in the
93869 following format before any other output for the corresponding entry:

93870 `%u ", <file serial number>`

93871 If the –**l** option is specified without –**L**, the following information shall be written:

93872 `"%s %u %s %s %u %s %s\n", <file mode>, <number of links>,`
93873 `<owner name>, <group name>, <number of bytes in the file>,`
93874 `<date and time>, <pathname>`

93875 If the file is a symbolic link, this information shall be about the link itself and the <*pathname*>
93876 field shall be of the form:

93877 `"%s –> %s", <pathname of link>, <contents of link>`

93878 If both –**l** and –**L** are specified, the following information shall be written:

93879 `"%s %u %s %s %u %s %s\n", <file mode>, <number of links>,`
93880 `<owner name>, <group name>, <number of bytes in the file>,`
93881 `<date and time>, <pathname of link>`

93882 where all fields except <*pathname of link*> shall be for the file resolved from the symbolic link.

93883 XSI The –**n**, –**g**, and –**o** options use the same format as –**l**, but with omitted items and their
93884 associated <blank> characters. See the OPTIONS section.

93885 In both the preceding –**l** forms, if <*owner name*> or <*group name*> cannot be determined, or if –**n**
93886 is given, they shall be replaced with their associated numeric values using the format %u.

93887 The <*date and time*> field shall contain the appropriate date and timestamp of when the file was
93888 last modified. In the POSIX locale, the field shall be the equivalent of the output of the following
93889 *date* command:

93890 `date "+%b %e %H:%M"`

93891 if the file has been modified in the last six months, or:

```
date "+%b %e %Y"
```

(where two <space> characters are used between %e and %Y) if the file has not been modified in the last six months or if the modification date is in the future, except that, in both cases, the final <newline> produced by *date* shall not be included and the output shall be as if the *date* command were executed at the time of the last modification date of the file rather than the current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the file is a character special or block special file, the size of the file may be replaced with implementation-defined information associated with the device in question.

If the pathname was specified as a *file* operand, it shall be written as specified.

XSI The file mode written under the **–l**, **–n**, **–g**, and **–o** options shall consist of the following format:

```
"%c%s%s%s%s", <entry type>, <owner permissions>,
    <group permissions>, <other permissions>,
    <optional alternate access method flag>
```

The *<optional alternate access method flag>* shall be the empty string if there is no alternate or additional access control method associated with the file; otherwise, it shall be a string containing a single printable character that is not a <blank>.

The *<entry type>* character shall describe the type of file, as follows:

`d` Directory.

`b` Block special file.

`c` Character special file.

`l` (ell) Symbolic link.

`p` FIFO.

– Regular file.

Implementations may add other characters to this list to represent other implementation-defined file types.

The next three fields shall be three characters each:

<owner permissions>
: Permissions for the file owner class (see XBD Section 4.4, on page 108).

<group permissions>
: Permissions for the file group class.

<other permissions>
: Permissions for the file other class.

Each field shall have three character positions:

1. If `'r'`, the file is readable; if `'–'`, the file is not readable.
2. If `'w'`, the file is writable; if `'–'`, the file is not writable.
3. The first of the following that applies:

   `S` If in *<owner permissions>*, the file is not executable and set-user-ID mode is set. If in *<group permissions>*, the file is not executable and set-group-ID mode is set.

93931 `s` If in <*owner permissions*>, the file is executable and set-user-ID mode is set. If in
93932 <*group permissions*>, the file is executable and set-group-ID mode is set.

93933 XSI `T` If in <*other permissions*> and the file is a directory, search permission is not granted to
93934 others, and the restricted deletion flag is set.

93935 XSI `t` If in <*other permissions*> and the file is a directory, search permission is granted to
93936 others, and the restricted deletion flag is set.

93937 `x` The file is executable or the directory is searchable.

93938 – None of the attributes of `'S'`, `'s'`, `'T'`, `'t'`, or `'x'` applies.

93939 Implementations may add other characters to this list for the third character position.
93940 Such additions shall, however, be written in lowercase if the file is executable or
93941 searchable, and in uppercase if it is not.

93942 XSI If any of the **–l**, **–n**, **–s**, **–g**, or **–o** options is specified, each list of files within the directory shall be
93943 preceded by a status line indicating the number of file system blocks occupied by files in the
93944 directory in 512-byte units if the **–k** option is not specified, or 1 024-byte units if the **–k** option is
93945 specified, rounded up to the next integral number of units, if necessary. In the POSIX locale, the
93946 format shall be:

93947 `"total %u\n", <number of units in the directory>`

93948 If more than one directory, or a combination of non-directory files and directories are written,
93949 either as a result of specifying multiple operands, or the **–R** option, each list of files within a
93950 directory shall be preceded by:

93951 `"\n%s:\n", <directory name>`

93952 If this string is the first thing to be written, the first <newline> shall not be written. This output
93953 shall precede the number of units in the directory.

93954 If the **–s** option is given, each file shall be written with the number of blocks used by the file.
93955 XSI Along with **–C**, **–1**, **–m**, or **–x**, the number and a <space> shall precede the filename; with **–l**, **–n**,
93956 **–g**, or **–o**, they shall precede each line describing a file.

93957 **STDERR**

93958 The standard error shall be used only for diagnostic messages.

93959 **OUTPUT FILES**

93960 None.

93961 **EXTENDED DESCRIPTION**

93962 None.

93963 **EXIT STATUS**

93964 The following exit values shall be returned:

93965 0 Successful completion.

93966 >0 An error occurred.

93967 **CONSEQUENCES OF ERRORS**

93968 Default.

APPLICATION USAGE

Many implementations use the <equals-sign> (`'='`) to denote sockets bound to the file system for the **–F** option. Similarly, many historical implementations use the `'s'` character to denote sockets as the entry type characters for the **–l** option.

It is difficult for an application to use every part of the file modes field of *ls* **–l** in a portable manner. Certain file types and executable bits are not guaranteed to be exactly as shown, as implementations may have extensions. Applications can use this field to pass directly to a user printout or prompt, but actions based on its contents should generally be deferred, instead, to the *test* utility.

The output of *ls* (with the **–l** and related options) contains information that logically could be used by utilities such as *chmod* and *touch* to restore files to a known state. However, this information is presented in a format that cannot be used directly by those utilities or be easily translated into a format that can be used. A character has been added to the end of the permissions string so that applications at least have an indication that they may be working in an area they do not understand instead of assuming that they can translate the permissions string into something that can be used. Future versions or related documents may define one or more specific characters to be used based on different standard additional or alternative access control mechanisms.

As with many of the utilities that deal with filenames, the output of *ls* for multiple files or in one of the long listing formats must be used carefully on systems where filenames can contain embedded white space. Systems and system administrators should institute policies and user training to limit the use of such filenames.

The number of disk blocks occupied by the file that it reports varies depending on underlying file system type, block size units reported, and the method of calculating the number of blocks. On some file system types, the number is the actual number of blocks occupied by the file (counting indirect blocks and ignoring holes in the file); on others it is calculated based on the file size (usually making an allowance for indirect blocks, but ignoring holes).

EXAMPLES

An example of a small directory tree being fully listed with *ls* **–laRF a** in the POSIX locale:

```
total 11
drwxr-xr-x   3 fox      prog          64 Jul  4 12:07 ./
drwxrwxrwx   4 fox      prog        3264 Jul  4 12:09 ../
drwxr-xr-x   2 fox      prog          48 Jul  4 12:07 b/
-rwxr--r--   1 fox      prog         572 Jul  4 12:07 foo*

a/b:
total 4
drwxr-xr-x   2 fox      prog          48 Jul  4 12:07 ./
drwxr-xr-x   3 fox      prog          64 Jul  4 12:07 ../
-rw-r--r--   1 fox      prog         700 Jul  4 12:07 bar
```

RATIONALE

Some historical implementations of the *ls* utility show all entries in a directory except dot and dot-dot when a superuser invokes *ls* without specifying the **–a** option. When "normal" users invoke *ls* without specifying **–a**, they should not see information about any files with names beginning with a <period> unless they were named as *file* operands.

Implementations are expected to traverse arbitrary depths when processing the **–R** option. The only limitation on depth should be based on running out of physical storage for keeping track of untraversed directories.

The **–1** (one) option was historically found in BSD and BSD-derived implementations only. It is required in this volume of POSIX.1-200x so that conforming applications might ensure that output is one entry per line, even if the output is to a terminal.

The **–S** option was added in Issue 7, but had been provided by several implementations for many years. The description given in the standard documents historic practice, but does not match much of the documentation that described its behavior. Historical documentation typically described it as something like:

–S Sort by size (largest size first) instead of by name. Special character devices (listed last) are sorted by name.

even though the file type was never considered when sorting the output. Character special files do typically sort close to the end of the list because their file size on most implementations is zero. But they are sorted alphabetically with any other files that happen to have the same file size (zero), not sorted separately and added to the end.

Generally, this volume of POSIX.1-200x is silent about what happens when options are given multiple times. In the cases of **–C**, **–l**, and **–1**, however, it does specify the results of these overlapping options. Since *ls* is one of the most aliased commands, it is important that the implementation perform intuitively. For example, if the alias were:

```
alias ls="ls –C"
```

and the user typed *ls* **–1**, single-text-column output should result, not an error.

Earlier versions of this standard did not describe the BSD **–A** option (like **–a**, but dot and dot-dot are not written out). It has been added due to widespread implementation.

Implementations may make **–q** the default for terminals to prevent trojan horse attacks on terminals with special escape sequences. This is not required because:

- Some control characters may be useful on some terminals; for example, a system might write them as `"\001"` or `"^A"`.
- Special behavior for terminals is not relevant to applications portability.

An early proposal specified that the <*optional alternate access method flag*> had to be `'+'` if there was an alternate access method used on the file or <space> if there was not. This was changed to be <space> if there is not and a single printable character if there is. This was done for three reasons:

1. There are historical implementations using characters other than `'+'`.
2. There are implementations that vary this character used in that position to distinguish between various alternate access methods in use.
3. The standard developers did not want to preclude future specifications that might need a way to specify more than one alternate access method.

Nonetheless, implementations providing a single alternate access method are encouraged to use `'+'`.

Earlier versions of this standard did not have the **–k** option, which meant that the **–s** option could not be used portably as its block size was implementation-defined, and the units used to specify the number of blocks occupied by files in a directory in an *ls* **–l** listing were fixed as 512-byte units. The **–k** option has been added to provide a way for the **–s** option to be used portably, and for consistency it also changes the aforementioned units from 512-byte to 1 024-byte.

The <*date and time*> field in the **–l** format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of POSIX.1-200x, as the appropriate vehicle is a messaging system; that is, the format should be specified as a "message".

FUTURE DIRECTIONS

None.

chmod, *find*

XBD Section 4.4 (on page 108), Chapter 8 (on page 173), Section 12.2 (on page 215), **<sys/stat.h>**

XSH *fstatat*( )

CHANGE HISTORY

First released in Issue 2.

Issue 5

A second FUTURE DIRECTION is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- In the **–F** option, other symbols are allowed for other file types.

Treatment of symbolic links is added, as defined in the IEEE P1003.2b draft standard.

The Open Group Base Resolution bwg2001-010 is applied, adding the `T` and `t` fields as part of the XSI option.

Issue 7

Austin Group Interpretation 1003.1-2001 #101 is applied, clarifying the optional alternate access method flag in the STDOUT section.

Austin Group Interpretation 1003.1-2001 #128 is applied, clarifying the DESCRIPTION and the definition of the **–R** option.

Austin Group Interpretation 1003.1-2001 #129 is applied, clarifying the behavior of *ls* when no operands are specified.

Austin Group Interpretation 1003.1-2001 #198 is applied, clarifying the requirements for the **–H** option.

SD5-XCU-ERN-50 is applied, adding the **–A** option.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The **–S** option is added from The Open Group Technical Standard, 2006, Extended API Set Part 1.

The **–f**, **–m**, **–n**, **–p**, **–s**, and **–x** options are moved from the XSI option to the Base.

The description of the **–f**, **–s**, and **–t** options are revised and the **–k** option is added.

NAME

m4 — macro processor

SYNOPSIS

```
m4 [-s] [-D name[=val]]... [-U name]... file...
```

DESCRIPTION

The *m4* utility is a macro processor that shall read one or more text files, process them according to their included macro statements, and write the results to standard output.

OPTIONS

The *m4* utility shall conform to XBD Section 12.2 (on page 215), except that the order of the **–D** and **–U** options shall be significant, and options can be interspersed with operands.

The following options shall be supported:

–s Enable line synchronization output for the *c99* preprocessor phase (that is, **#line** directives).

–D *name*[=*val*]
Define *name* to *val* or to null if =*val* is omitted.

–U *name* Undefine *name*.

OPERANDS

The following operand shall be supported:

file A pathname of a text file to be processed. If no *file* is given, or if it is `'-'`, the standard input shall be read.

STDIN

The standard input shall be a text file that is used if no *file* operand is given, or if it is `'-'`.

INPUT FILES

The input file named by the *file* operand shall be a text file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *m4*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

94135 **STDOUT**

94136 The standard output shall be the same as the input files, after being processed for macro
94137 expansion.

94138 **STDERR**

94139 The standard error shall be used to display strings with the **errprint** macro, macro tracing
94140 enabled by the **traceon** macro, the defined text for macros written by the **dumpdef** macro, or for
94141 diagnostic messages.

94142 **OUTPUT FILES**

94143 None.

94144 **EXTENDED DESCRIPTION**

94145 The *m4* utility shall compare each token from the input against the set of built-in and user-
94146 defined macros. If the token matches the name of a macro, then the token shall be replaced by
94147 the macro's defining text, if any, and rescanned for matching macro names. Once no portion of
94148 the token matches the name of a macro, it shall be written to standard output. Macros may have
94149 arguments, in which case the arguments shall be substituted into the defining text before it is
94150 rescanned.

94151 Macro calls have the form:

94152 *name*`(`*arg1*`, `*arg2*`, ..., `*argn*`)`

94153 Macro names shall consist of letters, digits, and underscores, where the first character is not a
94154 digit. Tokens not of this form shall not be treated as macros.

94155 The application shall ensure that the <left-parenthesis> immediately follows the name of the
94156 macro. If a token matching the name of a macro is not followed by a <left-parenthesis>, it is
94157 handled as a use of that macro without arguments.

94158 If a macro name is followed by a <left-parenthesis>, its arguments are the <comma>-separated
94159 tokens between the <left-parenthesis> and the matching <right-parenthesis>. Unquoted white-
94160 space characters preceding each argument shall be ignored. All other characters, including
94161 trailing white-space characters, are retained. <comma> characters enclosed between <left-
94162 parenthesis> and <right-parenthesis> characters do not delimit arguments.

94163 Arguments are positionally defined and referenced. The string `"$1"` in the defining text shall be
94164 replaced by the first argument. Systems shall support at least nine arguments; only the first nine
94165 can be referenced, using the strings `"$1"` to `"$9"`, inclusive. The string `"$0"` is replaced with
94166 the name of the macro. The string `"$#"` is replaced by the number of arguments as a string. The
94167 string `"$*"` is replaced by a list of all of the arguments, separated by <comma> characters. The
94168 string `"$@"` is replaced by a list of all of the arguments separated by <comma> characters, and
94169 each argument is quoted using the current left and right quoting strings. The string `"${"`
94170 produces unspecified behavior.

94171 If fewer arguments are supplied than are in the macro definition, the omitted arguments are
94172 taken to be null. It is not an error if more arguments are supplied than are in the macro
94173 definition.

94174 No special meaning is given to any characters enclosed between matching left and right quoting
94175 strings, but the quoting strings are themselves discarded. By default, the left quoting string
94176 consists of a grave accent (backquote) and the right quoting string consists of an acute accent
94177 (single-quote); see also the **changequote** macro.

94178 Comments are written but not scanned for matching macro names; by default, the begin-
94179 comment string consists of the <number-sign> character and the end-comment string consists of
94180 a <newline>. See also the **changecom** and **dnl** macros.

The *m4* utility shall make available the following built-in macros. They can be redefined, but once this is done the original meaning is lost. Their values shall be null unless otherwise stated. In the descriptions below, the term *defining text* refers to the value of the macro: the second argument to the **define** macro, among other things. Except for the first argument to the **eval** macro, all numeric arguments to built-in macros shall be interpreted as decimal values. The string values produced as the defining text of the **decr**, **divnum**, **incr**, **index**, **len**, and **sysval** built-in macros shall be in the form of a decimal-constant as defined in the C language.

changecom The **changecom** macro shall set the begin-comment and end-comment strings. With no arguments, the comment mechanism shall be disabled. With a single non-null argument, that argument shall become the begin-comment and the <newline> shall become the end-comment string. With two non-null arguments, the first argument shall become the begin-comment string and the second argument shall become the end-comment string. The behavior is unspecified if either argument is provided but null. Systems shall support comment strings of at least five characters.

changequote The **changequote** macro shall set the begin-quote and end-quote strings. With no arguments, the quote strings shall be set to the default values (that is, ‘ ’). The behavior is unspecified if there is a single argument or either argument is null. With two non-null arguments, the first argument shall become the begin-quote string and the second argument shall become the end-quote string. Systems shall support quote strings of at least five characters.

decr The defining text of the **decr** macro shall be its first argument decremented by 1. It shall be an error to specify an argument containing any non-numeric characters. The behavior is unspecified if **decr** is not immediately followed by a <left-parenthesis>.

define The second argument shall become the defining text of the macro whose name is the first argument. It is unspecified whether the **define** macro deletes all prior definitions of the macro named by its first argument or preserves all but the current definition of the macro. The behavior is unspecified if **define** is not immediately followed by a <left-parenthesis>.

defn The defining text of the **defn** macro shall be the quoted definition (using the current quoting strings) of its arguments. The behavior is unspecified if **defn** is not immediately followed by a <left-parenthesis>.

divert The *m4* utility maintains nine temporary buffers, numbered 1 to 9, inclusive. When the last of the input has been processed, any output that has been placed in these buffers shall be written to standard output in buffer-numerical order. The **divert** macro shall divert future output to the buffer specified by its argument. Specifying no argument or an argument of 0 shall resume the normal output process. Output diverted to a stream with a negative number shall be discarded. Behavior is implementation-defined if a stream number larger than 9 is specified. It shall be an error to specify an argument containing any non-numeric characters.

divnum The defining text of the **divnum** macro shall be the number of the current output stream as a string.

dnl The **dnl** macro shall cause *m4* to discard all input characters up to and including the next <newline>.

dumpdef The **dumpdef** macro shall write the defined text to standard error for each of the macros specified as arguments, or, if no arguments are specified, for all macros.

errprint The **errprint** macro shall write its arguments to standard error. The behavior is unspecified if **errprint** is not immediately followed by a <left-parenthesis>.

eval The **eval** macro shall evaluate its first argument as an arithmetic expression, using signed integer arithmetic with at least 32-bit precision. At least the following C-language operators shall be supported, with precedence, associativity, and behavior as described in Section 1.1.2.1 (on page 2283):

```
()
unary +
unary –
~

!
binary *
/
%
binary +
binary –
<<
>>
<
<=
>
>=
==
!=
binary &
^
|
&&
||
```

Systems shall support octal and hexadecimal numbers as in the ISO C standard. The second argument, if specified, shall set the radix for the result; if the argument is blank or unspecified, the default is 10. Behavior is unspecified if the radix falls outside the range 2 to 36, inclusive. The third argument, if specified, sets the minimum number of digits in the result. Behavior is unspecified if the third argument is less than zero. It shall be an error to specify the second or third argument containing any non-numeric characters. The behavior is unspecified if **eval** is not immediately followed by a <left-parenthesis>.

ifdef If the first argument to the **ifdef** macro is defined, the defining text shall be the second argument. Otherwise, the defining text shall be the third argument, if specified, or the null string, if not. The behavior is unspecified if **ifdef** is not immediately followed by a <left-parenthesis>.

ifelse The **ifelse** macro takes three or more arguments. If the first two arguments compare as equal strings (after macro expansion of both arguments), the defining text shall be the third argument. If the first two arguments do not compare as equal strings and there are three arguments, the defining text shall be null. If the first two arguments do not compare as equal strings and there are four or five arguments,

94274 94275 94276 94277 94278 the defining text shall be the fourth argument. If the first two arguments do not compare as equal strings and there are six or more arguments, the first three arguments shall be discarded and processing shall restart with the remaining arguments. The behavior is unspecified if **ifelse** is not immediately followed by a <left-parenthesis>.

94279 94280 94281 **include** The defining text for the **include** macro shall be the contents of the file named by the first argument. It shall be an error if the file cannot be read. The behavior is unspecified if **include** is not immediately followed by a <left-parenthesis>.

94282 94283 94284 94285 **incr** The defining text of the **incr** macro shall be its first argument incremented by 1. It shall be an error to specify an argument containing any non-numeric characters. The behavior is unspecified if **incr** is not immediately followed by a <left-parenthesis>.

94286 94287 94288 94289 **index** The defining text of the **index** macro shall be the first character position (as a string) in the first argument where a string matching the second argument begins (zero origin), or –1 if the second argument does not occur. The behavior is unspecified if **index** is not immediately followed by a <left-parenthesis>.

94290 94291 94292 **len** The defining text of the **len** macro shall be the length (as a string) of the first argument. The behavior is unspecified if **len** is not immediately followed by a <left-parenthesis>.

94293 94294 94295 **m4exit** Exit from the *m4* utility. If the first argument is specified, it is the exit code. The default is zero. It shall be an error to specify an argument containing any non-numeric characters.

94296 94297 94298 94299 **m4wrap** The first argument shall be processed when EOF is reached. If the **m4wrap** macro is used multiple times, the arguments specified shall be processed in the order in which the **m4wrap** macros were processed. The behavior is unspecified if **m4wrap** is not immediately followed by a <left-parenthesis>.

94300 OB 94301 94302 **maketemp** The defining text shall be the first argument, with any trailing `'X'` characters replaced with the current process ID as a string. The behavior is unspecified if **maketemp** is not immediately followed by a <left-parenthesis>.

94303 94304 94305 94306 94307 94308 94309 94310 94311 94312 94313 94314 **mkstemp** The first argument shall be taken as a template for creating an empty file, with trailing `'X'` characters replaced with characters from the portable filename character set. The behavior is unspecified if the first argument does not end in at least six `'X'` characters. If a temporary file is successfully created, then the defining text of the macro shall be the name of the new file. The user ID of the file shall be set to the effective user ID of the process. The group ID of the file shall be set to the group ID of the file's parent directory or to the effective group ID of the process. The file access permission bits are set such that only the owner can both read and write the file, regardless of the current *umask* of the process. If a file could not be created, the defining text of the macro shall be the empty string. The behavior is unspecified if **mkstemp** is not immediately followed by a <left-parenthesis>.

94315 94316 94317 94318 **popdef** The **popdef** macro shall delete the current definition of its arguments, replacing that definition with the previous one. If there is no previous definition, the macro is undefined. The behavior is unspecified if **popdef** is not immediately followed by a <left-parenthesis>.

pushdef The **pushdef** macro shall be equivalent to the **define** macro with the exception that it shall preserve any current definition for future retrieval using the **popdef** macro. The behavior is unspecified if **pushdef** is not immediately followed by a <left-parenthesis>.

shift The defining text for the **shift** macro shall be all of its arguments except for the first one. The behavior is unspecified if **shift** is not immediately followed by a <left-parenthesis>.

sinclude The **sinclude** macro shall be equivalent to the **include** macro, except that it shall not be an error if the file is inaccessible. The behavior is unspecified if **sinclude** is not immediately followed by a <left-parenthesis>.

substr The defining text for the **substr** macro shall be the substring of the first argument beginning at the zero-offset character position specified by the second argument. The third argument, if specified, shall be the number of characters to select; if not specified, the characters from the starting point to the end of the first argument shall become the defining text. It shall not be an error to specify a starting point beyond the end of the first argument and the defining text shall be null. It shall be an error to specify an argument containing any non-numeric characters. The behavior is unspecified if **substr** is not immediately followed by a <left-parenthesis>.

syscmd The **syscmd** macro shall interpret its first argument as a shell command line. The defining text shall be the string result of that command. The string result shall not be rescanned for macros while setting the defining text. No output redirection shall be performed by the *m4* utility. The exit status value from the command can be retrieved using the **sysval** macro. The behavior is unspecified if **syscmd** is not immediately followed by a <left-parenthesis>.

sysval The defining text of the **sysval** macro shall be the exit value of the utility last invoked by the **syscmd** macro (as a string).

traceon The **traceon** macro shall enable tracing for the macros specified as arguments, or, if no arguments are specified, for all macros. The trace output shall be written to standard error in an unspecified format.

traceoff The **traceoff** macro shall disable tracing for the macros specified as arguments, or, if no arguments are specified, for all macros.

translit The defining text of the **translit** macro shall be the first argument with every character that occurs in the second argument replaced with the corresponding character from the third argument. The behavior is unspecified if the '–' character appears within the second or third argument anywhere besides the first or last character. The behavior is unspecified if **translit** is not immediately followed by a <left-parenthesis>.

undefine The **undefine** macro shall delete all definitions (including those preserved using the **pushdef** macro) of the macros named by its arguments. The behavior is unspecified if **undefine** is not immediately followed by a <left-parenthesis>.

undivert The **undivert** macro shall cause immediate output of any text in temporary buffers named as arguments, or all temporary buffers if no arguments are specified. Buffers can be undiverted into other temporary buffers. Undiverting shall discard the contents of the temporary buffer. The behavior is unspecified if an argument contains any non-numeric characters.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred

If the **m4exit** macro is used, the exit value can be specified by the input file.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The **defn** macro is useful for renaming macros, especially built-ins.

Since **eval** defers to the ISO C standard, some operations have undefined behavior. In some implementations, division or remainder by zero cause a fatal signal, even if the division occurs on the short-circuited branch of "&&" or "||". Any operation that overflows in signed arithmetic produces undefined behavior. Likewise, using the **shift** operators with a shift amount that is not positive and smaller than the precision is undefined, as is shifting a negative number to the right. Historically, not all implementations obeyed C-language precedence rules: '~' and '!' were lower than '=='; '==' and '!=' were not lower than '<'; and '|' was not lower than '^'; the liberal use of "()" can force the desired precedence even with these non-compliant implementations. Furthermore, some traditional implementations treated '^' as an exponentiation operator, although most implementations now use "**" as an extension for this purpose.

When a macro has been multiply defined via the **pushdef** macro, it is unspecified whether the **define** macro will alter only the most recent definition (as though by **popdef** and **pushdef**), or replace the entire stack of definitions with a single definition (as though by **undefine** and **pushdef**). An application desiring particular behavior for the **define** macro in this case can redefine it accordingly.

Applications should use the **mkstemp** macro instead of the obsolescent **maketemp** macro for creating temporary files.

EXAMPLES

If the file **m4src** contains the lines:

```
The value of ‘VER’ is "VER".
ifdef(‘VER’, ‘‘VER’’ is defined to be VER., VER is not defined.)
ifelse(VER, 1, ‘‘VER’’ is ‘VER’.)
ifelse(VER, 2, ‘‘VER’’ is ‘VER’., ‘‘VER’’ is not 2.)
end
```

then the command

```
m4 m4src
```

or the command:

```
m4 –U VER m4src
```

produces the output:

```
The value of VER is "VER".
VER is not defined.

VER is not 2.
end
```

The command:

```
m4 –D VER m4src
```

produces the output:

```
The value of VER is "".
VER is defined to be .
VER is not 2.
end
```

The command:

```
m4 –D VER=1 m4src
```

produces the output:

```
The value of VER is "1".
VER is defined to be 1.
VER is 1.
VER is not 2.
end
```

The command:

```
m4 –D VER=2 m4src
```

produces the output:

```
The value of VER is "2".
VER is defined to be 2.
VER is 2.
end
```

RATIONALE

Historic System V-based behavior treated `"${"` in a macro definition as two literal characters. However, this sequence is left unspecified so that implementations may offer extensions such as `"${11}"` meaning the eleventh positional parameter. Macros can still be defined with appropriate uses of nested quoting to result in a literal `"${"` in the output after rescanning removes the nested quotes.

In the **translit** built-in, historic System V-based behavior treated `'–'` as a literal; GNU behavior treats it as a range. This version of the standard allows either behavior.

FUTURE DIRECTIONS

None.

SEE ALSO

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The phrase “the defined text for macros written by the **dumpdef** macro” is added to the description of STDERR, and the description of **dumpdef** is updated to indicate that output is written to standard error. The description of **eval** is updated to indicate that the list of excluded C operators excludes unary `'&'` and `'.'`. In the description of **ifdef**, the phrase “and it is not

94450 defined to be zero'' is deleted.

94451 **Issue 6**

94452 In the EXTENDED DESCRIPTION, the **eval** text is updated to include a `'&'` character in the
94453 excepted list.

94454 The EXTENDED DESCRIPTION of **divert** is updated to clarify that there are only nine diversion
94455 buffers.

94456 The normative text is reworded to avoid use of the term "must" for application requirements.

94457 The Open Group Base Resolution bwg2000-006 is applied.

94458 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/31 is applied, replacing the EXAMPLES
94459 section.

94460 **Issue 7**

94461 Austin Group Interpretation 1003.1-2001 #117 is applied, marking the **maketemp** macro
94462 obsolescent and adding a new **mkstemp** macro.

94463 Austin Group Interpretation 1003.1-2001 #207 is applied, clarifying the handling of white-space
94464 characters that precede or trail any macro arguments.

94465 SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not
94466 apply (options can be interspersed with operands).

94467 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

94468 SD5-XCU-ERN-99 is applied, clarifying the definition of the **divert** macro in the EXTENDED
94469 DESCRIPTION.

94470 SD5-XCU-ERN-100 is applied, clarifying the definition of the **syscmd** macro in the EXTENDED
94471 DESCRIPTION.

94472 SD5-XCU-ERN-101 is applied, clarifying the definition of the **undivert** macro in the EXTENDED
94473 DESCRIPTION.

94474 SD5-XCU-ERN-111 is applied to the EXTENDED DESCRIPTION, clarifying that the string `"${"`
94475 produces unspecified behavior.

94476 SD5-XCU-ERN-112 is applied, updating the **changequote** macro.

94477 SD5-XCU-ERN-118 is applied, clarifying the definition of the **define** macro in the EXTENDED
94478 DESCRIPTION and APPLICATION USAGE sections.

94479 SD5-XCU-ERN-119 is applied, clarifying the definition of the **translit** macro in the EXTENDED
94480 DESCRIPTION and RATIONALE sections.

94481 SD5-XCU-ERN-130, SD5-XCU-ERN-131, and SD5-XCU-ERN-137 are applied.

94482 The *m4* utility is moved from the XSI option to the Base.

NAME

mailx — process messages

SYNOPSIS

Send Mode

```
mailx [–s subject] address...
```

Receive Mode

UP

```
mailx –e
mailx [–HiNn] [–F] [–u user]
mailx –f [–HiNn] [–F] [file]
```

DESCRIPTION

The *mailx* utility provides a message sending and receiving facility. It has two major modes, selected by the options used: Send Mode and Receive Mode.

On systems that do not support the User Portability Utilities option, an application using *mailx* shall have the ability to send messages in an unspecified manner (Send Mode). Unless the first character of one or more lines is <tilde> (`'~'`), all characters in the input message shall appear in the delivered message, but additional characters may be inserted in the message before it is retrieved.

UP

On systems supporting the User Portability Utilities option, mail-receiving capabilities and other interactive features, Receive Mode, described below, also shall be enabled.

Send Mode

Send Mode can be used by applications or users to send messages from the text in standard input.

UP

Receive Mode

Receive Mode is more oriented towards interactive users. Mail can be read and sent in this interactive mode.

When reading mail, *mailx* provides commands to facilitate saving, deleting, and responding to messages. When sending mail, *mailx* allows editing, reviewing, and other modification of the message as it is entered.

Incoming mail shall be stored in one or more unspecified locations for each user, collectively called the system *mailbox* for that user. When *mailx* is invoked in Receive Mode, the system mailbox shall be the default place to find new mail. As messages are read, they shall be marked to be moved to a secondary file for storage, unless specific action is taken. This secondary file is called the **mbox** and is normally located in the directory referred to by the *HOME* environment variable (see *MBOX* in the ENVIRONMENT VARIABLES section for a description of this file). Messages shall remain in this file until explicitly removed. When the **–f** option is used to read mail messages from secondary files, messages shall be retained in those files unless specifically removed. All three of these locations—system mailbox, **mbox**, and secondary file—are referred to in this section as simply "mailboxes", unless more specific identification is required.

OPTIONS

The *mailx* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported. (Only the **–s** *subject* option shall be required on all systems. The other options are required only on systems supporting the User Portability Utilities option.)

UP **–e** Test for the presence of mail in the system mailbox. The *mailx* utility shall write nothing and exit with a successful return code if there is mail to read.

UP **–f** Read messages from the file named by the *file* operand instead of the system mailbox. (See also **folder**.) If no *file* operand is specified, read messages from **mbox** instead of the system mailbox.

UP **–F** Record the message in a file named after the first recipient. The name is the login-name portion of the address found first on the **To:** line in the mail header. Overrides the **record** variable, if set (see Internal Variables in mailx, on page 2889).

UP **–H** Write a header summary only.

UP **–i** Ignore interrupts. (See also **ignore**.)

UP **–n** Do not initialize from the system default start-up file. See the EXTENDED DESCRIPTION section.

UP **–N** Do not write an initial header summary.

–s *subject* Set the **Subject** header field to *subject*. All characters in the *subject* string shall appear in the delivered message. The results are unspecified if *subject* is longer than {LINE_MAX} – 10 bytes or contains a <newline>.

UP **–u** *user* Read the system mailbox of the login name *user*. This shall only be successful if the invoking user has appropriate privileges to read the system mailbox of that user.

OPERANDS

The following operands shall be supported:

address Addressee of message. When **–n** is specified and no user start-up files are accessed (see the EXTENDED DESCRIPTION section), the user or application shall ensure this is an address to pass to the mail delivery system. Any system or user start-up files may enable aliases (see **alias** under Commands in mailx, on page 2892) that may modify the form of *address* before it is passed to the mail delivery system.

UP *file* A pathname of a file to be read instead of the system mailbox when **–f** is specified. The meaning of the *file* option-argument shall be affected by the contents of the **folder** internal variable; see Internal Variables in mailx (on page 2889).

STDIN

When *mailx* is invoked in Send Mode (the first synopsis line), standard input shall be the UP message to be delivered to the specified addresses. When in Receive Mode, user commands shall be accepted from *stdin*. If the User Portability Utilities option is not supported, standard input lines beginning with a <tilde> (`'~'`) character produce unspecified results.

UP If the User Portability Utilities option is supported, then in both Send and Receive Modes, standard input lines beginning with the escape character (usually <tilde> (`'~'`)) shall affect processing as described in Command Escapes in mailx (on page 2901).

INPUT FILES

When *mailx* is used as described by this volume of POSIX.1-200x, the *file* option-argument (see the **–f** option) and the **mbox** shall be text files containing mail messages, formatted as described in the OUTPUT FILES section. The nature of the system mailbox is unspecified; it need not be a file.

ENVIRONMENT VARIABLES

UP Some of the functionality described in this section shall be provided on implementations that support the User Portability Utilities option as described in the text, and is not further shaded for this option.

The following environment variables shall affect the execution of *mailx*:

DEAD Determine the pathname of the file in which to save partial messages in case of interrupts or delivery errors. The default shall be **dead.letter** in the directory named by the *HOME* variable. The behavior of *mailx* in saving partial messages is unspecified if the User Portability Utilities option is not supported and *DEAD* is not defined with the value **/dev/null**.

EDITOR Determine the name of a utility to invoke when the **edit** (see Commands in mailx, on page 2892) or **~e** (see Command Escapes in mailx, on page 2901) command is used. The default editor is unspecified. XSI On XSI-conformant systems it is *ed*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

HOME Determine the pathname of the user's home directory.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the handling of case-insensitive address and header-field comparisons.

LC_TIME This variable may determine the format and contents of the date and time strings written by *mailx*. This volume of POSIX.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LISTER Determine a string representing the command for writing the contents of the **folder** directory to standard output when the **folders** command is given (see **folders** in Commands in mailx, on page 2892). Any string acceptable as a *command_string* operand to the *sh* **–c** command shall be valid. If this variable is null or not set, the output command shall be *ls*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

MAILRC Determine the pathname of the start-up file. The default shall be **.mailrc** in the directory referred to by the *HOME* environment variable. The behavior of *mailx* is unspecified if the User Portability Utilities option is not supported and *MAILRC* is

not defined with the value **/dev/null**.

MBOX Determine a pathname of the file to save messages from the system mailbox that have been read. The **exit** command shall override this function, as shall saving the message explicitly in another file. The default shall be **mbox** in the directory named by the *HOME* variable. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PAGER Determine a string representing an output filtering or pagination command for writing the output to the terminal. Any string acceptable as a *command_string* operand to the *sh* **–c** command shall be valid. When standard output is a terminal device, the message output shall be piped through the command if the *mailx* internal variable **crt** is set to a value less the number of lines in the message; see Internal Variables in mailx (on page 2889). If the *PAGER* variable is null or not set, the paginator shall be either *more* or another paginator utility documented in the system documentation. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

SHELL Determine the name of a preferred command interpreter. The default shall be *sh*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

TERM If the internal variable **screen** is not specified, determine the name of the terminal type to indicate in an unspecified manner the number of lines in a screenful of headers. If *TERM* is not set or is set to null, an unspecified default terminal type shall be used and the value of a screenful is unspecified. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

TZ This variable may determine the timezone used to calculate date and time strings written by *mailx*. If *TZ* is unset or null, an unspecified default timezone shall be used.

VISUAL Determine a pathname of a utility to invoke when the **visual** command (see Commands in mailx, on page 2892) or **~v** command-escape (see Command Escapes in mailx, on page 2901) is used. If this variable is null or not set, the full-screen editor shall be *vi*. The effects of this variable are unspecified if the User Portability Utilities option is not supported.

ASYNCHRONOUS EVENTS

When *mailx* is in Send Mode and standard input is not a terminal, it shall take the standard action for all signals.

UP In Receive Mode, or in Send Mode when standard input is a terminal, if a SIGINT signal is received:

UP 1. If in command mode, the current command, if there is one, shall be aborted, and a command-mode prompt shall be written.

2. If in input mode:

UP a. If **ignore** is set, *mailx* shall write "@\n", discard the current input line, and continue processing, bypassing the message-abort mechanism described in item 2b.

94652 UP b. If the interrupt was received while sending mail, either when in Receive Mode or
94653 in Send Mode, a message shall be written, and another subsequent interrupt, with
94654 no other intervening characters typed, shall be required to abort the mail message.
94655 UP If in Receive Mode and another interrupt is received, a command-mode prompt
94656 shall be written. If in Send Mode and another interrupt is received, *mailx* shall
94657 terminate with a non-zero status.

94658 In both cases listed in item b, if the message is not empty:

94659 UP i. If **save** is enabled and the file named by *DEAD* can be created, the message
94660 shall be written to the file named by *DEAD*. If the file exists, the message
94661 shall be written to replace the contents of the file.

94662 UP ii. If **save** is not enabled, or the file named by *DEAD* cannot be created, the
94663 message shall not be saved.

94664 The *mailx* utility shall take the standard action for all other signals.

94665 **STDOUT**

94666 In command and input modes, all output, including prompts and messages, shall be written to
94667 standard output.

94668 **STDERR**

94669 The standard error shall be used only for diagnostic messages.

94670 **OUTPUT FILES**

94671 Various *mailx* commands and command escapes can create or add to files, including the **mbox**,
94672 the dead-letter file, and secondary mailboxes. When *mailx* is used as described in this volume of
94673 POSIX.1-200x, these files shall be text files, formatted as follows:

94674 `line beginning with` **`From<space>`**
94675 **`[`**`one or more` *`header-lines`*; see Commands in mailx (on page 2892)**`]`**
94676 *`empty line`*
94677 **`[`**`zero or more` *`body lines`*
94678 *`empty line`**`]`**
94679 **`[`**`line beginning with` **`From<space>...]`**

94680 where each message begins with the **From <space>** line shown, preceded by the beginning of
94681 the file or an empty line. (The **From <space>** line is considered to be part of the message header,
94682 but not one of the header-lines referred to in Commands in mailx (on page 2892); thus, it shall
94683 not be affected by the **discard**, **ignore**, or **retain** commands.) The formats of the remainder of the
94684 **From <space>** line and any additional header lines are unspecified, except that none shall be
94685 empty. The format of a message body line is also unspecified, except that no line following an
94686 empty line shall start with **From <space>**; *mailx* shall modify any such user-entered message
94687 body lines (following an empty line and beginning with **From <space>**) by adding one or more
94688 characters to precede the `'F'`; it may add these characters to **From <space>** lines that are not
94689 preceded by an empty line.

94690 When a message from the system mailbox or entered by the user is not a text file, it is
94691 implementation-defined how such a message is stored in files written by *mailx*.

94692 **EXTENDED DESCRIPTION**

94693 UP The functionality in the entire EXTENDED DESCRIPTION section shall be provided on
94694 implementations supporting the User Portability Utilities option. The functionality described in
94695 this section shall be provided on implementations that support the User Portability Utilities
94696 option (and the rest of this section is not further shaded for this option).

The *mailx* utility need not support for all character encodings in all circumstances. For example, inter-system mail may be restricted to 7-bit data by the underlying network, 8-bit data need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used.

When *mailx* is invoked using one of the Receive Mode synopsis forms, it shall write a page of header-summary lines (if **–N** was not specified and there are messages, see below), followed by a prompt indicating that *mailx* can accept regular commands (see Commands in mailx, on page 2892); this is termed *command mode*. The page of header-summary lines shall contain the first new message if there are new messages, or the first unread message if there are unread messages, or the first message. When *mailx* is invoked using the Send Mode synopsis and standard input is a terminal, if no subject is specified on the command line and the **asksub** variable is set, a prompt for the subject shall be written. At this point, *mailx* shall be in input mode. This input mode shall also be entered when using one of the Receive Mode synopsis forms and a reply or new message is composed using the **reply**, **Reply**, **followup**, **Followup**, or **mail** commands and standard input is a terminal. When the message is typed and the end of the message is encountered, the message shall be passed to the mail delivery software. Commands can be entered by beginning a line with the escape character (by default, <tilde> (`'~'`)) followed by a single command letter and optional arguments. See Commands in mailx (on page 2892) for a summary of these commands. It is unspecified what effect these commands will have if standard input is not a terminal when a message is entered using either the Send Mode synopsis, or the Read Mode commands **reply**, **Reply**, **followup**, **Followup**, or **mail**.

Note: For notational convenience, this section uses the default escape character, <tilde>, in all references and examples.

At any time, the behavior of *mailx* shall be governed by a set of environmental and internal variables. These are flags and valued parameters that can be set and cleared via the *mailx* **set** and **unset** commands.

Regular commands are of the form:

[*command***] [***msglist***] [***argument ...***]**

If no *command* is specified in command mode, **next** shall be assumed. In input mode, commands shall be recognized by the escape character, and lines not treated as commands shall be taken as input for the message.

In command mode, each message shall be assigned a sequential number, starting with 1.

All messages have a state that shall affect how they are displayed in the header summary and how they are retained or deleted upon termination of *mailx*. There is at any time the notion of a *current* message, which shall be marked by a `'>'` at the beginning of a line in the header summary. When *mailx* is invoked using one of the Receive Mode synopsis forms, the current message shall be the first new message, if there is a new message, or the first unread message if there is an unread message, or the first message if there are any messages, or unspecified if there are no messages in the mailbox. Each command that takes an optional list of messages (*msglist*) or an optional single message (*message*) on which to operate shall leave the current message set to the highest-numbered message of the messages specified, unless the command deletes messages, in which case the current message shall be set to the first undeleted message (that is, a message not in the deleted state) after the highest-numbered message deleted by the command, if one exists, or the first undeleted message before the highest-numbered message deleted by the command, if one exists, or to an unspecified value if there are no remaining undeleted messages. All messages shall be in one of the following states:

94744 *new* The message is present in the system mailbox and has not been viewed by the user
94745 or moved to any other state. Messages in state *new* when *mailx* quits shall be
94746 retained in the system mailbox.

94747 *unread* The message has been present in the system mailbox for more than one invocation
94748 of *mailx* and has not been viewed by the user or moved to any other state.
94749 Messages in state *unread* when *mailx* quits shall be retained in the system mailbox.

94750 *read* The message has been processed by one of the following commands: **~f**, **~m**, **~F**, **~M**,
94751 **copy**, **mbox**, **next**, **pipe**, **print**, **Print**, **top**, **type**, **Type**, **undelete**. The **delete**, **dp**,
94752 and **dt** commands may also cause the next message to be marked as *read*,
94753 depending on the value of the **autoprint** variable. Messages that are in the system
94754 mailbox and in state *read* when *mailx* quits shall be saved in the **mbox**, unless the
94755 internal variable **hold** was set. Messages that are in the **mbox** or in a secondary
94756 mailbox and in state *read* when *mailx* quits shall be retained in their current
94757 location.

94758 *deleted* The message has been processed by one of the following commands: **delete**, **dp**, **dt**.
94759 Messages in state *deleted* when *mailx* quits shall be deleted. Deleted messages shall
94760 be ignored until *mailx* quits or changes mailboxes or they are specified to the
94761 undelete command; for example, the message specification */string* shall only
94762 search the subject lines of messages that have not yet been deleted, unless the
94763 command operating on the list of messages is **undelete**. No deleted message or
94764 deleted message header shall be displayed by any *mailx* command other than
94765 **undelete**.

94766 *preserved* The message has been processed by a **preserve** command. When *mailx* quits, the
94767 message shall be retained in its current location.

94768 *saved* The message has been processed by one of the following commands: **save** or **write**.
94769 If the current mailbox is the system mailbox, and the internal variable **keepsave** is
94770 set, messages in the state saved shall be saved to the file designated by the *MBOX*
94771 variable (see the ENVIRONMENT VARIABLES section). If the current mailbox is
94772 the system mailbox, messages in the state *saved* shall be deleted from the current
94773 mailbox, when the **quit** or **file** command is used to exit the current mailbox.

94774 The header-summary line for each message shall indicate the state of the message.

94775 Many commands take an optional list of messages (*msglist*) on which to operate, which defaults
94776 to the current message. A *msglist* is a list of message specifications separated by <blank>
94777 characters, which can include:

94778 n Message number *n*.

94779 + The next undeleted message, or the next deleted message for the **undelete** command.

94780 – The next previous undeleted message, or the next previous deleted message for the
94781 **undelete** command.

94782 . The current message.

94783 ^ The first undeleted message, or the first deleted message for the **undelete** command.

94784 $ The last message.

94785 * All messages.

94786 `n-m` An inclusive range of message numbers.

94787 *address* All messages from *address*; any address as shown in a header summary shall be
94788 matchable in this form.

94789 */string* All messages with *string* in the subject line (case ignored).

94790 `:c` All messages of type *c*, where *c* shall be one of:

94791 `d` Deleted messages.

94792 `n` New messages.

94793 `o` Old messages (any not in state *read* or *new*).

94794 `r` Read messages.

94795 `u` Unread messages.

94796 Other commands take an optional message (*message*) on which to operate, which defaults to the
94797 current message. All of the forms allowed for *msglist* are also allowed for *message*, but if more
94798 than one message is specified, only the first shall be operated on.

94799 Other arguments are usually arbitrary strings whose usage depends on the command involved.

94800 **Start-Up in mailx**

94801 At start-up time, *mailx* shall take the following steps in sequence:

94802 1. Establish all variables at their stated default values.

94803 2. Process command line options, overriding corresponding default values.

94804 3. Import any of the *DEAD*, *EDITOR*, *MBOX*, *LISTER*, *PAGER*, *SHELL*, or *VISUAL* variables
94805 that are present in the environment, overriding the corresponding default values.

94806 4. Read *mailx* commands from an unspecified system start-up file, unless the **−n** option is
94807 given, to initialize any internal *mailx* variables and aliases.

94808 5. Process the start-up file of *mailx* commands named in the user *MAILRC* variable.

94809 Most regular *mailx* commands are valid inside start-up files, the most common use being to set
94810 up initial display options and alias lists. The following commands shall be invalid in the start-up
94811 file: **!**, **edit**, **hold**, **mail**, **preserve**, **reply**, **Reply**, **shell**, **visual**, **Copy**, **followup**, and **Followup**.
94812 Any errors in the start-up file shall either cause *mailx* to terminate with a diagnostic message and
94813 a non-zero status or to continue after writing a diagnostic message, ignoring the remainder of
94814 the lines in the start-up file.

94815 A blank line in a start-up file shall be ignored.

94816 **Internal Variables in mailx**

94817 The following variables are internal *mailx* variables. Each internal variable can be set via the
94818 *mailx* **set** command at any time. The **unset** and **set no** *name* commands can be used to erase
94819 variables.

94820 In the following list, variables shown as:

94821 `variable`

94822 represent Boolean values. Variables shown as:

94823 `variable=value`

shall be assigned string or numeric values. For string values, the rules in Commands in mailx (on page 2892) concerning filenames and quoting shall also apply.

The defaults specified here may be changed by the unspecified system start-up file unless the user specifies the –**n** option.

allnet All network names whose login name components match shall be treated as identical. This shall cause the *msglist* message specifications to behave similarly. The default shall be **noallnet**. See also the **alternates** command and the **metoo** variable.

append Append messages to the end of the **mbox** file upon termination instead of placing them at the beginning. The default shall be **noappend**. This variable shall not affect the **save** command when saving to **mbox**.

ask, **asksub** Prompt for a subject line on outgoing mail if one is not specified on the command line with the –**s** option. The **ask** and **asksub** forms are synonyms; the system shall refer to **asksub** and **noasksub** in its messages, but shall accept **ask** and **noask** as user input to mean **asksub** and **noasksub**. It shall not be possible to set both **ask** and **noasksub**, or **noask** and **asksub**. The default shall be **asksub**, but no prompting shall be done if standard input is not a terminal.

askbcc Prompt for the blind copy list. The default shall be **noaskbcc**.

askcc Prompt for the copy list. The default shall be **noaskcc**.

autoprint Enable automatic writing of messages after **delete** and **undelete** commands. The default shall be **noautoprint**.

bang Enable the special-case treatment of <exclamation-mark> characters (`'!'`) in escape command lines; see the **escape** command and Command Escapes in mailx (on page 2901). The default shall be **nobang**, disabling the expansion of `'!'` in the *command* argument to the **~!** command and the **~<!***command* escape.

cmd=*command*
Set the default command to be invoked by the **pipe** command. The default shall be **nocmd**.

crt=*number* Pipe messages having more than *number* lines through the command specified by the value of the *PAGER* variable. The default shall be **nocrt**. If it is set to null, the value used is implementation-defined.

XSI **debug** Enable verbose diagnostics for debugging. Messages are not delivered. The default shall be **nodebug**.

dot When **dot** is set, a <period> on a line by itself during message input from a terminal shall also signify end-of-file (in addition to normal end-of-file). The default shall be **nodot**. If **ignoreeof** is set (see below), a setting of **nodot** shall be ignored and the <period> is the only method to terminate input mode.

escape=*c* Set the command escape character to be the character `'c'`. By default, the command escape character shall be <tilde>. If **escape** is unset, <tilde> shall be used; if it is set to null, command escaping shall be disabled.

flipr Reverse the meanings of the **R** and **r** commands. The default shall be **noflipr**.

folder=*directory*
The default directory for saving mail files. User-specified filenames beginning with a <plus-sign> (`'+'`) shall be expanded by preceding the filename with this

94868 directory name to obtain the real pathname. If *directory* does not start with a
94869 <slash> (`'/'`), the contents of *HOME* shall be prefixed to it. The default shall be
94870 **nofolder**. If **folder** is unset or set to null, user-specified filenames beginning with
94871 `'+'` shall refer to files in the current directory that begin with the literal `'+'`
94872 character. See also **outfolder** below. The **folder** value need not affect the processing
94873 of the files named in *MBOX* and *DEAD*.

94874 **header** Enable writing of the header summary when entering *mailx* in Receive Mode. The
94875 default shall be **header**.

94876 **hold** Preserve all messages that are read in the system mailbox instead of putting them
94877 in the **mbox** save file. The default shall be **nohold**.

94878 **ignore** Ignore interrupts while entering messages. The default shall be **noignore**.

94879 **ignoreeof** Ignore normal end-of-file during message input. Input can be terminated only by
94880 entering a <period> (`'.'`) on a line by itself or by the **~.** command escape. The
94881 default shall be **noignoreeof**. See also **dot** above.

94882 **indentprefix**=*string*
94883 A string that shall be added as a prefix to each line that is inserted into the message
94884 by the **~m** command escape. This variable shall default to one <tab>.

94885 **keep** When a system mailbox, secondary mailbox, or **mbox** is empty, truncate it to zero
94886 length instead of removing it. The default shall be **nokeep**.

94887 **keepsave** Keep the messages that have been saved from the system mailbox into other files
94888 in the file designated by the variable *MBOX*, instead of deleting them. The default
94889 shall be **nokeepsave**.

94890 **metoo** Suppress the deletion of the login name of the user from the recipient list when
94891 replying to a message or sending to a group. The default shall be **nometoo**.

94892 XSI **onehop** When responding to a message that was originally sent to several recipients, the
94893 other recipient addresses are normally forced to be relative to the originating
94894 author's machine for the response. This flag disables alteration of the recipients'
94895 addresses, improving efficiency in a network where all machines can send directly
94896 to all other machines (that is, one hop away). The default shall be **noonehop**.

94897 **outfolder** Cause the files used to record outgoing messages to be located in the directory
94898 specified by the **folder** variable unless the pathname is absolute. The default shall
94899 be **nooutfolder**. See the **record** variable.

94900 **page** Insert a <form-feed> after each message sent through the pipe created by the **pipe**
94901 command. The default shall be **nopage**.

94902 **prompt**=*string*
94903 Set the command-mode prompt to *string*. If *string* is null or if **noprompt** is set, no
94904 prompting shall occur. The default shall be to prompt with the string `"? "`.

94905 **quiet** Refrain from writing the opening message and version when entering *mailx*. The
94906 default shall be **noquiet**.

94907 **record**=*file* Record all outgoing mail in the file with the pathname *file*. The default shall be
94908 **norecord**. See also **outfolder** above.

94909 **save** Enable saving of messages in the dead-letter file on interrupt or delivery error. See
94910 the variable *DEAD* for the location of the dead-letter file. The default shall be **save**.

94911 **screen**=*number*
94912 Set the number of lines in a screenful of headers for the **headers** and **z** commands.
94913 If **screen** is not specified, a value based on the terminal type identified by the
94914 *TERM* environment variable, the window size, the baud rate, or some combination
94915 of these shall be used.

94916 **sendwait** Wait for the background mailer to finish before returning. The default shall be
94917 **nosendwait**.

94918 **showto** When the sender of the message was the user who is invoking *mailx*, write the
94919 information from the **To:** line instead of the **From:** line in the header summary. The
94920 default shall be **noshowto**.

94921 **sign**=*string* Set the variable inserted into the text of a message when the **~a** command escape is
94922 given. The default shall be **nosign**. The character sequences `'\t'` and `'\n'` shall
94923 be recognized in the variable as <tab> and <newline> characters, respectively. (See
94924 also **~i** in Command Escapes in mailx (on page 2901).)

94925 **Sign**=*string* Set the variable inserted into the text of a message when the **~A** command escape is
94926 given. The default shall be **noSign**. The character sequences `'\t'` and `'\n'` shall
94927 be recognized in the variable as <tab> and <newline> characters, respectively.

94928 **toplines**=*number*
94929 Set the number of lines of the message to write with the **top** command. The default
94930 shall be 5.

94931 **Commands in mailx**

94932 The following *mailx* commands shall be provided. In the following list, header refers to lines
94933 from the message header, as shown in the OUTPUT FILES section. Header-line refers to lines
94934 within the header that begin with one or more non-white-space characters, immediately
94935 followed by a <colon> and white space and continuing until the next line beginning with a non-
94936 white-space character or an empty line. Header-field refers to the portion of a header line prior
94937 to the first <colon> in that line.

94938 For each of the commands listed below, the command can be entered as the abbreviation (those
94939 characters in the Synopsis command word preceding the `'['`), the full command (all characters
94940 shown for the command word, omitting the `'['` and `']'`), or any truncation of the full
94941 command down to the abbreviation. For example, the **exit** command (shown as **ex[it]** in the
94942 Synopsis) can be entered as **ex**, **exi**, or **exit**.

94943 The arguments to commands can be quoted, using the following methods:

94944 • An argument can be enclosed between paired double-quotes (`""`) or single-quotes (`''`);
94945 any white space, shell word expansion, or <backslash> characters within the quotes shall
94946 be treated literally as part of the argument. A double-quote shall be treated literally within
94947 single-quotes and *vice versa*. These special properties of the <quotation-mark> characters
94948 shall occur only when they are paired at the beginning and end of the argument.

94949 • A <backslash> outside of the enclosing quotes shall be discarded and the following
94950 character treated literally as part of the argument.

94951 • An unquoted <backslash> at the end of a command line shall be discarded and the next
94952 line shall continue the command.

Filenames, where expected, shall be subjected to the following transformations, in sequence:

- If the filename begins with an unquoted <plus-sign>, and the **folder** variable is defined (see the **folder** variable), the <plus-sign> shall be replaced by the value of the **folder** variable followed by a <slash>. If the **folder** variable is unset or is set to null, the filename shall be unchanged.
- Shell word expansions shall be applied to the filename (see Section 2.6, on page 2305). If more than a single pathname results from this expansion and the command is expecting one file, the effects are unspecified.

Declare Aliases

Synopsis:
```
a[lias] [alias [address...]]
g[roup] [alias [address...]]
```

Add the given addresses to the alias specified by *alias*. The names shall be substituted when *alias* is used as a recipient address specified by the user in an outgoing message (that is, other recipients addressed indirectly through the **reply** command shall not be substituted in this manner). Mail address alias substitution shall apply only when the alias string is used as a full address; for example, when **hlj** is an alias, *hlj@posix.com* does not trigger the alias substitution. If no arguments are given, write a listing of the current aliases to standard output. If only an *alias* argument is given, write a listing of the specified alias to standard output. These listings need not reflect the same order of addresses that were entered.

Declare Alternatives

Synopsis:
```
alt[ernates] name...
```

(See also the **metoo** variable.) Declare a list of alternative names for the user's login. When responding to a message, these names shall be removed from the list of recipients for the response. The comparison of names shall be in a case-insensitive manner. With no arguments, **alternates** shall write the current list of alternative names.

Change Current Directory

Synopsis:
```
cd [directory]
ch[dir] [directory]
```

Change directory. If *directory* is not specified, the contents of *HOME* shall be used.

Copy Messages

Synopsis:
```
c[opy] [file]
c[opy] [msglist] file
C[opy] [msglist]
```

Copy messages to the file named by the pathname *file* without marking the messages as saved. Otherwise, it shall be equivalent to the **save** command.

In the capitalized form, save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise, it shall be equivalent to the **Save** command.

94991 **Delete Messages**

94992 *Synopsis*: `d[elete] [`*`msglist`*`]`

94993 Mark messages for deletion from the mailbox. The deletions shall not occur until *mailx* quits (see
94994 the **quit** command) or changes mailboxes (see the **folder** command). If **autoprint** is set and there
94995 are messages remaining after the **delete** command, the current message shall be written as
94996 described for the **print** command (see the **print** command); otherwise, the *mailx* prompt shall be
94997 written.

94998 **Discard Header Fields**

94999 *Synopsis*: `di[scard] [`*`header-field...`*`]`
95000 `ig[nore] [`*`header-field...`*`]`

95001 Suppress the specified header fields when writing messages. Specified *header-fields* shall be
95002 added to the list of suppressed header fields. Examples of header fields to ignore are **status** and
95003 **cc**. The fields shall be included when the message is saved. The **Print** and **Type** commands shall
95004 override this command. The comparison of header fields shall be in a case-insensitive manner. If
95005 no arguments are specified, write a list of the currently suppressed header fields to standard
95006 output; the listing need not reflect the same order of header fields that were entered.

95007 If both **retain** and **discard** commands are given, **discard** commands shall be ignored.

95008 **Delete Messages and Display**

95009 *Synopsis*: `dp [`*`msglist`*`]`
95010 `dt [`*`msglist`*`]`

95011 Delete the specified messages as described for the **delete** command, except that the **autoprint**
95012 variable shall have no effect, and the current message shall be written only if it was set to a
95013 message after the last message deleted by the command. Otherwise, an informational message
95014 to the effect that there are no further messages in the mailbox shall be written, followed by the
95015 *mailx* prompt.

95016 **Echo a String**

95017 *Synopsis*: `ec[ho]` *`string ...`*

95018 Echo the given strings, equivalent to the shell *echo* utility.

95019 **Edit Messages**

95020 *Synopsis*: `e[dit] [`*`msglist`*`]`

95021 Edit the given messages. The messages shall be placed in a temporary file and the utility named
95022 by the *EDITOR* variable is invoked to edit each file in sequence. The default *EDITOR* is
95023 unspecified.

95024 The **edit** command does not modify the contents of those messages in the mailbox.

95025 **Exit**

95026 *Synopsis*: `ex[it]`
95027 `x[it]`

95028 Exit from *mailx* without changing the mailbox. No messages shall be saved in the **mbox** (see also
95029 **quit**).

95030 **Change Folder**

95031 *Synopsis*: `fi[le] [file]`
95032 `fold[er] [file]`

95033 Quit (see the **quit** command) from the current file of messages and read in the file named by the
95034 pathname *file*. If no argument is given, the name and status of the current mailbox shall be
95035 written.

95036 Several unquoted special characters shall be recognized when used as *file* names, with the
95037 following substitutions:

95038 `%` The system mailbox for the invoking user.

95039 `%user` The system mailbox for *user*.

95040 `#` The previous file.

95041 `&` The current **mbox**.

95042 `+file` The named file in the **folder** directory. (See the **folder** variable.)

95043 The default file shall be the current mailbox.

95044 **Display List of Folders**

95045 *Synopsis*: `folders`

95046 Write the names of the files in the directory set by the **folder** variable. The command specified
95047 by the *LISTER* environment variable shall be used (see the ENVIRONMENT VARIABLES
95048 section).

95049 **Follow Up Specified Messages**

95050 *Synopsis*: `fo[llowup] [message]`
95051 `F[ollowup] [msglist]`

95052 In the lowercase form, respond to a message, recording the response in a file whose name is
95053 derived from the author of the message. See also the **save** and **copy** commands and **outfolder**.

95054 In the capitalized form, respond to the first message in the *msglist*, sending the message to the
95055 author of each message in the *msglist*. The subject line shall be taken from the first message and
95056 the response shall be recorded in a file whose name is derived from the author of the first
95057 message. See also the **Save** and **Copy** commands and **outfolder**.

95058 Both forms shall override the **record** variable, if set.

95059 **Display Header Summary for Specified Messages**

95060 *Synopsis*: `f[rom] [msglist]`

95061 Write the header summary for the specified messages.

95062 **Display Header Summary**

95063 *Synopsis*: `h[eaders] [message]`

95064 Write the page of headers that includes the message specified. If the *message* argument is not
95065 specified, the current message shall not change. However, if the *message* argument is specified,
95066 the current message shall become the message that appears at the top of the page of headers that
95067 includes the message specified. The **screen** variable sets the number of headers per page. See
95068 also the **z** command.

95069 **Help**

95070 *Synopsis*: `hel[p]`
95071 `?`

95072 Write a summary of commands.

95073 **Hold Messages**

95074 *Synopsis*: `ho[ld] [msglist]`
95075 `pre[serve] [msglist]`

95076 Mark the messages in *msglist* to be retained in the mailbox when *mailx* terminates. This shall
95077 override any commands that might previously have marked the messages to be deleted. During
95078 the current invocation of *mailx*, only the **delete**, **dp**, or **dt** commands shall remove the *preserve*
95079 marking of a message.

95080 **Execute Commands Conditionally**

95081 *Synopsis*: `i[f] s|r`
95082 *mail-command*`s`
95083 `el[se]`
95084 *mail-command*`s`
95085 `en[dif]`

95086 Execute commands conditionally, where **if s** executes the following *mail-command*s, up to an
95087 **else** or **endif**, if the program is in Send Mode, and **if r** shall cause the *mail-command*s to be
95088 executed only in Receive Mode.

95089 **List Available Commands**

95090 *Synopsis*: `l[ist]`

95091 Write a list of all commands available. No explanation shall be given.

95092 **Mail a Message**

95093 *Synopsis*: `m[ail] address...`

95094 Mail a message to the specified addresses or aliases.

95095 **Direct Messages to mbox**

95096 *Synopsis*: `mb[ox] [msglist]`

95097 Arrange for the given messages to end up in the **mbox** save file when *mailx* terminates normally.
95098 See *MBOX*. See also the **exit** and **quit** commands.

95099 **Process Next Specified Message**

95100 *Synopsis*: `n[ext] [message]`

95101 If the current message has not been written (for example, by the **print** command) since *mailx*
95102 started or since any other message was the current message, behave as if the **print** command
95103 was entered. Otherwise, if there is an undeleted message after the current message, make it the
95104 current message and behave as if the **print** command was entered. Otherwise, an informational
95105 message to the effect that there are no further messages in the mailbox shall be written, followed
95106 by the *mailx* prompt. Should the current message location be the result of an immediately
95107 preceding **hold**, **mbox**, **preserve**, or **touch** command, **next** will act as if the current message has
95108 already been written.

95109 **Pipe Message**

95110 *Synopsis*: `pi[pe] [[msglist] command]`
95111 `| [[msglist] command]`

95112 Pipe the messages through the given *command* by invoking the command interpreter specified
95113 by *SHELL* with two arguments: **–c** and *command*. (See also *sh* **–c**.) The application shall ensure
95114 that the command is given as a single argument. Quoting, described previously, can be used to
95115 accomplish this. If no arguments are given, the current message shall be piped through the
95116 command specified by the value of the **cmd** variable. If the **page** variable is set, a <form-feed>
95117 shall be inserted after each message.

95118 **Display Message with Headers**

95119 *Synopsis*: `P[rint] [msglist]`
95120 `T[ype] [msglist]`

95121 Write the specified messages, including all header lines, to standard output. Override
95122 suppression of lines by the **discard**, **ignore**, and **retain** commands. If **crt** is set, the messages
95123 longer than the number of lines specified by the **crt** variable shall be paged through the
95124 command specified by the *PAGER* environment variable.

95125 **Display Message**

95126 *Synopsis*: `p[rint] [msglist]`
95127 `t[ype] [msglist]`

95128 Write the specified messages to standard output. If **crt** is set, the messages longer than the
95129 number of lines specified by the **crt** variable shall be paged through the command specified by
95130 the *PAGER* environment variable.

95131 **Quit**

95132 *Synopsis*: `q[uit]`
95133 `end-of-file`

95134 Terminate *mailx*, storing messages that were read in **mbox** (if the current mailbox is the system
95135 mailbox and unless **hold** is set), deleting messages that have been explicitly saved (unless
95136 **keepsave** is set), discarding messages that have been deleted, and saving all remaining messages
95137 in the mailbox.

95138 **Reply to a Message List**

95139 *Synopsis*: `R[eply] [msglist]`
95140 `R[espond] [msglist]`

95141 Mail a reply message to the sender of each message in the *msglist*. The subject line shall be
95142 formed by concatenating **Re:**<space> (unless it already begins with that string) and the subject
95143 from the first message. If **record** is set to a filename, the response shall be saved at the end of that
95144 file.

95145 See also the **flipr** variable.

95146 **Reply to a Message**

95147 *Synopsis*: `r[eply] [message]`
95148 `r[espond] [message]`

95149 Mail a reply message to all recipients included in the header of the message. The subject line
95150 shall be formed by concatenating **Re:**<space> (unless it already begins with that string) and the
95151 subject from the message. If **record** is set to a filename, the response shall be saved at the end of
95152 that file.

95153 See also the **flipr** variable.

95154 **Retain Header Fields**

95155 *Synopsis*: `ret[ain] [header-field...]`

95156 Retain the specified header fields when writing messages. This command shall override all
95157 **discard** and **ignore** commands. The comparison of header fields shall be in a case-insensitive
95158 manner. If no arguments are specified, write a list of the currently retained header fields to
95159 standard output; the listing need not reflect the same order of header fields that were entered.

95160 **Save Messages**

95161 *Synopsis*: `s[ave] [file]`
95162 `s[ave] [msglist] file`
95163 `S[ave] [msglist]`

95164 Save the specified messages in the file named by the pathname *file*, or the **mbox** if the *file*
95165 argument is omitted. The file shall be created if it does not exist; otherwise, the messages shall be
95166 appended to the file. The message shall be put in the state *saved*, and shall behave as specified in
95167 the description of the *saved* state when the current mailbox is exited by the **quit** or **file**
95168 command.

95169 In the capitalized form, save the specified messages in a file whose name is derived from the
95170 author of the first message. The name of the file shall be taken to be the author's name with all
95171 network addressing stripped off. See also the **Copy**, **followup**, and **Followup** commands and

outfolder variable.

Set Variables

Synopsis: `se[t] [`*`name`*`[=[`*`string`*`]] ...] [`*`name`*`=`*`number`* `...] [no`*`name`* `...]`

Define one or more variables called *name*. The variable can be given a null, string, or numeric value. Quoting and <backslash>-escapes can occur anywhere in *string*, as described previously, as if the *string* portion of the argument were the entire argument. The forms *name* and *name*= shall be equivalent to *name*="" for variables that take string values. The **set** command without arguments shall write a list of all defined variables and their values. The **no** *name* form shall be equivalent to **unset** *name*.

Invoke a Shell

Synopsis: `sh[ell]`

Invoke an interactive command interpreter (see also *SHELL*).

Display Message Size

Synopsis: `si[ze] [`*`msglist`*`]`

Write the size in bytes of each of the specified messages.

Read mailx Commands From a File

Synopsis: `so[urce]` *`file`*

Read and execute commands from the file named by the pathname *file* and return to command mode.

Display Beginning of Messages

Synopsis: `to[p] [`*`msglist`*`]`

Write the top few lines of each of the specified messages. If the **toplines** variable is set, it is taken as the number of lines to write. The default shall be 5.

Touch Messages

Synopsis: `tou[ch] [`*`msglist`*`]`

Touch the specified messages. If any message in *msglist* is not specifically deleted nor saved in a file, it shall be placed in the **mbox** upon normal termination. See **exit** and **quit**.

Delete Aliases

Synopsis: `una[lias] [`*`alias`*`]...`

Delete the specified alias names. If a specified alias does not exist, the results are unspecified.

95202 **Undelete Messages**

95203 *Synopsis*: `u[ndelete] [`*`msglist`*`]`

95204 Change the state of the specified messages from deleted to read. If **autoprint** is set, the last
95205 message of those restored shall be written. If *msglist* is not specified, the message shall be
95206 selected as follows:

95207 • If there are any deleted messages that follow the current message, the first of these shall be
95208 chosen.

95209 • Otherwise, the last deleted message that also precedes the current message shall be chosen.

95210 **Unset Variables**

95211 *Synopsis*: `uns[et]` *`name...`*

95212 Cause the specified variables to be erased.

95213 **Edit Message with Full-Screen Editor**

95214 *Synopsis*: `v[isual] [`*`msglist`*`]`

95215 Edit the given messages with a screen editor. Each message shall be placed in a temporary file,
95216 and the utility named by the *VISUAL* variable shall be invoked to edit each file in sequence. The
95217 default editor shall be *vi*.

95218 The **visual** command does not modify the contents of those messages in the mailbox.

95219 **Write Messages to a File**

95220 *Synopsis*: `w[rite] [`*`msglist`*`]` *`file`*

95221 Write the given messages to the file specified by the pathname *file*, minus the message header.
95222 Otherwise, it shall be equivalent to the **save** command.

95223 **Scroll Header Display**

95224 *Synopsis*: `z[+|-]`

95225 Scroll the header display forward (if `'+'` is specified or if no option is specified) or backward (if
95226 `'-'` is specified) one screenful. The number of headers written shall be set by the **screen**
95227 variable.

95228 **Invoke Shell Command**

95229 *Synopsis*: `!`*`command`*

95230 Invoke the command interpreter specified by *SHELL* with two arguments: **-c** and *command*. (See
95231 also *sh* **-c**.) If the **bang** variable is set, each unescaped occurrence of `'!'` in *command* shall be
95232 replaced with the command executed by the previous `!` command or `~!` command escape.

95233 **Null Command**

95234 *Synopsis*: `# comment`

95235 This null command (comment) shall be ignored by *mailx*.

95236 **Display Current Message Number**

95237 *Synopsis*: `=`

95238 Write the current message number.

95239 **Command Escapes in mailx**

95240 The following commands can be entered only from input mode, by beginning a line with the
95241 escape character (by default, <tilde> (`'~'`)). See the **escape** variable description for changing
95242 this special character. The format for the commands shall be:

95243 `<escape-character><command-char><separator>[<arguments>]`

95244 where the <*separator*> can be zero or more <blank> characters.

95245 In the following descriptions, the application shall ensure that the argument *command* (but not
95246 *mailx-command)* is a shell command string. Any string acceptable to the command interpreter
95247 specified by the *SHELL* variable when it is invoked as *SHELL* **–c** *command_string* shall be valid.
95248 The command can be presented as multiple arguments (that is, quoting is not required).

95249 Command escapes that are listed with *msglist* or *mailx-command* arguments are invalid in Send
95250 Mode and produce unspecified results.

95251 **~!** *command* Invoke the command interpreter specified by *SHELL* with two arguments: **–c** and
95252 *command*; and then return to input mode. If the **bang** variable is set, each
95253 unescaped occurrence of `'!'` in *command* shall be replaced with the command
95254 executed by the previous **!** command or **~!** command escape.

95255 **~.** Simulate end-of-file (terminate message input).

95256 **~:** *mailx-command*, **~_** *mailx-command*
95257 Perform the command-level request.

95258 **~?** Write a summary of command escapes.

95259 **~A** This shall be equivalent to **~i Sign**.

95260 **~a** This shall be equivalent to **~i sign**.

95261 **~b** *name*... Add the *name*s to the blind carbon copy (**Bcc**) list.

95262 **~c** *name*... Add the *name*s to the carbon copy (**Cc**) list.

95263 **~d** Read in the dead-letter file. See *DEAD* for a description of this file.

95264 **~e** Invoke the editor, as specified by the *EDITOR* environment variable, on the partial
95265 message.

95266 **~f** [*msglist*] Forward the specified messages. The specified messages shall be inserted into the
95267 current message without alteration. This command escape also shall insert
95268 message headers into the message with field selection affected by the **discard**,
95269 **ignore**, and **retain** commands.

95270 **~F** [*msglist*] This shall be the equivalent of the **~f** command escape, except that all headers shall
95271 be included in the message, regardless of previous **discard**, **ignore**, and **retain**
95272 commands.

95273 **~h** If standard input is a terminal, prompt for a **Subject** line and the **To**, **Cc**, and **Bcc**
95274 lists. Other implementation-defined headers may also be presented for editing. If
95275 the field is written with an initial value, it can be edited as if it had just been typed.

95276 **~i** *string* Insert the value of the named variable, followed by a <newline>, into the text of
95277 the message. If the string is unset or null, the message shall not be changed.

95278 **~m** [*msglist*] Insert the specified messages into the message, prefixing non-empty lines with the
95279 string in the **indentprefix** variable. This command escape also shall insert message
95280 headers into the message, with field selection affected by the **discard**, **ignore**, and
95281 **retain** commands.

95282 **~M** [*msglist*] This shall be the equivalent of the **~m** command escape, except that all headers
95283 shall be included in the message, regardless of previous **discard**, **ignore**, and **retain**
95284 commands.

95285 **~p** Write the message being entered. If the message is longer than **crt** lines (see
95286 Internal Variables in mailx, on page 2889), the output shall be paginated as
95287 described for the *PAGER* variable.

95288 **~q** Quit (see the **quit** command) from input mode by simulating an interrupt. If the
95289 body of the message is not empty, the partial message shall be saved in the dead-
95290 letter file. See *DEAD* for a description of this file.

95291 **~r** *file*, **~<** *file*, **~r** **!***command*, **~<** **!***command*
95292 Read in the file specified by the pathname *file*. If the argument begins with an
95293 <exclamation-mark> ('**!**'), the rest of the string shall be taken as an arbitrary
95294 system command; the command interpreter specified by *SHELL* shall be invoked
95295 with two arguments: **–c** and *command*. The standard output of *command* shall be
95296 inserted into the message.

95297 **~s** *string* Set the subject line to *string*.

95298 **~t** *name*... Add the given *name*s to the **To** list.

95299 **~v** Invoke the full-screen editor, as specified by the *VISUAL* environment variable, on
95300 the partial message.

95301 **~w** *file* Write the partial message, without the header, onto the file named by the
95302 pathname *file*. The file shall be created or the message shall be appended to it if
95303 the file exists.

95304 **~x** Exit as with **~q**, except the message shall not be saved in the dead-letter file.

95305 **~|** *command* Pipe the body of the message through the given *command* by invoking the
95306 command interpreter specified by *SHELL* with two arguments: **–c** and *command*. If
95307 the *command* returns a successful exit status, the standard output of the command
95308 shall replace the message. Otherwise, the message shall remain unchanged. If the
95309 *command* fails, an error message giving the exit status shall be written.

EXIT STATUS

When the **–e** option is specified, the following exit values are returned:

0 Mail was found.

>0 Mail was not found or an error occurred.

Otherwise, the following exit values are returned:

0 Successful completion; note that this status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*.

>0 An error occurred.

CONSEQUENCES OF ERRORS

When in input mode (Receive Mode) or Send Mode:

- If an error is encountered processing an input line beginning with a <tilde> ('~') character, (see Command Escapes in mailx, on page 2901), a diagnostic message shall be written to standard error, and the message being composed may be modified, but this condition shall not prevent the message from being sent.
- Other errors shall prevent the sending of the message.

When in command mode:

- Default.

APPLICATION USAGE

Delivery of messages to remote systems requires the existence of communication paths to such systems. These need not exist.

Input lines are limited to {LINE_MAX} bytes, but mailers between systems may impose more severe line-length restrictions. This volume of POSIX.1-200x does not place any restrictions on the length of messages handled by *mailx*, and for delivery of local messages the only limitations should be the normal problems of available disk space for the target mail file. When sending messages to external machines, applications are advised to limit messages to less than 100 000 bytes because some mail gateways impose message-length restrictions.

The format of the system mailbox is intentionally unspecified. Not all systems implement system mailboxes as flat files, particularly with the advent of multimedia mail messages. Some system mailboxes may be multiple files, others records in a database. The internal format of the messages themselves is specified with the historical format from Version 7, but only after the messages have been saved in some file other than the system mailbox. This was done so that many historical applications expecting text-file mailboxes are not broken.

Some new formats for messages can be expected in the future, probably including binary data, bit maps, and various multimedia objects. As described here, *mailx* is not prohibited from handling such messages, but it must store them as text files in secondary mailboxes (unless some extension, such as a variable or command line option, is used to change the stored format). Its method of doing so is implementation-defined and might include translating the data into text file-compatible or readable form or omitting certain portions of the message from the stored output.

The **discard** and **ignore** commands are not inverses of the **retain** command. The **retain** command discards all header-fields except those explicitly retained. The **discard** command keeps all header-fields except those explicitly discarded. If headers exist on the retained header

95352 list, **discard** and **ignore** commands are ignored.

95353 **EXAMPLES**

95354 None.

95355 **RATIONALE**

95356 The standard developers felt strongly that a method for applications to send messages to specific
95357 users was necessary. The obvious example is a batch utility, running non-interactively, that
95358 wishes to communicate errors or results to a user. However, the actual format, delivery
95359 mechanism, and method of reading the message are clearly beyond the scope of this volume of
95360 POSIX.1-200x.

95361 The intent of this command is to provide a simple, portable interface for sending messages non-
95362 interactively. It merely defines a "front-end" to the historical mail system. It is suggested that
95363 implementations explicitly denote the sender and recipient in the body of the delivered message.
95364 Further specification of formats for either the message envelope or the message itself were
95365 deliberately not made, as the industry is in the midst of changing from the current standards to a
95366 more internationalized standard and it is probably incorrect, at this time, to require either one.

95367 Implementations are encouraged to conform to the various delivery mechanisms described in
95368 the CCITT X.400 standards or to the equivalent Internet standards, described in Internet Request
95369 for Comment (RFC) documents RFC 819, RFC 822, RFC 920, RFC 921, and RFC 1123.

95370 Many historical systems modified each body line that started with **From** by prefixing the `'F'`
95371 with `'>'`. It is unnecessary, but allowed, to do that when the string does not follow a blank line
95372 because it cannot be confused with the next header.

95373 The **edit** and **visual** commands merely edit the specified messages in a temporary file. They do
95374 not modify the contents of those messages in the mailbox; such a capability could be added as an
95375 extension, such as by using different command names.

95376 The restriction on a subject line being {LINE_MAX}–10 bytes is based on the historical format
95377 that consumes 10 bytes for **Subject:** and the trailing <newline>. Many historical mailers that a
95378 message may encounter on other systems are not able to handle lines that long, however.

95379 Like the utilities *logger* and *lp*, *mailx* admittedly is difficult to test. This was not deemed sufficient
95380 justification to exclude this utility from this volume of POSIX.1-200x. It is also arguable that it is,
95381 in fact, testable, but that the tests themselves are not portable.

95382 When *mailx* is being used by an application that wishes to receive the results as if none of the
95383 User Portability Utilities option features were supported, the *DEAD* environment variable must
95384 be set to **/dev/null**. Otherwise, it may be subject to the file creations described in *mailx*
95385 ASYNCHRONOUS EVENTS. Similarly, if the *MAILRC* environment variable is not set to
95386 **/dev/null**, historical versions of *mailx* and *Mail* read initialization commands from a file before
95387 processing begins. Since the initialization that a user specifies could alter the contents of
95388 messages an application is trying to send, such applications must set *MAILRC* to **/dev/null**.

95389 The description of *LC_TIME* uses "may affect" because many historical implementations do not
95390 or cannot manipulate the date and time strings in the incoming mail headers. Some headers
95391 found in incoming mail do not have enough information to determine the timezone in which the
95392 mail originated, and, therefore, *mailx* cannot convert the date and time strings into the internal
95393 form that then is parsed by routines like *strftime*( ) that can take *LC_TIME* settings into account.
95394 Changing all these times to a user-specified format is allowed, but not required.

95395 The paginator selected when *PAGER* is null or unset is partially unspecified to allow the System
95396 V historical practice of using *pg* as the default. Bypassing the pagination function, such as by
95397 declaring that *cat* is the paginator, would not meet with the intended meaning of this

description. However, any "portable user" would have to set *PAGER* explicitly to get his or her preferred paginator on all systems. The paginator choice was made partially unspecified, unlike the *VISUAL* editor choice (mandated to be *vi*) because most historical pagers follow a common theme of user input, whereas editors differ dramatically.

Options to specify addresses as **cc** (carbon copy) or **bcc** (blind carbon copy) were considered to be format details and were omitted.

A zero exit status implies that all messages were *sent*, but it gives no assurances that any of them were actually *delivered*. The reliability of the delivery mechanism is unspecified and is an appropriate marketing distinction between systems.

In order to conform to the Utility Syntax Guidelines, a solution was required to the optional *file* option-argument to **–f**. By making *file* an operand, the guidelines are satisfied and users remain portable. However, it does force implementations to support usage such as:

```
mailx –fin mymail.box
```

The **no** *name* method of unsetting variables is not present in all historical systems, but it is in System V and provides a logical set of commands corresponding to the format of the display of options from the *mailx set* command without arguments.

The **ask** and **asksub** variables are the names selected by BSD and System V, respectively, for the same feature. They are synonyms in this volume of POSIX.1-200x.

The *mailx echo* command was not documented in the BSD version and has been omitted here because it is not obviously useful for interactive users.

The default prompt on the System V *mailx* is a <question-mark>, on BSD *Mail* an <ampersand>. Since this volume of POSIX.1-200x chose the *mailx* name, it kept the System V default, assuming that BSD users would not have difficulty with this minor incompatibility (that they can override).

The meanings of **r** and **R** are reversed between System V *mailx* and SunOS *Mail*. Once again, since this volume of POSIX.1-200x chose the *mailx* name, it kept the System V default, but allows the SunOS user to achieve the desired results using **flipr**, an internal variable in System V *mailx*, although it has not been documented in the SVID.

The **indentprefix** variable, the **retain** and **unalias** commands, and the **~F** and **~M** command escapes were adopted from 4.3 BSD *Mail*.

The **version** command was not included because no sufficiently general specification of the version information could be devised that would still be useful to a portable user. This command name should be used by suppliers who wish to provide version information about the *mailx* command.

The "implementation-specific (unspecified) system start-up file" historically has been named **/etc/mailx.rc**, but this specific name and location are not required.

The intent of the wording for the **next** command is that if any command has already displayed the current message it should display a following message, but, otherwise, it should display the current message. Consider the command sequence:

```
next 3
delete 3
next
```

where the **autoprint** option was not set. The normative text specifies that the second **next** command should display a message following the third message, because even though the

current message has not been displayed since it was set by the **delete** command, it has been displayed since the current message was anything other than message number 3. This does not always match historical practice in some implementations, where the command file address followed by **next** (or the default command) would skip the message for which the user had searched.

FUTURE DIRECTIONS

None.

SEE ALSO

Chapter 2 (on page 2297), *ed*, *ls*, *more*, *vi*

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 2.

Issue 5

The description of the *EDITOR* environment variable is changed to indicate that *ed* is the default editor if this variable is not set. In previous issues, this default was not stated explicitly at this point but was implied further down in the text.

The FUTURE DIRECTIONS section is added.

Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **–F** option is added.
- The **allnet**, **debug**, and **sendwait** internal variables are added.
- The **C**, **ec**, **fo**, **F**, and **S** *mailx* commands are added.

In the DESCRIPTION and ENVIRONMENT VARIABLES sections, text stating "*HOME* directory" is replaced by "directory referred to by the *HOME* environment variable".

The *mailx* utility is aligned with the IEEE P1003.2b draft standard, which includes various clarifications to resolve IEEE PASC Interpretations submitted for the ISO POSIX-2:1993 standard. In particular, the changes here address IEEE PASC Interpretations 1003.2 #10, #11, #103, #106, #108, #114, #115, #122, and #129.

The normative text is reworded to avoid use of the term "must" for application requirements.

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/32 is applied, applying a change to the EXTENDED DESCRIPTION, raised by IEEE PASC Interpretation 1003.2 #122, which was overlooked in the first version of this standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/17 is applied, updating the EXTENDED DESCRIPTION (Internal Variables in *mailx*). The system start-up file is changed from "implementation-defined" to "unspecified" for consistency with other text in the EXTENDED DESCRIPTION.

Issue 7

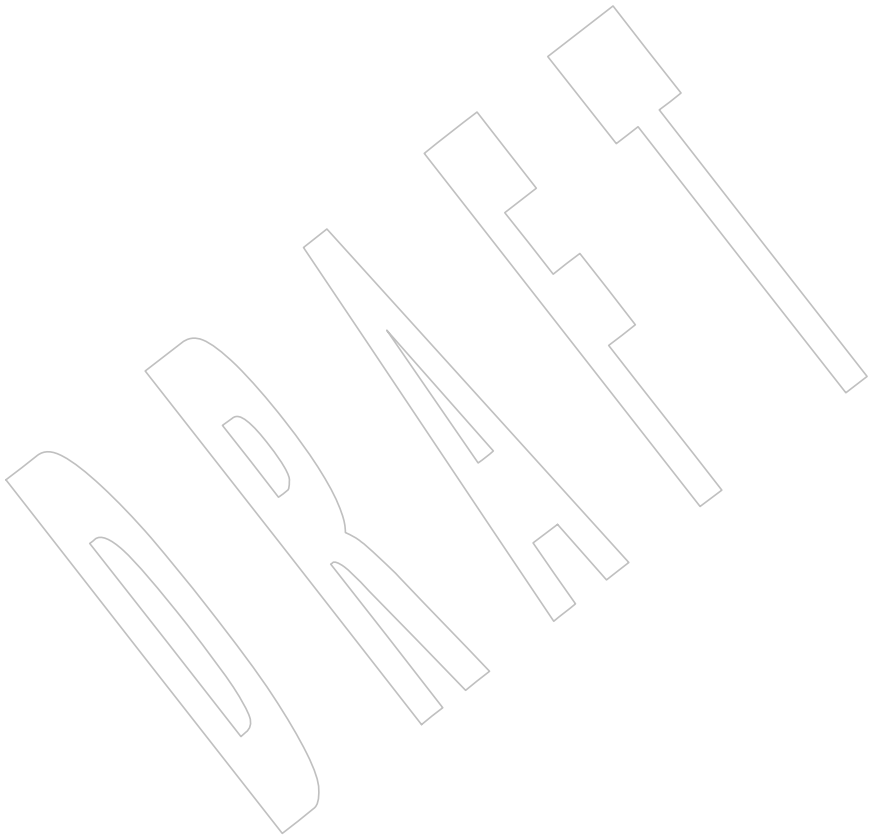
Austin Group Interpretation 1003.1-2001 #089 is applied, clarifying the effect of the *LC_TIME* environment variable.

Austin Group Interpretation 1003.1-2001 #090 is applied, updating the description of the **next** command.

95485 SD5-XCU-ERN-69 is applied.

95486 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

95487 Shading to indicate support for the User Portability Utilities option is added.



95488 **NAME**

95489 make — maintain, update, and regenerate groups of programs (**DEVELOPMENT**)

95490 **SYNOPSIS**

95491 SD
```
make [–einpqrst] [–f makefile]... [–k|–S] [macro=value...]
    [target_name...]
```

95492

95493 **DESCRIPTION**

95494 The *make* utility shall update files that are derived from other files. A typical case is one where
95495 object files are derived from the corresponding source files. The *make* utility examines time
95496 relationships and shall update those derived files (called targets) that have modified times
95497 earlier than the modified times of the files (called prerequisites) from which they are derived. A
95498 description file (makefile) contains a description of the relationships between files, and the
95499 commands that need to be executed to update the targets to reflect changes in their
95500 prerequisites. Each specification, or rule, shall consist of a target, optional prerequisites, and
95501 optional commands to be executed when a prerequisite is newer than the target. There are two
95502 types of rule:

95503 1. *Inference rules*, which have one target name with at least one <period> (`'.'`) and no
95504 <slash> (`'/'`)

95505 2. *Target rules*, which can have more than one target name

95506 In addition, *make* shall have a collection of built-in macros and inference rules that infer
95507 prerequisite relationships to simplify maintenance of programs.

95508 To receive exactly the behavior described in this section, the user shall ensure that a portable
95509 makefile shall:

95510 • Include the special target **.POSIX**

95511 • Omit any special target reserved for implementations (a leading period followed by
95512 uppercase letters) that has not been specified by this section

95513 The behavior of *make* is unspecified if either or both of these conditions are not met.

95514 **OPTIONS**

95515 The *make* utility shall conform to XBD Section 12.2 (on page 215), except for Guideline 9.

95516 The following options shall be supported:

95517 **–e** Cause environment variables, including those with null values, to override macro
95518 assignments within makefiles.

95519 **–f** *makefile* Specify a different makefile. The argument *makefile* is a pathname of a description
95520 file, which is also referred to as the *makefile*. A pathname of `'–'` shall denote the
95521 standard input. There can be multiple instances of this option, and they shall be
95522 processed in the order specified. The effect of specifying the same option-argument
95523 more than once is unspecified.

95524 **–i** Ignore error codes returned by invoked commands. This mode is the same as if the
95525 special target **.IGNORE** were specified without prerequisites.

95526 **–k** Continue to update other targets that do not depend on the current target if a non-
95527 ignored error occurs while executing the commands to bring a target up-to-date.

95528 **–n** Write commands that would be executed on standard output, but do not execute
95529 them. However, lines with a <plus-sign> (`'+'`) prefix shall be executed. In this
95530 mode, lines with an at-sign (`'@'`) character prefix shall be written to standard

output.

−p Write to standard output the complete set of macro definitions and target descriptions. The output format is unspecified.

−q Return a zero exit value if the target file is up-to-date; otherwise, return an exit value of 1. Targets shall not be updated if this option is specified. However, a makefile command line (associated with the targets) with a <plus-sign> ('+') prefix shall be executed.

−r Clear the suffix list and do not use the built-in rules.

−S Terminate *make* if an error occurs while executing the commands to bring a target up-to-date. This shall be the default and the opposite of **−k**.

−s Do not write makefile command lines or touch messages (see **−t**) to standard output before executing. This mode shall be the same as if the special target **.SILENT** were specified without prerequisites.

−t Update the modification time of each target as though a *touch target* had been executed. Targets that have prerequisites but no commands (see Target Rules, on page 2913), or that are already up-to-date, shall not be touched in this manner. Write messages to standard output for each target file indicating the name of the file and that it was touched. Normally, the *makefile* command lines associated with each target are not executed. However, a command line with a <plus-sign> ('+') prefix shall be executed.

Any options specified in the *MAKEFLAGS* environment variable shall be evaluated before any options specified on the *make* utility command line. If the **−k** and **−S** options are both specified on the *make* utility command line or by the *MAKEFLAGS* environment variable, the last option specified shall take precedence. If the **−f** or **−p** options appear in the *MAKEFLAGS* environment variable, the result is undefined.

OPERANDS

The following operands shall be supported:

target_name Target names, as defined in the EXTENDED DESCRIPTION section. If no target is specified, while *make* is processing the makefiles, the first target that *make* encounters that is not a special target or an inference rule shall be used.

macro=value Macro definitions, as defined in Macros (on page 2914).

If the *target_name* and *macro=value* operands are intermixed on the *make* utility command line, the results are unspecified.

STDIN

The standard input shall be used only if the *makefile* option-argument is '−'. See the INPUT FILES section.

INPUT FILES

The input file, otherwise known as the makefile, is a text file containing rules, macro definitions, and comments. See the EXTENDED DESCRIPTION section.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *make*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

95575 *LC_ALL* If set to a non-empty string value, override the values of all the other
95576 internationalization variables.

95577 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
95578 characters (for example, single-byte as opposed to multi-byte characters in
95579 arguments and input files).

95580 *LC_MESSAGES*
95581 Determine the locale that should be used to affect the format and contents of
95582 diagnostic messages written to standard error.

95583 *MAKEFLAGS*
95584 This variable shall be interpreted as a character string representing a series of
95585 option characters to be used as the default options. The implementation shall
95586 accept both of the following formats (but need not accept them when intermixed):

95587 • The characters are option letters without the leading <hyphen> characters or
95588 <blank> separation used on a *make* utility command line.

95589 • The characters are formatted in a manner similar to a portion of the *make*
95590 utility command line: options are preceded by <hyphen> characters and
95591 <blank>-separated as described in XBD Section 12.2 (on page 215). The
95592 *macro=value* macro definition operands can also be included. The difference
95593 between the contents of *MAKEFLAGS* and the *make* utility command line is
95594 that the contents of the variable shall not be subjected to the word expansions
95595 (see Section 2.6, on page 2305) associated with parsing the command line
95596 values.

95597 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

95598 XSI *PROJECTDIR*
95599 Provide a directory to be used to search for SCCS files not found in the current
95600 directory. In all of the following cases, the search for SCCS files is made in the
95601 directory **SCCS** in the identified directory. If the value of *PROJECTDIR* begins with
95602 a <slash>, it shall be considered an absolute pathname; otherwise, the value of
95603 *PROJECTDIR* is treated as a user name and that user's initial working directory
95604 shall be examined for a subdirectory **src** or **source**. If such a directory is found, it
95605 shall be used. Otherwise, the value is used as a relative pathname.

95606 If *PROJECTDIR* is not set or has a null value, the search for SCCS files shall be
95607 made in the directory **SCCS** in the current directory.

95608 The setting of *PROJECTDIR* affects all files listed in the remainder of this utility
95609 description for files with a component named **SCCS**.

95610 The value of the *SHELL* environment variable shall not be used as a macro and shall not be
95611 modified by defining the **SHELL** macro in a makefile or on the command line. All other
95612 environment variables, including those with null values, shall be used as macros, as defined in
95613 Macros (on page 2914).

95614 **ASYNCHRONOUS EVENTS**

95615 If not already ignored, *make* shall trap SIGHUP, SIGTERM, SIGINT, and SIGQUIT and remove
95616 the current target unless the target is a directory or the target is a prerequisite of the special
95617 target **.PRECIOUS** or unless one of the **–n**, **–p**, or **–q** options was specified. Any targets removed
95618 in this manner shall be reported in diagnostic messages of unspecified format, written to
95619 standard error. After this cleanup process, if any, *make* shall take the standard action for all other
95620 signals.

95621 **STDOUT**

95622 The *make* utility shall write all commands to be executed to standard output unless the **–s** option
95623 was specified, the command is prefixed with an at-sign, or the special target **.SILENT** has either
95624 the current target as a prerequisite or has no prerequisites. If *make* is invoked without any work
95625 needing to be done, it shall write a message to standard output indicating that no action was
95626 taken. If the **–t** option is present and a file is touched, *make* shall write to standard output a
95627 message of unspecified format indicating that the file was touched, including the filename of the
95628 file.

95629 **STDERR**

95630 The standard error shall be used only for diagnostic messages.

95631 **OUTPUT FILES**

95632 Files can be created when the **–t** option is present. Additional files can also be created by the
95633 utilities invoked by *make*.

95634 **EXTENDED DESCRIPTION**

95635 The *make* utility attempts to perform the actions required to ensure that the specified targets are
95636 up-to-date. A target is considered out-of-date if it is older than any of its prerequisites or if it
95637 does not exist. The *make* utility shall treat all prerequisites as targets themselves and recursively
95638 ensure that they are up-to-date, processing them in the order in which they appear in the rule.
95639 The *make* utility shall use the modification times of files to determine whether the corresponding
95640 targets are out-of-date.

95641 After *make* has ensured that all of the prerequisites of a target are up-to-date and if the target is
95642 out-of-date, the commands associated with the target entry shall be executed. If there are no
95643 commands listed for the target, the target shall be treated as up-to-date.

95644 **Makefile Syntax**

95645 A makefile can contain rules, macro definitions (see Macros, on page 2914), include lines, and
95646 comments. There are two kinds of rules: *inference rules* and *target rules*. The *make* utility shall
95647 contain a set of built-in inference rules. If the **–r** option is present, the built-in rules shall not be
95648 used and the suffix list shall be cleared. Additional rules of both types can be specified in a
95649 makefile. If a rule is defined more than once, the value of the rule shall be that of the last one
95650 specified. Macros can also be defined more than once, and the value of the macro is specified in
95651 Macros (on page 2914). Comments start with a <number-sign> (`'#'`) and continue until an
95652 unescaped <newline> is reached.

95653 By default, the following files shall be tried in sequence: **./makefile** and **./Makefile**. If neither
95654 XSI **./makefile** or **./Makefile** are found, other implementation-defined files may also be tried. On
95655 XSI-conformant systems, the additional files **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and
95656 **SCCS/s.Makefile** shall also be tried.

95657 The **–f** option shall direct *make* to ignore any of these default files and use the specified argument
95658 as a makefile instead. If the `'–'` argument is specified, standard input shall be used.

95659 The term *makefile* is used to refer to any rules provided by the user, whether in **./makefile** or its
95660 variants, or specified by the **–f** option.

95661 The rules in makefiles shall consist of the following types of lines: target rules, including special
95662 targets (see Target Rules, on page 2913), inference rules (see Inference Rules, on page 2916),
95663 macro definitions (see Macros, on page 2914), empty lines, and comments.

95664 Target and Inference Rules may contain *command lines*. Command lines can have a prefix that
95665 shall be removed before execution (see Makefile Execution, on page 2912).

When an escaped <newline> (one preceded by a <backslash>) is found anywhere in the makefile except in a command line, an include line, or a line immediately preceding an include line, it shall be replaced, along with any leading white space on the following line, with a single <space>. When an escaped <newline> is found in a command line in a makefile, the command line shall contain the <backslash>, the <newline>, and the next line, except that the first character of the next line shall not be included if it is a <tab>. When an escaped <newline> is found in an include line or in a line immediately preceding an include line, the behavior is unspecified.

Include Lines

If the word **include** appears at the beginning of a line and is followed by one or more <blank> characters, the string formed by the remainder of the line shall be processed as follows to produce a pathname:

- The trailing <newline> and any comment shall be discarded. If the resulting string contains any double-quote characters (`'"'`) the behavior is unspecified.
- The resulting string shall be processed for macro expansion (see Macros (on page 2914).
- Any <blank> characters that appear after the first non-<blank> shall be used as separators to divide the macro-expanded string into fields. It is unspecified whether any other white-space characters are also used as separators. It is unspecified whether pathname expansion (see Section 2.13, on page 2332) is also performed.
- If the processing of separators and optional pathname expansion results in either zero or two or more non-empty fields, the behavior is unspecified. If it results in one non-empty field, that field is taken as the pathname.

If the pathname does not begin with a `'/'` it shall be treated as relative to the current working directory of the process, not relative to the directory containing the makefile. If the file does not exist in this location, it is unspecified whether additional directories are searched.

The contents of the file specified by the pathname shall be read and processed as if they appeared in the makefile in place of the include line. If the file ends with an escaped <newline> the behavior is unspecified.

The file may itself contain further include lines. Implementations shall support nesting of include files up to a depth of at least 16.

Makefile Execution

Makefile command lines shall be processed one at a time.

Makefile command lines can have one or more of the following prefixes: a <hyphen> (`'-'`), an at-sign (`'@'`), or a <plus-sign> (`'+'`). These shall modify the way in which *make* processes the command.

– If the command prefix contains a <hyphen>, or the **–i** option is present, or the special target **.IGNORE** has either the current target as a prerequisite or has no prerequisites, any error found while executing the command shall be ignored.

@ If the command prefix contains an at-sign and the *make* utility command line **–n** option is not specified, or the **–s** option is present, or the special target **.SILENT** has either the current target as a prerequisite or has no prerequisites, the command shall not be written to standard output before it is executed.

95708 95709 + If the command prefix contains a <plus-sign>, this indicates a makefile command line that shall be executed even if **–n**, **–q**, or **–t** is specified.

95710 95711 95712 95713 95714 95715 An *execution line* is built from the command line by removing any prefix characters. Except as described under the at-sign prefix, the execution line shall be written to the standard output, optionally preceded by a <tab>. The execution line shall then be executed by a shell as if it were passed as the argument to the *system*( ) interface, except that the shell **–e** option shall also be in effect. The environment for the command being executed shall contain all of the variables in the environment of *make*.

95716 95717 By default, when *make* receives a non-zero status from the execution of a command, it shall terminate with an error message to standard error.

95718 **Target Rules**

95719 Target rules are formatted as follows:

```
95720 target [target...]: [prerequisite...][;command]
95721 [<tab>command
95722 <tab>command
95723 ...]

95724 line that does not begin with <tab>
```

95725 95726 95727 95728 95729 Target entries are specified by a <blank>-separated, non-null list of targets, then a <colon>, then a <blank>-separated, possibly empty list of prerequisites. Text following a <semicolon>, if any, and all following lines that begin with a <tab>, are makefile command lines to be executed to update the target. The first non-empty line that does not begin with a <tab> or `'#'` shall begin a new entry. An empty or blank line, or a line beginning with `'#'`, may begin a new entry.

95730 95731 95732 95733 Applications shall select target names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see XBD Section 6.1, on page 125). Implementations may allow other characters in target names as extensions. The interpretation of targets containing the characters `'%'` and `'"'` is implementation-defined.

95734 95735 A target that has prerequisites, but does not have any commands, can be used to add to the prerequisite list for that target. Only one target rule for any given target can contain commands.

95736 95737 Lines that begin with one of the following are called *special targets* and control the operation of *make*:

95738 95739 95740 **.DEFAULT** If the makefile uses this special target, the application shall ensure that it is specified with commands, but without prerequisites. The commands shall be used by *make* if there are no other rules available to build a target.

95741 95742 95743 95744 95745 95746 **.IGNORE** Prerequisites of this special target are targets themselves; this shall cause errors from commands associated with them to be ignored in the same manner as specified by the **–i** option. Subsequent occurrences of **.IGNORE** shall add to the list of targets ignoring command errors. If no prerequisites are specified, *make* shall behave as if the **–i** option had been specified and errors from all commands associated with all targets shall be ignored.

95747 95748 95749 95750 **.POSIX** The application shall ensure that this special target is specified without prerequisites or commands. If it appears as the first non-comment line in the makefile, *make* shall process the makefile as specified by this section; otherwise, the behavior of *make* is unspecified.

.PRECIOUS Prerequisites of this special target shall not be removed if *make* receives one of the asynchronous events explicitly described in the ASYNCHRONOUS EVENTS section. Subsequent occurrences of **.PRECIOUS** shall add to the list of precious files. If no prerequisites are specified, all targets in the makefile shall be treated as if specified with **.PRECIOUS**.

XSI **.SCCS_GET** The application shall ensure that this special target is specified without prerequisites. If this special target is included in a makefile, the commands specified with this target shall replace the default commands associated with this special target (see Default Rules, on page 2919). The commands specified with this target are used to get all SCCS files that are not found in the current directory.

When source files are named in a dependency list, *make* shall treat them just like any other target. Because the source file is presumed to be present in the directory, there is no need to add an entry for it to the makefile. When a target has no dependencies, but is present in the directory, *make* shall assume that that file is up-to-date. If, however, an SCCS file named **SCCS/s.***source_file* is found for a target *source_file*, *make* compares the timestamp of the target file with that of the **SCCS/s.source_file** to ensure the target is up-to-date. If the target is missing, or if the SCCS file is newer, *make* shall automatically issue the commands specified for the **.SCCS_GET** special target to retrieve the most recent version. However, if the target is writable by anyone, *make* shall not retrieve a new version.

.SILENT Prerequisites of this special target are targets themselves; this shall cause commands associated with them not to be written to the standard output before they are executed. Subsequent occurrences of **.SILENT** shall add to the list of targets with silent commands. If no prerequisites are specified, *make* shall behave as if the **–s** option had been specified and no commands or touch messages associated with any target shall be written to standard output.

.SUFFIXES Prerequisites of **.SUFFIXES** shall be appended to the list of known suffixes and are used in conjunction with the inference rules (see Inference Rules, on page 2916). If **.SUFFIXES** does not have any prerequisites, the list of known suffixes shall be cleared.

The special targets **.IGNORE**, **.POSIX**, **.PRECIOUS**, **.SILENT**, and **.SUFFIXES** shall be specified without commands.

Targets with names consisting of a leading <period> followed by the uppercase letters `"POSIX"` and then any other characters are reserved for future standardization. Targets with names consisting of a leading <period> followed by one or more uppercase letters are reserved for implementation extensions.

Macros

Macro definitions are in the form:

string1 **=** **[***string2***]**

The macro named *string1* is defined as having the value of *string2*, where *string2* is defined as all characters, if any, after the <equals-sign>, up to a comment character (`'#'`) or an unescaped <newline>. Any <blank> characters immediately before or after the <equals-sign> shall be ignored.

Applications shall select macro names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see XBD Section 6.1, on page 125). A macro name shall not contain an <equals-sign>. Implementations may allow other

95797 characters in macro names as extensions.

95798 Macros can appear anywhere in the makefile. Macro expansions using the forms $(*string1*) or
95799 ${*string1*} shall be replaced by *string2*, as follows:

95800 • Macros in target lines shall be evaluated when the target line is read.

95801 • Macros in makefile command lines shall be evaluated when the command is executed.

95802 • Macros in the string before the <equals-sign> in a macro definition shall be evaluated
95803 when the macro assignment is made.

95804 • Macros after the <equals-sign> in a macro definition shall not be evaluated until the
95805 defined macro is used in a rule or command, or before the <equals-sign> in a macro
95806 definition.

95807 The parentheses or braces are optional if *string1* is a single character. The macro $$ shall be
95808 replaced by the single character `'$'`. If *string1* in a macro expansion contains a macro
95809 expansion, the results are unspecified.

95810 Macro expansions using the forms $(*string1*[**:***subst1***=**[*subst2*]]) or ${*string1*[**:***subst1***=**[*subst2*]]} can
95811 be used to replace all occurrences of *subst1* with *subst2* when the macro substitution is
95812 performed. The *subst1* to be replaced shall be recognized when it is a suffix at the end of a word
95813 in *string1* (where a *word*, in this context, is defined to be a string delimited by the beginning of
95814 the line, a <blank>, or a <newline>). If *string1* in a macro expansion contains a macro expansion,
95815 the results are unspecified.

95816 Macro expansions in *string1* of macro definition lines shall be evaluated when read. Macro
95817 expansions in *string2* of macro definition lines shall be performed when the macro identified by
95818 *string1* is expanded in a rule or command.

95819 Macro definitions shall be taken from the following sources, in the following logical order,
95820 before the makefile(s) are read.

95821 1. Macros specified on the *make* utility command line, in the order specified on the
95822 command line. It is unspecified whether the internal macros defined in Internal Macros
95823 (on page 2917) are accepted from this source.

95824 2. Macros defined by the *MAKEFLAGS* environment variable, in the order specified in the
95825 environment variable. It is unspecified whether the internal macros defined in Internal
95826 Macros (on page 2917) are accepted from this source.

95827 3. The contents of the environment, excluding the *MAKEFLAGS* and *SHELL* variables and
95828 including the variables with null values.

95829 4. Macros defined in the inference rules built into *make*.

95830 Macro definitions from these sources shall not override macro definitions from a lower-
95831 numbered source. Macro definitions from a single source (for example, the *make* utility
95832 command line, the *MAKEFLAGS* environment variable, or the other environment variables)
95833 shall override previous macro definitions from the same source.

95834 Macros defined in the makefile(s) shall override macro definitions that occur before them in the
95835 makefile(s) and macro definitions from source 4. If the **–e** option is not specified, macros defined
95836 in the makefile(s) shall override macro definitions from source 3. Macros defined in the
95837 makefile(s) shall not override macro definitions from source 1 or source 2.

95838 Before the makefile(s) are read, all of the *make* utility command line options (except **–f** and **–p**)
95839 and *make* utility command line macro definitions (except any for the *MAKEFLAGS* macro), not
95840 already included in the *MAKEFLAGS* macro, shall be added to the *MAKEFLAGS* macro, quoted

in an implementation-defined manner such that when *MAKEFLAGS* is read by another instance of the *make* command, the original macro's value is recovered. Other implementation-defined options and macros may also be added to the *MAKEFLAGS* macro. If this modifies the value of the *MAKEFLAGS* macro, or, if the *MAKEFLAGS* macro is modified at any subsequent time, the *MAKEFLAGS* environment variable shall be modified to match the new value of the *MAKEFLAGS* macro. The result of setting *MAKEFLAGS* in the Makefile is unspecified.

Before the makefile(s) are read, all of the *make* utility command line macro definitions (except the *MAKEFLAGS* macro or the *SHELL* macro) shall be added to the environment of *make*. Other implementation-defined variables may also be added to the environment of *make*.

The **SHELL** macro shall be treated specially. It shall be provided by *make* and set to the pathname of the shell command language interpreter (see *sh*). The *SHELL* environment variable shall not affect the value of the **SHELL** macro. If **SHELL** is defined in the makefile or is specified on the command line, it shall replace the original value of the **SHELL** macro, but shall not affect the *SHELL* environment variable. Other effects of defining **SHELL** in the makefile or on the command line are implementation-defined.

Inference Rules

Inference rules are formatted as follows:

```
target:
<tab>command
[<tab>command]
...

line that does not begin with <tab> or #
```

The application shall ensure that the *target* portion is a valid target name (see Target Rules, on page 2913) of the form **.s2** or **.s1.s2** (where **.s1** and **.s2** are suffixes that have been given as prerequisites of the **.SUFFIXES** special target and *s1* and *s2* do not contain any <slash> or <period> characters.) If there is only one <period> in the target, it is a single-suffix inference rule. Targets with two periods are double-suffix inference rules. Inference rules can have only one target before the <colon>.

The application shall ensure that the makefile does not specify prerequisites for inference rules; no characters other than white space shall follow the <colon> in the first line, except when creating the *empty rule*, described below. Prerequisites are inferred, as described below.

Inference rules can be redefined. A target that matches an existing inference rule shall overwrite the old inference rule. An empty rule can be created with a command consisting of simply a <semicolon> (that is, the rule still exists and is found during inference rule search, but since it is empty, execution has no effect). The empty rule can also be formatted as follows:

```
rule: ;
```

where zero or more <blank> characters separate the <colon> and <semicolon>.

The *make* utility uses the suffixes of targets and their prerequisites to infer how a target can be made up-to-date. A list of inference rules defines the commands to be executed. By default, *make* contains a built-in set of inference rules. Additional rules can be specified in the makefile.

The special target **.SUFFIXES** contains as its prerequisites a list of suffixes that shall be used by the inference rules. The order in which the suffixes are specified defines the order in which the inference rules for the suffixes are used. New suffixes shall be appended to the current list by specifying a **.SUFFIXES** special target in the makefile. A **.SUFFIXES** target with no prerequisites shall clear the list of suffixes. An empty **.SUFFIXES** target followed by a new **.SUFFIXES** list is

95886 required to change the order of the suffixes.

95887 Normally, the user would provide an inference rule for each suffix. The inference rule to update
95888 a target with a suffix **.s1** from a prerequisite with a suffix **.s2** is specified as a target **.s2.s1**. The
95889 internal macros provide the means to specify general inference rules (see Internal Macros).

95890 When no target rule is found to update a target, the inference rules shall be checked. The suffix
95891 of the target (**.s1**) to be built is compared to the list of suffixes specified by the **.SUFFIXES** special
95892 targets. If the **.s1** suffix is found in **.SUFFIXES**, the inference rules shall be searched in the order
95893 defined for the first **.s2.s1** rule whose prerequisite file (**$*.s2**) exists. If the target is out-of-date
95894 with respect to this prerequisite, the commands for that inference rule shall be executed.

95895 If the target to be built does not contain a suffix and there is no rule for the target, the single
95896 suffix inference rules shall be checked. The single-suffix inference rules define how to build a
95897 target if a file is found with a name that matches the target name with one of the single suffixes
95898 appended. A rule with one suffix **.s2** is the definition of how to build *target* from **target.s2**. The
95899 other suffix (**.s1**) is treated as null.

95900 XSI A <tilde> (`'~'`) in the above rules refers to an SCCS file in the current directory. Thus, the rule
95901 **.c~.o** would transform an SCCS C-language source file into an object file (**.o**). Because the **s.** of
95902 the SCCS files is a prefix, it is incompatible with *make*'s suffix point of view. Hence, the `'~'` is a
95903 way of changing any file reference into an SCCS file reference.

95904 ### Libraries

95905 If a target or prerequisite contains parentheses, it shall be treated as a member of an archive
95906 library. For the *lib*(*member***.o**) expression *lib* refers to the name of the archive library and *member***.o**
95907 to the member name. The application shall ensure that the member is an object file with the **.o**
95908 suffix. The modification time of the expression is the modification time for the member as kept
95909 in the archive library; see *ar*. The **.a** suffix shall refer to an archive library. The **.s2.a** rule shall be
95910 used to update a member in the library from a file with a suffix **.s2**.

95911 ### Internal Macros

95912 The *make* utility shall maintain five internal macros that can be used in target and inference rules.
95913 In order to clearly define the meaning of these macros, some clarification of the terms *target rule*,
95914 *inference rule*, *target*, and *prerequisite* is necessary.

95915 Target rules are specified by the user in a makefile for a particular target. Inference rules are
95916 user-specified or *make*-specified rules for a particular class of target name. Explicit prerequisites
95917 are those prerequisites specified in a makefile on target lines. Implicit prerequisites are those
95918 prerequisites that are generated when inference rules are used. Inference rules are applied to
95919 implicit prerequisites or to explicit prerequisites that do not have target rules defined for them in
95920 the makefile. Target rules are applied to targets specified in the makefile.

95921 Before any target in the makefile is updated, each of its prerequisites (both explicit and implicit)
95922 shall be updated. This shall be accomplished by recursively processing each prerequisite. Upon
95923 recursion, each prerequisite shall become a target itself. Its prerequisites in turn shall be
95924 processed recursively until a target is found that has no prerequisites, at which point the
95925 recursion stops. The recursion shall then back up, updating each target as it goes.

95926 In the definitions that follow, the word *target* refers to one of:

95927 - A target specified in the makefile

- An explicit prerequisite specified in the makefile that becomes the target when *make* processes it during recursion
- An implicit prerequisite that becomes a target when *make* processes it during recursion

In the definitions that follow, the word *prerequisite* refers to one of the following:

- An explicit prerequisite specified in the makefile for a particular target
- An implicit prerequisite generated as a result of locating an appropriate inference rule and corresponding file that matches the suffix of the target

The five internal macros are:

$@ The $@ shall evaluate to the full target name of the current target, or the archive filename part of a library archive target. It shall be evaluated for both target and inference rules.

For example, in the **.c.a** inference rule, $@ represents the out-of-date **.a** file to be built. Similarly, in a makefile target rule to build **lib.a** from **file.c**, $@ represents the out-of-date **lib.a**.

$% The $% macro shall be evaluated only when the current target is an archive library member of the form *libname*(*member***.o**). In these cases, $@ shall evaluate to *libname* and $% shall evaluate to *member***.o**. The $% macro shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build **lib.a**(**file.o**), $% represents **file.o**, as opposed to $@, which represents **lib.a**.

$? The $? macro shall evaluate to the list of prerequisites that are newer than the current target. It shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build *prog* from **file1.o**, **file2.o**, and **file3.o**, and where *prog* is not out-of-date with respect to **file1.o**, but is out-of-date with respect to **file2.o** and **file3.o**, $? represents **file2.o** and **file3.o**.

$< In an inference rule, the $< macro shall evaluate to the filename whose existence allowed the inference rule to be chosen for the target. In the **.DEFAULT** rule, the $< macro shall evaluate to the current target name. The meaning of the $< macro shall be otherwise unspecified.

For example, in the **.c.a** inference rule, $< represents the prerequisite **.c** file.

$* The $* macro shall evaluate to the current target name with its suffix deleted. It shall be evaluated at least for inference rules.

For example, in the **.c.a** inference rule, $*.o represents the out-of-date **.o** file that corresponds to the prerequisite **.c** file.

Each of the internal macros has an alternative form. When an uppercase `'D'` or `'F'` is appended to any of the macros, the meaning shall be changed to the *directory part* for `'D'` and *filename part* for `'F'`. The directory part is the path prefix of the file without a trailing <slash>; for the current directory, the directory part is `'.'`. When the $? macro contains more than one prerequisite filename, the $(?D) and $(?F) (or ${?D} and ${?F}) macros expand to a list of directory name parts and filename parts respectively.

For the target *lib*(*member***.o**) and the **s2.a** rule, the internal macros shall be defined as:

95969 $< *member*.**s2**

95970 $* *member*

95971 $@ *lib*

95972 $? *member*.**s2**

95973 $% *member*.**o**

95974 **Default Rules**

95975 The default rules for *make* shall achieve results that are the same as if the following were used.
95976 Implementations that do not support the C-Language Development Utilities option may omit
95977 **CC**, **CFLAGS**, **YACC**, **YFLAGS**, **LEX**, **LFLAGS**, **LDFLAGS**, and the **.c**, **.y**, and **.l** inference rules.
95978 Implementations that do not support FORTRAN may omit **FC**, **FFLAGS**, and the **.f** inference
95979 rules. Implementations may provide additional macros and rules.

95980 *SPECIAL TARGETS*

    rm –f $*.o
```

EXIT STATUS

When the **–q** option is specified, the *make* utility shall exit with one of the following values:

0 Successful completion.

1 The target was not up-to-date.

>1 An error occurred.

When the **–q** option is not specified, the *make* utility shall exit with one of the following values:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

If there is a source file (such as **./source.c**) and there are two SCCS files corresponding to it (**./s.source.c** and **./SCCS/s.source.c**), on XSI-conformant systems *make* uses the SCCS file in the current directory. However, users are advised to use the underlying SCCS utilities (*admin*, *delta*, *get*, and so on) or the *sccs* utility for all source files in a given directory. If both forms are used for a given source file, future developers are very likely to be confused.

It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The **–k** and **–S** options are both present so that the relationship between the command line, the *MAKEFLAGS* variable, and the makefile can be controlled precisely. If the **k** flag is passed in *MAKEFLAGS* and a command is of the form:

```
$(MAKE) –S foo
```

then the default behavior is restored for the child *make*.

When the **–n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* **–n** *target* to be used to see all of the action that would be taken to update *target*.

Because of widespread historical practice, interpreting a <number-sign> (`'#'`) inside a variable as the start of a comment has the unfortunate side-effect of making it impossible to place a <number-sign> in a variable, thus forbidding something like:

```
CFLAGS = "–D COMMENT_CHAR='#'"
```

Many historical *make* utilities stop chaining together inference rules when an intermediate target is nonexistent. For example, it might be possible for a *make* to determine that both **.y.c** and **.c.o** could be used to convert a **.y** to a **.o**. Instead, in this case, *make* requires the use of a **.y.o** rule.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other parts of this volume of POSIX.1-200x. The default rules include rules for optional commands in this volume of POSIX.1-200x. Only rules pertaining to commands that are provided are needed in an implementation's default set.

Macros used within other macros are evaluated when the new macro is used rather than when the new macro is defined. Therefore:

```
MACRO = value1
NEW   = $(MACRO)
MACRO = value2

target:
    echo $(NEW)
```

would produce *value2* and not *value1* since **NEW** was not expanded until it was needed in the *echo* command line.

Some historical applications have been known to intermix *target_name* and *macro=name* operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, although some backwards-compatibility support may be included in some implementations.

The following characters in filenames may give trouble: `'='`, `':'`, `'''`, single-quote, and `'@'`. In include filenames, pattern matching characters and `'"'` should also be avoided, as they may be treated as special by some implementations.

For inference rules, the description of $< and $? seem similar. However, an example shows the minor difference. In a makefile containing:

```
foo.o: foo.h
```

if **foo.h** is newer than **foo.o**, yet **foo.c** is older than **foo.o**, the built-in rule to make **foo.o** from **foo.c** is used, with $< equal to **foo.c** and $? equal to **foo.h**. If **foo.c** is also newer than **foo.o**, $< is equal to **foo.c** and $? is equal to **foo.h foo.c**.

EXAMPLES

1. The following command:

   ```
   make
   ```

   makes the first target found in the makefile.

2. The following command:

   ```
   make junk
   ```

makes the target **junk**.

3. The following makefile says that **pgm** depends on two files, **a.o** and **b.o**, and that they in turn depend on their corresponding source files (**a.c** and **b.c**), and a common file **incl.h**:

```
pgm: a.o b.o
    c99 a.o b.o –o pgm
a.o: incl.h a.c
    c99 –c a.c
b.o: incl.h b.c
    c99 –c b.c
```

4. An example for making optimized **.o** files from **.c** files is:

```
.c.o:
    c99 –c –O $*.c
```

or:

```
.c.o:
    c99 –c –O $<
```

5. The most common use of the archive interface follows. Here, it is assumed that the source files are all C-language source:

```
lib: lib(file1.o) lib(file2.o) lib(file3.o)
    @echo lib is now up-to-date
```

The **.c.a** rule is used to make **file1.o**, **file2.o**, and **file3.o** and insert them into **lib**.

The treatment of escaped <newline> characters throughout the makefile is historical practice. For example, the inference rule:

```
.c.o\
:
```

works, and the macro:

```
f=  bar baz\
    biz
a:
    echo ==$f==
```

echoes `"==bar baz biz=="`.

If $? were:

```
/usr/include/stdio.h /usr/include/unistd.h foo.h
```

then $(?D) would be:

```
/usr/include /usr/include .
```

and $(?F) would be:

```
stdio.h unistd.h foo.h
```

6. The contents of the built-in rules can be viewed by running:

```
make –p –f /dev/null 2>/dev/null
```

RATIONALE

The *make* utility described in this volume of POSIX.1-200x is intended to provide the means for changing portable source code into executables that can be run on an POSIX.1-200x-conforming system. It reflects the most common features present in System V and BSD *make*s.

Historically, the *make* utility has been an especially fertile ground for vendor and research organization-specific syntax modifications and extensions. Examples include:

- Syntax supporting parallel execution (such as from various multi-processor vendors, GNU, and others)
- Additional "operators" separating targets and their prerequisites (System V, BSD, and others)
- Specifying that command lines containing the strings `"${MAKE}"` and `"$(MAKE)"` are executed when the **–n** option is specified (GNU and System V)
- Modifications of the meaning of internal macros when referencing libraries (BSD and others)
- Using a single instance of the shell for all of the command lines of the target (BSD and others)
- Allowing <space> characters as well as <tab> characters to delimit command lines (BSD)
- Adding C preprocessor-style "include" and "ifdef" constructs (System V, GNU, BSD, and others)
- Remote execution of command lines (Sprite and others)
- Specifying additional special targets (BSD, System V, and most others)

Additionally, many vendors and research organizations have rethought the basic concepts of *make*, creating vastly extended, as well as completely new, syntaxes. Each of these versions of *make* fulfills the needs of a different community of users; it is unreasonable for this volume of POSIX.1-200x to require behavior that would be incompatible (and probably inferior) to historical practice for such a community.

In similar circumstances, when the industry has enough sufficiently incompatible formats as to make them irreconcilable, this volume of POSIX.1-200x has followed one or both of two courses of action. Commands have been renamed (*cksum*, *echo*, and *pax*) and/or command line options have been provided to select the desired behavior (*grep*, *od*, and *pax*).

Because the syntax specified for the *make* utility is, by and large, a subset of the syntaxes accepted by almost all versions of *make*, it was decided that it would be counter-productive to change the name. And since the makefile itself is a basic unit of portability, it would not be completely effective to reserve a new option letter, such as *make* **–P**, to achieve the portable behavior. Therefore, the special target **.POSIX** was added to the makefile, allowing users to specify "standard" behavior. This special target does not preclude extensions in the *make* utility, nor does it preclude such extensions being used by the makefile specifying the target; it does, however, preclude any extensions from being applied that could alter the behavior of previously valid syntax; such extensions must be controlled via command line options or new special targets. It is incumbent upon portable makefiles to specify the **.POSIX** special target in order to guarantee that they are not affected by local extensions.

The portable version of *make* described in this reference page is not intended to be the state-of-the-art software generation tool and, as such, some newer and more leading-edge features have not been included. An attempt has been made to describe the portable makefile in a manner that does not preclude such extensions as long as they do not disturb the portable behavior described

here.

When the **–n** option is specified, it is always added to *MAKEFLAGS*. This allows a recursive *make* **–n** *target* to be used to see all of the action that would be taken to update *target*.

The definition of *MAKEFLAGS* allows both the System V letter string and the BSD command line formats. The two formats are sufficiently different to allow implementations to support both without ambiguity.

Early proposals stated that an "unquoted" <number-sign> was treated as the start of a comment. The *make* utility does not pay any attention to quotes. A <number-sign> starts a comment regardless of its surroundings.

The text about "other implementation-defined pathnames may also be tried" in addition to **./makefile** and **./Makefile** is to allow such extensions as **SCCS/s.Makefile** and other variations. It was made an implementation-defined requirement (as opposed to unspecified behavior) to highlight surprising implementations that might select something unexpected like **/etc/Makefile**. XSI-conformant systems also try **./s.makefile**, **SCCS/s.makefile**, **./s.Makefile**, and **SCCS/s.Makefile**.

Early proposals contained the macro **NPROC** as a means of specifying that *make* should use *n* processes to do the work required. While this feature is a valuable extension for many systems, it is not common usage and could require other non-trivial extensions to makefile syntax. This extension is not required by this volume of POSIX.1-200x, but could be provided as a compatible extension. The macro **PARALLEL** is used by some historical systems with essentially the same meaning (but without using a name that is a common system limit value). It is suggested that implementors recognize the existing use of **NPROC** and/or **PARALLEL** as extensions to *make*.

The default rules are based on System V. The default **CC=** value is *c99* instead of *cc* because this volume of POSIX.1-200x does not standardize the utility named *cc*. Thus, every conforming application would be required to define **CC=***c99* to expect to run. There is no advantage conferred by the hope that the makefile might hit the "preferred" compiler because this cannot be guaranteed to work. Also, since the portable makescript can only use the *c99* options, no advantage is conferred in terms of what the script can do. It is a quality-of-implementation issue as to whether *c99* is as valuable as *cc*.

The **–d** option to *make* is frequently used to produce debugging information, but is too implementation-defined to add to this volume of POSIX.1-200x.

The **–p** option is not passed in *MAKEFLAGS* on most historical implementations and to change this would cause many implementations to break without sufficiently increased portability.

Commands that begin with a <plus-sign> (`'+'`) are executed even if the **–n** option is present. Based on the GNU version of *make*, the behavior of **–n** when the <plus-sign> prefix is encountered has been extended to apply to **–q** and **–t** as well. However, the System V convention of forcing command execution with **–n** when the command line of a target contains either of the strings `"$(MAKE)"` or `"${MAKE}"` has not been adopted. This functionality appeared in early proposals, but the danger of this approach was pointed out with the following example of a portion of a makefile:

```
subdir:
    cd subdir; rm all_the_files; $(MAKE)
```

The loss of the System V behavior in this case is well-balanced by the safety afforded to other makefiles that were not aware of this situation. In any event, the command line <plus-sign> prefix can provide the desired functionality.

The double <colon> in the target rule format is supported in BSD systems to allow more than

one target line containing the same target name to have commands associated with it. Since this is not functionality described in the SVID or XPG3 it has been allowed as an extension, but not mandated.

The default rules are provided with text specifying that the built-in rules shall be the same as if the listed set were used. The intent is that implementations should be able to use the rules without change, but will be allowed to alter them in ways that do not affect the primary behavior.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other portions of this volume of POSIX.1-200x. The default rules include rules for optional commands in this volume of POSIX.1-200x. Only rules pertaining to commands that are provided are needed in the default set of an implementation.

One point of discussion was whether to drop the default rules list from this volume of POSIX.1-200x. They provide convenience, but do not enhance portability of applications. The prime benefit is in portability of users who wish to type *make command* and have the command build from a **command.c** file.

The historical *MAKESHELL* feature was omitted. In some implementations it is used to let a user override the shell to be used to run *make* commands. This was confusing; for a portable *make*, the shell should be chosen by the makefile writer or specified on the *make* command line and not by a user running *make*.

The *make* utilities in most historical implementations process the prerequisites of a target in left-to-right order, and the makefile format requires this. It supports the standard idiom used in many makefiles that produce *yacc* programs; for example:

```
foo: y.tab.o lex.o main.o
    $(CC) $(CFLAGS) –o $@ t.tab.o lex.o main.o
```

In this example, if *make* chose any arbitrary order, the **lex.o** might not be made with the correct **y.tab.h**. Although there may be better ways to express this relationship, it is widely used historically. Implementations that desire to update prerequisites in parallel should require an explicit extension to *make* or the makefile format to accomplish it, as described previously.

The algorithm for determining a new entry for target rules is partially unspecified. Some historical *make*s allow blank, empty, or comment lines within the collection of commands marked by leading <tab> characters. A conforming makefile must ensure that each command starts with a <tab>, but implementations are free to ignore blank, empty, and comment lines without triggering the start of a new entry.

The ASYNCHRONOUS EVENTS section includes having SIGTERM and SIGHUP, along with the more traditional SIGINT and SIGQUIT, remove the current target unless directed not to do so. SIGTERM and SIGHUP were added to parallel other utilities that have historically cleaned up their work as a result of these signals. When *make* receives any signal other than SIGQUIT, it is required to resend itself the signal it received so that it exits with a status that reflects the signal. The results from SIGQUIT are partially unspecified because, on systems that create **core** files upon receipt of SIGQUIT, the **core** from *make* would conflict with a **core** file from the command that was running when the SIGQUIT arrived. The main concern was to prevent damaged files from appearing up-to-date when *make* is rerun.

The **.PRECIOUS** special target was extended to affect all targets globally (by specifying no prerequisites). The **.IGNORE** and **.SILENT** special targets were extended to allow prerequisites; it was judged to be more useful in some cases to be able to turn off errors or echoing for a list of targets than for the entire makefile. These extensions to *make* in System V were made to match

historical practice from the BSD *make*.

Macros are not exported to the environment of commands to be run. This was never the case in any historical *make* and would have serious consequences. The environment is the same as the environment to *make* except that *MAKEFLAGS* and macros defined on the *make* command line are added.

Some implementations do not use *system*() for all command lines, as required by the portable makefile format; as a performance enhancement, they select lines without shell metacharacters for direct execution by *execve*(). There is no requirement that *system*() be used specifically, but merely that the same results be achieved. The metacharacters typically used to bypass the direct *execve*() execution have been any of:

```
= | ^ ( ) ; & < > * ? [ ] : $ ‘ ’ " \ \n
```

The default in some advanced versions of *make* is to group all the command lines for a target and execute them using a single shell invocation; the System V method is to pass each line individually to a separate shell. The single-shell method has the advantages in performance and the lack of a requirement for many continued lines. However, converting to this newer method has caused portability problems with many historical makefiles, so the behavior with the POSIX makefile is specified to be the same as that of System V. It is suggested that the special target **.ONESHELL** be used as an implementation extension to achieve the single-shell grouping for a target or group of targets.

Novice users of *make* have had difficulty with the historical need to start commands with a <tab>. Since it is often difficult to discern differences between <tab> and <space> characters on terminals or printed listings, confusing bugs can arise. In early proposals, an attempt was made to correct this problem by allowing leading <blank> characters instead of <tab> characters. However, implementors reported many makefiles that failed in subtle ways following this change, and it is difficult to implement a *make* that unambiguously can differentiate between macro and command lines. There is extensive historical practice of allowing leading <space> characters before macro definitions. Forcing macro lines into column 1 would be a significant backwards-compatibility problem for some makefiles. Therefore, historical practice was restored.

There is substantial variation in the handling of include lines by different implementations. However, there is enough commonality for the standard to be able to specify a minimum set of requirements that allow the feature to be used portably. Known variations have been explicitly called out as unspecified behavior in the description.

The System V dynamic dependency feature was not included. It would support:

```
cat: $$@.c
```

that would expand to;

```
cat: cat.c
```

This feature exists only in the new version of System V *make* and, while useful, is not in wide usage. This means that macros are expanded twice for prerequisites: once at makefile parse time and once at target update time.

Consideration was given to adding metarules to the POSIX *make*. This would make **%.o: %.c** the same as **.c.o:**. This is quite useful and available from some vendors, but it would cause too many changes to this *make* to support. It would have introduced rule chaining and new substitution rules. However, the rules for target names have been set to reserve the `'%'` and `'"'` characters. These are traditionally used to implement metarules and quoting of target names, respectively. Implementors are strongly encouraged to use these characters only for these purposes.

A request was made to extend the suffix delimiter character from a <period> to any character. The metarules feature in newer *make*s solves this problem in a more general way. This volume of POSIX.1-200x is staying with the more conservative historical definition.

The standard output format for the **−p** option is not described because it is primarily a debugging option and because the format is not generally useful to programs. In historical implementations the output is not suitable for use in generating makefiles. The **−p** format has been variable across historical implementations. Therefore, the definition of **−p** was only to provide a consistently named option for obtaining *make* script debugging information.

Some historical implementations have not cleared the suffix list with **−r**.

Implementations should be aware that some historical applications have intermixed *target_name* and *macro=value* operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, but some backwards-compatibility support may be warranted.

Empty inference rules are specified with a <semicolon> command rather than omitting all commands, as described in an early proposal. The latter case has no traditional meaning and is reserved for implementation extensions, such as in GNU *make*.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the Software Development Utilities option.

The Open Group Corrigendum U029/1 is applied, correcting a typographical error in the SPECIAL TARGETS section.

In the ENVIRONMENT VARIABLES section, the *PROJECTDIR* description is updated from "otherwise, the home directory of a user of that name is examined" to "otherwise, the value of *PROJECTDIR* is treated as a user name and that user's initial working directory is examined".

It is specified whether the command line is related to the makefile or to the *make* command, and the macro processing rules are updated to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

PASC Interpretation 1003.2 #193 is applied.

Issue 7

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

Include lines in makefiles are introduced.

Austin Group Interpretation 1003.1-2001 #131 is applied, changing the **Makefile Execution** section.

96404 **NAME**

96405 man — display system documentation

96406 **SYNOPSIS**

96407 `man [–k] name...`

96408 **DESCRIPTION**

96409 The *man* utility shall write information about each of the *name* operands. If *name* is the name of a
96410 standard utility, *man* at a minimum shall write a message describing the syntax used by the
96411 standard utility, its options, and operands. If more information is available, the *man* utility shall
96412 provide it in an implementation-defined manner.

96413 An implementation may provide information for values of *name* other than the standard utilities.
96414 Standard utilities that are listed as optional and that are not supported by the implementation
96415 either shall cause a brief message indicating that fact to be displayed or shall cause a full display
96416 of information as described previously.

96417 **OPTIONS**

96418 The *man* utility shall conform to XBD Section 12.2 (on page 215).

96419 The following option shall be supported:

96420 **–k** Interpret *name* operands as keywords to be used in searching a utilities summary
96421 database that contains a brief purpose entry for each standard utility and write lines
96422 from the summary database that match any of the keywords. The keyword search shall
96423 produce results that are the equivalent of the output of the following command:

96424 `grep –Ei '`
96425 *`name`*
96426 *`name`*
96427 `...`
96428 `' summary-database`

96429 This assumes that the *summary-database* is a text file with a single entry per line; this
96430 organization is not required and the example using *grep* **–Ei** is merely illustrative of the
96431 type of search intended. The purpose entry to be included in the database shall consist
96432 of a terse description of the purpose of the utility.

96433 **OPERANDS**

96434 The following operand shall be supported:

96435 *name* A keyword or the name of a standard utility. When **–k** is not specified and *name*
96436 does not represent one of the standard utilities, the results are unspecified.

96437 **STDIN**

96438 Not used.

96439 **INPUT FILES**

96440 None.

96441 **ENVIRONMENT VARIABLES**

96442 The following environment variables shall affect the execution of *man*:

96443 *LANG* Provide a default value for the internationalization variables that are unset or null.
96444 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
96445 variables used to determine the values of locale categories.)

96446 *LC_ALL* If set to a non-empty string value, override the values of all the other
96447 internationalization variables.

96448 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
96449 characters (for example, single-byte as opposed to multi-byte characters in
96450 arguments and in the summary database). The value of *LC_CTYPE* need not affect
96451 the format of the information written about the *name* operands.

96452 *LC_MESSAGES*
96453 Determine the locale that should be used to affect the format and contents of
96454 diagnostic messages written to standard error and informative messages written to
96455 standard output.

96456 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

96457 *PAGER* Determine an output filtering command for writing the output to a terminal. Any
96458 string acceptable as a *command_string* operand to the *sh* **−c** command shall be valid.
96459 When standard output is a terminal device, the reference page output shall be
96460 piped through the command. If the *PAGER* variable is null or not set, the command
96461 shall be either *more* or another paginator utility documented in the system
96462 documentation.

96463 **ASYNCHRONOUS EVENTS**
96464 Default.

96465 **STDOUT**
96466 The *man* utility shall write text describing the syntax of the utility *name*, its options and its
96467 operands, or, when **−k** is specified, lines from the summary database. The format of this text is
96468 implementation-defined.

96469 **STDERR**
96470 The standard error shall be used for diagnostic messages, and may also be used for
96471 informational messages of unspecified format.

96472 **OUTPUT FILES**
96473 None.

96474 **EXTENDED DESCRIPTION**
96475 None.

96476 **EXIT STATUS**
96477 The following exit values shall be returned:

96478 0 Successful completion.

96479 >0 An error occurred.

96480 **CONSEQUENCES OF ERRORS**
96481 Default.

96482 **APPLICATION USAGE**
96483 None.

96484 **EXAMPLES**
96485 None.

96486 **RATIONALE**
96487 It is recognized that the *man* utility is only of minimal usefulness as specified. The opinion of the
96488 standard developers was strongly divided as to how much or how little information *man* should
96489 be required to provide. They considered, however, that the provision of some portable way of
96490 accessing documentation would aid user portability. The arguments against a fuller specification
96491 were:

- Large quantities of documentation should not be required on a system that does not have excess disk space.
- The current manual system does not present information in a manner that greatly aids user portability.
- A "better help system" is currently an area in which vendors feel that they can add value to their POSIX implementations.

The **–f** option was considered, but due to implementation differences, it was not included in this volume of POSIX.1-200x.

The description was changed to be more specific about what has to be displayed for a utility. The standard developers considered it insufficient to allow a display of only the synopsis without giving a short description of what each option and operand does.

The "purpose" entry to be included in the database can be similar to the section title (less the numeric prefix) from this volume of POSIX.1-200x for each utility. These titles are similar to those used in historical systems for this purpose.

See *mailx* for rationale concerning the default paginator.

The caveat in the *LC_CTYPE* description was added because it is not a requirement that an implementation provide reference pages for all of its supported locales on each system; changing *LC_CTYPE* does not necessarily translate the reference page into another language. This is equivalent to the current state of *LC_MESSAGES* in POSIX.1-200x—locale-specific messages are not yet a requirement.

The historical *MANPATH* variable is not included in POSIX because no attempt is made to specify naming conventions for reference page files, nor even to mandate that they are files at all. On some implementations they could be a true database, a hypertext file, or even fixed strings within the *man* executable. The standard developers considered the portability of reference pages to be outside their scope of work. However, users should be aware that *MANPATH* is implemented on a number of historical systems and that it can be used to tailor the search pattern for reference pages from the various categories (utilities, functions, file formats, and so on) when the system administrator reveals the location and conventions for reference pages on the system.

The keyword search can rely on at least the text of the section titles from these utility descriptions, and the implementation may add more keywords. The term "section titles" refers to the strings such as:

```
man — Display system documentation
ps — Report process status
```

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 7

Austin Group Interpretation 1003.1-2001 #108 is applied, clarifying that informational messages may appear on standard error.

NAME

mesg — permit or deny messages

SYNOPSIS

```
mesg [y|n]
```

DESCRIPTION

The *mesg* utility shall control whether other users are allowed to send messages via *write*, *talk*, or other utilities to a terminal device. The terminal device affected shall be determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, *mesg* shall report the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

OPTIONS

None.

OPERANDS

The following operands shall be supported in the POSIX locale:

y Grant permission to other users to send messages to the terminal device.

n Deny permission to other users to send messages to the terminal device.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mesg*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written (by *mesg*) to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If no operand is specified, *mesg* shall display the current terminal state in an unspecified format.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Receiving messages is allowed.

1 Receiving messages is not allowed.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The mechanism by which the message status of the terminal is changed is unspecified. Therefore, unspecified actions may cause the status of the terminal to change after *mesg* has successfully completed. These actions may include, but are not limited to: another invocation of the *mesg* utility, login procedures; invocation of the *stty* utility, invocation of the *chmod* utility or *chmod*( ) function, and so on.

EXAMPLES

None.

RATIONALE

The terminal changed by *mesg* is that associated with the standard input, output, or error, rather than the controlling terminal for the session. This is because users logged in more than once should be able to change any of their login terminals without having to stop the job running in those sessions. This is not a security problem involving the terminals of other users because appropriate privileges would be required to affect the terminal of another user.

The method of checking each of the first three file descriptors in sequence until a terminal is found was adopted from System V.

The file **/dev/tty** is not specified for the terminal device because it was thought to be too restrictive. Typical environment changes for the *n* operand are that write permissions are removed for *others* and *group* from the appropriate device. It was decided to leave the actual description of what is done as unspecified because of potential differences between implementations.

The format for standard output is unspecified because of differences between historical implementations. This output is generally not useful to shell scripts (they can use the exit status), so exact parsing of the output is unnecessary.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

Issue 7

The *mesg* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME

mkdir — make directories

SYNOPSIS

```
mkdir [–p] [–m mode] dir...
```

DESCRIPTION

The *mkdir* utility shall create the directories specified by the operands, in the order specified.

For each *dir* operand, the *mkdir* utility shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of POSIX.1-200x, called with the following arguments:

1. The *dir* operand is used as the *path* argument.
2. The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO is used as the *mode* argument. (If the **–m** option is specified, the value of the *mkdir*( ) *mode* argument is unspecified, but the directory shall at no time have permissions less restrictive than the **–m** *mode* option-argument.)

OPTIONS

The *mkdir* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–m *mode* Set the file permission bits of the newly-created directory to the specified *mode* value. The *mode* option-argument shall be the same as the *mode* operand defined for the *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'–'` shall be interpreted relative to an assumed initial mode of *a=rwx*; `'+'` shall add permissions to the default mode, `'–'` shall delete permissions from the default mode.

–p Create any missing intermediate pathname components.

For each *dir* operand that does not name an existing directory, effects equivalent to those caused by the following command shall occur:

```
mkdir –p –m $(umask –S),u+wx $(dirname dir) &&
mkdir [–m mode] dir
```

where the **–m** *mode* option represents that option supplied to the original invocation of *mkdir*, if any.

Each *dir* operand that names an existing directory shall be ignored without error.

OPERANDS

The following operand shall be supported:

dir A pathname of a directory to be created.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mkdir*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS
Default.

STDOUT
Not used.

STDERR
The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

EXTENDED DESCRIPTION
None.

EXIT STATUS
The following exit values shall be returned:

0 All the specified directories were created successfully or the **−p** option was specified and all the specified directories now exist.

>0 An error occurred.

CONSEQUENCES OF ERRORS
Default.

APPLICATION USAGE
The default file mode for directories is *a=rwx* (777 on most systems) with selected permissions removed in accordance with the file mode creation mask. For intermediate pathname components created by *mkdir*, the mode is the default modified by *u+wx* so that the subdirectories can always be created regardless of the file mode creation mask; if different ultimate permissions are desired for the intermediate directories, they can be changed afterwards with *chmod*.

Note that some of the requested directories may have been created even if an error occurs.

EXAMPLES
None.

RATIONALE
The System V **−m** option was included to control the file mode.

The System V **−p** option was included to create any needed intermediate directories and to complement the functionality provided by *rmdir* for removing directories in the path prefix as they become empty. Because no error is produced if any path component already exists, the **−p** option is also useful to ensure that a particular directory exists.

The functionality of *mkdir* is described substantially through a reference to the *mkdir*( ) function

in the System Interfaces volume of POSIX.1-200x. For example, by default, the mode of the directory is affected by the file mode creation mask in accordance with the specified behavior of the *mkdir*( ) function. In this way, there is less duplication of effort required for describing details of the directory creation.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 7

SD5-XCU-ERN-56 is applied, aligning the **–m** option with the IEEE P1003.2b draft standard to clarify an ambiguity.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

96729 **NAME**

96730 mkfifo — make FIFO special files

96731 **SYNOPSIS**

96732 `mkfifo [–m mode] file...`

96733 **DESCRIPTION**

96734 The *mkfifo* utility shall create the FIFO special files specified by the operands, in the order
96735 specified.

96736 For each *file* operand, the *mkfifo* utility shall perform actions equivalent to the *mkfifo*() function
96737 defined in the System Interfaces volume of POSIX.1-200x, called with the following arguments:

96738 1. The *file* operand is used as the *path* argument.

96739 2. The value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP,
96740 S_IROTH, and S_IWOTH is used as the *mode* argument. (If the **–m** option is specified, the
96741 value of the *mkfifo*() *mode* argument is unspecified, but the FIFO shall at no time have
96742 permissions less restrictive than the **–m** *mode* option-argument.)

96743 **OPTIONS**

96744 The *mkfifo* utility shall conform to XBD Section 12.2 (on page 215).

96745 The following option shall be supported:

96746 **–m** *mode* Set the file permission bits of the newly-created FIFO to the specified *mode* value.
96747 The *mode* option-argument shall be the same as the *mode* operand defined for the
96748 *chmod* utility. In the *symbolic_mode* strings, the *op* characters `'+'` and `'–'` shall be
96749 interpreted relative to an assumed initial mode of *a=rw*.

96750 **OPERANDS**

96751 The following operand shall be supported:

96752 *file* A pathname of the FIFO special file to be created.

96753 **STDIN**

96754 Not used.

96755 **INPUT FILES**

96756 None.

96757 **ENVIRONMENT VARIABLES**

96758 The following environment variables shall affect the execution of *mkfifo*:

96759 *LANG* Provide a default value for the internationalization variables that are unset or null.
96760 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
96761 variables used to determine the values of locale categories.)

96762 *LC_ALL* If set to a non-empty string value, override the values of all the other
96763 internationalization variables.

96764 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
96765 characters (for example, single-byte as opposed to multi-byte characters in
96766 arguments).

96767 *LC_MESSAGES*
96768 Determine the locale that should be used to affect the format and contents of
96769 diagnostic messages written to standard error.

96770 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

96771 **ASYNCHRONOUS EVENTS**
96772 Default.

96773 **STDOUT**
96774 Not used.

96775 **STDERR**
96776 The standard error shall be used only for diagnostic messages.

96777 **OUTPUT FILES**
96778 None.

96779 **EXTENDED DESCRIPTION**
96780 None.

96781 **EXIT STATUS**
96782 The following exit values shall be returned:

96783 0 All the specified FIFO special files were created successfully.

96784 >0 An error occurred.

96785 **CONSEQUENCES OF ERRORS**
96786 Default.

96787 **APPLICATION USAGE**
96788 None.

96789 **EXAMPLES**
96790 None.

96791 **RATIONALE**
96792 This utility was added to permit shell applications to create FIFO special files.

96793 The **–m** option was added to control the file mode, for consistency with the similar functionality
96794 provided by the *mkdir* utility.

96795 Early proposals included a **–p** option similar to the *mkdir* **–p** option that created intermediate
96796 directories leading up to the FIFO specified by the final component. This was removed because
96797 it is not commonly needed and is not common practice with similar utilities.

96798 The functionality of *mkfifo* is described substantially through a reference to the *mkfifo*( ) function
96799 in the System Interfaces volume of POSIX.1-200x. For example, by default, the mode of the FIFO
96800 file is affected by the file mode creation mask in accordance with the specified behavior of the
96801 *mkfifo*( ) function. In this way, there is less duplication of effort required for describing details of
96802 the file creation.

96803 **FUTURE DIRECTIONS**
96804 None.

96805 **SEE ALSO**
96806 *chmod*, *umask*

96807 XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

96808 XSH *mkfifo*( )

CHANGE HISTORY

First released in Issue 3.

Issue 6

The **–m** option is aligned with the IEEE P1003.2b draft standard to clarify an ambiguity.

96813 **NAME**

96814 more — display files on a page-by-page basis

96815 **SYNOPSIS**

96816 UP `more [–ceisu] [–n number] [–p command] [–t tagstring] [file...]`

96817 **DESCRIPTION**

96818 The *more* utility shall read files and either write them to the terminal on a page-by-page basis or
96819 filter them to standard output. If standard output is not a terminal device, all input files shall be
96820 copied to standard output in their entirety, without modification, except as specified for the **–s**
96821 option. If standard output is a terminal device, the files shall be written a number of lines (one
96822 screenful) at a time under the control of user commands. See the EXTENDED DESCRIPTION
96823 section.

96824 Certain block-mode terminals do not have all the capabilities necessary to support the complete
96825 *more* definition; they are incapable of accepting commands that are not terminated with a
96826 <newline>. Implementations that support such terminals shall provide an operating mode to
96827 *more* in which all commands can be terminated with a <newline> on those terminals. This mode:

96828 - Shall be documented in the system documentation
96829 - Shall, at invocation, inform the user of the terminal deficiency that requires the <newline>
96830 usage and provide instructions on how this warning can be suppressed in future
96831 invocations
96832 - Shall not be required for implementations supporting only fully capable terminals
96833 - Shall not affect commands already requiring <newline> characters
96834 - Shall not affect users on the capable terminals from using *more* as described in this volume
96835 of POSIX.1-200x

96836 **OPTIONS**

96837 The *more* utility shall conform to XBD Section 12.2 (on page 215), except that `'+'` may be
96838 recognized as an option delimiter as well as `'–'`.

96839 The following options shall be supported:

96840 **–c** If a screen is to be written that has no lines in common with the current screen, or
96841 *more* is writing its first screen, *more* shall not scroll the screen, but instead shall
96842 redraw each line of the screen in turn, from the top of the screen to the bottom. In
96843 addition, if *more* is writing its first screen, the screen shall be cleared. This option
96844 may be silently ignored on devices with insufficient terminal capabilities.

96845 **–e** By default, *more* shall exit immediately after writing the last line of the last file in
96846 the argument list. If the **–e** option is specified:

96847 1. If there is only a single file in the argument list and that file was completely
96848 displayed on a single screen, *more* shall exit immediately after writing the
96849 last line of that file.

96850 2. Otherwise, *more* shall exit only after reaching end-of-file on the last file in
96851 the argument list twice without an intervening operation. See the
96852 EXTENDED DESCRIPTION section.

96853 **–i** Perform pattern matching in searches without regard to case; see XBD Section 9.2
96854 (on page 182).

96855 **–n** *number* Specify the number of lines per screenful. The *number* argument is a positive
96856 decimal integer. The **–n** option shall override any values obtained from any other
96857 source.

96858 **–p** *command* Each time a screen from a new file is displayed or redisplayed (including as a
96859 result of *more* commands; for example, **:p**), execute the *more* command(s) in the
96860 command arguments in the order specified, as if entered by the user after the first
96861 screen has been displayed. No intermediate results shall be displayed (that is, if the
96862 command is a movement to a screen different from the normal first screen, only the
96863 screen resulting from the command shall be displayed.) If any of the commands
96864 fail for any reason, an informational message to this effect shall be written, and no
96865 further commands specified using the **–p** option shall be executed for this file.

96866 **–s** Behave as if consecutive empty lines were a single empty line.

96867 **–t** *tagstring* Write the screenful of the file containing the tag named by the *tagstring* argument.
96868 See the *ctags* utility. The tags feature represented by **–t** *tagstring* and the **:t**
96869 command is optional. It shall be provided on any system that also provides a
96870 conforming implementation of *ctags*; otherwise, the use of **–t** produces undefined
96871 results.

96872 The filename resulting from the **–t** option shall be logically added as a prefix to the
96873 list of command line files, as if specified by the user. If the tag named by the
96874 *tagstring* argument is not found, it shall be an error, and *more* shall take no further
96875 action.

96876 If the tag specifies a line number, the first line of the display shall contain the
96877 beginning of that line. If the tag specifies a pattern, the first line of the display shall
96878 contain the beginning of the matching text from the first line of the file that
96879 contains that pattern. If the line does not exist in the file or matching text is not
96880 found, an informational message to this effect shall be displayed, and *more* shall
96881 display the default screen as if **–t** had not been specified.

96882 If both the **–t** *tagstring* and **–p** *command* options are given, the **–t** *tagstring* shall be
96883 processed first; that is, the file and starting line for the display shall be as specified
96884 by **–t**, and then the **–p** *more* command shall be executed. If the line (matching text)
96885 specified by the **–t** command does not exist (is not found), no **–p** *more* command
96886 shall be executed for this file at any time.

96887 **–u** Treat a <backspace> as a printable control character, displayed as an
96888 implementation-defined character sequence (see the EXTENDED DESCRIPTION
96889 section), suppressing backspacing and the special handling that produces
96890 underlined or standout mode text on some terminal types. Also, do not ignore a
96891 <carriage-return> at the end of a line.

96892 **OPERANDS**

96893 The following operand shall be supported:

96894 *file* A pathname of an input file. If no *file* operands are specified, the standard input
96895 shall be used. If a *file* is `'–'`, the standard input shall be read at that point in the
96896 sequence.

96897 **STDIN**

96898 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'–'`.

INPUT FILES

The input files being examined shall be text files. If standard output is a terminal, standard error shall be used to read commands from the user. If standard output is a terminal, standard error is not readable, and command input is needed, *more* may attempt to obtain user commands from the controlling terminal (for example, **/dev/tty**); otherwise, *more* shall terminate with an error indicating that it was unable to read user commands. If standard output is not a terminal, no error shall result if standard error cannot be opened for reading.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *more*:

COLUMNS Override the system-selected horizontal display line size. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null.

EDITOR Used by the **v** command to select an editor. See the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LINES Override the system-selected vertical screen size, used as the number of lines in a screenful. See XBD Chapter 8 (on page 173) for valid values and results when it is unset or null. The **–n** option shall take precedence over the *LINES* variable for determining the number of lines in a screenful.

MORE Determine a string containing options described in the OPTIONS section preceded with <hyphen> characters and <blank>-separated as on the command line. Any command line options shall be processed after those in the *MORE* variable, as if the command line were:

```
more $MORE options operands
```

The *MORE* variable shall take precedence over the *TERM* and *LINES* variables for determining the number of lines in a screenful.

TERM Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type is used.

96942 **ASYNCHRONOUS EVENTS**
96943 Default.

96944 **STDOUT**
96945 The standard output shall be used to write the contents of the input files.

96946 **STDERR**
96947 The standard error shall be used for diagnostic messages and user commands (see the INPUT
96948 FILES section), and, if standard output is a terminal device, to write a prompting string. The
96949 prompting string shall appear on the screen line below the last line of the file displayed in the
96950 current screenful. The prompt shall contain the name of the file currently being examined and
96951 shall contain an end-of-file indication and the name of the next file, if any, when prompting at
96952 the end-of-file. If an error or informational message is displayed, it is unspecified whether it is
96953 contained in the prompt. If it is not contained in the prompt, it shall be displayed and then the
96954 user shall be prompted for a continuation character, at which point another message or the user
96955 prompt may be displayed. The prompt is otherwise unspecified. It is unspecified whether
96956 informational messages are written for other user commands.

96957 **OUTPUT FILES**
96958 None.

96959 **EXTENDED DESCRIPTION**
96960 The following section describes the behavior of *more* when the standard output is a terminal
96961 device. If the standard output is not a terminal device, no options other than **–s** shall have any
96962 effect, and all input files shall be copied to standard output otherwise unmodified, at which time
96963 *more* shall exit without further action.

96964 The number of lines available per screen shall be determined by the **–n** option, if present, or by
96965 examining values in the environment (see the ENVIRONMENT VARIABLES section). If neither
96966 method yields a number, an unspecified number of lines shall be used.

96967 The maximum number of lines written shall be one less than this number, because the screen
96968 line after the last line written shall be used to write a user prompt and user input. If the number
96969 of lines in the screen is less than two, the results are undefined. It is unspecified whether user
96970 input is permitted to be longer than the remainder of the single line where the prompt has been
96971 written.

96972 The number of columns available per line shall be determined by examining values in the
96973 environment (see the ENVIRONMENT VARIABLES section), with a default value as described
96974 in XBD Chapter 8 (on page 173).

96975 Lines that are longer than the display shall be folded; the length at which folding occurs is
96976 unspecified, but should be appropriate for the output device. Folding may occur between glyphs
96977 of single characters that take up multiple display columns.

96978 When standard output is a terminal and **–u** is not specified, *more* shall treat <backspace> and
96979 <carriage-return> characters specially:

96980 • A character, followed first by a sequence of *n* <backspace> characters (where *n* is the same
96981 as the number of column positions that the character occupies), then by *n* <underscore>
96982 characters (`'_'`), shall cause that character to be written as underlined text, if the terminal
96983 type supports that. The *n* <underscore> characters, followed first by *n* <backspace>
96984 characters, then any character with *n* column positions, shall also cause that character to be
96985 written as underlined text, if the terminal type supports that.

- A sequence of *n* <backspace> characters (where *n* is the same as the number of column positions that the previous character occupies) that appears between two identical printable characters shall cause the first of those two characters to be written as emboldened text (that is, visually brighter, standout mode, or inverse-video mode), if the terminal type supports that, and the second to be discarded. Immediately subsequent occurrences of <backspace>/character pairs for that same character shall also be discarded. (For example, the sequence `"a\ba\ba\ba"` is interpreted as a single emboldened `'a'`.)
- The *more* utility shall logically discard all other <backspace> characters from the line as well as the character which precedes them, if any.
- A <carriage-return> at the end of a line shall be ignored, rather than being written as a non-printable character, as described in the next paragraph.

It is implementation-defined how other non-printable characters are written. Implementations should use the same format that they use for the *ex* **print** command; see the OPTIONS section within the *ed* utility. It is unspecified whether a multi-column character shall be separated if it crosses a display line boundary; it shall not be discarded. The behavior is unspecified if the number of columns on the display is less than the number of columns any single character in the line being displayed would occupy.

When each new file is displayed (or redisplayed), *more* shall write the first screen of the file. Once the initial screen has been written, *more* shall prompt for a user command. If the execution of the user command results in a screen that has lines in common with the current screen, and the device has sufficient terminal capabilities, *more* shall scroll the screen; otherwise, it is unspecified whether the screen is scrolled or redrawn.

For all files but the last (including standard input if no file was specified, and for the last file as well, if the **–e** option was not specified), when *more* has written the last line in the file, *more* shall prompt for a user command. This prompt shall contain the name of the next file as well as an indication that *more* has reached end-of-file. If the user command is **f**, <control>-F, <space>, **j**, <newline>, **d**, <control>-D, or **s**, *more* shall display the next file. Otherwise, if displaying the last file, *more* shall exit. Otherwise, *more* shall execute the user command specified.

Several of the commands described in this section display a previous screen from the input stream. In the case that text is being taken from a non-rewindable stream, such as a pipe, it is implementation-defined how much backwards motion is supported. If a command cannot be executed because of a limitation on backwards motion, an error message to this effect shall be displayed, the current screen shall not change, and the user shall be prompted for another command.

If a command cannot be performed because there are insufficient lines to display, *more* shall alert the terminal. If a command cannot be performed because there are insufficient lines to display or a **/** command fails: if the input is the standard input, the last screen in the file may be displayed; otherwise, the current file and screen shall not change, and the user shall be prompted for another command.

The interactive commands in the following sections shall be supported. Some commands can be preceded by a decimal integer, called *count* in the following descriptions. If not specified with the command, *count* shall default to 1. In the following descriptions, *pattern* is a basic regular expression, as described in XBD Section 9.3 (on page 183). The term "examine" is historical usage meaning "open the file for viewing"; for example, *more* **foo** would be expressed as examining file **foo**.

In the following descriptions, unless otherwise specified, *line* is a line in the *more* display, not a

line from the file being examined.

In the following descriptions, the *current position* refers to two things:

1. The position of the current line on the screen
2. The line number (in the file) of the current line on the screen

Usually, the line on the screen corresponding to the current position is the third line on the screen. If this is not possible (there are fewer than three lines to display or this is the first page of the file, or it is the last page of the file), then the current position is either the first or last line on the screen as described later.

Help

Synopsis: `h`

Write a summary of these commands and other implementation-defined commands. The behavior shall be as if the *more* utility were executed with the **–e** option on a file that contained the summary information. The user shall be prompted as described earlier in this section when end-of-file is reached. If the user command is one of those specified to continue to the next file, *more* shall return to the file and screen state from which the **h** command was executed.

Scroll Forward One Screenful

Synopsis: `[`*count*`]f`
`[`*count*`]<control>-F`

Scroll forward *count* lines, with a default of one screenful. If *count* is more than the screen size, only the final screenful shall be written.

Scroll Backward One Screenful

Synopsis: `[`*count*`]b`
`[`*count*`]<control>-B`

Scroll backward *count* lines, with a default of one screenful (see the **–n** option). If *count* is more than the screen size, only the final screenful shall be written.

Scroll Forward One Line

Synopsis: `[`*count*`]<space>`
`[`*count*`]j`
`[`*count*`]<newline>`

Scroll forward *count* lines. The default *count* for the <space> shall be one screenful; for **j** and <newline>, one line. The entire *count* lines shall be written, even if *count* is more than the screen size.

Scroll Backward One Line

Synopsis: `[`*count*`]k`

Scroll backward *count* lines. The entire *count* lines shall be written, even if *count* is more than the screen size.

97069 **Scroll Forward One Half Screenful**

97070 *Synopsis*: **[***count***]d**
97071 **[***count***]<control>-D**

97072 Scroll forward *count* lines, with a default of one half of the screen size. If *count* is specified, it
97073 shall become the new default for subsequent **d**, <control>-D, and **u** commands.

97074 **Skip Forward One Line**

97075 *Synopsis*: **[***count***]s**

97076 Display the screenful beginning with the line *count* lines after the last line on the current screen.
97077 If *count* would cause the current position to be such that less than one screenful would be
97078 written, the last screenful in the file shall be written.

97079 **Scroll Backward One Half Screenful**

97080 *Synopsis*: **[***count***]u**
97081 **[***count***]<control>-U**

97082 Scroll backward *count* lines, with a default of one half of the screen size. If *count* is specified, it
97083 shall become the new default for subsequent **d**, <control>–D, **u**, and <control>–U commands.
97084 The entire *count* lines shall be written, even if *count* is more than the screen size.

97085 **Go to Beginning of File**

97086 *Synopsis*: **[***count***]g**

97087 Display the screenful beginning with line *count*.

97088 **Go to End-of-File**

97089 *Synopsis*: **[***count***]G**

97090 If *count* is specified, display the screenful beginning with the line *count*. Otherwise, display the
97091 last screenful of the file.

97092 **Refresh the Screen**

97093 *Synopsis*: **r**
97094 **<control>-L**

97095 Refresh the screen.

97096 **Discard and Refresh**

97097 *Synopsis*: **R**

97098 Refresh the screen, discarding any buffered input. If the current file is non-seekable, buffered
97099 input shall not be discarded and the **R** command shall be equivalent to the **r** command.

97100 **Mark Position**

97101 *Synopsis*: `mletter`

97102 Mark the current position with the letter named by *letter*, where *letter* represents the name of one
97103 of the lowercase letters of the portable character set. When a new file is examined, all marks may
97104 be lost.

97105 **Return to Mark**

97106 *Synopsis*: `'letter`

97107 Return to the position that was previously marked with the letter named by *letter*, making that
97108 line the current position.

97109 **Return to Previous Position**

97110 *Synopsis*: `''`

97111 Return to the position from which the last large movement command was executed (where a
97112 "large movement" is defined as any movement of more than a screenful of lines). If no such
97113 movements have been made, return to the beginning of the file.

97114 **Search Forward for Pattern**

97115 *Synopsis*: `[`*count*`]/[!]`*pattern*`<newline>`

97116 Display the screenful beginning with the *count*th line containing the pattern. The search shall
97117 start after the first line currently displayed. The null regular expression (`'/'` followed by a
97118 <newline>) shall repeat the search using the previous regular expression, with a default *count*. If
97119 the character `'!'` is included, the matching lines shall be those that do not contain the *pattern*. If
97120 no match is found for the *pattern*, a message to that effect shall be displayed.

97121 **Search Backward for Pattern**

97122 *Synopsis*: `[`*count*`]?[!]`*pattern*`<newline>`

97123 Display the screenful beginning with the *count*th previous line containing the pattern. The search
97124 shall start on the last line before the first line currently displayed. The null regular expression
97125 (`'?'` followed by a <newline>) shall repeat the search using the previous regular expression,
97126 with a default *count*. If the character `'!'` is included, matching lines shall be those that do not
97127 contain the *pattern*. If no match is found for the *pattern*, a message to that effect shall be
97128 displayed.

97129 **Repeat Search**

97130 *Synopsis*: `[`*count*`]n`

97131 Repeat the previous search for *count*th line containing the last *pattern* (or not containing the last
97132 *pattern*, if the previous search was `"/!"` or `"?!"`).

97133 **Repeat Search in Reverse**

97134 *Synopsis*: `[count]N`

97135 Repeat the search in the opposite direction of the previous search for the *count*th line containing
97136 the last *pattern* (or not containing the last *pattern*, if the previous search was "/!" or "?!").

97137 **Examine New File**

97138 *Synopsis*: `:e [filename]<newline>`

97139 Examine a new file. If the *filename* argument is not specified, the current file (see the **:n** and **:p**
97140 commands below) shall be re-examined. The *filename* shall be subjected to the process of shell
97141 word expansions (see Section 2.6, on page 2305); if more than a single pathname results, the
97142 effects are unspecified. If *filename* is a <number-sign> ('#'), the previously examined file shall
97143 be re-examined. If *filename* is not accessible for any reason (including that it is a non-seekable
97144 file), an error message to this effect shall be displayed and the current file and screen shall not
97145 change.

97146 **Examine Next File**

97147 *Synopsis*: `[count]:n`

97148 Examine the next file. If a number *count* is specified, the *count*th next file shall be examined. If
97149 *filename* refers to a non-seekable file, the results are unspecified.

97150 **Examine Previous File**

97151 *Synopsis*: `[count]:p`

97152 Examine the previous file. If a number *count* is specified, the *count*th previous file shall be
97153 examined. If *filename* refers to a non-seekable file, the results are unspecified.

97154 **Go to Tag**

97155 *Synopsis*: `:t tagstring<newline>`

97156 If the file containing the tag named by the *tagstring* argument is not the current file, examine the
97157 file, as if the **:e** command was executed with that file as the argument. Otherwise, or in addition,
97158 display the screenful beginning with the tag, as described for the **−t** option (see the OPTIONS
97159 section). If the *ctags* utility is not supported by the system, the use of **:t** produces undefined
97160 results.

97161 **Invoke Editor**

97162 *Synopsis*: `v`

97163 Invoke an editor to edit the current file being examined. If standard input is being examined, the
97164 results are unspecified. The name of the editor shall be taken from the environment variable
97165 *EDITOR*, or shall default to *vi*. If the last pathname component in *EDITOR* is either *vi* or *ex*, the
97166 editor shall be invoked with a **−c** *linenumber* command line argument, where *linenumber* is the
97167 line number of the file line containing the display line currently displayed as the first line of the
97168 screen. It is implementation-defined whether line-setting options are passed to editors other
97169 than *vi* and *ex*.

97170 When the editor exits, *more* shall resume with the same file and screen as when the editor was
97171 invoked.

97172 **Display Position**

97173 *Synopsis*: `=`
97174 `<control>-G`

97175 Write a message for which the information references the first byte of the line after the last line of
97176 the file on the screen. This message shall include the name of the file currently being examined,
97177 its number relative to the total number of files there are to examine, the line number in the file,
97178 the byte number and the total bytes in the file, and what percentage of the file precedes the
97179 current position. If *more* is reading from standard input, or the file is shorter than a single screen,
97180 the line number, the byte number, the total bytes, and the percentage need not be written.

97181 **Quit**

97182 *Synopsis*: `q`
97183 `:q`
97184 `ZZ`

97185 Exit *more*.

97186 **EXIT STATUS**

97187 The following exit values shall be returned:

97188 0 Successful completion.

97189 >0 An error occurred.

97190 **CONSEQUENCES OF ERRORS**

97191 If an error is encountered accessing a file when using the **:n** command, *more* shall attempt to
97192 examine the next file in the argument list, but the final exit status shall be affected. If an error is
97193 encountered accessing a file via the **:p** command, *more* shall attempt to examine the previous file
97194 in the argument list, but the final exit status shall be affected. If an error is encountered accessing
97195 a file via the **:e** command, *more* shall remain in the current file and the final exit status shall not
97196 be affected.

97197 **APPLICATION USAGE**

97198 When the standard output is not a terminal, only the –**s** filter-modification option is effective.
97199 This is based on historical practice. For example, a typical implementation of *man* pipes its
97200 output through *more* –**s** to squeeze excess white space for terminal users. When *man* is piped to
97201 *lp*, however, it is undesirable for this squeezing to happen.

97202 **EXAMPLES**

97203 The –**p** allows arbitrary commands to be executed at the start of each file. Examples are:

97204 *more* –**p G** *file1 file2*
97205 Examine each file starting with its last screenful.

97206 *more* –**p** 100 *file1 file2*
97207 Examine each file starting with line 100 in the current position (usually the third line, so line
97208 98 would be the first line written).

97209 *more* –**p** /100 *file1 file2*
97210 Examine each file starting with the first line containing the string `"100"` in the current
97211 position

RATIONALE

The *more* utility, available in BSD and BSD-derived systems, was chosen as the prototype for the POSIX file display program since it is more widely available than either the public-domain program *less* or than *pg*, a pager provided in System V. The 4.4 BSD *more* is the model for the features selected; it is almost fully upwards-compatible from the 4.3 BSD version in wide use and has become more amenable for *vi* users. Several features originally derived from various file editors, found in both *less* and *pg*, have been added to this volume of POSIX.1-200x as they have proved extremely popular with users.

There are inconsistencies between *more* and *vi* that result from historical practice. For example, the single-character commands **h**, **f**, **b**, and <space> are screen movers in *more*, but cursor movers in *vi*. These inconsistencies were maintained because the cursor movements are not applicable to *more* and the powerful functionality achieved without the use of the control key justifies the differences.

The tags interface has been included in a program that is not a text editor because it promotes another degree of consistent operation with *vi*. It is conceivable that the paging environment of *more* would be superior for browsing source code files in some circumstances.

The operating mode referred to for block-mode terminals effectively adds a <newline> to each Synopsis line that currently has none. So, for example, **d**<newline> would page one screenful. The mode could be triggered by a command line option, environment variable, or some other method. The details are not imposed by this volume of POSIX.1-200x because there are so few systems known to support such terminals. Nevertheless, it was considered that all systems should be able to support *more* given the exception cited for this small community of terminals because, in comparison to *vi*, the cursor movements are few and the command set relatively amenable to the optional <newline> characters.

Some versions of *more* provide a shell escaping mechanism similar to the *ex* **!** command. The standard developers did not consider that this was necessary in a paginator, particularly given the wide acceptance of multiple window terminals and job control features. (They chose to retain such features in the editors and *mailx* because the shell interaction also gives an opportunity to modify the editing buffer, which is not applicable to *more*.)

The **−p** (position) option replaces the **+** command because of the Utility Syntax Guidelines. The *+command* option is no longer specified by POSIX.1-200x but may be present in some implementations. In early proposals, it took a *pattern* argument, but historical *less* provided the *more* general facility of a command. It would have been desirable to use the same **−c** as *ex* and *vi*, but the letter was already in use.

The text stating "from a non-rewindable stream ... implementations may limit the amount of backwards motion supported" would allow an implementation that permitted no backwards motion beyond text already on the screen. It was not possible to require a minimum amount of backwards motion that would be effective for all conceivable device types. The implementation should allow the user to back up as far as possible, within device and reasonable memory allocation constraints.

Historically, non-printable characters were displayed using the ARPA standard mappings, which are as follows:

1. Printable characters are left alone.
2. Control characters less than \177 are represented as followed by the character offset from the `'@'` character in the ASCII map; for example, \007 is represented as `'G'`.

3. \177 is represented as followed by '?'.

The display of characters having their eighth bit set was less standard. Existing implementations use hex (0x00), octal (\000), and a meta-bit display. (The latter displayed characters with their eighth bit set as the two characters "M–", followed by the seven-bit display as described previously.) The latter probably has the best claim to historical practice because it was used with the **–v** option of 4 BSD and 4 BSD-derived versions of the *cat* utility since 1980.

No specific display format is required by POSIX.1-200x. Implementations are encouraged to conform to historic practice in the absence of any strong reason to diverge.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The utility has been extensively reworked for alignment with the IEEE P1003.2b draft standard:

- Changes have been made as a result of IEEE PASC Interpretations 1003.2 #37 and #109.
- The *more* utility should be able to handle underlined and emboldened displays of characters that are wider than a single column position.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that '+' may be recognized as an option delimiter in the OPTIONS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

mv — move files

SYNOPSIS

```
mv [-if] source_file target_file
mv [-if] source_file... target_dir
```

DESCRIPTION

In the first synopsis form, the *mv* utility shall move the file named by the *source_file* operand to the destination specified by the *target_file*. This first synopsis form is assumed when the final operand does not name an existing directory and is not a symbolic link referring to an existing directory. In this case, if *target_file* ends with a trailing <slash> character, *mv* shall treat this as an error and no *source_file* operands will be processed.

In the second synopsis form, *mv* shall move each file named by a *source_file* operand to a destination file in the existing directory named by the *target_dir* operand, or referenced if *target_dir* is a symbolic link referring to an existing directory. The destination path for each *source_file* shall be the concatenation of the target directory, a single <slash> character if the target did not end in a <slash>, and the last pathname component of the *source_file*. This second form is assumed when the final operand names an existing directory.

If any operand specifies an existing file of a type not specified by the System Interfaces volume of POSIX.1-200x, the behavior is implementation-defined.

For each *source_file* the following steps shall be taken:

1. If the destination path exists, the **–f** option is not specified, and either of the following conditions is true:

   a. The permissions of the destination path do not permit writing and the standard input is a terminal.

   b. The **–i** option is specified.

   the *mv* utility shall write a prompt to standard error and read a line from standard input. If the response is not affirmative, *mv* shall do nothing more with the current *source_file* and go on to any remaining *source_file*s.

2. If the *source_file* operand and destination path name the same existing file, then the destination path shall not be removed, and one of the following shall occur:

   a. No change is made to *source_file*, no error occurs, and no diagnostic is issued.

   b. No change is made to *source_file*, a diagnostic is issued to standard error identifying the two names, and the exit status is affected.

   c. If the *source_file* operand and destination path name distinct directory entries, then the *source_file* operand is removed, no error occurs, and no diagnostic is issued.

   The *mv* utility shall do nothing more with the current *source_file*, and go on to any remaining *source_file*s.

3. The *mv* utility shall perform actions equivalent to the *rename*() function defined in the System Interfaces volume of POSIX.1-200x, called with the following arguments:

   a. The *source_file* operand is used as the *old* argument.

   b. The destination path is used as the *new* argument.

   If this succeeds, *mv* shall do nothing more with the current *source_file* and go on to any remaining *source_file*s. If this fails for any reasons other than those described for the *errno*

97329 [EXDEV] in the System Interfaces volume of POSIX.1-200x, *mv* shall write a diagnostic
97330 message to standard error, do nothing more with the current *source_file*, and go on to any
97331 remaining *source_file*s.

97332 4. If the destination path exists, and it is a file of type directory and *source_file* is not a file of
97333 type directory, or it is a file not of type directory and *source_file* is a file of type directory,
97334 *mv* shall write a diagnostic message to standard error, do nothing more with the current
97335 *source_file*, and go on to any remaining *source_file*s. If the destination path exists and was
97336 created by a previous step, it is unspecified whether this will treated as an error or the
97337 destination path will be overwritten.

97338 5. If the destination path exists, *mv* shall attempt to remove it. If this fails for any reason, *mv*
97339 shall write a diagnostic message to standard error, do nothing more with the current
97340 *source_file*, and go on to any remaining *source_file*s.

97341 6. The file hierarchy rooted in *source_file* shall be duplicated as a file hierarchy rooted in the
97342 destination path. If *source_file* or any of the files below it in the hierarchy are symbolic
97343 links, the links themselves shall be duplicated, including their contents, rather than any
97344 files to which they refer. The following characteristics of each file in the file hierarchy
97345 shall be duplicated:

97346 • The time of last data modification and time of last access

97347 • The user ID and group ID

97348 • The file mode

97349 If the user ID, group ID, or file mode of a regular file cannot be duplicated, the file mode
97350 bits S_ISUID and S_ISGID shall not be duplicated.

97351 When files are duplicated to another file system, the implementation may require that the
97352 process invoking *mv* has read access to each file being duplicated.

97353 If files being duplicated to another file system have hard links to other files, it is
97354 unspecified whether the files copied to the new file system have the hard links preserved
97355 or separate copies are created for the linked files.

97356 If the duplication of the file hierarchy fails for any reason, *mv* shall write a diagnostic
97357 message to standard error, do nothing more with the current *source_file*, and go on to any
97358 remaining *source_file*s.

97359 If the duplication of the file characteristics fails for any reason, *mv* shall write a diagnostic
97360 message to standard error, but this failure shall not cause *mv* to modify its exit status.

97361 7. The file hierarchy rooted in *source_file* shall be removed. If this fails for any reason, *mv*
97362 shall write a diagnostic message to the standard error, do nothing more with the current
97363 *source_file*, and go on to any remaining *source_file*s.

97364 **OPTIONS**

97365 The *mv* utility shall conform to XBD Section 12.2 (on page 215).

97366 The following options shall be supported:

97367 **–f** Do not prompt for confirmation if the destination path exists. Any previous
97368 occurrence of the **–i** option is ignored.

97369 **–i** Prompt for confirmation if the destination path exists. Any previous occurrence of
97370 the **–f** option is ignored.

97371 Specifying more than one of the **–f** or **–i** options shall not be considered an error. The last option

specified shall determine the behavior of *mv*.

OPERANDS

The following operands shall be supported:

source_file A pathname of a file or directory to be moved.

target_file A new pathname for the file or directory being moved.

target_dir A pathname of an existing directory into which to move the input files.

STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used.

INPUT FILES

The input files specified by each *source_file* operand can be of any file type.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *mv*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages and prompts written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

Prompts shall be written to the standard error under the conditions specified in the DESCRIPTION section. The prompts shall contain the destination pathname, but their format is otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

OUTPUT FILES

The output files may be of any file type.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All input files were moved successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

If the copying or removal of *source_file* is prematurely terminated by a signal or error, *mv* may leave a partial copy of *source_file* at the source or destination. The *mv* utility shall not modify both *source_file* and the destination path simultaneously; termination at any point shall leave either *source_file* or the destination path complete.

APPLICATION USAGE

Some implementations mark for update the last file status change timestamp of renamed files and some do not. Applications which make use of the last file status change timestamp may behave differently with respect to renamed files unless they are designed to allow for either behavior.

The specification ensures that *mv* **a a** will not alter the contents of file **a**, and allows the implementation to issue an error that a file cannot be moved onto itself. Likewise, when **a** and **b** are hard links to the same file, *mv* **a b** will not alter **b**, but if a diagnostic is not issued, then it is unspecified whether **a** is left untouched (as it would be by the *rename*( ) function) or unlinked (reducing the link count of **b**).

EXAMPLES

If the current directory contains only files **a** (of any type defined by the System Interfaces volume of POSIX.1-200x), **b** (also of any type), and a directory **c**:

```
mv a b c
mv c d
```

results with the original files **a** and **b** residing in the directory **d** in the current directory.

RATIONALE

Early proposals diverged from the SVID and BSD historical practice in that they required that when the destination path exists, the **–f** option is not specified, and input is not a terminal, *mv* fails. This was done for compatibility with *cp*. The current text returns to historical practice. It should be noted that this is consistent with the *rename*( ) function defined in the System Interfaces volume of POSIX.1-200x, which does not require write permission on the target.

For absolute clarity, paragraph (1), describing the behavior of *mv* when prompting for confirmation, should be interpreted in the following manner:

```
if (exists AND (NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The **–i** option exists on BSD systems, giving applications and users a way to avoid accidentally unlinking files when moving others. When the standard input is not a terminal, the 4.3 BSD *mv* deletes all existing destination paths without prompting, even when **–i** is specified; this is inconsistent with the behavior of the 4.3 BSD *cp* utility, which always generates an error when the file is unwritable and the standard input is not a terminal. The standard developers decided that use of **–i** is a request for interaction, so when the destination path exists, the utility takes

instructions from whatever responds to standard input.

The *rename*( ) function is able to move directories within the same file system. Some historical versions of *mv* have been able to move directories, but not to a different file system. The standard developers considered that this was an annoying inconsistency, so this volume of POSIX.1-200x requires directories to be able to be moved even across file systems. There is no **–R** option to confirm that moving a directory is actually intended, since such an option was not required for moving directories in historical practice. Requiring the application to specify it sometimes, depending on the destination, seemed just as inconsistent. The semantics of the *rename*( ) function were preserved as much as possible. For example, *mv* is not permitted to "rename" files to or from directories, even though they might be empty and removable.

Historic implementations of *mv* did not exit with a non-zero exit status if they were unable to duplicate any file characteristics when moving a file across file systems, nor did they write a diagnostic message for the user. The former behavior has been preserved to prevent scripts from breaking; a diagnostic message is now required, however, so that users are alerted that the file characteristics have changed.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the **–f** option or using the **–i** option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

When *mv* is dealing with a single file system and *source_file* is a symbolic link, the link itself is moved as a consequence of the dependence on the *rename*( ) functionality, per the DESCRIPTION. Across file systems, this has to be made explicit.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

The *mv* utility is changed to describe processing of symbolic links as specified in the IEEE P1003.2b draft standard.

The APPLICATION USAGE section is added.

Issue 7

Austin Group Interpretation 1003.1-2001 #016 is applied.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

Austin Group Interpretations 1003.1-2001 #164, #168, and #169 are applied.

SD5-XCU-ERN-13 is applied, making an editorial correction to the SYNOPSIS.

SD5-XCU-ERN-51 is applied to the DESCRIPTION, defining the behavior for when files are being duplicated to another file system while having hard links.

97501 Changes are made related to support for finegrained timestamps.

97502 **NAME**

97503 newgrp — change to a new group

97504 **SYNOPSIS**

97505 `newgrp [-l] [group]`

97506 **DESCRIPTION**

97507 The *newgrp* utility shall create a new shell execution environment with a new real and effective
97508 group identification. Of the attributes listed in Section 2.12 (on page 2331), the new shell
97509 execution environment shall retain the working directory, file creation mask, and exported
97510 variables from the previous environment (that is, open files, traps, unexported variables, alias
97511 definitions, shell functions, and *set* options may be lost). All other aspects of the process
97512 environment that are preserved by the *exec* family of functions defined in the System Interfaces
97513 volume of POSIX.1-200x shall also be preserved by *newgrp*; whether other aspects are preserved
97514 is unspecified.

97515 A failure to assign the new group identifications (for example, for security or password-related
97516 reasons) shall not prevent the new shell execution environment from being created.

97517 The *newgrp* utility shall affect the supplemental groups for the process as follows:

97518 • On systems where the effective group ID is normally in the supplementary group list (or
97519 whenever the old effective group ID actually is in the supplementary group list):

97520 — If the new effective group ID is also in the supplementary group list, *newgrp* shall
97521 change the effective group ID.

97522 — If the new effective group ID is not in the supplementary group list, *newgrp* shall add
97523 the new effective group ID to the list, if there is room to add it.

97524 • On systems where the effective group ID is not normally in the supplementary group list
97525 (or whenever the old effective group ID is not in the supplementary group list):

97526 — If the new effective group ID is in the supplementary group list, *newgrp* shall delete
97527 it.

97528 — If the old effective group ID is not in the supplementary list, *newgrp* shall add it if
97529 there is room.

97530 **Note:** The System Interfaces volume of POSIX.1-200x does not specify whether the effective group ID
97531 of a process is included in its supplementary group list.

97532 With no operands, *newgrp* shall change the effective group back to the groups identified in the
97533 user's user entry, and shall set the list of supplementary groups to that set in the user's group
97534 database entries.

97535 If the first argument is `'-'`, the results are unspecified.

97536 If a password is required for the specified group, and the user is not listed as a member of that
97537 group in the group database, the user shall be prompted to enter the correct password for that
97538 group. If the user is listed as a member of that group, no password shall be requested. If no
97539 password is required for the specified group, it is implementation-defined whether users not
97540 listed as members of that group can change to that group. Whether or not a password is
97541 required, implementation-defined system accounting or security mechanisms may impose
97542 additional authorization restrictions that may cause *newgrp* to write a diagnostic message and
97543 suppress the changing of the group identification.

97544 **OPTIONS**

97545 The *newgrp* utility shall conform to XBD Section 12.2 (on page 215), except for the unspecified
97546 usage of '–'.

97547 The following option shall be supported:

97548 **–l** (The letter ell.) Change the environment to what would be expected if the user
97549 actually logged in again.

97550 **OPERANDS**

97551 The following operand shall be supported:

97552 *group* A group name from the group database or a non-negative numeric group ID.
97553 Specifies the group ID to which the real and effective group IDs shall be set. If
97554 *group* is a non-negative numeric string and exists in the group database as a group
97555 name (see *getgrnam*()), the numeric group ID associated with that group name
97556 shall be used as the group ID.

97557 **STDIN**

97558 Not used.

97559 **INPUT FILES**

97560 The file **/dev/tty** shall be used to read a single line of text for password checking, when one is
97561 required.

97562 **ENVIRONMENT VARIABLES**

97563 The following environment variables shall affect the execution of *newgrp*:

97564 *LANG* Provide a default value for the internationalization variables that are unset or null.
97565 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
97566 variables used to determine the values of locale categories.)

97567 *LC_ALL* If set to a non-empty string value, override the values of all the other
97568 internationalization variables.

97569 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
97570 characters (for example, single-byte as opposed to multi-byte characters in
97571 arguments).

97572 *LC_MESSAGES*
97573 Determine the locale that should be used to affect the format and contents of
97574 diagnostic messages written to standard error.

97575 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

97576 **ASYNCHRONOUS EVENTS**

97577 Default.

97578 **STDOUT**

97579 Not used.

97580 **STDERR**

97581 The standard error shall be used for diagnostic messages and a prompt string for a password, if
97582 one is required. Diagnostic messages may be written in cases where the exit status is not
97583 available. See the EXIT STATUS section.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *newgrp* succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status shall be the exit status of the shell. Otherwise, the following exit value shall be returned:

>0 An error occurred.

CONSEQUENCES OF ERRORS

The invoking shell may terminate.

APPLICATION USAGE

There is no convenient way to enter a password into the group database. Use of group passwords is not encouraged, because by their very nature they encourage poor security practices. Group passwords may disappear in the future.

A common implementation of *newgrp* is that the current shell uses *exec* to overlay itself with *newgrp*, which in turn overlays itself with a new shell after changing group. On some implementations, however, this may not occur and *newgrp* may be invoked as a subprocess.

The *newgrp* command is intended only for use from an interactive terminal. It does not offer a useful interface for the support of applications.

The exit status of *newgrp* is generally inapplicable. If *newgrp* is used in a script, in most cases it successfully invokes a new shell and the rest of the original shell script is bypassed when the new shell exits. Used interactively, *newgrp* displays diagnostic messages to indicate problems. But usage such as:

```
newgrp foo
echo $?
```

is not useful because the new shell might not have access to any status *newgrp* may have generated (and most historical systems do not provide this status). A zero status echoed here does not necessarily indicate that the user has changed to the new group successfully. Following *newgrp* with the *id* command provides a portable means of determining whether the group change was successful or not.

EXAMPLES

None.

RATIONALE

Most historical implementations use one of the *exec* functions to implement the behavior of *newgrp*. Errors detected before the *exec* leave the environment unchanged, while errors detected after the *exec* leave the user in a changed environment. While it would be useful to have *newgrp* issue a diagnostic message to tell the user that the environment changed, it would be inappropriate to require this change to some historical implementations.

The password mechanism is allowed in the group database, but how this would be implemented is not specified.

The *newgrp* utility was retained in this volume of POSIX.1-200x, even given the existence of the multiple group permissions feature in the System Interfaces volume of POSIX.1-200x, for several reasons. First, in some implementations, the group ownership of a newly created file is determined by the group of the directory in which the file is created, as allowed by the System

Interfaces volume of POSIX.1-200x; on other implementations, the group ownership of a newly created file is determined by the effective group ID. On implementations of the latter type, *newgrp* allows files to be created with a specific group ownership. Finally, many implementations use the real group ID in accounting, and on such systems, *newgrp* allows the accounting identity of the user to be changed.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The obsolescent SYNOPSIS is removed.

The text describing supplemental groups is no longer conditional on {NGROUPS_MAX} being greater than 1. This is because {NGROUPS_MAX} now has a minimum value of 8. This is a FIPS requirement.

Issue 7

Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying the behavior if the first argument is '−'.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *newgrp* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

97654 **NAME**

97655 nice — invoke a utility with an altered nice value

97656 **SYNOPSIS**

97657 `nice [–n increment] utility [argument...]`

97658 **DESCRIPTION**

97659 The *nice* utility shall invoke a utility, requesting that it be run with a different nice value (see
97660 XBD Section 3.239, on page 71). With no options, the executed utility shall be run with a nice
97661 value that is some implementation-defined quantity greater than or equal to the nice value of the
97662 current process. If the user lacks appropriate privileges to affect the nice value in the requested
97663 manner, the *nice* utility shall not affect the nice value; in this case, a warning message may be
97664 written to standard error, but this shall not prevent the invocation of *utility* or affect the exit
97665 status.

97666 **OPTIONS**

97667 The *nice* utility shall conform to XBD Section 12.2 (on page 215).

97668 The following option is supported:

97669 **–n** *increment* A positive or negative decimal integer which shall have the same effect on the
97670 execution of the utility as if the utility had called the *nice*( ) function with the
97671 numeric value of the *increment* option-argument.

97672 **OPERANDS**

97673 The following operands shall be supported:

97674 *utility* The name of a utility that is to be invoked. If the *utility* operand names any of the
97675 special built-in utilities in Section 2.14 (on page 2334), the results are undefined.

97676 *argument* Any string to be supplied as an argument when invoking the utility named by the
97677 *utility* operand.

97678 **STDIN**

97679 Not used.

97680 **INPUT FILES**

97681 None.

97682 **ENVIRONMENT VARIABLES**

97683 The following environment variables shall affect the execution of *nice*:

97684 *LANG* Provide a default value for the internationalization variables that are unset or null.
97685 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
97686 variables used to determine the values of locale categories.)

97687 *LC_ALL* If set to a non-empty string value, override the values of all the other
97688 internationalization variables.

97689 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
97690 characters (for example, single-byte as opposed to multi-byte characters in
97691 arguments).

97692 *LC_MESSAGES*

97693 Determine the locale that should be used to affect the format and contents of
97694 diagnostic messages written to standard error.

97695 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path used to locate the utility to be invoked. See XBD Chapter 8 (on page 173).

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

If *utility* is invoked, the exit status of *nice* shall be the exit status of *utility*; otherwise, the *nice* utility shall exit with one of the following values:

1-125 An error occurred in the *nice* utility.

126 The utility specified by *utility* was found but could not be invoked.

127 The utility specified by *utility* could not be found.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The only guaranteed portable uses of this utility are:

nice utility
Run *utility* with the default higher or equal nice value.

nice **–n** <*positive integer*> *utility*
Run *utility* with a higher nice value.

On some implementations they have no discernible effect on the invoked utility and on some others they are exactly equivalent.

Historical systems have frequently supported the <*positive integer*> up to 20. Since there is no error penalty associated with guessing a number that is too high, users without access to the system conformance document (to see what limits are actually in place) could use the historical 1 to 20 range or attempt to use very large numbers if the job should be truly low priority.

The nice value of a process can be displayed using the command:

```
ps –o nice
```

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for

any other reason.

EXAMPLES

None.

RATIONALE

The 4.3 BSD version of *nice* does not check whether *increment* is a valid decimal integer. The command *nice* **–x** *utility*, for example, would be treated the same as the command *nice* **––1** *utility*. If the user does not have appropriate privileges, this results in a "permission denied" error. This is considered a bug.

When a user without appropriate privileges gives a negative *increment*, System V treats it like the command *nice* **–0** *utility*, while 4.3 BSD writes a "permission denied" message and does not run the utility. The standard specifies the System V behavior together with an optional BSD-style "permission denied" message.

The C shell has a built-in version of *nice* that has a different interface from the one described in this volume of POSIX.1-200x.

The term "utility" is used, rather than "command", to highlight the fact that shell compound commands, pipelines, and so on, cannot be used. Special built-ins also cannot be used. However, "utility" includes user application programs and shell scripts, not just utilities defined in this volume of POSIX.1-200x.

Historical implementations of *nice* provide a nice value range of 40 or 41 discrete steps, with the default nice value being the midpoint of that range. By default, they raise the nice value of the executed utility by 10.

Some historical documentation states that the *increment* value must be within a fixed range. This is misleading; the valid *increment* values on any invocation are determined by the current process nice value, which is not always the default.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of POSIX.1-200x make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the *nice*-related features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of POSIX.1-200x, and others may have no effect at all. Because of the use of "implementation-defined" in *nice* and *renice*, a wide range of implementation strategies are possible.

Earlier versions of this standard allowed a –*increment* option. This form is no longer specified by POSIX.1-200x but may be present in some implementations.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 4.

97781 **Issue 6**

97782 This utility is marked as part of the User Portability Utilities option.

97783 The obsolescent SYNOPSIS is removed.

97784 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/18 is applied, deleting a paragraph of
97785 RATIONALE that referred to text no longer in the standard.

97786 **Issue 7**

97787 Austin Group Interpretation 1003.1-2001 #027 is applied.

97788 SD5-XCU-ERN-32 and SD5-XCU-ERN-33 are applied, updating the DESCRIPTION,
97789 APPLICATION USAGE, and RATIONALE sections.

97790 The *nice* utility is moved from the User Portability Utilities option to the Base. User Portability
97791 Utilities is now an option for interactive utilities.

NAME

nl — line numbering filter

SYNOPSIS

XSI
```
nl [–p] [–b type] [–d delim] [–f type] [–h type] [–i incr] [–l num]
    [–n format] [–s sep] [–v startnum] [–w width] [file]
```

DESCRIPTION

The *nl* utility shall read lines from the named *file* or the standard input if no *file* is named and shall reproduce the lines to standard output. Lines shall be numbered on the left. Additional functionality may be provided in accordance with the command options in effect.

The *nl* utility views the text it reads in terms of logical pages. Line numbering shall be reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (for example, no numbering of header and footer lines while numbering blank lines only in the body).

The starts of logical page sections shall be signaled by input lines containing nothing but the following delimiter characters:

Line	Start of
`\:\:\:`	Header
`\:\:`	Body
`\:`	Footer

Unless otherwise specified, *nl* shall assume the text being read is in a single logical page body.

OPTIONS

The *nl* utility shall conform to XBD Section 12.2 (on page 215). Only one file can be named.

The following options shall be supported:

–b *type* Specify which logical page body lines shall be numbered. Recognized *types* and their meaning are:

- **a** Number all lines.
- **t** Number only non-empty lines.
- **n** No line numbering.
- **p***string* Number only lines that contain the basic regular expression specified in *string*.

The default *type* for logical page body shall be **t** (text lines numbered).

–d *delim* Specify the delimiter characters that indicate the start of a logical page section. These can be changed from the default characters `"\:"` to two user-specified characters. If only one character is entered, the second character shall remain the default character `':'`.

–f *type* Specify the same as **b** *type* except for footer. The default for logical page footer shall be **n** (no lines numbered).

–h *type* Specify the same as **b** *type* except for header. The default *type* for logical page header shall be **n** (no lines numbered).

97832 **–i** *incr* Specify the increment value used to number logical page lines. The default shall be
97833 1.

97834 **–l** *num* Specify the number of blank lines to be considered as one. For example, **–l 2** results
97835 in only the second adjacent blank line being numbered (if the appropriate **–h a**,
97836 **–b a**, or **–f a** option is set). The default shall be 1.

97837 **–n** *format* Specify the line numbering format. Recognized values are: **ln**, left justified, leading
97838 zeros suppressed; **rn**, right justified, leading zeros suppressed; **rz**, right justified,
97839 leading zeros kept. The default *format* shall be **rn** (right justified).

97840 **–p** Specify that numbering should not be restarted at logical page delimiters.

97841 **–s** *sep* Specify the characters used in separating the line number and the corresponding
97842 text line. The default *sep* shall be a <tab>.

97843 **–v** *startnum* Specify the initial value used to number logical page lines. The default shall be 1.

97844 **–w** *width* Specify the number of characters to be used for the line number. The default *width*
97845 shall be 6.

97846 **OPERANDS**

97847 The following operand shall be supported:

97848 *file* A pathname of a text file to be line-numbered.

97849 **STDIN**

97850 The standard input shall be used if no *file* operand is specified, and shall be used if the *file*
97851 operand is `'–'` and the implementation treats the `'–'` as meaning standard input. Otherwise,
97852 the standard input shall not be used. See the INPUT FILES section.

97853 **INPUT FILES**

97854 The input file shall be a text file.

97855 **ENVIRONMENT VARIABLES**

97856 The following environment variables shall affect the execution of *nl*:

97857 *LANG* Provide a default value for the internationalization variables that are unset or null.
97858 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
97859 variables used to determine the values of locale categories.)

97860 *LC_ALL* If set to a non-empty string value, override the values of all the other
97861 internationalization variables.

97862 *LC_COLLATE*
97863 Determine the locale for the behavior of ranges, equivalence classes, and multi-
97864 character collating elements within regular expressions.

97865 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
97866 characters (for example, single-byte as opposed to multi-byte characters in
97867 arguments and input files), the behavior of character classes within regular
97868 expressions, and for deciding which characters are in character class **graph** (for the
97869 **–b t**, **–f t**, and **–h t** options).

97870 *LC_MESSAGES*
97871 Determine the locale that should be used to affect the format and contents of
97872 diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

The standard output shall be a text file in the following format:

`"%s%s%s", <line number>, <separator>, <input line>`

where <*line number*> is one of the following numeric formats:

`%6d` When the **rn** format is used (the default; see –**n**).

`%06d` When the **rz** format is used.

`%–6d` When the **ln** format is used.

<empty> When line numbers are suppressed for a portion of the page; the <*separator*> is also suppressed.

In the preceding list, the number 6 is the default width; the –**w** option can change this value.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

In using the –**d** *delim* option, care should be taken to escape characters that have special meaning to the command interpreter.

EXAMPLES

The command:

```
nl –v 10 –i 10 –d \!+ file1
```

numbers *file1* starting at line number 10 with an increment of 10. The logical page delimiter is `"!+"`. Note that the `'!'` has to be escaped when using *csh* as a command interpreter because of its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but does not do any harm.

RATIONALE

None.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 5

The option [**–f** *type*] is added to the SYNOPSIS. The option descriptions are presented in alphabetic order. The description of **–bt** is changed to "Number only non-empty lines".

Issue 6

The obsolescent behavior allowing the options to be intermingled with the optional *file* operand is removed.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

97926 **NAME**

97927 nm — write the name list of an object file (**DEVELOPMENT**)

97928 **SYNOPSIS**

97929 SD
```
nm [–APv] [–g|–u] [–t format] file...
```
97930 XSI
```
nm [–APv] [–efox] [–g|–u] [–t format] file...
```

97931 **DESCRIPTION**

97932 The *nm* utility shall display symbolic information appearing in the object file, executable file, or
97933 object-file library named by *file*. If no symbolic information is available for a valid input file, the
97934 *nm* utility shall report that fact, but not consider it an error condition.

97935 XSI The default base used when numeric values are written is unspecified. On XSI-conformant
97936 systems, it shall be decimal.

97937 **OPTIONS**

97938 The *nm* utility shall conform to XBD Section 12.2 (on page 215).

97939 The following options shall be supported:

97940 **–A** Write the full pathname or library name of an object on each line.

97941 XSI **–e** Write only external (global) and static symbol information.

97942 XSI **–f** Produce full output. Write redundant symbols (**.text**, **.data**, and **.bss**), normally
97943 suppressed.

97944 **–g** Write only external (global) symbol information.

97945 XSI **–o** Write numeric values in octal (equivalent to **–t o**).

97946 **–P** Write information in a portable output format, as specified in the STDOUT section.

97947 **–t** *format* Write each numeric value in the specified format. The format shall be dependent
97948 on the single character used as the *format* option-argument:

97949 XSI d The offset is written in decimal (default).

97950 o The offset is written in octal.

97951 x The offset is written in hexadecimal.

97952 **–u** Write only undefined symbols.

97953 **–v** Sort output by value instead of alphabetically.

97954 XSI **–x** Write numeric values in hexadecimal (equivalent to **–t x**).

97955 **OPERANDS**

97956 The following operand shall be supported:

97957 *file* A pathname of an object file, executable file, or object-file library.

97958 **STDIN**

97959 See the INPUT FILES section.

97960 **INPUT FILES**

97961 The input file shall be an object file, an object-file library whose format is the same as those
97962 produced by the *ar* utility for link editing, or an executable file. The *nm* utility may accept
97963 additional implementation-defined object library formats for the input file.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nm*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for character collation information for the symbol-name and symbol-value collation sequences.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

If symbolic information is present in the input files, then for each file or for each member of an archive, the *nm* utility shall write the following information to standard output. By default, the format is unspecified, but the output shall be sorted alphabetically by symbol name:

- Library or object name, if **−A** is specified
- Symbol name
- Symbol type, which shall either be one of the following single characters or an implementation-defined type represented by a single character:

  `A` Global absolute symbol.

  `a` Local absolute symbol.

  `B` Global “bss” (that is, uninitialized data space) symbol.

  `b` Local bss symbol.

  `D` Global data symbol.

  `d` Local data symbol.

  `T` Global text symbol.

  `t` Local text symbol.

  `U` Undefined symbol.

- Value of the symbol
- The size associated with the symbol, if applicable

This information may be supplemented by additional information specific to the implementation.

If the **–P** option is specified, the previous information shall be displayed using the following portable format. The three versions differ depending on whether **–t d**, **–t o**, or **–t x** was specified, respectively:

```
"%s%s %s %d %d\n", <library/object name>, <name>, <type>,
    <value>, <size>

"%s%s %s %o %o\n", <library/object name>, <name>, <type>,
    <value>, <size>

"%s%s %s %x %x\n", <library/object name>, <name>, <type>,
    <value>, <size>
```

where <*library/object name*> shall be formatted as follows:

- If **–A** is not specified, <*library/object name*> shall be an empty string.
- If **–A** is specified and the corresponding *file* operand does not name a library:

  ```
  "%s: ", <file>
  ```

- If **–A** is specified and the corresponding *file* operand names a library. In this case, <*object file*> shall name the object file in the library containing the symbol being described:

  ```
  "%s[%s]: ", <file>, <object file>
  ```

If **–A** is not specified, then if more than one *file* operand is specified or if only one *file* operand is specified and it names a library, *nm* shall write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding *file* operand does not name a library:

  ```
  "%s:\n", <file>
  ```

- If the corresponding *file* operand names a library; in this case, <*object file*> shall be the name of the file in the library containing the following symbols:

  ```
  "%s[%s]:\n", <file>, <object file>
  ```

If **–P** is specified, but **–t** is not, the format shall be as if **–t x** had been specified.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

Mechanisms for dynamic linking make this utility less meaningful when applied to an executable file because a dynamically linked executable may omit numerous library routines that would be found in a statically linked executable.

EXAMPLES

None.

RATIONALE

Historical implementations of *nm* have used different bases for numeric output and supplied different default types of symbols that were reported. The **–t** *format* option, similar to that used in *od* and *strings*, can be used to specify the numeric base; **–g** and **–u** can be used to restrict the amount of output or the types of symbols included in the output.

The compromise of using **–t** *format versus* using **–d**, **–o**, and other similar options was necessary because of differences in the meaning of **–o** between implementations. The **–o** option from BSD has been provided here as **–A** to avoid confusion with the **–o** from System V (which has been provided here as **–t** and as **–o** on XSI-conformant systems).

The option list was significantly reduced from that provided by historical implementations.

The *nm* description is a subset of both the System V and BSD *nm* utilities with no specified default output.

It was recognized that mechanisms for dynamic linking make this utility less meaningful when applied to an executable file (because a dynamically linked executable file may omit numerous library routines that would be found in a statically linked executable file), but the value of *nm* during software development was judged to outweigh other limitations.

The default output format of *nm* is not specified because of differences in historical implementations. The **–P** option was added to allow some type of portable output format. After a comparison of the different formats used in SunOS, BSD, SVR3, and SVR4, it was decided to create one that did not match the current format of any of these four systems. The format devised is easy to parse by humans, easy to parse in shell scripts, and does not need to vary depending on locale (because no English descriptions are included). All of the systems currently have the information available to use this format.

The format given in *nm* STDOUT uses <space> characters between the fields, which may be any number of <blank> characters required to align the columns. The single-character types were selected to match historical practice, and the requirement that implementation additions also be single characters made parsing the information easier for shell scripts.

FUTURE DIRECTIONS

None.

CHANGE HISTORY

First released in Issue 2.

Issue 6

This utility is marked as supported when both the User Portability Utilities option and the Software Development Utilities option are supported.

Issue 7

The *nm* utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

nohup — invoke a utility immune to hangups

SYNOPSIS

```
nohup utility [argument...]
```

DESCRIPTION

The *nohup* utility shall invoke the utility named by the *utility* operand with arguments supplied as the *argument* operands. At the time the named *utility* is invoked, the SIGHUP signal shall be set to be ignored.

If standard input is associated with a terminal, the *nohup* utility may redirect standard input from an unspecified file.

If the standard output is a terminal, all output written by the named *utility* to its standard output shall be appended to the end of the file **nohup.out** in the current directory. If **nohup.out** cannot be created or opened for appending, the output shall be appended to the end of the file **nohup.out** in the directory specified by the *HOME* environment variable. If neither file can be created or opened for appending, *utility* shall not be invoked. If a file is created, the file's permission bits shall be set to S_IRUSR | S_IWUSR.

If standard error is a terminal and standard output is open but is not a terminal, all output written by the named utility to its standard error shall be redirected to the same open file description as the standard output. If standard error is a terminal and standard output either is a terminal or is closed, the same output shall instead be appended to the end of the **nohup.out** file as described above.

OPTIONS

None.

OPERANDS

The following operands shall be supported:

utility The name of a utility that is to be invoked. If the *utility* operand names any of the special built-in utilities in Section 2.14 (on page 2334), the results are undefined.

argument Any string to be supplied as an argument when invoking the utility named by the *utility* operand.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *nohup*:

HOME Determine the pathname of the user's home directory: if the output file **nohup.out** cannot be created in the current directory, the *nohup* utility shall use the directory named by *HOME* to create the file.

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

PATH Determine the search path that is used to locate the utility to be invoked. See XBD Chapter 8 (on page 173).

ASYNCHRONOUS EVENTS

The *nohup* utility shall take the standard action for all signals except that SIGHUP shall be ignored.

STDOUT

If the standard output is not a terminal, the standard output of *nohup* shall be the standard output generated by the execution of the *utility* specified by the operands. Otherwise, nothing shall be written to the standard output.

STDERR

If the standard output is a terminal, a message shall be written to the standard error, indicating the name of the file to which the output is being appended. The name of the file shall be either **nohup.out** or **$HOME/nohup.out**.

OUTPUT FILES

Output written by the named utility is appended to the file **nohup.out** (or **$HOME/nohup.out**), if the conditions hold as described in the DESCRIPTION.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

126 The utility specified by *utility* was found but could not be invoked.

127 An error occurred in the *nohup* utility or the utility specified by *utility* could not be found.

Otherwise, the exit status of *nohup* shall be that of the utility specified by the *utility* operand.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

EXAMPLES

It is frequently desirable to apply *nohup* to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the *nohup* applies to everything in the file.

Alternatively, the following command can be used to apply *nohup* to a complex command:

```
nohup sh -c 'complex-command-line' </dev/null
```

RATIONALE

The 4.3 BSD version ignores SIGTERM and SIGHUP, and if **./nohup.out** cannot be used, it fails instead of trying to use **$HOME/nohup.out**.

The *csh* utility has a built-in version of *nohup* that acts differently from the *nohup* defined in this volume of POSIX.1-200x.

The term *utility* is used, rather than *command*, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility* includes user application programs and shell scripts, not just the standard utilities.

Historical versions of the *nohup* utility use default file creation semantics. Some more recent versions use the permissions specified here as an added security precaution.

Some historical implementations ignore SIGQUIT in addition to SIGHUP; others ignore SIGTERM. An early proposal allowed, but did not require, SIGQUIT to be ignored. Several reviewers objected that *nohup* should only modify the handling of SIGHUP as required by this volume of POSIX.1-200x.

Historical versions of *nohup* did not affect standard input, but that causes problems in the common scenario where the user logs into a system, types the command:

```
nohup make &
```

at the prompt, and then logs out. If standard input is not affected by *nohup*, the login session may not terminate for quite some time, since standard input remains open until *make* exits. To avoid this problem, POSIX.1-200x allows implementations to redirect standard input if it is a terminal. Since the behavior is implementation-defined, portable applications that may run into the problem should redirect standard input themselves. For example, instead of:

```
nohup make &
```

an application can invoke:

```
nohup make </dev/null &
```

CHANGE HISTORY

First released in Issue 2.

98214 **Issue 7**
98215 Austin Group Interpretations 1003.1-2001 #104, #105, and #106 are applied.

NAME

od — dump files in various formats

SYNOPSIS

```
od [–v] [–A address_base] [–j skip] [–N count] [–t type_string]...
    [file...]
```

XSI

```
od [–bcdosx] [file] [[+]offset[.][b]]
```

DESCRIPTION

The *od* utility shall write the contents of its input files to standard output in a user-specified format.

OPTIONS

The *od* utility shall conform to XBD Section 12.2 (on page 215), except that the order of presentation of the **–t** options and the **–bcdosx** options is significant.

The following options shall be supported:

–A *address_base*
: Specify the input offset base. See the EXTENDED DESCRIPTION section. The application shall ensure that the *address_base* option-argument is a character. The characters `'d'`, `'o'`, and `'x'` specify that the offset base shall be written in decimal, octal, or hexadecimal, respectively. The character `'n'` specifies that the offset shall not be written.

XSI **–b**
: Interpret bytes in octal. This shall be equivalent to **–t o1**.

XSI **–c**
: Interpret bytes as characters specified by the current setting of the *LC_CTYPE* category. Certain non-graphic characters appear as C escapes: `"NUL=\0"`, `"BS=\b"`, `"FF=\f"`, `"NL=\n"`, `"CR=\r"`, `"HT=\t"`; others appear as 3-digit octal numbers.

XSI **–d**
: Interpret *word*s (two-byte units) in unsigned decimal. This shall be equivalent to **–t u2**.

–j *skip*
: Jump over *skip* bytes from the beginning of the input. The *od* utility shall read or seek past the first *skip* bytes in the concatenated input files. If the combined input is not at least *skip* bytes long, the *od* utility shall write a diagnostic message to standard error and exit with a non-zero exit status.

  By default, the *skip* option-argument shall be interpreted as a decimal number. With a leading 0x or 0X, the offset shall be interpreted as a hexadecimal number; otherwise, with a leading `'0'`, the offset shall be interpreted as an octal number. Appending the character `'b'`, `'k'`, or `'m'` to offset shall cause it to be interpreted as a multiple of 512, 1 024, or 1 048 576 bytes, respectively. If the *skip* number is hexadecimal, any appended `'b'` shall be considered to be the final hexadecimal digit.

–N *count*
: Format no more than *count* bytes of input. By default, *count* shall be interpreted as a decimal number. With a leading 0x or 0X, *count* shall be interpreted as a hexadecimal number; otherwise, with a leading `'0'`, it shall be interpreted as an octal number. If *count* bytes of input (after successfully skipping, if **–j** *skip* is specified) are not available, it shall not be considered an error; the *od* utility shall format the input that is available.

98259 XSI **–o** Interpret *word*s (two-byte units) in octal. This shall be equivalent to **–t o2**.

98260 XSI **–s** Interpret *word*s (two-byte units) in signed decimal. This shall be equivalent to
98261 **–t d2**.

98262 **–t** *type_string*
98263 Specify one or more output types. See the EXTENDED DESCRIPTION section. The
98264 application shall ensure that the *type_string* option-argument is a string specifying
98265 the types to be used when writing the input data. The string shall consist of the
98266 type specification characters `a`, `c`, `d`, `f`, `o`, `u`, and `x`, specifying named character,
98267 character, signed decimal, floating point, octal, unsigned decimal, and
98268 hexadecimal, respectively. The type specification characters `d`, `f`, `o`, `u`, and `x` can be
98269 followed by an optional unsigned decimal integer that specifies the number of
98270 bytes to be transformed by each instance of the output type. The type specification
98271 character `f` can be followed by an optional `F`, `D`, or `L` indicating that the conversion
98272 should be applied to an item of type **float**, **double**, or **long double**, respectively.
98273 The type specification characters `d`, `o`, `u`, and `x` can be followed by an optional `C`, `S`,
98274 `I`, or `L` indicating that the conversion should be applied to an item of type **char**,
98275 **short**, **int**, or **long**, respectively. Multiple types can be concatenated within the
98276 same *type_string* and multiple **–t** options can be specified. Output lines shall be
98277 written for each type specified in the order in which the type specification
98278 characters are specified.

98279 **–v** Write all input data. Without the **–v** option, any number of groups of output lines,
98280 which would be identical to the immediately preceding group of output lines
98281 (except for the byte offsets), shall be replaced with a line containing only an
98282 <asterisk> (`'*'`).

98283 XSI **–x** Interpret *word*s (two-byte units) in hexadecimal. This shall be equivalent to **–t x2**.

98284 XSI Multiple types can be specified by using multiple **–bcdostx** options. Output lines are written for
98285 each type specified in the order in which the types are specified.

98286 **OPERANDS**
98287 The following operands shall be supported:

98288 *file* A pathname of a file to be read. If no *file* operands are specified, the standard input
98289 shall be used.

98290 If there are no more than two operands, none of the **–A**, **–j**, **–N**, **–t**, or **–v** options is
98291 specified, and either of the following is true: the first character of the last operand
98292 is a <plus-sign> (`'+'`), or there are two operands and the first character of the last
98293 XSI operand is numeric; the last operand shall be interpreted as an offset operand on
98294 XSI-conformant systems. Under these conditions, the results are unspecified on
98295 systems that are not XSI-conformant systems.

98296 XSI **[+]***offset***[.][b]** The *offset* operand specifies the offset in the file where dumping is to commence.
98297 This operand is normally interpreted as octal bytes. If `'.'` is appended, the offset
98298 shall be interpreted in decimal. If `'b'` is appended, the offset shall be interpreted
98299 in units of 512 bytes.

98300 **STDIN**
98301 The standard input shall be used if no *file* operands are specified, and shall be used if a *file*
98302 operand is `'–'` and the implementation treats the `'–'` as meaning standard input. Otherwise,
98303 the standard input shall not be used. See the INPUT FILES section.

98304 **INPUT FILES**

98305 The input files can be any file type.

98306 **ENVIRONMENT VARIABLES**

98307 The following environment variables shall affect the execution of *od*:

98308 *LANG* Provide a default value for the internationalization variables that are unset or null.
98309 (See XBD Section 8.2 (on page 174) for the precedence of internationalization
98310 variables used to determine the values of locale categories.)

98311 *LC_ALL* If set to a non-empty string value, override the values of all the other
98312 internationalization variables.

98313 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
98314 characters (for example, single-byte as opposed to multi-byte characters in
98315 arguments and input files).

98316 *LC_MESSAGES*
98317 Determine the locale that should be used to affect the format and contents of
98318 diagnostic messages written to standard error.

98319 *LC_NUMERIC*
98320 Determine the locale for selecting the radix character used when writing floating-
98321 point formatted output.

98322 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

98323 **ASYNCHRONOUS EVENTS**

98324 Default.

98325 **STDOUT**

98326 See the EXTENDED DESCRIPTION section.

98327 **STDERR**

98328 The standard error shall be used only for diagnostic messages.

98329 **OUTPUT FILES**

98330 None.

98331 **EXTENDED DESCRIPTION**

98332 The *od* utility shall copy sequentially each input file to standard output, transforming the input
98333 XSI data according to the output types specified by the **–t** option or the **–bcdosx** options. If no
98334 output type is specified, the default output shall be as if **–t oS** had been specified.

98335 The number of bytes transformed by the output type specifier `c` may be variable depending on
98336 the *LC_CTYPE* category.

98337 The default number of bytes transformed by output type specifiers `d`, `f`, `o`, `u`, and `x` corresponds
98338 to the various C-language types as follows. If the *c99* compiler is present on the system, these
98339 specifiers shall correspond to the sizes used by default in that compiler. Otherwise, these sizes
98340 may vary among systems that conform to POSIX.1-200x.

98341 • For the type specifier characters `d`, `o`, `u`, and `x`, the default number of bytes shall
98342 correspond to the size of the underlying implementation's basic integer type. For these
98343 specifier characters, the implementation shall support values of the optional number of
98344 bytes to be converted corresponding to the number of bytes in the C-language types **char**,
98345 **short**, **int**, and **long**. These numbers can also be specified by an application as the
98346 characters `'C'`, `'S'`, `'I'`, and `'L'`, respectively. The implementation shall also support
98347 the values 1, 2, 4, and 8, even if it provides no C-Language types of those sizes. The

implementation shall support the decimal value corresponding to the C-language type **long long**. The byte order used when interpreting numeric values is implementation-defined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.

- For the type specifier character `f`, the default number of bytes shall correspond to the number of bytes in the underlying implementation's basic double precision floating-point data type. The implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types **float, double**, and **long double**. These numbers can also be specified by an application as the characters `'F'`, `'D'`, and `'L'`, respectively.

The type specifier character `a` specifies that bytes shall be interpreted as named characters from the International Reference Version (IRV) of the ISO/IEC 646:1991 standard. Only the least significant seven bits of each byte shall be used for this type specification. Bytes with the values listed in the following table shall be written using the corresponding names for those characters.

Table 4-13 Named Characters in *od*

Value	Name	Value	Name	Value	Name	Value	Name
\000	**nul**	\001	**soh**	\002	**stx**	\003	**etx**
\004	**eot**	\005	**enq**	\006	**ack**	\007	**bel**
\010	**bs**	\011	**ht**	\012	**lf** or **nl***	\013	**vt**
\014	**ff**	\015	**cr**	\016	**so**	\017	**si**
\020	**dle**	\021	**dc1**	\022	**dc2**	\023	**dc3**
\024	**dc4**	\025	**nak**	\026	**syn**	\027	**etb**
\030	**can**	\031	**em**	\032	**sub**	\033	**esc**
\034	**fs**	\035	**gs**	\036	**rs**	\037	**us**
\040	**sp**	\177	**del**				

Note: The `"\012"` value may be written either as **lf** or **nl**.

The type specifier character `c` specifies that bytes shall be interpreted as characters specified by the current setting of the *LC_CTYPE* locale category. Characters listed in the table in XBD Chapter 5 (on page 121) (`'\\'`, `'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`) shall be written as the corresponding escape sequences, except that <backslash> shall be written as a single <backslash> and a NUL shall be written as `'\0'`. Other non-printable characters shall be written as one three-digit octal number for each byte in the character. Printable multi-byte characters shall be written in the area corresponding to the first byte of the character; the two-character sequence `"**"` shall be written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. When either the **–j** *skip* or **–N** *count* option is specified along with the `c` type specifier, and this results in an attempt to start or finish in the middle of a multi-byte character, the result is implementation-defined.

The input data shall be manipulated in blocks, where a block is defined as a multiple of the least common multiple of the number of bytes transformed by the specified output types. If the least common multiple is greater than 16, the results are unspecified. Each input block shall be written as transformed by each output type, one per written line, in the order that the output types were specified. If the input block size is larger than the number of bytes transformed by the output type, the output type shall sequentially transform the parts of the input block, and the output from each of the transformations shall be separated by one or more <blank> characters.

If, as a result of the specification of the **–N** option or end-of-file being reached on the last input file, input data only partially satisfies an output type, the input shall be extended sufficiently

with null bytes to write the last byte of the input.

Unless –**A n** is specified, the first output line produced for each input block shall be preceded by the input offset, cumulative across input files, of the next byte to be written. The format of the input offset is unspecified; however, it shall not contain any <blank> characters, shall start at the first character of the output line, and shall be followed by one or more <blank> characters. In addition, the offset of the byte following the last byte written shall be written after all the input data has been processed, but shall not be followed by any <blank> characters.

If no –**A** option is specified, the input offset base is unspecified.

EXIT STATUS

The following exit values shall be returned:

0 All input files were processed successfully.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

XSI-conformant applications are warned not to use filenames starting with '+' or a first operand starting with a numeric character so that the old functionality can be maintained by implementations, unless they specify one of the –**A**, –**j**, or –**N** options. To guarantee that one of these filenames is always interpreted as a filename, an application could always specify the address base format with the –**A** option.

EXAMPLES

If a file containing 128 bytes with decimal values zero to 127, in increasing order, is supplied as standard input to the command:

```
od –A d –t a
```

on an implementation using an input block size of 16 bytes, the standard output, independent of the current locale setting, would be similar to:

```
0000000 nul soh stx etx eot enq ack bel  bs  ht  nl  vt  ff  cr  so  si
0000016 dle dc1 dc2 dc3 dc4 nak syn etb can  em sub esc  fs  gs  rs  us
0000032  sp   !   "   #   $   %   &   ’   (   )   *   +   ,   –   .   /
0000048   0   1   2   3   4   5   6   7   8   9   :   ;   <   =   >   ?
0000064   @   A   B   C   D   E   F   G   H   I   J   K   L   M   N   O
0000080   P   Q   R   S   T   U   V   W   X   Y   Z   [   \   ]   ^   _
0000096   ‘   a   b   c   d   e   f   g   h   i   j   k   l   m   n   o
0000112   p   q   r   s   t   u   v   w   x   y   z   {   |   }   ~ del
0000128
```

Note that this volume of POSIX.1-200x allows **nl** or **lf** to be used as the name for the ISO/IEC 646:1991 standard IRV character with decimal value 10. The IRV names this character **lf** (line feed), but traditional implementations have referred to this character as newline (**nl**) and the POSIX locale character set symbolic name for the corresponding character is a <newline>.

The command:

```
od –A o –t o2x2x –N 18
```

on a system with 32-bit words and an implementation using an input block size of 16 bytes could write 18 bytes in approximately the following format:

```
0000000 032056 031440 041123 042040 052516 044530 020043 031464
```

```
                342e   3320   4253   4420   554e   4958   2023   3334
                  342e3320       42534420       554e4958       20233334
0000020 032472
                353a
                  353a0000
0000022
```

The command:

```
od -A d -t f -t o4 -t x4 -N 24 -j 0x15
```

on a system with 64-bit doubles (for example, IEEE Std 754-1985 double precision floating-point format) would skip 21 bytes of input data and then write 24 bytes in approximately the following format:

```
0000000    1.00000000000000e+00    1.57350000000000e+01
         07774000000 00000000000 10013674121 35341217270
            3ff00000    00000000    402f3851    eb851eb8
0000016    1.40668230000000e+02
         10030312542 04370303230
            40619562    23e18698
0000024
```

RATIONALE

The *od* utility went through several names in early proposals, including *hd*, *xd*, and most recently *hexdump*. There were several objections to all of these based on the following reasons:

- The *hd* and *xd* names conflicted with historical utilities that behaved differently.
- The *hexdump* description was much more complex than needed for a simple dump utility.
- The *od* utility has been available on all historical implementations and there was no need to create a new name for a utility so similar to the historical *od* utility.

The original reasons for not standardizing historical *od* were also fairly widespread. Those reasons are given below along with rationale explaining why the standard developers believe that this version does not suffer from the indicated problem:

- The BSD and System V versions of *od* have diverged, and the intersection of features provided by both does not meet the needs of the user community. In fact, the System V version only provides a mechanism for dumping octal bytes and **short**s, signed and unsigned decimal **short**s, hexadecimal **short**s, and ASCII characters. BSD added the ability to dump **float**s, **double**s, named ASCII characters, and octal, signed decimal, unsigned decimal, and hexadecimal **long**s. The version presented here provides more normalized forms for dumping bytes, **short**s, **int**s, and **long**s in octal, signed decimal, unsigned decimal, and hexadecimal; **float**, **double**, and **long double**; and named ASCII as well as current locale characters.
- It would not be possible to come up with a compatible superset of the BSD and System V flags that met the requirements of the standard developers. The historical default *od* output is the specified default output of this utility. None of the option letters chosen for this version of *od* conflict with any of the options to historical versions of *od*.
- On systems with different sizes for **short**, **int**, and **long**, there was no way to ask for dumps of **int**s, even in the BSD version. Because of the way options are named, the name space could not be extended to solve these problems. This is why the **-t** option was added (with type specifiers more closely matched to the *printf*( ) formats used in the rest of this volume of POSIX.1-200x) and the optional field sizes were added to the `d`, `f`, `o`, `u`, and `x` type

specifiers. It is also one of the reasons why the historical practice was not mandated as a required obsolescent form of *od*. (Although the old versions of *od* are not listed as an obsolescent form, implementations are urged to continue to recognize the older forms for several more years.) The `a`, `c`, `f`, `o`, and `x` types match the meaning of the corresponding format characters in the historical implementations of *od* except for the default sizes of the fields converted. The `d` format is signed in this volume of POSIX.1-200x to match the *printf*( ) notation. (Historical versions of *od* used `d` as a synonym for `u` in this version. The System V implementation uses `s` for signed decimal; BSD uses `i` for signed decimal and `s` for null-terminated strings.) Other than `d` and `u`, all of the type specifiers match format characters in the historical BSD version of **od**.

The sizes of the C-language types **char**, **short**, **int**, **long**, **float**, **double**, and **long double** are used even though it is recognized that there may be zero or more than one compiler for the C language on an implementation and that they may use different sizes for some of these types. (For example, one compiler might use 2 bytes **short**s, 2 bytes **int**s, and 4 bytes **long**s, while another compiler (or an option to the same compiler) uses 2 bytes **short**s, 4 bytes **int**s, and 4 bytes **long**s.) Nonetheless, there has to be a basic size known by the implementation for these types, corresponding to the values reported by invocations of the *getconf* utility when called with *system_var* operands {UCHAR_MAX}, {USHORT_MAX}, {UINT_MAX}, and {ULONG_MAX} for the types **char**, **short**, **int**, and **long**, respectively. There are similar constants required by the ISO C standard, but not required by the System Interfaces volume of POSIX.1-200x or this volume of POSIX.1-200x. They are {FLT_MANT_DIG}, {DBL_MANT_DIG}, and {LDBL_MANT_DIG} for the types **float**, **double**, and **long double**, respectively. If the optional *c99* utility is provided by the implementation and used as specified by this volume of POSIX.1-200x, these are the sizes that would be provided. If an option is used that specifies different sizes for these types, there is no guarantee that the *od* utility is able to interpret binary data output by such a program correctly.

This volume of POSIX.1-200x requires that the numeric values of these lengths be recognized by the *od* utility and that symbolic forms also be recognized. Thus, a conforming application can always look at an array of **unsigned long** data elements using *od* **–t** *uL*.

- The method of specifying the format for the address field based on specifying a starting offset in a file unnecessarily tied the two together. The **–A** option now specifies the address base and the **–S** option specifies a starting offset.
- It would be difficult to break the dependence on U.S. ASCII to achieve an internationalized utility. It does not seem to be any harder for *od* to dump characters in the current locale than it is for the *ed* or *sed* **l** commands. The `c` type specifier does this without difficulty and is completely compatible with the historical implementations of the **c** format character when the current locale uses a superset of the ISO/IEC 646: 1991 standard as a codeset. The `a` type specifier (from the BSD **a** format character) was left as a portable means to dump ASCII (or more correctly ISO/IEC 646: 1991 standard (IRV)) so that headers produced by *pax* could be deciphered even on systems that do not use the ISO/IEC 646: 1991 standard as a subset of their base codeset.

The use of `"**"` as an indication of continuation of a multi-byte character in `c` specifier output was chosen based on seeing an implementation that uses this method. The continuation bytes have to be marked in a way that is not ambiguous with another single-byte or multi-byte character.

An early proposal used **–S** and **–n**, respectively, for the **–j** and **–N** options eventually selected. These were changed to avoid conflicts with historical implementations.

The original standard specified **–t o2** as the default when no output type was given. This was changed to **–t oS** (the length of a **short**) to accommodate a supercomputer implementation that historically used 64 bits as its default (and that defined shorts as 64 bits). This change should not affect conforming applications. The requirement to support lengths of 1, 2, and 4 was added at the same time to address an historical implementation that had no two-byte data types in its C compiler.

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

Earlier versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

FUTURE DIRECTIONS

All option and operand interfaces marked XSI may be removed in a future version.

CHANGE HISTORY

First released in Issue 2.

Issue 5

In the description of the **–c** option, the phrase "This is equivalent to **–t c**." is deleted.

The FUTURE DIRECTIONS section is modified.

Issue 6

The *od* utility is changed to remove the assumption that **short** was a two-byte entity, as per the revisions in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/33 is applied, correcting the examples which used an undefined **–n** option, which should have been **–N**.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/19 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7

Austin Group Interpretation 1003.1-2001 #092 is applied.

SD5-XCU-ERN-37 is applied, updating the OPERANDS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

paste — merge corresponding or subsequent lines of files

SYNOPSIS

```
paste [–s] [–d list] file...
```

DESCRIPTION

The *paste* utility shall concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.

The default operation of *paste* shall concatenate the corresponding lines of the input files. The <newline> of every line except the line from the last input file shall be replaced with a <tab>.

If an end-of-file condition is detected on one or more input files, but not all input files, *paste* shall behave as though empty lines were read from the files on which end-of-file was detected, unless the **–s** option is specified.

OPTIONS

The *paste* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–d *list* Unless a <backslash> character appears in *list*, each character in *list* is an element specifying a delimiter character. If a <backslash> character appears in *list*, the <backslash> character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <tab>, to replace the <newline> of the input lines. The elements in *list* shall be used circularly; that is, when the list is exhausted the first element from the list is reused. When the **–s** option is specified:

- The last <newline> in a file shall not be modified.
- The delimiter shall be reset to the first element of *list* after each *file* operand is processed.

When the **–s** option is not specified:

- The <newline> characters in the file specified by the last *file* operand shall not be modified.
- The delimiter shall be reset to the first element of list each time a line is processed from each file.

If a <backslash> character appears in *list*, it and the character following it shall be used to represent the following delimiter characters:

`\n` <newline>.

`\t` <tab>.

`\\` <backslash> character.

`\0` Empty string (not a null character). If `'\0'` is immediately followed by the character `'x'`, the character `'X'`, or any character defined by the *LC_CTYPE* **digit** keyword (see XBD Chapter 7, on page 135), the results are unspecified.

If any other characters follow the <backslash>, the results are unspecified.

–s Concatenate all of the lines of each separate input file in command line order. The <newline> of every line except the last line in each input file shall be replaced with the <tab>, unless otherwise specified by the **–d** option.

98608 **OPERANDS**

98609 The following operand shall be supported:

98610 *file* A pathname of an input file. If '−' is specified for one or more of the *file*s, the
98611 standard input shall be used; the standard input shall be read one line at a time,
98612 circularly, for each instance of '−'. Implementations shall support pasting of at
98613 least 12 *file* operands.

98614 **STDIN**

98615 The standard input shall be used only if one or more *file* operands is '−'. See the INPUT FILES
98616 section.

98617 **INPUT FILES**

98618 The input files shall be text files, except that line lengths shall be unlimited.

98619 **ENVIRONMENT VARIABLES**

98620 The following environment variables shall affect the execution of *paste*:

98621 *LANG* Provide a default value for the internationalization variables that are unset or null.
98622 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
98623 used to determine the values of locale categories.)

98624 *LC_ALL* If set to a non-empty string value, override the values of all the other
98625 internationalization variables.

98626 *LC_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as
98627 characters (for example, single-byte as opposed to multi-byte characters in
98628 arguments and input files).

98629 *LC_MESSAGES*
98630 Determine the locale that should be used to affect the format and contents of
98631 diagnostic messages written to standard error.

98632 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

98633 **ASYNCHRONOUS EVENTS**

98634 Default.

98635 **STDOUT**

98636 Concatenated lines of input files shall be separated by the <tab> (or other characters under the
98637 control of the **−d** option) and terminated by a <newline>.

98638 **STDERR**

98639 The standard error shall be used only for diagnostic messages.

98640 **OUTPUT FILES**

98641 None.

98642 **EXTENDED DESCRIPTION**

98643 None.

98644 **EXIT STATUS**

98645 The following exit values shall be returned:

98646 0 Successful completion.

98647 >0 An error occurred.

CONSEQUENCES OF ERRORS

If one or more input files cannot be opened when the **–s** option is not specified, a diagnostic message shall be written to standard error, but no output is written to standard output. If the **–s** option is specified, the *paste* utility shall provide the default behavior described in Section 1.4 (on page 2288).

APPLICATION USAGE

When the escape sequences of the *list* option-argument are used in a shell script, they must be quoted; otherwise, the shell treats the <backslash> as a special character.

Conforming applications should only use the specific <backslash>-escaped delimiters presented in this volume of POSIX.1-200x. Historical implementations treat `'\x'`, where `'x'` is not in this list, as `'x'`, but future implementations are free to expand this list to recognize other common escapes similar to those accepted by *printf* and other standard utilities.

Most of the standard utilities work on text files. The *cut* utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The *paste* utility can be used to create (or recreate) files with arbitrary line lengths. For example, if *file* contains long lines:

```
cut –b 1–500 –n file > file1
cut –b 501– –n file > file2
```

creates **file1** (a text file) with lines no longer than 500 bytes (plus the <newline>) and **file2** that contains the remainder of the data from *file*. Note that **file2** is not a text file if there are lines in *file* that are longer than 500 + {LINE_MAX} bytes. The original file can be recreated from **file1** and **file2** using the command:

```
paste –d "\0" file1 file2 > file
```

The commands:

```
paste –d "\0" ...
paste –d "" ...
```

are not necessarily equivalent; the latter is not specified by this volume of POSIX.1-200x and may result in an error. The construct `'\0'` is used to mean "no separator" because historical versions of *paste* did not follow the syntax guidelines, and the command:

```
paste –d"" ...
```

could not be handled properly by *getopt*( ).

EXAMPLES

1. Write out a directory in four columns:

   ```
   ls | paste – – – –
   ```

2. Combine pairs of lines from a file into single lines:

   ```
   paste –s –d "\t\n" file
   ```

RATIONALE

None.

FUTURE DIRECTIONS

None.

NAME

patch — apply changes to files

SYNOPSIS

```
patch [–blNR] [–c|–e|–n|–u] [–d dir] [–D define] [–i patchfile]
    [–o outfile] [–p num] [–r rejectfile] [file]
```

DESCRIPTION

The *patch* utility shall read a source (patch) file containing any of four forms of difference (diff) listings produced by the *diff* utility (normal, copied context, unified context, or in the style of *ed*) and apply those differences to a file. By default, *patch* shall read from the standard input.

The *patch* utility shall attempt to determine the type of the *diff* listing, unless overruled by a **–c**, **–e**, **–n**, or **–u** option.

If the patch file contains more than one patch, *patch* shall attempt to apply each of them as if they came from separate patch files. (In this case, the application shall ensure that the name of the patch file is determinable for each *diff* listing.)

OPTIONS

The *patch* utility shall conform to XBD Section 12.2 (on page 215).

The following options shall be supported:

–b Save a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix **.orig** appended to it. If the file already exists, it shall be overwritten; if multiple patches are applied to the same file, the **.orig** file shall be written only for the first patch. When the **–o** *outfile* option is also specified, *file***.orig** shall not be created but, if *outfile* already exists, *outfile***.orig** shall be created.

–c Interpret the patch file as a copied context difference (the output of the utility *diff* when the **–c** or **–C** options are specified).

–d *dir* Change the current directory to *dir* before processing as described in the EXTENDED DESCRIPTION section.

–D *define* Mark changes with one of the following C preprocessor constructs:

```
#ifdef define
...
#endif
```

```
#ifndef define
...
#endif
```

optionally combined with the C preprocessor construct **#else**. If the patched file is processed with the C preprocessor, where the macro *define* is defined, the output shall contain the changes from the patch file; otherwise, the output shall not contain the patches specified in the patch file.

–e Interpret the patch file as an *ed* script, rather than a *diff* script.

–i *patchfile* Read the patch information from the file named by the pathname *patchfile*, rather than the standard input.

–l (The letter ell.) Cause any sequence of <blank> characters in the difference script to match any sequence of <blank> characters in the input file. Other characters shall be matched exactly.

98740 **−n** Interpret the script as a normal difference.

98741 **−N** Ignore patches where the differences have already been applied to the file; by
98742 default, already-applied patches shall be rejected.

98743 **−o** *outfile* Instead of modifying the files (specified by the *file* operand or the difference
98744 listings) directly, write a copy of the file referenced by each patch, with the
98745 appropriate differences applied, to *outfile*. Multiple patches for a single file shall be
98746 applied to the intermediate versions of the file created by any previous patches,
98747 and shall result in multiple, concatenated versions of the file being written to
98748 *outfile*.

98749 **−p** *num* For all pathnames in the patch file that indicate the names of files to be patched,
98750 delete *num* pathname components from the beginning of each pathname. If the
98751 pathname in the patch file is absolute, any leading <slash> characters shall be
98752 considered the first component (that is, **−p 1** shall remove the leading <slash>
98753 characters). Specifying **−p 0** shall cause the full pathname to be used. If **−p** is not
98754 specified, only the basename (the final pathname component) shall be used.

98755 **−R** Reverse the sense of the patch script; that is, assume that the difference script was
98756 created from the new version to the old version. The **−R** option cannot be used
98757 with *ed* scripts. The *patch* utility shall attempt to reverse each portion of the script
98758 before applying it. Rejected differences shall be saved in swapped format. If this
98759 option is not specified, and until a portion of the patch file is successfully applied,
98760 *patch* attempts to apply each portion in its reversed sense as well as in its normal
98761 sense. If the attempt is successful, the user shall be prompted to determine whether
98762 the **−R** option should be set.

98763 **−r** *rejectfile* Override the default reject filename. In the default case, the reject file shall have the
98764 same name as the output file, with the suffix **.rej** appended to it; see Patch
98765 Application (on page 2997).

98766 **−u** Interpret the patch file as a unified context difference (the output of the *diff* utility
98767 when the **−u** or **−U** options are specified).

98768 **OPERANDS**

98769 The following operand shall be supported:

98770 *file* A pathname of a file to patch.

98771 **STDIN**

98772 See the INPUT FILES section.

98773 **INPUT FILES**

98774 Input files shall be text files.

98775 **ENVIRONMENT VARIABLES**

98776 The following environment variables shall affect the execution of *patch*:

98777 *LANG* Provide a default value for the internationalization variables that are unset or null.
98778 (See XBD Section 8.2 (on page 174) the precedence of internationalization variables
98779 used to determine the values of locale categories.)

98780 *LC_ALL* If set to a non-empty string value, override the values of all the other
98781 internationalization variables.

98782 *LC_COLLATE*
98783 Determine the locale for the behavior of ranges, equivalence classes, and multi-
98784 character collating elements used in the extended regular expression defined for

the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages and prompts written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

LC_TIME Determine the locale for recognizing the format of file timestamps written by the *diff* utility in a context-difference input file.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used for diagnostic and informational messages.

OUTPUT FILES

The output of the *patch* utility, the save files (**.orig** suffixes), and the reject files (**.rej** suffixes) shall be text files.

EXTENDED DESCRIPTION

A patch file may contain patching instructions for more than one file; filenames shall be determined as specified in Filename Determination (on page 2997). When the **−b** option is specified, for each patched file, the original shall be saved in a file of the same name with the suffix **.orig** appended to it.

For each patched file, a reject file may also be created as noted in Patch Application (on page 2997). In the absence of a **−r** option, the name of this file shall be formed by appending the suffix **.rej** to the original filename.

Patch File Format

The patch file shall contain zero or more lines of header information followed by one or more patches. Each patch shall contain zero or more lines of filename identification in the format produced by the **−c**, **−C**, **−u**, or **−U** options of the *diff* utility, and one or more sets of *diff* output, which are customarily called *hunks*.

The *patch* utility shall recognize the following expression in the header information:

Index: *pathname*
The file to be patched is named *pathname*.

If all lines (including headers) within a patch begin with the same leading sequence of <blank> characters, the *patch* utility shall remove this sequence before proceeding. Within each patch, if the type of difference is common context, the *patch* utility shall recognize the following expressions:

98827 *** *filename timestamp*
98828 The patches arose from *filename*.

98829 −−− *filename timestamp*
98830 The patches should be applied to *filename*.

98831 If the type of difference is unified context, the *patch* utility shall recognize the following
98832 expressions:

98833 −−− *filename timestamp*
98834 The patches arose from *filename*.

98835 +++ *filename timestamp*
98836 The patches should be applied to *filename*.

98837 Each hunk within a patch shall be the *diff* output to change a line range within the original file.
98838 The line numbers for successive hunks within a patch shall occur in ascending order.

98839 **Filename Determination**

98840 If no *file* operand is specified, *patch* shall perform the following steps to determine the filename
98841 to use:

98842 1. If the type of *diff* is context, the *patch* utility shall delete pathname components (as
98843 specified by the −**p** option) from the filename on the line beginning with "****" (if copied
98844 context) or "−−−" (if unified context), then test for the existence of this file relative to the
98845 current directory (or the directory specified with the −**d** option). If the file exists, the *patch*
98846 utility shall use this filename.

98847 2. If the type of *diff* is context, the *patch* utility shall delete the pathname components (as
98848 specified by the −**p** option) from the filename on the line beginning with "−−−" (if copied
98849 context) or "+++" (if unified context), then test for the existence of this file relative to the
98850 current directory (or the directory specified with the −**d** option). If the file exists, the *patch*
98851 utility shall use this filename.

98852 3. If the header information contains a line beginning with the string **Index:**, the *patch* utility
98853 shall delete pathname components (as specified by the −**p** option) from this line, then test
98854 for the existence of this file relative to the current directory (or the directory specified
98855 with the −**d** option). If the file exists, the *patch* utility shall use this filename.

98856 XSI 4. If an **SCCS** directory exists in the current directory, *patch* shall attempt to perform a *get* −**e**
98857 **SCCS/s.***filename* command to retrieve an editable version of the file. If the file exists, the
98858 *patch* utility shall use this filename.

98859 5. The *patch* utility shall write a prompt to standard output and request a filename
98860 interactively from the controlling terminal (for example, **/dev/tty**).

98861 **Patch Application**

98862 If the −**c**, −**e**, −**n**, or −**u** option is present, the *patch* utility shall interpret information within each
98863 hunk as a copied context difference, an *ed* difference, a normal difference, or a unified context
98864 difference, respectively. In the absence of any of these options, the *patch* utility shall determine
98865 the type of difference based on the format of information within the hunk.

98866 For each hunk, the *patch* utility shall begin to search for the place to apply the patch at the line
98867 number at the beginning of the hunk, plus or minus any offset used in applying the previous
98868 hunk. If lines matching the hunk context are not found, *patch* shall scan both forwards and
98869 backwards at least 1 000 bytes for a set of lines that match the hunk context.

If no such place is found and it is a context difference, then another scan shall take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context shall be ignored and another scan shall be made. Implementations may search more extensively for installation locations.

If no location can be found, the *patch* utility shall append the hunk to the reject file. A rejected hunk that is a copied context difference, an *ed* difference, or a normal difference shall be written in copied-context-difference format regardless of the format of the patch file. It is implementation-defined whether a rejected hunk that is a unified context difference is written in copied-context-difference format or in unified-context-difference format. If the input was a normal or *ed*-style difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they shall reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an *ed* diff, the implementation may accomplish the patching by invoking the *ed* utility.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

1 One or more lines were written to a reject file.

>1 An error occurred.

CONSEQUENCES OF ERRORS

Patches that cannot be correctly placed in the file shall be written to a reject file.

APPLICATION USAGE

The **−R** option does not work with *ed* scripts because there is too little information to reconstruct the reverse operation.

The **−p** option makes it possible to customize a patch file to local user directory structures without manually editing the patch file. For example, if the filename in the patch file was:

```
/curds/whey/src/blurfl/blurfl.c
```

Setting **−p 0** gives the entire pathname unmodified; **−p 1** gives:

```
curds/whey/src/blurfl/blurfl.c
```

without the leading <slash>, **−p 4** gives:

```
blurfl/blurfl.c
```

and not specifying **−p** at all gives:

```
blurfl.c .
```

EXAMPLES

None.

RATIONALE

Some of the functionality in historical *patch* implementations was not specified. The following documents those features present in historical implementations that have not been specified.

A deleted piece of functionality was the `'+'` pseudo-option allowing an additional set of options and a patch file operand to be given. This was seen as being insufficiently useful to standardize.

In historical implementations, if the string `"Prereq:"` appeared in the header, the *patch* utility

would search for the corresponding version information (the string specified in the header, delimited by <blank> characters or the beginning or end of a line or the file) anywhere in the original file. This was deleted as too simplistic and insufficiently trustworthy a mechanism to standardize. For example, if:

```
Prereq: 1.2
```

were in the header, the presence of a delimited 1.2 anywhere in the file would satisfy the prerequisite.

The following options were dropped from historical implementations of *patch* as insufficiently useful to standardize:

–b The **–b** option historically provided a method for changing the name extension of the backup file from the default **.orig**. This option has been modified and retained in this volume of POSIX.1-200x.

–F The **–F** option specified the number of lines of a context diff to ignore when searching for a place to install a patch.

–f The **–f** option historically caused *patch* not to request additional information from the user.

–r The **–r** option historically provided a method of overriding the extension of the reject file from the default **.rej**.

–s The **–s** option historically caused *patch* to work silently unless an error occurred.

–x The **–x** option historically set internal debugging flags.

In some file system implementations, the saving of a **.orig** file may produce unwanted results. In the case of 12, 13, or 14-character filenames (on file systems supporting 14-character maximum filenames), the **.orig** file overwrites the new file. The reject file may also exceed this filename limit. It was suggested, due to some historical practice, that a <tilde> (`'~'`) suffix be used instead of **.orig** and some other character instead of the **.rej** suffix. This was rejected because it is not obvious to the user which file is which. The suffixes **.orig** and **.rej** are clearer and more understandable.

The **–b** option has the opposite sense in some historical implementations—do not save the **.orig** file. The default case here is not to save the files, making *patch* behave more consistently with the other standard utilities.

The **–w** option in early proposals was changed to **–l** to match historical practice.

The **–N** option was included because without it, a non-interactive application cannot reject previously applied patches. For example, if a user is piping the output of *diff* into the *patch* utility, and the user only wants to patch a file to a newer version non-interactively, the **–N** option is required.

Changes to the **–l** option description were proposed to allow matching across <newline> characters in addition to just <blank> characters. Since this is not historical practice, and since some ambiguities could result, it is suggested that future developments in this area utilize another option letter, such as **–L**.

The **–u** option of GNU *patch* has been added, along with support for unified context formats.

FUTURE DIRECTIONS

None.

XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

CHANGE HISTORY

First released in Issue 4.

Issue 5

The FUTURE DIRECTIONS section is added.

Issue 6

This utility is marked as part of the User Portability Utilities option.

The description of the –**D** option and the steps in Filename Determination (on page 2997) are changed to match historical practice as defined in the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/34 is applied, clarifying the way that the *patch* utility performs **ifdef** selection for the –**D** option.

Issue 7

The *patch* utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

SD5-XCU-ERN-103 and SD5-XCU-ERN-120 are applied, adding the –**u** option.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* and *LC_CTYPE* environment variables and adding the *LC_COLLATE* environment variable.

NAME

pathchk — check pathnames

SYNOPSIS

```
pathchk [–p] [–P] pathname...
```

DESCRIPTION

The *pathchk* utility shall check that one or more pathnames are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation results). More extensive portability checks are provided by the **–p** and **–P** options.

By default, the *pathchk* utility shall check each component of each *pathname* operand based on the underlying file system. A diagnostic shall be written for each *pathname* operand that:

- Is longer than {PATH_MAX} bytes (see **Pathname Variable Values** in XBD Chapter 13 (on page 219), **<limits.h>**)
- Contains any component longer than {NAME_MAX} bytes in its containing directory
- Contains any component in a directory that is not searchable
- Contains any character in any component that is not valid in its containing directory

The format of the diagnostic message is not specified, but shall indicate the error detected and the corresponding *pathname* operand.

It shall not be considered an error if one or more components of a *pathname* operand do not exist as long as a file matching the pathname specified by the missing components could be created that does not violate any of the checks specified above.

OPTIONS

The *pathchk* utility shall conform to XBD Section 12.2 (on page 215).

The following option shall be supported:

–p Instead of performing checks based on the underlying file system, write a diagnostic for each *pathname* operand that:

- Is longer than {_POSIX_PATH_MAX} bytes (see **Minimum Values** in XBD Chapter 13 (on page 219), **<limits.h>**)
- Contains any component longer than {_POSIX_NAME_MAX} bytes
- Contains any character in any component that is not in the portable filename character set

–P Write a diagnostic for each *pathname* operand that:

- Contains a component whose first character is the <hyphen> character
- Is empty

OPERANDS

The following operand shall be supported:

pathname A pathname to be checked.

STDIN

Not used.

INPUT FILES

None.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pathchk*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

ASYNCHRONOUS EVENTS

Default.

STDOUT

Not used.

STDERR

The standard error shall be used only for diagnostic messages.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 All *pathname* operands passed all of the checks.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

The *test* utility can be used to determine whether a given pathname names an existing file; it does not, however, give any indication of whether or not any component of the pathname was truncated in a directory where the _POSIX_NO_TRUNC feature is not in effect. The *pathchk* utility does not check for file existence; it performs checks to determine whether a pathname does exist or could be created with no pathname component truncation.

The *noclobber* option in the shell (see the *set* special built-in) can be used to atomically create a file. As with all file creation semantics in the System Interfaces volume of POSIX.1-200x, it guarantees atomic creation, but still depends on applications to agree on conventions and cooperate on the use of files after they have been created.

To verify that a pathname meets the requirements of filename portability, applications should

use both the **–p** and **–P** options together.

EXAMPLES

To verify that all pathnames in an imported data interchange archive are legitimate and unambiguous on the current system:

```
# This example assumes that no pathnames in the archive
# contain <newline> characters.
pax –f archive | sed –e 's/[^[:alnum:]]/\\&/g' | xargs pathchk ––
if [ $? –eq 0 ]
then
    pax –r –f archive
else
    echo Investigate problems before importing files.
    exit 1
fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the System Interfaces volume of POSIX.1-200x that also supports the *pax* utility:

```
find . –exec pathchk –p –P {} +
if [ $? –eq 0 ]
then
    pax –w –f ../archive .
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied pathname names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```
case $– in
    *C*)    reset="";;
    *)      reset="set +C"
            set –C;;
esac
test –r "$path" && pathchk "$path.out" &&
    rm "$path.out" > "$path.out"
if [ $? –ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset    # Reset the noclobber option in case a trap
              # on EXIT depends on it.
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. **PROCESSING** represents the code that is used by the application to use **$path** once it is verified that **$path.out** works as intended.

2. The state of the *noclobber* option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The **reset** variable is used in this example to restore the initial state.)

3. Note the usage of:

   ```
   rm "$path.out" > "$path.out"
   ```

   a. The *pathchk* command has already verified, at this point, that **$path.out** is not truncated.

   b. With the *noclobber* option set, the shell verifies that **$path.out** does not already exist before invoking *rm*.

   c. If the shell succeeded in creating **$path.out**, *rm* removes it so that the application can create the file again in the **PROCESSING** step.

   d. If the **PROCESSING** step wants the file to exist already when it is invoked, the:

      ```
      rm "$path.out" > "$path.out"
      ```

      should be replaced with:

      ```
      > "$path.out"
      ```

      which verifies that the file did not already exist, but leaves **$path.out** in place for use by **PROCESSING**.

RATIONALE

The *pathchk* utility was new for the ISO POSIX-2: 1993 standard. It, along with the *set* **–C**(*noclobber*) option added to the shell, replaces the *mktemp*, *validfnam*, and *create* utilities that appeared in early proposals. All of these utilities were attempts to solve several common problems:

- Verify the validity (for several different definitions of "valid") of a pathname supplied by a user, generated by an application, or imported from an external source.
- Atomically create a file.
- Perform various string handling functions to generate a temporary filename.

The *create* utility, included in an early proposal, provided checking and atomic creation in a single invocation of the utility; these are orthogonal issues and need not be grouped into a single utility. Note that the *noclobber* option also provides a way of creating a lock for process synchronization; since it provides an atomic *create*, there is no race between a test for existence and the following creation if it did not exist.

Having a function like *tmpnam*( ) in the ISO C standard is important in many high-level languages. The shell programming language, however, has built-in string manipulation facilities, making it very easy to construct temporary filenames. The names needed obviously depend on the application, but are frequently of a form similar to:

**$TMPDIR**/*application_abbreviation*$$.*suffix*

In cases where there is likely to be contention for a given suffix, a simple shell **for** or **while** loop can be used with the shell *noclobber* option to create a file without risk of collisions, as long as applications trying to use the same filename name space are cooperating on the use of files after they have been created.

For historical purposes, **–p** does not check for the use of the <hyphen> character as the first character in a component of the pathname, or for an empty *pathname* operand.

FUTURE DIRECTIONS

None.

SD5-XCU-ERN-121 is applied, updating the EXAMPLES section.

NAME

pax — portable archive interchange

SYNOPSIS

```
pax [–dv] [–c|–n] [–H|–L] [–o options] [–f archive] [–s replstr]...
    [pattern...]

pax –r[–c|–n] [–dikuv] [–H|–L] [–f archive] [–o options]... [–p string]...
    [–s replstr]... [pattern...]

pax –w [–dituvX] [–H|–L] [–b blocksize] [[–a] [–f archive]] [–o options]...
    [–s replstr]... [–x format] [file...]

pax –r –w [–diklntuvX] [–H|–L] [–o options]... [–p string]...
    [–s replstr]... [file...] directory
```

DESCRIPTION

The *pax* utility shall read, write, and write lists of the members of archive files and copy directory hierarchies. A variety of archive formats shall be supported; see the **–x** *format* option.

The action to be taken depends on the presence of the **–r** and **–w** options. The four combinations of **–r** and **–w** are referred to as the four modes of operation: **list**, **read**, **write**, and **copy** modes, corresponding respectively to the four forms shown in the SYNOPSIS section.

list In **list** mode (when neither **–r** nor **–w** are specified), *pax* shall write the names of the members of the archive file read from the standard input, with pathnames matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file shall be listed as well.

read In **read** mode (when **–r** is specified, but **–w** is not), *pax* shall extract the members of the archive file read from the standard input, with pathnames matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file shall be extracted as well. The extracted files shall be created performing pathname resolution with the directory in which *pax* was invoked as the current working directory.

If an attempt is made to extract a directory when the directory already exists, this shall not be considered an error. If an attempt is made to extract a FIFO when the FIFO already exists, this shall not be considered an error.

The ownership, access, and modification times, and file mode of the restored files are discussed under the **–p** option.

write In **write** mode (when **–w** is specified, but **–r** is not), *pax* shall write the contents of the *file* operands to the standard output in an archive format. If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input and each entry in this list shall be processed as if it had been a *file* operand on the command line. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

copy In **copy** mode (when both **–r** and **–w** are specified), *pax* shall copy the *file* operands to the destination directory.

If no *file* operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.

The effect of the **copy** shall be as if the copied files were written to a *pax* format archive file and then subsequently extracted, except that there may be hard links

between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. If the destination directory is a file of a type not defined by the System Interfaces volume of POSIX.1-200x, the results are implementation-defined; otherwise, it shall be an error for the file named by the *directory* operand not to exist, not be writable by the user, or not be a file of type directory.

In **read** or **copy** modes, if intermediate directories are necessary to extract an archive member, *pax* shall perform actions equivalent to the *mkdir*( ) function defined in the System Interfaces volume of POSIX.1-200x, called with the following arguments:

- The intermediate directory used as the *path* argument
- The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO as the *mode* argument

If any specified *pattern* or *file* operands are not matched by at least one file or archive member, *pax* shall write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The archive formats described in the EXTENDED DESCRIPTION section shall be automatically detected on input. The default output archive format shall be implementation-defined.

A single archive can span multiple files. The *pax* utility shall determine, in an implementation-defined manner, what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it shall be an error if these files cannot be linked when the archive is extracted. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this *pax* session, either the data shall be restored from the original file, or a diagnostic message shall be displayed with the name of a file that can be used to extract the data. In traversing directories, *pax* shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, *pax* shall write a diagnostic message to standard error and shall terminate.

OPTIONS

The *pax* utility shall conform to XBD Section 12.2 (on page 215), except that the order of presentation of the **–o**, **–p**, and **–s** options is significant.

The following options shall be supported:

–r Read an archive file from standard input.

–w Write files to the standard output in the specified archive format.

–a Append files to the end of the archive. It is implementation-defined which devices on the system support appending. Additional file formats unspecified by this volume of POSIX.1-200x may impose restrictions on appending.

–b *blocksize* Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking shall be automatically determined on input. Conforming applications shall not specify a *blocksize* value larger than 32 256. Default blocking when creating archives depends on the archive format. (See the **–x** option below.)

–c Match all file or archive members except those specified by the *pattern* or *file* operands.

99241 **–d** Cause files of type directory being copied or archived or archive members of type
99242 directory being extracted or listed to match only the file or archive member itself
99243 and not the file hierarchy rooted at the file.

99244 **–f** *archive* Specify the pathname of the input or output archive, overriding the default
99245 standard input (in **list** or **read** modes) or standard output (**write** mode).

99246 **–H** If a symbolic link referencing a file of type directory is specified on the command
99247 line, *pax* shall archive the file hierarchy rooted in the file referenced by the link,
99248 using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic
99249 link referencing a file of any other file type which *pax* can normally archive is
99250 specified on the command line, then *pax* shall archive the file referenced by the
99251 link, using the name of the link. The default behavior, when neither **–H** or **–L** are
99252 specified, shall be to archive the symbolic link itself.

99253 **–i** Interactively rename files or archive members. For each archive member matching
99254 a *pattern* operand or file matching a *file* operand, a prompt shall be written to the
99255 file **/dev/tty**. The prompt shall contain the name of the file or archive member, but
99256 the format is otherwise unspecified. A line shall then be read from **/dev/tty**. If this
99257 line is blank, the file or archive member shall be skipped. If this line consists of a
99258 single period, the file or archive member shall be processed with no modification
99259 to its name. Otherwise, its name shall be replaced with the contents of the line. The
99260 *pax* utility shall immediately exit with a non-zero exit status if end-of-file is
99261 encountered when reading a response or if **/dev/tty** cannot be opened for reading
99262 and writing.

99263 The results of extracting a hard link to a file that has been renamed during
99264 extraction are unspecified.

99265 **–k** Prevent the overwriting of existing files.

99266 **–l** (The letter ell.) In **copy** mode, hard links shall be made between the source and
99267 destination file hierarchies whenever possible. If specified in conjunction with **–H**
99268 or **–L**, when a symbolic link is encountered, the hard link created in the destination
99269 file hierarchy shall be to the file referenced by the symbolic link. If specified when
99270 neither **–H** nor **–L** is specified, when a symbolic link is encountered, the
99271 implementation shall create a hard link to the symbolic link in the source file
99272 hierarchy or copy the symbolic link to the destination.

99273 **–L** If a symbolic link referencing a file of type directory is specified on the command
99274 line or encountered during the traversal of a file hierarchy, *pax* shall archive the file
99275 hierarchy rooted in the file referenced by the link, using the name of the link as the
99276 root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any
99277 other file type which *pax* can normally archive is specified on the command line or
99278 encountered during the traversal of a file hierarchy, *pax* shall archive the file
99279 referenced by the link, using the name of the link. The default behavior, when
99280 neither **–H** or **–L** are specified, shall be to archive the symbolic link itself.

99281 **–n** Select the first archive member that matches each *pattern* operand. No more than
99282 one archive member shall be matched for each pattern (although members of type
99283 directory shall still match the file hierarchy rooted at that file).

99284 **–o** *options* Provide information to the implementation to modify the algorithm for extracting
99285 or writing files. The value of *options* shall consist of one or more
99286 <comma>-separated keywords of the form:

99287 *keyword*`[[:]=`*value*`][,`*keyword*`[[:]=`*value*`], ...]`

Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being processed produces undefined results.

Keywords in the *options* argument shall be a string that would be a valid portable filename as described in XBD Section 3.276 (on page 77).

Note: Keywords are not expected to be filenames, merely to follow the same character composition rules as portable filenames.

Keywords can be preceded with white space. The *value* field shall consist of zero or more characters; within *value*, the application shall precede any literal <comma> with a <backslash>, which shall be ignored, but preserves the <comma> as part of *value*. A <comma> as the final character, or a <comma> followed solely by white space as the final characters, in *options* shall be ignored. Multiple **–o** options can be specified; if keywords given to these multiple **–o** options conflict, the keywords and values appearing later in command line sequence shall take precedence and the earlier shall be silently ignored. The following keyword values of *options* shall be supported for the file formats as indicated:

delete=*pattern*

(Applicable only to the **–x pax** format.) When used in **write** or **copy** mode, *pax* shall omit from extended header records that it produces any keywords matching the string pattern. When used in **read** or **list** mode, *pax* shall ignore any keywords matching the string pattern in the extended header records. In both cases, matching shall be performed using the pattern matching notation described in Section 2.13.1 (on page 2332) and Section 2.13.2 (on page 2332). For example:

```
–o delete=security.*
```

would suppress security-related information. See pax Extended Header (on page 3019) for extended header record keyword usage.

When multiple **–odelete=pattern** options are specified, the patterns shall be additive; all keywords matching the specified string patterns shall be omitted from extended header records that *pax* produces.

exthdr.name=*string*

(Applicable only to the **–x pax** format.) This keyword allows user control over the name that is written into the **ustar** header blocks for the extended header produced under the circumstances described in pax Header Block (on page 3019). The name shall be the contents of *string*, after the following character substitutions have been made:

string **Includes:**	**Replaced By:**
`%d`	The directory name of the file, equivalent to the result of the *dirname* utility on the translated pathname.
`%f`	The filename of the file, equivalent to the result of the *basename* utility on the translated pathname.
`%p`	The process ID of the *pax* process.
`%%`	A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no **–o exthdr.name=string** is specified, *pax* shall use the following default

value:

```
%d/PaxHeaders.%p/%f
```

globexthdr.name=*string*

(Applicable only to the **–x pax** format.) When used in **write** or **copy** mode with the appropriate options, *pax* shall create global extended header records with **ustar** header blocks that will be treated as regular files by previous versions of *pax*. This keyword allows user control over the name that is written into the **ustar** header blocks for global extended header records. The name shall be the contents of string, after the following character substitutions have been made:

string **Includes:**	**Replaced By:**
`%n`	An integer that represents the sequence number of the global extended header record in the archive, starting at 1.
`%p`	The process ID of the *pax* process.
`%%`	A `'%'` character.

Any other `'%'` characters in *string* produce undefined results.

If no **–o globexthdr.name=string** is specified, *pax* shall use the following default value:

```
$TMPDIR/GlobalHead.%p.%n
```

where $*TMPDIR* represents the value of the *TMPDIR* environment variable. If *TMPDIR* is not set, *pax* shall use **/tmp**.

invalid=*action*

(Applicable only to the **–x pax** format.) This keyword allows user control over the action *pax* takes upon encountering values in an extended header record that, in **read** or **copy** mode, are invalid in the destination hierarchy or, in **list** mode, cannot be written in the codeset and current locale of the implementation. The following are invalid values that shall be recognized by *pax*:

— In **read** or **copy** mode, a filename or link name that contains character encodings invalid in the destination hierarchy. (For example, the name may contain embedded NULs.)

— In **read** or **copy** mode, a filename or link name that is longer than the maximum allowed in the destination hierarchy (for either a pathname component or the entire pathname).

— In **list** mode, any character string value (filename, link name, user name, and so on) that cannot be written in the codeset and current locale of the implementation.

The following mutually-exclusive values of the *action* argument are supported:

binary In **write** mode, *pax* shall generate a **hdrcharset**=**BINARY** extended header record for each file with a filename, link name, group name, owner name, or any other field in an extended header record that cannot be translated to the UTF-8 codeset, allowing the archive to contain the files with unencoded extended header record values. In **read** or **copy** mode, *pax* shall

use the values specified in the header without translation, regardless of whether this may overwrite an existing file with a valid name. In **list** mode, *pax* shall behave identically to the **bypass** action.

bypass In **read** or **copy** mode, *pax* shall bypass the file, causing no change to the destination hierarchy. In **list** mode, *pax* shall write all requested valid values for the file, but its method for writing invalid values is unspecified.

rename In **read** or **copy** mode, *pax* shall act as if the –**i** option were in effect for each file with invalid filename or link name values, allowing the user to provide a replacement name interactively. In **list** mode, *pax* shall behave identically to the **bypass** action.

UTF-8 When used in **read**, **copy**, or **list** mode and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the **pax** UTF-8 codeset format to the codeset and current locale of the implementation, *pax* shall use the actual UTF-8 encoding for the name. If a **hdrcharset** extended header record is in effect for this file, the character set specified by that record shall be used instead of UTF-8. If a **hdrcharset**=**BINARY** extended header record is in effect for this file, no translation shall be performed.

write In **read** or **copy** mode, *pax* shall write the file, translating the name, regardless of whether this may overwrite an existing file with a valid name. In **list** mode, *pax* shall behave identically to the **bypass** action.

If no –**o invalid=option** is specified, *pax* shall act as if –**oinvalid=bypass** were specified. Any overwriting of existing files that may be allowed by the –**oinvalid=** actions shall be subject to permission (–**p**) and modification time (–**u**) restrictions, and shall be suppressed if the –**k** option is also specified.

linkdata
(Applicable only to the –**x pax** format.) In **write** mode, *pax* shall write the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

listopt=*format*
This keyword specifies the output format of the table of contents produced when the –**v** option is specified in **list** mode. See List Mode Format Specifications (on page 3014). To avoid ambiguity, the **listopt=format** shall be the only or final **keyword=value** pair in a –**o** option-argument; all characters in the remainder of the option-argument shall be considered part of the format string. When multiple –**olistopt=format** options are specified, the format strings shall be considered a single, concatenated string, evaluated in command line order.

times
(Applicable only to the –**x** *pax* format.) When used in **write** or **copy** mode, *pax* shall include **atime** and **mtime** extended header records for each file. See pax Extended Header File Times (on page 3023).

In addition to these keywords, if the –**x** *pax* format is specified, any of the

keywords and values defined in pax Extended Header (on page 3019), including implementation extensions, can be used in **–o** option-arguments, in either of two modes:

keyword=*value*

When used in **write** or **copy** mode, these keyword/value pairs shall be included at the beginning of the archive as **typeflag g** global extended header records. When used in **read** or **list** mode, these keyword/value pairs shall act as if they had been at the beginning of the archive as **typeflag g** global extended header records.

keyword:=*value*

When used in **write** or **copy** mode, these keyword/value pairs shall be included as records at the beginning of a **typeflag x** extended header for each file. (This shall be equivalent to the <equals-sign> form except that it creates no **typeflag g** global extended header records.) When used in **read** or **list** mode, these keyword/value pairs shall act as if they were included as records at the end of each extended header; thus, they shall override any global or file-specific extended header record keywords of the same names. For example, in the command:

```
pax –r –o "
gname:=mygroup,
" <archive
```

the group name will be forced to a new value for all files read from the archive.

The precedence of **–o** keywords over various fields in the archive is described in pax Extended Header Keyword Precedence (on page 3022).

–p *string* Specify one or more file characteristic options (privileges). The *string* option-argument shall be a string specifying file characteristics to be retained or discarded on extraction. The string shall consist of the specification characters `a`, `e`, `m`, `o`, and `p`. Other implementation-defined characters can be included. Multiple characteristics can be concatenated within the same string and multiple **–p** options can be specified. The meaning of the specification characters are as follows:

`a` Do not preserve file access times.

`e` Preserve the user ID, group ID, file mode bits (see XBD Section 3.169, on page 60), access time, modification time, and any other implementation-defined file characteristics.

`m` Do not preserve file modification times.

`o` Preserve the user ID and group ID.

`p` Preserve the file mode bits. Other implementation-defined file mode attributes may be preserved.

In the preceding list, "preserve" indicates that an attribute stored in the archive shall be given to the extracted file, subject to the permissions of the invoking process. The access and modification times of the file shall be preserved unless otherwise specified with the **–p** option or not stored in the archive. All attributes that are not preserved shall be determined as part of the normal file creation action (see Section 1.1.1.4, on page 2280).

If neither the `e` nor the `o` specification character is specified, or the user ID and group ID are not preserved for any reason, *pax* shall not set the S_ISUID and S_ISGID bits of the file mode.

If the preservation of any of these items fails for any reason, *pax* shall write a diagnostic message to standard error. Failure to preserve these items shall affect the final exit status, but shall not cause the extracted file to be deleted.

If file characteristic letters in any of the *string* option-arguments are duplicated or conflict with each other, the ones given last shall take precedence. For example, if **−p** `eme` is specified, file modification times are preserved.

−s *replstr* Modify file or archive member names named by *pattern* or *file* operands according to the substitution expression *replstr*, using the syntax of the *ed* utility. The concepts of "address" and "line" are meaningless in the context of the *pax* utility, and shall not be supplied. The format shall be:

```
−s /old/new/[gp]
```

where as in *ed*, *old* is a basic regular expression and *new* can contain an <ampersand>, `'\n'` (where *n* is a digit) back-references, or subexpression matching. The *old* string shall also be permitted to contain <newline> characters.

Any non-null character can be used as a delimiter (`'/'` shown here). Multiple **−s** expressions can be specified; the expressions shall be applied in the order specified, terminating with the first successful substitution. The optional trailing `'g'` is as defined in the *ed* utility. The optional trailing `'p'` shall cause successful substitutions to be written to standard error. File or archive member names that substitute to the empty string shall be ignored when reading and writing archives.

−t When reading files from the file system, and if the user has the permissions required by *utime*() to do so, set the access time of each file read to the access time that it had before being read by *pax*.

−u Ignore files that are older (having a less recent file modification time) than a pre-existing file or archive member with the same name. In **read** mode, an archive member with the same name as a file in the file system shall be extracted if the archive member is newer than the file. In **write** mode, an archive file member with the same name as a file in the file system shall be superseded if the file is newer than the archive member. If **−a** is also specified, this is accomplished by appending to the archive; otherwise, it is unspecified whether this is accomplished by actual replacement in the archive or by appending to the archive. In **copy** mode, the file in the destination hierarchy shall be replaced by the file in the source hierarchy or by a link to the file in the source hierarchy if the file in the source hierarchy is newer.

−v In **list** mode, produce a verbose table of contents (see the STDOUT section). Otherwise, write archive member pathnames to standard error (see the STDERR section).

−x *format* Specify the output archive format. The *pax* utility shall support the following formats:

cpio The **cpio** interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 5 120. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

pax The **pax** interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 5 120. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

ustar The **tar** interchange format; see the EXTENDED DESCRIPTION section. The default *blocksize* for this format for character special archive files shall be 10 240. Implementations shall support all *blocksize* values less than or equal to 32 256 that are multiples of 512.

Implementation-defined formats shall specify a default block size as well as any other block sizes supported for character special archive files.

Any attempt to append to an archive file in a format different from the existing archive format shall cause *pax* to exit immediately with a non-zero exit status.

–X When traversing the file hierarchy specified by a pathname, *pax* shall not descend into directories that have a different device ID (*st_dev*; see the System Interfaces volume of POSIX.1-200x, *stat*( )).

Specifying more than one of the mutually-exclusive options **–H** and **–L** shall not be considered an error and the last option specified shall determine the behavior of the utility.

The options that operate on the names of files or archive members (**–c**, **–i**, **–n**, **–s**, **–u**, and **–v**) shall interact as follows. In **read** mode, the archive members shall be selected based on the user-specified *pattern* operands as modified by the **–c**, **–n**, and **–u** options. Then, any **–s** and **–i** options shall modify, in that order, the names of the selected files. The **–v** option shall write names resulting from these modifications.

In **write** mode, the files shall be selected based on the user-specified pathnames as modified by the **–n** and **–u** options. Then, any **–s** and **–i** options shall modify, in that order, the names of these selected files. The **–v** option shall write names resulting from these modifications.

If both the **–u** and **–n** options are specified, *pax* shall not consider a file selected unless it is newer than the file to which it is compared.

List Mode Format Specifications

In **list** mode with the **–o listopt=format** option, the *format* argument shall be applied for each selected file. The *pax* utility shall append a <newline> to the **listopt** output for each selected file. The *format* argument shall be used as the *format* string described in XBD Chapter 5 (on page 121), with the exceptions 1. through 5. defined in the EXTENDED DESCRIPTION section of *printf*, plus the following exceptions:

6. The sequence (*keyword*) can occur before a format conversion specifier. The conversion argument is defined by the value of *keyword*. The implementation shall support the following keywords:

   — Any of the Field Name entries in Table 4-14 (on page 3024) and Table 4-16 (on page 3027). The implementation may support the *cpio* keywords without the leading **c_** in addition to the form required by Table 4-16 (on page 3027).

   — Any keyword defined for the extended header in pax Extended Header (on page 3019).

   — Any keyword provided as an implementation-defined extension within the extended header defined in pax Extended Header (on page 3019).

   For example, the sequence `"%(charset)s"` is the string value of the name of the character

set in the extended header.

The result of the keyword conversion argument shall be the value from the applicable header field or extended header, without any trailing NULs.

All keyword values used as conversion arguments shall be translated from the UTF-8 encoding (or alternative encoding specified by any **hdrcharset** extended header record) to the character set appropriate for the local file system, user database, and so on, as applicable.

7. An additional conversion specifier character, `T`, shall be used to specify time formats. The `T` conversion specifier character can be preceded by the sequence (*keyword=subformat*), where *subformat* is a date format as defined by *date* operands. The default *keyword* shall be **mtime** and the default subformat shall be:

   `%b %e %H:%M %Y`

8. An additional conversion specifier character, `M`, shall be used to specify the file mode string as defined in *ls* Standard Output. If (*keyword*) is omitted, the **mode** keyword shall be used. For example, `%.1M` writes the single character corresponding to the <*entry type*> field of the *ls* **–l** command.

9. An additional conversion specifier character, `D`, shall be used to specify the device for block or special files, if applicable, in an implementation-defined format. If not applicable, and (*keyword*) is specified, then this conversion shall be equivalent to `%(`*keyword*`)u`. If not applicable, and (*keyword*) is omitted, then this conversion shall be equivalent to <space>.

10. An additional conversion specifier character, `F`, shall be used to specify a pathname. The `F` conversion character can be preceded by a sequence of <comma>-separated keywords:

    `(`*keyword*`[,`*keyword*`] ... )`

    The values for all the keywords that are non-null shall be concatenated together, each separated by a `'/'`. The default shall be (**path**) if the keyword **path** is defined; otherwise, the default shall be (**prefix**,**name**).

11. An additional conversion specifier character, `L`, shall be used to specify a symbolic link expansion. If the current file is a symbolic link, then `%L` shall expand to:

    `"%s –> %s", <`*value of keyword*`>, <`*contents of link*`>`

    Otherwise, the `%L` conversion specification shall be the equivalent of `%F`.

OPERANDS

The following operands shall be supported:

directory The destination directory pathname for **copy** mode.

file A pathname of a file to be copied or archived.

pattern A pattern matching one or more pathnames of archive members. A pattern must be given in the name-generating notation of the pattern matching notation in Section 2.13 (on page 2332), including the filename expansion rules in Section 2.13.3 (on page 2333). The default, if no *pattern* is specified, is to select all members in the archive.

STDIN

In **write** mode, the standard input shall be used only if no *file* operands are specified. It shall be a text file containing a list of pathnames, one per line, without leading or trailing <blank> characters.

In **list** and **read** modes, if **–f** is not specified, the standard input shall be an archive file.

Otherwise, the standard input shall not be used.

INPUT FILES

The input file named by the *archive* option-argument, or standard input when the archive is read from there, shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section or some other implementation-defined format.

The file **/dev/tty** shall be used to write prompts and read responses.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pax*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multi-character collating elements used in the pattern matching expressions for the *pattern* operand, the basic regular expression for the **–s** option, and the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the **yesexpr** locale keyword in the *LC_MESSAGES* category, and pattern matching.

LC_MESSAGES
Determine the locale used to process affirmative responses, and the locale used to affect the format and contents of diagnostic messages and prompts written to standard error.

LC_TIME Determine the format and contents of date and time strings when the **–v** option is specified.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TMPDIR Determine the pathname that provides part of the default global extended header record file, as described for the **–o globexthdr=** keyword in the OPTIONS section.

TZ Determine the timezone used to calculate date and time strings when the **–v** option is specified. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

Default.

STDOUT

In **write** mode, if **–f** is not specified, the standard output shall be the archive formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format (see **–x** *format*).

In **list** mode, when the **–olistopt**=*format* has been specified, the selected archive members shall be written to standard output using the format described under List Mode Format Specifications

(on page 3014). In **list** mode without the –**olistopt**=*format* option, the table of contents of the selected archive members shall be written to standard output using the following format:

```
"%s\n", <pathname>
```

If the –**v** option is specified in **list** mode, the table of contents of the selected archive members shall be written to standard output using the following formats.

For pathnames representing hard links to previous members of the archive:

```
"%sΔ==Δ%s\n", <ls –l listing>, <linkname>
```

For all other pathnames:

```
"%s\n", <ls –l listing>
```

where <*ls* –l *listing*> shall be the format specified by the *ls* utility with the –**l** option. When writing pathnames in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of <blank>-separated fields shall be written.

In **list** mode, standard output shall not be buffered more than a line at a time.

STDERR

If –**v** is specified in **read**, **write**, or **copy** modes, *pax* shall write the pathnames it processes to the standard error output using the following format:

```
"%s\n", <pathname>
```

These pathnames shall be written as soon as processing is begun on the file or archive member, and shall be flushed to standard error. The trailing <newline>, which shall not be buffered, is written when the file has been read or written.

If the –**s** option is specified, and the replacement string has a trailing `'p'`, substitutions shall be written to standard error in the following format:

```
"%sΔ>>Δ%s\n", <original pathname>, <new pathname>
```

In all operating modes of *pax*, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages may be written to standard error.

In all formats, for both standard output and standard error, it is unspecified how non-printable characters in pathnames or link names are written.

When using the –**xpax** archive format, if a filename, link name, group name, owner name, or any other field in an extended header record cannot be translated between the codeset in use for that extended header record and the character set of the current locale, *pax* shall write a diagnostic message to standard error, shall process the file as described for the –**o invalid=** option, and then shall continue processing with the next file.

OUTPUT FILES

In **read** mode, the extracted output files shall be of the archived file type. In **copy** mode, the copied output files shall be the type of the file being copied. In either mode, existing files in the destination hierarchy shall be overwritten only when all permission (–**p**), modification time (–**u**), and invalid-value (–**oinvalid=**) tests allow it.

In **write** mode, the output file named by the –**f** option-argument shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format.

EXTENDED DESCRIPTION

pax Interchange Format

A *pax* archive tape or file produced in the **–xpax** format shall contain a series of blocks. The physical layout of the archive shall be identical to the **ustar** format described in ustar Interchange Format (on page 3023). Each file archived shall be represented by the following sequence:

- An optional header block with extended header records. This header block is of the form described in pax Header Block (on page 3019), with a *typeflag* value of **x** or **g**. The extended header records, described in pax Extended Header (on page 3019), shall be included as the data for this header block.
- A header block that describes the file. Any fields in the preceding optional extended header shall override the associated fields in this header block for this file.
- Zero or more blocks that contain the contents of the file.

At the end of the archive file there shall be two 512-byte blocks filled with binary zeros, interpreted as an end-of-archive indicator.

A schematic of an example archive with global extended header records and two actual files is shown in Figure 4-1. In the example, the second file in the archive has no extended header preceding it, presumably because it has no need for extended attributes.

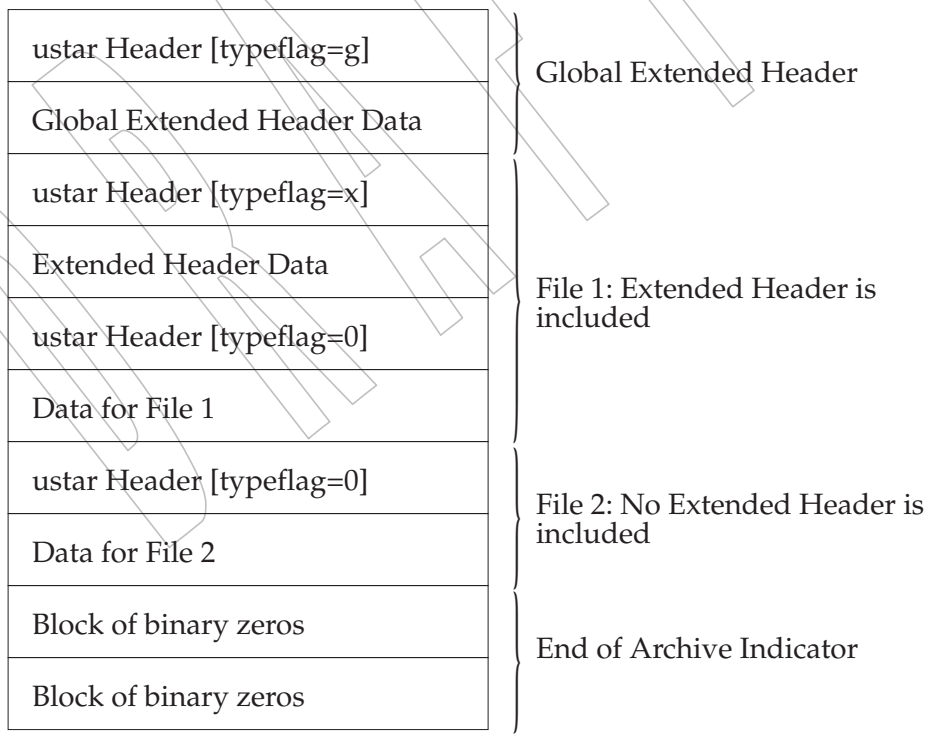

Figure 4-1 pax Format Archive Example

99709 **pax Header Block**

99710 The **pax** header block shall be identical to the **ustar** header block described in ustar Interchange
99711 Format (on page 3023), except that two additional *typeflag* values are defined:

99712 x Represents extended header records for the following file in the archive (which shall have
99713 its own **ustar** header block). The format of these extended header records shall be as
99714 described in pax Extended Header.

99715 g Represents global extended header records for the following files in the archive. The format
99716 of these extended header records shall be as described in pax Extended Header. Each value
99717 shall affect all subsequent files that do not override that value in their own extended header
99718 record and until another global extended header record is reached that provides another
99719 value for the same field. The *typeflag* **g** global headers should not be used with interchange
99720 media that could suffer partial data loss in transporting the archive.

99721 For both of these types, the *size* field shall be the size of the extended header records in octets.
99722 The other fields in the header block are not meaningful to this version of the *pax* utility.
99723 However, if this archive is read by a *pax* utility conforming to the ISO POSIX-2: 1993 standard,
99724 the header block fields are used to create a regular file that contains the extended header records
99725 as data. Therefore, header block field values should be selected to provide reasonable file access
99726 to this regular file.

99727 A further difference from the **ustar** header block is that data blocks for files of *typeflag* 1 (the digit
99728 one) (hard link) may be included, which means that the size field may be greater than zero.
99729 Archives created by *pax* **–o linkdata** shall include these data blocks with the hard links.

99730 **pax Extended Header**

99731 A **pax** extended header contains values that are inappropriate for the **ustar** header block because
99732 of limitations in that format: fields requiring a character encoding other than that described in
99733 the ISO/IEC 646: 1991 standard, fields representing file attributes not described in the **ustar**
99734 header, and fields whose format or length do not fit the requirements of the **ustar** header. The
99735 values in an extended header add attributes to the following file (or files; see the description of
99736 the *typeflag* **g** header block) or override values in the following header block(s), as indicated in
99737 the following list of keywords.

99738 An extended header shall consist of one or more records, each constructed as follows:

99739 `"%d %s=%s\n", <length>, <keyword>, <value>`

99740 The extended header records shall be encoded according to the ISO/IEC 10646-1: 2000 standard
99741 UTF-8 encoding. The <*length*> field, <blank>, <equals-sign>, and <newline> shown shall be
99742 limited to the portable character set, as encoded in UTF-8. The <*keyword*> fields can be any
99743 UTF-8 characters. The <*length*> field shall be the decimal length of the extended header record
99744 in octets, including the trailing <newline>. If there is a **hdrcharset** extended header in effect for
99745 a file, the *value* field for any **gname**, **linkpath**, **path**, and **uname** extended header records shall be
99746 encoded using the character set specified by the **hdrcharset** extended header record; otherwise,
99747 the *value* field shall be encoded using UTF-8. The *value* field for all other keywords specified by
99748 POSIX.1-200x shall be encoded using UTF-8.

99749 The <*keyword*> field shall be one of the entries from the following list or a keyword provided as
99750 an implementation extension. Keywords consisting entirely of lowercase letters, digits, and
99751 periods are reserved for future standardization. A keyword shall not include an <equals-sign>.
99752 (In the following list, the notations "file(s)" or "block(s)" is used to acknowledge that a keyword
99753 affects the following single file after a *typeflag* **x** extended header, but possibly multiple files after
99754 *typeflag* **g**. Any requirements in the list for *pax* to include a record when in **write** or **copy** mode

shall apply only when such a record has not already been provided through the use of the **–o** option. When used in **copy** mode, *pax* shall behave as if an archive had been created with applicable extended header records and then extracted.)

atime The file access time for the following file(s), equivalent to the value of the *st_atime* member of the **stat** structure for a file, as described by the *stat*( ) function. The access time shall be restored if the process has appropriate privileges required to do so. The format of the <*value*> shall be as described in pax Extended Header File Times (on page 3023).

charset The name of the character set used to encode the data in the following file(s). The entries in the following table are defined to refer to known standards; additional names may be agreed on between the originator and recipient.

<value>	Formal Standard
ISO-IR∆646∆1990	ISO/IEC 646: 1990
ISO-IR∆8859∆1∆1998	ISO/IEC 8859-1: 1998
ISO-IR∆8859∆2∆1999	ISO/IEC 8859-2: 1999
ISO-IR∆8859∆3∆1999	ISO/IEC 8859-3: 1999
ISO-IR∆8859∆4∆1998	ISO/IEC 8859-4: 1998
ISO-IR∆8859∆5∆1999	ISO/IEC 8859-5: 1999
ISO-IR∆8859∆6∆1999	ISO/IEC 8859-6: 1999
ISO-IR∆8859∆7∆1987	ISO/IEC 8859-7: 1987
ISO-IR∆8859∆8∆1999	ISO/IEC 8859-8: 1999
ISO-IR∆8859∆9∆1999	ISO/IEC 8859-9: 1999
ISO-IR∆8859∆10∆1998	ISO/IEC 8859-10: 1998
ISO-IR∆8859∆13∆1998	ISO/IEC 8859-13: 1998
ISO-IR∆8859∆14∆1998	ISO/IEC 8859-14: 1998
ISO-IR∆8859∆15∆1999	ISO/IEC 8859-15: 1999
ISO-IR∆10646∆2000	ISO/IEC 10646: 2000
ISO-IR∆10646∆2000∆UTF-8	ISO/IEC 10646, UTF-8 encoding
BINARY	None.

The encoding is included in an extended header for information only; when *pax* is used as described in POSIX.1-200x, it shall not translate the file data into any other encoding. The **BINARY** entry indicates unencoded binary data.

When used in **write** or **copy** mode, it is implementation-defined whether *pax* includes a **charset** extended header record for a file.

comment A series of characters used as a comment. All characters in the <*value*> field shall be ignored by *pax*.

gid The group ID of the group that owns the file, expressed as a decimal number using digits from the ISO/IEC 646: 1991 standard. This record shall override the *gid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *gid* extended header record for each file whose group ID is greater than 2 097 151 (octal 7 777 777).

gname The group of the file(s), formatted as a group name in the group database. This record shall override the *gid* and *gname* fields in the following header block(s), and any *gid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the characters cannot be translated, and if neither the **–oinvalid=UTF-8** option nor the

99802 –**oinvalid=binary** option is specified, the results are implementation-defined.
99803 When used in **write** or **copy** mode, *pax* shall include a **gname** extended header
99804 record for each file whose group name cannot be represented entirely with the
99805 letters and digits of the portable character set.

99806 **hdrcharset** The name of the character set used to encode the value field of the **gname**,
99807 **linkpath**, **path**, and **uname** *pax* extended header records. The entries in the
99808 following table are defined to refer to known standards; additional names may be
99809 agreed between the originator and the recipient.

99810

<value>	Formal Standard
ISO-IRΔ10646Δ2000ΔUTF-8	ISO/IEC 10646, UTF-8 encoding
BINARY	None.

99811
99812

99813 If no **hdrcharset** extended header record is specified, the default character set used
99814 to encode all values in extended header records shall be the ISO/IEC 10646-1:2000
99815 standard UTF-8 encoding.

99816 The **BINARY** entry indicates that all values recorded in extended headers for
99817 affected files are unencoded binary data from the underlying system.

99818 **linkpath** The pathname of a link being created to another file, of any type, previously
99819 archived. This record shall override the *linkname* field in the following **ustar** header
99820 block(s). The following **ustar** header block shall determine the type of link created.
99821 If *typeflag* of the following header block is 1, it shall be a hard link. If *typeflag* is 2, it
99822 shall be a symbolic link and the **linkpath** value shall be the contents of the
99823 symbolic link. The *pax* utility shall translate the name of the link (contents of the
99824 symbolic link) from the encoding in the header to the character set appropriate for
99825 the local file system. When used in **write** or **copy** mode, *pax* shall include a
99826 **linkpath** extended header record for each link whose pathname cannot be
99827 represented entirely with the members of the portable character set other than
99828 NUL.

99829 **mtime** The file modification time of the following file(s), equivalent to the value of the
99830 *st_mtime* member of the **stat** structure for a file, as described in the *stat*( ) function.
99831 This record shall override the *mtime* field in the following header block(s). The
99832 modification time shall be restored if the process has appropriate privileges
99833 required to do so. The format of the <*value*> shall be as described in pax Extended
99834 Header File Times (on page 3023).

99835 **path** The pathname of the following file(s). This record shall override the *name* and
99836 *prefix* fields in the following header block(s). The *pax* utility shall translate the
99837 pathname of the file from the encoding in the header to the character set
99838 appropriate for the local file system.

99839 When used in **write** or **copy** mode, *pax* shall include a *path* extended header record
99840 for each file whose pathname cannot be represented entirely with the members of
99841 the portable character set other than NUL.

99842 **realtime.***any* The keywords prefixed by "realtime." are reserved for future standardization.

99843 **security.***any* The keywords prefixed by "security." are reserved for future standardization.

99844 **size** The size of the file in octets, expressed as a decimal number using digits from the
99845 ISO/IEC 646:1991 standard. This record shall override the *size* field in the
99846 following header block(s). When used in **write** or **copy** mode, *pax* shall include a
99847 *size* extended header record for each file with a size value greater than 8 589 934 591

(octal 77 777 777 777).

uid The user ID of the file owner, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the *uid* field in the following header block(s). When used in **write** or **copy** mode, *pax* shall include a *uid* extended header record for each file whose owner ID is greater than 2 097 151 (octal 7 777 777).

uname The owner of the following file(s), formatted as a user name in the user database. This record shall override the *uid* and *uname* fields in the following header block(s), and any *uid* extended header record. When used in **read**, **copy**, or **list** mode, *pax* shall translate the name from the encoding in the header record to the character set appropriate for the user database on the receiving system. If any of the characters cannot be translated, and if neither the **–oinvalid=UTF-8** option nor the **–oinvalid=binary** option is specified, the results are implementation-defined. When used in **write** or **copy** mode, *pax* shall include a **uname** extended header record for each file whose user name cannot be represented entirely with the letters and digits of the portable character set.

If the <*value*> field is zero length, it shall delete any header block field, previously entered extended header value, or global extended header value of the same name.

If a keyword in an extended header record (or in a **–o** option-argument) overrides or deletes a corresponding field in the **ustar** header block, *pax* shall ignore the contents of that header block field.

Unlike the **ustar** header block fields, NULs shall not delimit <*value*>s; all characters within the <*value*> field shall be considered data for the field. None of the length limitations of the **ustar** header block fields in Table 4-14 (on page 3024) shall apply to the extended header records.

pax Extended Header Keyword Precedence

This section describes the precedence in which the various header records and fields and command line options are selected to apply to a file in the archive. When *pax* is used in **read** or **list** modes, it shall determine a file attribute in the following sequence:

1. If **–odelete=keyword-prefix** is used, the affected attributes shall be determined from step 7., if applicable, or ignored otherwise.
2. If **–o***keyword*:= is used, the affected attributes shall be ignored.
3. If **–okeyword:=value** is used, the affected attribute shall be assigned the value.
4. If there is a *typeflag* **x** extended header record, the affected attribute shall be assigned the <*value*>. When extended header records conflict, the last one given in the header shall take precedence.
5. If **–okeyword=value** is used, the affected attribute shall be assigned the value.
6. If there is a *typeflag* **g** global extended header record, the affected attribute shall be assigned the <*value*>. When global extended header records conflict, the last one given in the global header shall take precedence.
7. Otherwise, the attribute shall be determined from the **ustar** header block.

pax Extended Header File Times

The *pax* utility shall write an **mtime** record for each file in **write** or **copy** modes if the file's modification time cannot be represented exactly in the **ustar** header logical record described in ustar Interchange Format. This can occur if the time is out of **ustar** range, or if the file system of the underlying implementation supports non-integer time granularities and the time is not an integer. All of these time records shall be formatted as a decimal representation of the time in seconds since the Epoch. If a <period> (`'.'`) decimal point character is present, the digits to the right of the point shall represent the units of a subsecond timing granularity, where the first digit is tenths of a second and each subsequent digit is a tenth of the previous digit. In **read** or **copy** mode, the *pax* utility shall truncate the time of a file to the greatest value that is not greater than the input header file time. In **write** or **copy** mode, the *pax* utility shall output a time exactly if it can be represented exactly as a decimal number, and otherwise shall generate only enough digits so that the same time shall be recovered if the file is extracted on a system whose underlying implementation supports the same time granularity.

ustar Interchange Format

A **ustar** archive tape or file shall contain a series of logical records. Each logical record shall be a fixed-size logical record of 512 octets (see below). Although this format may be thought of as being stored on 9-track industry-standard 12.7 mm (0.5 in) magnetic tape, other types of transportable media are not excluded. Each file archived shall be represented by a header logical record that describes the file, followed by zero or more logical records that give the contents of the file. At the end of the archive file there shall be two 512-octet logical records filled with binary zeros, interpreted as an end-of-archive indicator.

The logical records may be grouped for physical I/O operations, as described under the **–b***blocksize* and **–x ustar** options. Each group of logical records may be written with a single operation equivalent to the *write*() function. On magnetic tape, the result of this write shall be a single tape physical block. The last physical block shall always be the full size, so logical records after the two zero logical records may contain undefined data.

The header logical record shall be structured as shown in the following table. All lengths and offsets are in decimal.

99917 **Table 4-14** ustar Header Block

Field Name	Octet Offset	Length (in Octets)
name	0	100
mode	100	8
uid	108	8
gid	116	8
size	124	12
mtime	136	12
chksum	148	8
typeflag	156	1
linkname	157	100
magic	257	6
version	263	2
uname	265	32
gname	297	32
devmajor	329	8
devminor	337	8
prefix	345	155

99935 All characters in the header logical record shall be represented in the coded character set of the
99936 ISO/IEC 646:1991 standard. For maximum portability between implementations, names should
99937 be selected from characters represented by the portable filename character set as octets with the
99938 most significant bit zero. If an implementation supports the use of characters outside of <slash>
99939 and the portable filename character set in names for files, users, and groups, one or more
99940 implementation-defined encodings of these characters shall be provided for interchange
99941 purposes.

99942 However, the *pax* utility shall never create filenames on the local system that cannot be accessed
99943 via the procedures described in POSIX.1-200x. If a filename is found on the medium that would
99944 create an invalid filename, it is implementation-defined whether the data from the file is stored
99945 on the file hierarchy and under what name it is stored. The *pax* utility may choose to ignore these
99946 files as long as it produces an error indicating that the file is being ignored.

99947 Each field within the header logical record is contiguous; that is, there is no padding used. Each
99948 character on the archive medium shall be stored contiguously.

99949 The fields *magic*, *uname*, and *gname* are character strings each terminated by a NUL character.
99950 The fields *name*, *linkname*, and *prefix* are NUL-terminated character strings except when all
99951 characters in the array contain non-NUL characters including the last character. The *version* field
99952 is two octets containing the characters `"00"` (zero-zero). The *typeflag* contains a single character.
99953 All other fields are leading zero-filled octal numbers using digits from the ISO/IEC 646:1991
99954 standard IRV. Each numeric field is terminated by one or more <space> or NUL characters.

99955 The *name* and the *prefix* fields shall produce the pathname of the file. A new pathname shall be
99956 formed, if *prefix* is not an empty string (its first character is not NUL), by concatenating *prefix* (up
99957 to the first NUL character), a <slash> character, and *name*; otherwise, *name* is used alone. In
99958 either case, *name* is terminated at the first NUL character. If *prefix* begins with a NUL character, it
99959 shall be ignored. In this manner, pathnames of at most 256 characters can be supported. If a
99960 pathname does not fit in the space provided, *pax* shall notify the user of the error, and shall not
99961 store any part of the file—header or data—on the medium.

99962 The *linkname* field, described below, shall not use the *prefix* to produce a pathname. As such, a
99963 *linkname* is limited to 100 characters. If the name does not fit in the space provided, *pax* shall

notify the user of the error, and shall not attempt to store the link on the medium.

The *mode* field provides 12 bits encoded in the ISO/IEC 646:1991 standard octal digit representation. The encoded bits shall represent the following values:

Table 4-15 ustar *mode* Field

Bit Value	POSIX.1-200x Bit	Description
04 000	S_ISUID	Set UID on execution.
02 000	S_ISGID	Set GID on execution.
01 000	<reserved>	Reserved for future standardization.
00 400	S_IRUSR	Read permission for file owner class.
00 200	S_IWUSR	Write permission for file owner class.
00 100	S_IXUSR	Execute/search permission for file owner class.
00 040	S_IRGRP	Read permission for file group class.
00 020	S_IWGRP	Write permission for file group class.
00 010	S_IXGRP	Execute/search permission for file group class.
00 004	S_IROTH	Read permission for file other class.
00 002	S_IWOTH	Write permission for file other class.
00 001	S_IXOTH	Execute/search permission for file other class.

When appropriate privileges are required to set one of these mode bits, and the user restoring the files from the archive does not have appropriate privileges, the mode bits for which the user does not have appropriate privileges shall be ignored. Some of the mode bits in the archive format are not mentioned elsewhere in this volume of POSIX.1-200x. If the implementation does not support those bits, they may be ignored.

The *uid* and *gid* fields are the user and group ID of the owner and group of the file, respectively.

The *size* field is the size of the file in octets. If the *typeflag* field is set to specify a file to be of type 1 (a link) or 2 (a symbolic link), the *size* field shall be specified as zero. If the *typeflag* field is set to specify a file of type 5 (directory), the *size* field shall be interpreted as described under the definition of that record type. No data logical records are stored for types 1, 2, or 5. If the *typeflag* field is set to 3 (character special file), 4 (block special file), or 6 (FIFO), the meaning of the *size* field is unspecified by this volume of POSIX.1-200x, and no data logical records shall be stored on the medium. Additionally, for type 6, the *size* field shall be ignored when reading. If the *typeflag* field is set to any other value, the number of logical records written following the header shall be (*size*+511)/512, ignoring any fraction in the result of the division.

The *mtime* field shall be the modification time of the file at the time it was archived. It is the ISO/IEC 646:1991 standard representation of the octal value of the modification time obtained from the *stat*( ) function.

The *chksum* field shall be the ISO/IEC 646:1991 standard IRV representation of the octal value of the simple sum of all octets in the header logical record. Each octet in the header shall be treated as an unsigned value. These values shall be added to an unsigned integer, initialized to zero, the precision of which is not less than 17 bits. When calculating the checksum, the *chksum* field is treated as if it were all <space> characters.

The *typeflag* field specifies the type of file archived. If a particular implementation does not recognize the type, or the user does not have appropriate privileges to create that type, the file shall be extracted as if it were a regular file if the file type is defined to have a meaning for the *size* field that could cause data logical records to be written on the medium (see the previous description for *size*). If conversion to a regular file occurs, the *pax* utility shall produce an error indicating that the conversion took place. All of the *typeflag* fields shall be coded in the

ISO/IEC 646:1991 standard IRV:

`0` Represents a regular file. For backwards-compatibility, a *typeflag* value of binary zero (`'\0'`) should be recognized as meaning a regular file when extracting files from the archive. Archives written with this version of the archive file format create regular files with a *typeflag* value of the ISO/IEC 646:1991 standard IRV `'0'`.

`1` Represents a file linked to another file, of any type, previously archived. Such files are identified by having the same device and file serial numbers, and pathnames that refer to different directory entries. All such files shall be archived as linked files. The linked-to name is specified in the *linkname* field with a NUL-character terminator if it is less than 100 octets in length.

`2` Represents a symbolic link. The contents of the symbolic link shall be stored in the *linkname* field.

`3,4` Represent character special files and block special files respectively. In this case the *devmajor* and *devminor* fields shall contain information defining the device, the format of which is unspecified by this volume of POSIX.1-200x. Implementations may map the device specifications to their own local specification or may ignore the entry.

`5` Specifies a directory or subdirectory. On systems where disk allocation is performed on a directory basis, the *size* field shall contain the maximum number of octets (which may be rounded to the nearest disk block allocation unit) that the directory may hold. A *size* field of zero indicates no such limiting. Systems that do not support limiting in this manner should ignore the *size* field.

`6` Specifies a FIFO special file. Note that the archiving of a FIFO file archives the existence of this file and not its contents.

`7` Reserved to represent a file to which an implementation has associated some high-performance attribute. Implementations without such extensions should treat this file as a regular file (type 0).

`A-Z` The letters `'A'` to `'Z'`, inclusive, are reserved for custom implementations. All other values are reserved for future versions of this standard.

It is unspecified whether files with pathnames that refer to the same directory entry are archived as linked files or as separate files. If they are archived as linked files, this means that attempting to extract both pathnames from the resulting archive will always cause an error (unless the **–u** option is used) because the link cannot be created.

It is unspecified whether files with the same device and file serial numbers being appended to an archive are treated as linked files to members that were in the archive before the append.

Attempts to archive a socket using **ustar** interchange format shall produce a diagnostic message. Handling of other file types is implementation-defined.

The *magic* field is the specification that this archive was output in this archive format. If this field contains **ustar** (the five characters from the ISO/IEC 646:1991 standard IRV shown followed by NUL), the *uname* and *gname* fields shall contain the ISO/IEC 646:1991 standard IRV representation of the owner and group of the file, respectively (truncated to fit, if necessary). When the file is restored by a privileged, protection-preserving version of the utility, the user and group databases shall be scanned for these names. If found, the user and group IDs contained within these files shall be used rather than the values contained within the *uid* and *gid* fields.

100054 **cpio Interchange Format**

100055 The octet-oriented **cpio** archive format shall be a series of entries, each comprising a header that
100056 describes the file, the name of the file, and then the contents of the file.

100057 An archive may be recorded as a series of fixed-size blocks of octets. This blocking shall be used
100058 only to make physical I/O more efficient. The last group of blocks shall always be at the full
100059 size.

100060 For the octet-oriented **cpio** archive format, the individual entry information shall be in the order
100061 indicated and described by the following table; see also the **<cpio.h>** header.

100062 **Table 4-16** Octet-Oriented cpio Archive Entry

100063

Header Field Name	Length (in Octets)	Interpreted as
c_magic	6	Octal number
c_dev	6	Octal number
c_ino	6	Octal number
c_mode	6	Octal number
c_uid	6	Octal number
c_gid	6	Octal number
c_nlink	6	Octal number
c_rdev	6	Octal number
c_mtime	11	Octal number
c_namesize	6	Octal number
c_filesize	11	Octal number
Filename Field Name	**Length**	**Interpreted as**
c_name	*c_namesize*	Pathname string
File Data Field Name	**Length**	**Interpreted as**
c_filedata	*c_filesize*	Data

100079 **cpio Header**

100080 For each file in the archive, a header as defined previously shall be written. The information in
100081 the header fields is written as streams of the ISO/IEC 646:1991 standard characters interpreted
100082 as octal numbers. The octal numbers shall be extended to the necessary length by appending the
100083 ISO/IEC 646:1991 standard IRV zeros at the most-significant-digit end of the number; the result
100084 is written to the most-significant digit of the stream of octets first. The fields shall be interpreted
100085 as follows:

100086 *c_magic* Identify the archive as being a transportable archive by containing the identifying
100087 value `"070707"`.

100088 *c_dev*, *c_ino* Contains values that uniquely identify the file within the archive (that is, no files
100089 contain the same pair of *c_dev* and *c_ino* values unless they are links to the same
100090 file). The values shall be determined in an unspecified manner.

100091 *c_mode* Contains the file type and access permissions as defined in the following table.

Table 4-17 Values for cpio c_mode Field

File Permissions Name	Value	Indicates
C_IRUSR	000 400	Read by owner
C_IWUSR	000 200	Write by owner
C_IXUSR	000 100	Execute by owner
C_IRGRP	000 040	Read by group
C_IWGRP	000 020	Write by group
C_IXGRP	000 010	Execute by group
C_IROTH	000 004	Read by others
C_IWOTH	000 002	Write by others
C_IXOTH	000 001	Execute by others
C_ISUID	004 000	Set *uid*
C_ISGID	002 000	Set *gid*
C_ISVTX	001 000	Reserved
File Type Name	**Value**	**Indicates**
C_ISDIR	040 000	Directory
C_ISFIFO	010 000	FIFO
C_ISREG	0100 000	Regular file
C_ISLNK	0120 000	Symbolic link
C_ISBLK	060 000	Block special file
C_ISCHR	020 000	Character special file
C_ISSOCK	0140 000	Socket
C_ISCTG	0110 000	Reserved

Directories, FIFOs, symbolic links, and regular files shall be supported on a system conforming to this volume of POSIX.1-200x; additional values defined previously are reserved for compatibility with existing systems. Additional file types may be supported; however, such files should not be written to archives intended to be transported to other systems.

c_uid Contains the user ID of the owner.

c_gid Contains the group ID of the group.

c_nlink Contains a number greater than or equal to the number of links in the archive referencing the file. If the **–a** option is used to append to a *cpio* archive, then the *pax* utility need not account for the files in the existing part of the archive when calculating the *c_nlink* values for the appended part of the archive, and need not alter the *c_nlink* values in the existing part of the archive if additional files with the same *c_dev* and *c_ino* values are appended to the archive.

c_rdev Contains implementation-defined information for character or block special files.

c_mtime Contains the latest time of modification of the file at the time the archive was created.

c_namesize Contains the length of the pathname, including the terminating NUL character.

c_filesize Contains the length in octets of the data section following the header structure.

100133 **cpio Filename**

100134 The *c_name* field shall contain the pathname of the file. The length of this field in octets is the
100135 value of *c_namesize*.

100136 If a filename is found on the medium that would create an invalid pathname, it is
100137 implementation-defined whether the data from the file is stored on the file hierarchy and under
100138 what name it is stored.

100139 All characters shall be represented in the ISO/IEC 646:1991 standard IRV. For maximum
100140 portability between implementations, names should be selected from characters represented by
100141 the portable filename character set as octets with the most significant bit zero. If an
100142 implementation supports the use of characters outside the portable filename character set in
100143 names for files, users, and groups, one or more implementation-defined encodings of these
100144 characters shall be provided for interchange purposes. However, the *pax* utility shall never create
100145 filenames on the local system that cannot be accessed via the procedures described previously in
100146 this volume of POSIX.1-200x. If a filename is found on the medium that would create an invalid
100147 filename, it is implementation-defined whether the data from the file is stored on the local file
100148 system and under what name it is stored. The *pax* utility may choose to ignore these files as long
100149 as it produces an error indicating that the file is being ignored.

100150 **cpio File Data**

100151 Following *c_name*, there shall be *c_filesize* octets of data. Interpretation of such data occurs in a
100152 manner dependent on the file. For regular files, the data shall consist of the contents of the file.
100153 For symbolic links, the data shall consist of the contents of the symbolic link. If *c_filesize* is zero,
100154 no data shall be contained in *c_filedata*.

100155 When restoring from an archive:

100156 • If the user does not have appropriate privileges to create a file of the specified type, *pax*
100157 shall ignore the entry and write an error message to standard error.

100158 • Only regular files and symbolic links have data to be restored. Presuming a regular file
100159 meets any selection criteria that might be imposed on the format-reading utility by the
100160 user, such data shall be restored.

100161 • If a user does not have appropriate privileges to set a particular mode flag, the flag shall be
100162 ignored. Some of the mode flags in the archive format are not mentioned elsewhere in this
100163 volume of POSIX.1-200x. If the implementation does not support those flags, they may be
100164 ignored.

100165 **cpio Special Entries**

100166 FIFO special files, directories, and the trailer shall be recorded with *c_filesize* equal to zero.
100167 Symbolic links shall be recorded with *c_filesize* equal to the length of the contents of the symbolic
100168 link. For other special files, *c_filesize* is unspecified by this volume of POSIX.1-200x. The header
100169 for the next file entry in the archive shall be written directly after the last octet of the file entry
100170 preceding it. A header denoting the filename **TRAILER!!!** shall indicate the end of the archive;
100171 the contents of octets in the last block of the archive following such a header are undefined.

100172 **EXIT STATUS**

100173 The following exit values shall be returned:

100174 0 All files were processed successfully.

100175 >0 An error occurred.

100176 **CONSEQUENCES OF ERRORS**

100177 If *pax* cannot create a file or a link when reading an archive or cannot find a file when writing an
100178 archive, or cannot preserve the user ID, group ID, or file mode when the **–p** option is specified, a
100179 diagnostic message shall be written to standard error and a non-zero exit status shall be
100180 returned, but processing shall continue. In the case where *pax* cannot create a link to a file, *pax*
100181 shall not, by default, create a second copy of the file.

100182 If the extraction of a file from an archive is prematurely terminated by a signal or error, *pax* may
100183 have only partially extracted the file or (if the **–n** option was not specified) may have extracted a
100184 file of the same name as that specified by the user, but which is not the file the user wanted.
100185 Additionally, the file modes of extracted directories may have additional bits from the S_IRWXU
100186 mask set as well as incorrect modification and access times.

100187 **APPLICATION USAGE**

100188 Caution is advised when using the **–a** option to append to a *cpio* format archive. If any of the
100189 files being appended happen to be given the same *c_dev* and *c_ino* values as a file in the existing
100190 part of the archive, then they may be treated as links to that file on extraction. Thus, it is risky to
100191 use **–a** with *cpio* format except when it is done on the same system that the original archive was
100192 created on, and with the same *pax* utility, and in the knowledge that there has been little or no
100193 file system activity since the original archive was created that could lead to any of the files
100194 appended being given the same *c_dev* and *c_ino* values as an unrelated file in the existing part of
100195 the archive. Also, when (intentionally) appending additional links to a file in the existing part of
100196 the archive, the *c_nlink* values in the modified archive can be smaller than the number of links to
100197 the file in the archive, which may mean that the links are not preserved on extraction.

100198 The **–p** (privileges) option was invented to reconcile differences between historical *tar* and *cpio*
100199 implementations. In particular, the two utilities use **–m** in diametrically opposed ways. The **–p**
100200 option also provides a consistent means of extending the ways in which future file attributes can
100201 be addressed, such as for enhanced security systems or high-performance files. Although it may
100202 seem complex, there are really two modes that are most commonly used:

100203 **–p e** "Preserve everything". This would be used by the historical superuser, someone with
100204 all appropriate privileges, to preserve all aspects of the files as they are recorded in the
100205 archive. The **e** flag is the sum of **o** and **p**, and other implementation-defined attributes.

100206 **–p p** "Preserve" the file mode bits. This would be used by the user with regular privileges
100207 who wished to preserve aspects of the file other than the ownership. The file times are
100208 preserved by default, but two other flags are offered to disable these and use the time
100209 of extraction.

100210 The one pathname per line format of standard input precludes pathnames containing <newline>
100211 characters. Although such pathnames violate the portable filename guidelines, they may exist
100212 and their presence may inhibit usage of *pax* within shell scripts. This problem is inherited from
100213 historical archive programs. The problem can be avoided by listing filename arguments on the
100214 command line instead of on standard input.

100215 It is almost certain that appropriate privileges are required for *pax* to accomplish parts of this
100216 volume of POSIX.1-200x. Specifically, creating files of type block special or character special,
100217 restoring file access times unless the files are owned by the user (the **–t** option), or preserving file
100218 owner, group, and mode (the **–p** option) all probably require appropriate privileges.

100219 In **read** mode, implementations are permitted to overwrite files when the archive has multiple
100220 members with the same name. This may fail if permissions on the first version of the file do not
100221 permit it to be overwritten.

The **cpio** and **ustar** formats can only support files up to 8 589 934 592 bytes (8 * 2^30) in size.

When archives containing binary header information are listed , the filenames printed may cause strange behavior on some terminals.

EXAMPLES

The following command:

```
pax -w -f /dev/rmt/1m .
```

copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures—the historical BSD device name would be **/dev/rmt9**).

The following commands:

```
mkdir newdir
pax -rw olddir newdir
```

copy the *olddir* directory hierarchy to *newdir*.

```
pax -r -s ',^//*usr//*,,' -f a.pax
```

reads the archive **a.pax**, with all files rooted in **/usr** in the archive extracted relative to the current directory.

Using the option:

```
-o listopt="%M %(atime)T %(size)D %(name)s"
```

overrides the default output description in Standard Output and instead writes:

```
-rw-rw--- Jan 12 15:53 2003 1492 /usr/foo/bar
```

Using the options:

```
-o listopt='%L\t%(size)D\n%.7' \
-o listopt='(name)s\n%(atime)T\n%T'
```

overrides the default output description in Standard Output and instead writes:

```
/usr/foo/bar -> /tmp   1492
/usr/fo
Jan 12 15:53 1991
Jan 31 15:53 2003
```

RATIONALE

The *pax* utility was new for the ISO POSIX-2: 1993 standard. It represents a peaceful compromise between advocates of the historical *tar* and *cpio* utilities.

A fundamental difference between *cpio* and *tar* was in the way directories were treated. The *cpio* utility did not treat directories differently from other files, and to select a directory and its contents required that each file in the hierarchy be explicitly specified. For *tar*, a directory matched every file in the file hierarchy it rooted.

The *pax* utility offers both interfaces; by default, directories map into the file hierarchy they root. The **-d** option causes *pax* to skip any file not explicitly referenced, as *cpio* historically did. The *tar -style* behavior was chosen as the default because it was believed that this was the more common usage and because *tar* is the more commonly available interface, as it was historically provided on both System V and BSD implementations.

The data interchange format specification in this volume of POSIX.1-200x requires that processes with "appropriate privileges" shall always restore the ownership and permissions of extracted

files exactly as archived. If viewed from the historic equivalence between superuser and "appropriate privileges", there are two problems with this requirement. First, users running as superusers may unknowingly set dangerous permissions on extracted files. Second, it is needlessly limiting, in that superusers cannot extract files and own them as superuser unless the archive was created by the superuser. (It should be noted that restoration of ownerships and permissions for the superuser, by default, is historical practice in *cpio*, but not in *tar*.) In order to avoid these two problems, the *pax* specification has an additional "privilege" mechanism, the **–p** option. Only a *pax* invocation with the privileges needed, and which has the **–p** option set using the e specification character, has appropriate privileges to restore full ownership and permission information.

Note also that this volume of POSIX.1-200x requires that the file ownership and access permissions shall be set, on extraction, in the same fashion as the *creat*( ) function when provided with the mode stored in the archive. This means that the file creation mask of the user is applied to the file permissions.

Users should note that directories may be created by *pax* while extracting files with permissions that are different from those that existed at the time the archive was created. When extracting sensitive information into a directory hierarchy that no longer exists, users are encouraged to set their file creation mask appropriately to protect these files during extraction.

The table of contents output is written to standard output to facilitate pipeline processing.

An early proposal had hard links displaying for all pathnames. This was removed because it complicates the output of the case where **–v** is not specified and does not match historical *cpio* usage. The hard-link information is available in the **–v** display.

The description of the **–l** option allows implementations to make hard links to symbolic links. POSIX.1-200x does not specify any way to create a hard link to a symbolic link, but many implementations provide this capability as an extension. If there are hard links to symbolic links when an archive is created, the implementation is required to archive the hard link in the archive (unless **–H** or **–L** is specified). When in **read** mode and in **copy** mode, implementations supporting hard links to symbolic links should use them when appropriate.

The archive formats inherited from the POSIX.1-1990 standard have certain restrictions that have been brought along from historical usage. For example, there are restrictions on the length of pathnames stored in the archive. When *pax* is used in **copy**(**–rw**) mode (copying directory hierarchies), the ability to use extensions from the **–xpax** format overcomes these restrictions.

The default *blocksize* value of 5 120 bytes for *cpio* was selected because it is one of the standard block-size values for *cpio*, set when the **–B** option is specified. (The other default block-size value for *cpio* is 512 bytes, and this was considered to be too small.) The default block value of 10 240 bytes for *tar* was selected because that is the standard block-size value for BSD *tar*. The maximum block size of 32 256 bytes (2^{15}–512 bytes) is the largest multiple of 512 bytes that fits into a signed 16-bit tape controller transfer register. There are known limitations in some historical systems that would prevent larger blocks from being accepted. Historical values were chosen to improve compatibility with historical scripts using *dd* or similar utilities to manipulate archives. Also, default block sizes for any file type other than character special file has been deleted from this volume of POSIX.1-200x as unimportant and not likely to affect the structure of the resulting archive.

Implementations are permitted to modify the block-size value based on the archive format or the device to which the archive is being written. This is to provide implementations with the opportunity to take advantage of special types of devices, and it should not be used without a great deal of consideration as it almost certainly decreases archive portability.

The intended use of the **–n** option was to permit extraction of one or more files from the archive without processing the entire archive. This was viewed by the standard developers as offering significant performance advantages over historical implementations. The **–n** option in early proposals had three effects; the first was to cause special characters in patterns to not be treated specially. The second was to cause only the first file that matched a pattern to be extracted. The third was to cause *pax* to write a diagnostic message to standard error when no file was found matching a specified pattern. Only the second behavior is retained by this volume of POSIX.1-200x, for many reasons. First, it is in general not acceptable for a single option to have multiple effects. Second, the ability to make pattern matching characters act as normal characters is useful for parts of *pax* other than file extraction. Third, a finer degree of control over the special characters is useful because users may wish to normalize only a single special character in a single filename. Fourth, given a more general escape mechanism, the previous behavior of the **–n** option can be easily obtained using the **–s** option or a *sed* script. Finally, writing a diagnostic message when a pattern specified by the user is unmatched by any file is useful behavior in all cases.

In this version, the **–n** was removed from the **copy** mode synopsis of *pax*; it is inapplicable because there are no pattern operands specified in this mode.

There is another method than *pax* for copying subtrees in POSIX.1-200x described as part of the *cp* utility. Both methods are historical practice: *cp* provides a simpler, more intuitive interface, while *pax* offers a finer granularity of control. Each provides additional functionality to the other; in particular, *pax* maintains the hard-link structure of the hierarchy while *cp* does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

A single archive may span more than one file. It is suggested that implementations provide informative messages to the user on standard error whenever the archive file is changed.

The **–d** option (do not create intermediate directories not listed in the archive) found in early proposals was originally provided as a complement to the historic **–d** option of *cpio*. It has been deleted.

The **–s** option in early proposals specified a subset of the substitution command from the *ed* utility. As there was no reason for only a subset to be supported, the **–s** option is now compatible with the current *ed* specification. Since the delimiter can be any non-null character, the following usage with single <space> characters is valid:

```
pax –s " foo bar " ...
```

The **–t** description is worded so as to note that this may cause the access time update caused by some other activity (which occurs while the file is being read) to be overwritten.

The default behavior of *pax* with regard to file modification times is the same as historical implementations of *tar*. It is not the historical behavior of *cpio*.

Because the **–i** option uses **/dev/tty**, utilities without a controlling terminal are not able to use this option.

The **–y** option, found in early proposals, has been deleted because a line containing a single <period> for the **–i** option has equivalent functionality. The special lines for the **–i** option (a single <period> and the empty line) are historical practice in *cpio*.

In early drafts, a **–e***charmap* option was included to increase portability of files between systems using different coded character sets. This option was omitted because it was apparent that

consensus could not be formed for it. In this version, the use of UTF-8 should be an adequate substitute.

The ISO POSIX-2:1993 standard and ISO POSIX-1 standard requirements for *pax*, however, made it very difficult to create a single archive containing files created using extended characters provided by different locales. This version adds the **hdrcharset** keyword to make it possible to archive files in these cases without dropping files due to translation errors.

Translating filenames and other attributes from a locale's encoding to UTF-8 and then back again can lose information, as the resulting filename might not be byte-for-byte equivalent to the original. To avoid this problem, users can specify the **–o hdrcharset=binary** option, which will cause the resulting archive to use binary format for all names and attributes. Such archives are not portable among hosts that use different native encodings (e.g., EBCDIC *versus* ASCII-based encodings), but they will allow interchange among the vast majority of POSIX file systems in practical use. Also, the **–o hdrcharset=binary** option will cause *pax* in **copy** mode to behave more like other standard utilities such as *cp*.

If the values specified by the **–o exthdr.name=value**, **–o globexthdr.name=value**, or by **$TMPDIR** (if **–o globexthdr.name** is not specified) require a character encoding other than that described in the ISO/IEC 646:1991 standard, a **path** extended header record will have to be created for the file. If a **hdrcharset** extended header record is active for such headers, it will determine the codeset used for the value field in these extended **path** header records. These **path** extended header records always need to be created when writing an archive even if **hdrcharset=binary** has been specified and would contain the same (binary) data that appears in the **ustar** header record prefix and *name* fields. (In other words, an extended header **path** record is always required to be generated if the *prefix* or *name* fields contain non-ASCII characters even when **hdrcharset=binary** is also in effect for that file.)

The **–k** option was added to address international concerns about the dangers involved in the character set transformations of **–e** (if the target character set were different from the source, the filenames might be transformed into names matching existing files) and also was made more general to protect files transferred between file systems with different {NAME_MAX} values (truncating a filename on a smaller system might also inadvertently overwrite existing files). As stated, it prevents any overwriting, even if the target file is older than the source. This version adds more granularity of options to solve this problem by introducing the **–oinvalid=option**—specifically the **UTF-8** and **binary** actions. (Note that an existing file is still subject to overwriting in this case. The **–k** option closes that loophole.)

Some of the file characteristics referenced in this volume of POSIX.1-200x might not be supported by some archive formats. For example, neither the **tar** nor **cpio** formats contain the file access time. For this reason, the `e` specification character has been provided, intended to cause all file characteristics specified in the archive to be retained.

It is required that extracted directories, by default, have their access and modification times and permissions set to the values specified in the archive. This has obvious problems in that the directories are almost certainly modified after being extracted and that directory permissions may not permit file creation. One possible solution is to create directories with the mode specified in the archive, as modified by the *umask* of the user, with sufficient permissions to allow file creation. After all files have been extracted, *pax* would then reset the access and modification times and permissions as necessary.

The list-mode formatting description borrows heavily from the one defined by the *printf* utility. However, since there is no separate operand list to get conversion arguments, the format was extended to allow specifying the name of the conversion argument as part of the conversion specification.

The `T` conversion specifier allows time fields to be displayed in any of the date formats. Unlike the *ls* utility, *pax* does not adjust the format when the date is less than six months in the past. This makes parsing the output more predictable.

The `D` conversion specifier handles the ability to display the major/minor or file size, as with *ls*, by using `%–8(`*`size`*`)D`.

The `L` conversion specifier handles the *ls* display for symbolic links.

Conversion specifiers were added to generate existing known types used for *ls*.

pax Interchange Format

The new POSIX data interchange format was developed primarily to satisfy international concerns that the **ustar** and **cpio** formats did not provide for file, user, and group names encoded in characters outside a subset of the ISO/IEC 646:1991 standard. The standard developers realized that this new POSIX data interchange format should be very extensible because there were other requirements they foresaw in the near future:

- Support international character encodings and locale information
- Support security information (ACLs, and so on)
- Support future file types, such as realtime or contiguous files
- Include data areas for implementation use
- Support systems with words larger than 32 bits and timers with subsecond granularity

The following were not goals for this format because these are better handled by separate utilities or are inappropriate for a portable format:

- Encryption
- Compression
- Data translation between locales and codesets
- *inode* storage

The format chosen to support the goals is an extension of the **ustar** format. Of the two formats previously available, only the **ustar** format was selected for extensions because:

- It was easier to extend in an upwards-compatible way. It offered version flags and header block type fields with room for future standardization. The **cpio** format, while possessing a more flexible file naming methodology, could not be extended without breaking some theoretical implementation or using a dummy filename that could be a legitimate filename.
- Industry experience since the original "*tar* wars" fought in developing the ISO POSIX-1 standard has clearly been in favor of the **ustar** format, which is generally the default output format selected for *pax* implementations on new systems.

The new format was designed with one additional goal in mind: reasonable behavior when an older *tar* or *pax* utility happened to read an archive. Since the POSIX.1-1990 standard mandated that a "format-reading utility" had to treat unrecognized *typeflag* values as regular files, this allowed the format to include all the extended information in a pseudo-regular file that preceded each real file. An option is given that allows the archive creator to set up reasonable names for these files on the older systems. Also, the normative text suggests that reasonable file access values be used for this **ustar** header block. Making these header files inaccessible for convenient reading and deleting would not be reasonable. File permissions of 600 or 700 are suggested.

The **ustar** *typeflag* field was used to accommodate the additional functionality of the new format rather than magic or version because the POSIX.1-1990 standard (and, by reference, the previous version of *pax*), mandated the behavior of the format-reading utility when it encountered an unknown *typeflag*, but was silent about the other two fields.

Early proposals for the first version of this standard contained a proposed archive format that was based on compatibility with the standard for tape files (ISO 1001, similar to the format used historically on many mainframes and minicomputers). This format was overly complex and required considerable overhead in volume and header records. Furthermore, the standard developers felt that it would not be acceptable to the community of POSIX developers, so it was later changed to be a format more closely related to historical practice on POSIX systems.

The prefix and name split of pathnames in **ustar** was replaced by the single path extended header record for simplicity.

The concept of a global extended header (*typeflag* **g**) was controversial. If this were applied to an archive being recorded on magnetic tape, a few unreadable blocks at the beginning of the tape could be a serious problem; a utility attempting to extract as many files as possible from a damaged archive could lose a large percentage of file header information in this case. However, if the archive were on a reliable medium, such as a CD-ROM, the global extended header offers considerable potential size reductions by eliminating redundant information. Thus, the text warns against using the global method for unreliable media and provides a method for implanting global information in the extended header for each file, rather than in the *typeflag* **g** records.

No facility for data translation or filtering on a per-file basis is included because the standard developers could not invent an interface that would allow this in an efficient manner. If a filter, such as encryption or compression, is to be applied to all the files, it is more efficient to apply the filter to the entire archive as a single file. The standard developers considered interfaces that would invoke a shell script for each file going into or out of the archive, but the system overhead in this approach was considered to be too high.

One such approach would be to have **filter=** records that give a pathname for an executable. When the program is invoked, the file and archive would be open for standard input/output and all the header fields would be available as environment variables or command-line arguments. The standard developers did discuss such schemes, but they were omitted from POSIX.1-200x due to concerns about excessive overhead. Also, the program itself would need to be in the archive if it were to be used portably.

There is currently no portable means of identifying the character set(s) used for a file in the file system. Therefore, *pax* has not been given a mechanism to generate charset records automatically. The only portable means of doing this is for the user to write the archive using the **−ocharset=string** command line option. This assumes that all of the files in the archive use the same encoding. The "implementation-defined" text is included to allow for a system that can identify the encodings used for each of its files.

The table of standards that accompanies the charset record description is acknowledged to be very limited. Only a limited number of character set standards is reasonable for maximal interchange. Any character set is, of course, possible by prior agreement. It was suggested that EBCDIC be listed, but it was omitted because it is not defined by a formal standard. Formal standards, and then only those with reasonably large followings, can be included here, simply as a matter of practicality. The <*value*>s represent names of officially registered character sets in the format required by the ISO 2375: 1985 standard.

The normal <comma> or <blank>-separated list rules are not followed in the case of keyword options to allow ease of argument parsing for *getopts*.

Further information on character encodings is in pax Archive Character Set Encoding/Decoding (on page 3038).

The standard developers have reserved keyword name space for vendor extensions. It is suggested that the format to be used is:

```
VENDOR.keyword
```

where *VENDOR* is the name of the vendor or organization in all uppercase letters. It is further suggested that the keyword following the <period> be named differently than any of the standard keywords so that it could be used for future standardization, if appropriate, by omitting the *VENDOR* prefix.

The <*length*> field in the extended header record was included to make it simpler to step through the records, even if a record contains an unknown format (to a particular *pax*) with complex interactions of special characters. It also provides a minor integrity checkpoint within the records to aid a program attempting to recover files from a damaged archive.

There are no extended header versions of the *devmajor* and *devminor* fields because the unspecified format **ustar** header field should be sufficient. If they are not, vendor-specific extended keywords (such as *VENDOR.devmajor*) should be used.

Device and *i*-number labeling of files was not adopted from *cpio*; files are interchanged strictly on a symbolic name basis, as in **ustar**.

Just as with the **ustar** format descriptions, the new format makes no special arrangements for multi-volume archives. Each of the *pax* archive types is assumed to be inside a single POSIX file and splitting that file over multiple volumes (diskettes, tape cartridges, and so on), processing their labels, and mounting each in the proper sequence are considered to be implementation details that cannot be described portably.

The **pax** format is intended for interchange, not only for backup on a single (family of) systems. It is not as densely packed as might be possible for backup:

- It contains information as coded characters that could be coded in binary.
- It identifies extended records with name fields that could be omitted in favor of a fixed-field layout.
- It translates names into a portable character set and identifies locale-related information, both of which are probably unnecessary for backup.

The requirements on restoring from an archive are slightly different from the historical wording, allowing for non-monolithic privilege to bring forward as much as possible. In particular, attributes such as "high performance file" might be broadly but not universally granted while set-user-ID or *chown*() might be much more restricted. There is no implication in POSIX.1-200x that the security information be honored after it is restored to the file hierarchy, in spite of what might be improperly inferred by the silence on that topic. That is a topic for another standard.

Links are recorded in the fashion described here because a link can be to any file type. It is desirable in general to be able to restore part of an archive selectively and restore all of those files completely. If the data is not associated with each link, it is not possible to do this. However, the data associated with a file can be large, and when selective restoration is not needed, this can be a significant burden. The archive is structured so that files that have no associated data can always be restored by the name of any link name of any link, and the user may choose whether data is recorded with each instance of a file that contains data. The format permits mixing of both types of links in a single archive; this can be done for special needs, and *pax* is expected to interpret such archives on input properly, despite the fact that there is no *pax* option that would

force this mixed case on output. (When **–o linkdata** is used, the output must contain the duplicate data, but the implementation is free to include it or omit it when **–o linkdata** is not used.)

The time values are included as extended header records for those implementations needing more than the eleven octal digits allowed by the **ustar** format. Portable file timestamps cannot be negative. If *pax* encounters a file with a negative timestamp in **copy** or **write** mode, it can reject the file, substitute a non-negative timestamp, or generate a non-portable timestamp with a leading `'–'`. Even though some implementations can support finer file-time granularities than seconds, the normative text requires support only for seconds since the Epoch because the ISO POSIX-1 standard states them that way. The **ustar** format includes only *mtime*; the new format adds *atime* and *ctime* for symmetry. The *atime* access time restored to the file system will be affected by the **–p a** and **–p e** options. The *ctime* creation time (actually *inode* modification time) is described with appropriate privileges so that it can be ignored when writing to the file system. POSIX does not provide a portable means to change file creation time. Nothing is intended to prevent a non-portable implementation of *pax* from restoring the value.

The *gid*, *size*, and *uid* extended header records were included to allow expansion beyond the sizes specified in the regular *tar* header. New file system architectures are emerging that will exhaust the 12-digit size field. There are probably not many systems requiring more than 8 digits for user and group IDs, but the extended header values were included for completeness, allowing overrides for all of the decimal values in the *tar* header.

The standard developers intended to describe the effective results of *pax* with regard to file ownerships and permissions; implementations are not restricted in timing or sequencing the restoration of such, provided the results are as specified.

Much of the text describing the extended headers refers to use in "**write** or **copy** modes". The **copy** mode references are due to the normative text: "The effect of the copy shall be as if the copied files were written to an archive file and then subsequently extracted ...". There is certainly no way to test whether *pax* is actually generating the extended headers in **copy** mode, but the effects must be as if it had.

pax Archive Character Set Encoding/Decoding

There is a need to exchange archives of files between systems of different native codesets. Filenames, group names, and user names must be preserved to the fullest extent possible when an archive is read on the receiving platform. Translation of the contents of files is not within the scope of the *pax* utility.

There will also be the need to represent characters that are not available on the receiving platform. These unsupported characters cannot be automatically folded to the local set of characters due to the chance of collisions. This could result in overwriting previous extracted files from the archive or pre-existing files on the system.

For these reasons, the codeset used to represent characters within the extended header records of the *pax* archive must be sufficiently rich to handle all commonly used character sets. The fields requiring translation include, at a minimum, filenames, user names, group names, and link pathnames. Implementations may wish to have localized extended keywords that use non-portable characters.

The standard developers considered the following options:

- The archive creator specifies the well-defined name of the source codeset. The receiver must then recognize the codeset name and perform the appropriate translations to the destination codeset.

- The archive creator includes within the archive the character mapping table for the source codeset used to encode extended header records. The receiver must then read the character mapping table and perform the appropriate translations to the destination codeset.
- The archive creator translates the extended header records in the source codeset into a canonical form. The receiver must then perform the appropriate translations to the destination codeset.

The approach that incorporates the name of the source codeset poses the problem of codeset name registration, and makes the archive useless to *pax* archive decoders that do not recognize that codeset.

Because parts of an archive may be corrupted, the standard developers felt that including the character map of the source codeset was too fragile. The loss of this one key component could result in making the entire archive useless. (The difference between this and the global extended header decision was that the latter has a workaround—duplicating extended header records on unreliable media—but this would be too burdensome for large character set maps.)

Both of the above approaches also put an undue burden on the *pax* archive receiver to handle the cross-product of all source and destination codesets.

To simplify the translation from the source codeset to the canonical form and from the canonical form to the destination codeset, the standard developers decided that the internal representation should be a stateless encoding. A stateless encoding is one where each codepoint has the same meaning, without regard to the decoder being in a specific state. An example of a stateful encoding would be the Japanese Shift-JIS; an example of a stateless encoding would be the ISO/IEC 646:1991 standard (equivalent to 7-bit ASCII).

For these reasons, the standard developers decided to adopt a canonical format for the representation of file information strings. The obvious, well-endorsed candidate is the ISO/IEC 10646-1:2000 standard (based in part on Unicode), which can be used to represent the characters of virtually all standardized character sets. The standard developers initially agreed upon using UCS2 (16-bit Unicode) as the internal representation. This repertoire of characters provides a sufficiently rich set to represent all commonly-used codesets.

However, the standard developers found that the 16-bit Unicode representation had some problems. It forced the issue of standardizing byte ordering. The 2-byte length of each character made the extended header records twice as long for the case of strings coded entirely from historical 7-bit ASCII. For these reasons, the standard developers chose the UTF-8 defined in the ISO/IEC 10646-1:2000 standard. This multi-byte representation encodes UCS2 or UCS4 characters reliably and deterministically, eliminating the need for a canonical byte ordering. In addition, NUL octets and other characters possibly confusing to POSIX file systems do not appear, except to represent themselves. It was realized that certain national codesets take up more space after the encoding, due to their placement within the UCS range; it was felt that the usefulness of the encoding of the names outweighs the disadvantage of size increase for file, user, and group names.

The encoding of UTF-8 is as follows:

```
UCS4 Hex Encoding  UTF-8 Binary Encoding

00000000-0000007F  0xxxxxxx
00000080-000007FF  110xxxxx 10xxxxxx
00000800-0000FFFF  1110xxxx 10xxxxxx 10xxxxxx
00010000-001FFFFF  11110xxx 10xxxxxx 10xxxxxx 10xxxxxx
00200000-03FFFFFF  111110xx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
```

```
04000000-7FFFFFFF  1111110x 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
```

where each `'x'` represents a bit value from the character being translated.

ustar Interchange Format

The description of the **ustar** format reflects numerous enhancements over pre-1988 versions of the historical *tar* utility. The goal of these changes was not only to provide the functional enhancements desired, but also to retain compatibility between new and old versions. This compatibility has been retained. Archives written using the old archive format are compatible with the new format.

Implementors should be aware that the previous file format did not include a mechanism to archive directory type files. For this reason, the convention of using a filename ending with <slash> was adopted to specify a directory on the archive.

The total size of the *name* and *prefix* fields have been set to meet the minimum requirements for {PATH_MAX}. If a pathname will fit within the *name* field, it is recommended that the pathname be stored there without the use of the *prefix* field. Although the name field is known to be too small to contain {PATH_MAX} characters, the value was not changed in this version of the archive file format to retain backwards-compatibility, and instead the prefix was introduced. Also, because of the earlier version of the format, there is no way to remove the restriction on the *linkname* field being limited in size to just that of the *name* field.

The *size* field is required to be meaningful in all implementation extensions, although it could be zero. This is required so that the data blocks can always be properly counted.

It is suggested that if device special files need to be represented that cannot be represented in the standard format, that one of the extension types (**A**-**Z**) be used, and that the additional information for the special file be represented as data and be reflected in the *size* field.

Attempting to restore a special file type, where it is converted to ordinary data and conflicts with an existing filename, need not be specially detected by the utility. If run as an ordinary user, *pax* should not be able to overwrite the entries in, for example, **/dev** in any case (whether the file is converted to another type or not). If run as a privileged user, it should be able to do so, and it would be considered a bug if it did not. The same is true of ordinary data files and similarly named special files; it is impossible to anticipate the needs of the user (who could really intend to overwrite the file), so the behavior should be predictable (and thus regular) and rely on the protection system as required.

The value 7 in the *typeflag* field is intended to define how contiguous files can be stored in a **ustar** archive. POSIX.1-200x does not require the contiguous file extension, but does define a standard way of archiving such files so that all conforming systems can interpret these file types in a meaningful and consistent manner. On a system that does not support extended file types, the *pax* utility should do the best it can with the file and go on to the next.

The file protection modes are those conventionally used by the *ls* utility. This is extended beyond the usage in the ISO POSIX-2 standard to support the "shared text" or "sticky" bit. It is intended that the conformance document should not document anything beyond the existence of and support of such a mode. Further extensions are expected to these bits, particularly with overloading the set-user-ID and set-group-ID flags.

100673 **cpio Interchange Format**

100674 The reference to appropriate privileges in the **cpio** format refers to an error on standard output;
100675 the **ustar** format does not make comparable statements.

100676 The model for this format was the historical System V *cpio*–**c** data interchange format. This
100677 model documents the portable version of the **cpio** format and not the binary version. It has the
100678 flexibility to transfer data of any type described within POSIX.1-200x, yet is extensible to transfer
100679 data types specific to extensions beyond POSIX.1-200x (for example, contiguous files). Because it
100680 describes existing practice, there is no question of maintaining upwards-compatibility.

100681 **cpio Header**

100682 There has been some concern that the size of the *c_ino* field of the header is too small to handle
100683 those systems that have very large *inode* numbers. However, the *c_ino* field in the header is used
100684 strictly as a hard-link resolution mechanism for archives. It is not necessarily the same value as
100685 the *inode* number of the file in the location from which that file is extracted.

100686 The name *c_magic* is based on historical usage.

100687 **cpio Filename**

100688 For most historical implementations of the *cpio* utility, {PATH_MAX} octets can be used to
100689 describe the pathname without the addition of any other header fields (the NUL character
100690 would be included in this count). {PATH_MAX} is the minimum value for pathname size,
100691 documented as 256 bytes. However, an implementation may use *c_namesize* to determine the
100692 exact length of the pathname. With the current description of the **<cpio.h>** header, this
100693 pathname size can be as large as a number that is described in six octal digits.

100694 Two values are documented under the *c_mode* field values to provide for extensibility for known
100695 file types:

100696 **0110 000** Reserved for contiguous files. The implementation may treat the rest of the
100697 information for this archive like a regular file. If this file type is undefined, the
100698 implementation may create the file as a regular file.

100699 This provides for extensibility of the **cpio** format while allowing for the ability to read old
100700 archives. Files of an unknown type may be read as "regular files" on some implementations. On
100701 a system that does not support extended file types, the *pax* utility should do the best it can with
100702 the file and go on to the next.

100703 **FUTURE DIRECTIONS**

100704 None.

100705 **SEE ALSO**

100710 **CHANGE HISTORY**

100711 First released in Issue 4.

Issue 5

A note is added to the APPLICATION USAGE indicating that the **cpio** and **tar** formats can only support files up to 8 gigabytes in size.

Issue 6

The *pax* utility is aligned with the IEEE P1003.2b draft standard:

- Support has been added for symbolic links in the options and interchange formats.
- A new format has been devised, based on extensions to **ustar**.
- References to the "extended" **tar** and **cpio** formats derived from the POSIX.1-1990 standard have been changed to remove the "extended" adjective because this could cause confusion with the extended *tar* header added in this version. (All references to *tar* are actually to **ustar**.)

The *TZ* entry is added to the ENVIRONMENT VARIABLES section.

IEEE PASC Interpretation 1003.2 #168 is applied, clarifying that *mkdir*( ) and *mkfifo*( ) calls can ignore an [EEXIST] error when extracting an archive.

IEEE PASC Interpretation 1003.2 #180 is applied, clarifying how extracted files are created when in **read** mode.

IEEE PASC Interpretation 1003.2 #181 is applied, clarifying the description of the **–t** option.

IEEE PASC Interpretation 1003.2 #195 is applied.

IEEE PASC Interpretation 1003.2 #206 is applied, clarifying the handling of links for the **–H**, **–L**, and **–l** options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/35 is applied, adding the process ID of the *pax* process into certain fields. This change provides a method for the implementation to ensure that different instances of *pax* extracting a file named **/a/b/foo** will not collide when processing the extended header information associated with **foo**.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/36 is applied, changing **–x B** to **–x** *pax* in the OPTIONS section.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/20 is applied, updating the SYNOPSIS to be consistent with the normative text.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/21 is applied, updating the DESCRIPTION to describe the behavior when files to be linked are symbolic links and the system is not capable of making hard links to symbolic links.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/22 is applied, updating the OPTIONS section to describe the behavior for how multiple **–odelete=pattern** options are to be handled.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/23 is applied, updating the **write** option within the OPTIONS section.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/24 is applied, adding a paragraph into the OPTIONS section that states that specifying more than one of the mutually-exclusive options (**–H** and **–L**) is not considered an error and that the last option specified will determine the behavior of the utility.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/25 is applied, removing the *ctime* paragraph within the EXTENDED DESCRIPTION. There is a contradiction in the definition of the *ctime* keyword for the *pax* extended header, in that the *st_ctime* member of the **stat** structure does not refer to a file creation time. No field in the standard **stat** structure from **<sys/stat.h>**

includes a file creation time.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/26 is applied, making it clear that *typeflag* 1 (**ustar** Interchange Format) applies not only to files that are hard-linked, but also to files that are aliased via symbolic links.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/27 is applied, clarifying the *cpio c_nlink* field.

Issue 7

Austin Group Interpretations 1003.1-2001 #011, #036, #086, and #109 are applied.

Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the *LC_MESSAGES* environment variable.

SD5-XCU-ERN-2 is applied, making **–c** and **–n** mutually-exclusive in the SYNOPSIS.

SD5-XCU-ERN-3 is applied, revising the default behavior of **–H** and **–L**.

SD5-XCU-ERN-5, SD5-XCU-ERN-6, SD5-XCU-ERN-7, SD5-XCU-ERN-60 are applied.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The *pax* utility is no longer allowed to create separate identical symbolic links when extracting linked symbolic links from an archive.

100771 **NAME**

100772 pr — print files

100773 **SYNOPSIS**

100774 `pr [+`*page*`] [–`*column*`] [–adFmrt] [–e[`*char*`][`*gap*`]] [–h` *header*`] [–i[`*char*`][`*gap*`]]`

100775 XSI `[–l` *lines*`] [–n[`*char*`][`*width*`]] [–o` *offset*`] [–s[`*char*`]] [–w` *width*`] [ –fp]`

100776 `[`*file*`...]`

100777 **DESCRIPTION**

100778 The *pr* utility is a printing and pagination filter. If multiple input files are specified, each shall be
100779 read, formatted, and written to standard output. By default, the input shall be separated into
100780 66-line pages, each with:

100781 • A 5-line header that includes the page number, date, time, and the pathname of the file

100782 • A 5-line trailer consisting of blank lines

100783 If standard output is associated with a terminal, diagnostic messages shall be deferred until the
100784 *pr* utility has completed processing.

100785 When options specifying multi-column output are specified, output text columns shall be of
100786 equal width; input lines that do not fit into a text column shall be truncated. By default, text
100787 columns shall be separated with at least one <blank>.

100788 **OPTIONS**

100789 The *pr* utility shall conform to XBD Section 12.2 (on page 215), except that: the *page* option has a
100790 '+' delimiter; *page* and *column* can be multi-digit numbers; some of the option-arguments are
100791 optional; and some of the option-arguments cannot be specified as separate arguments from the
100792 preceding option letter. In particular, the –**s** option does not allow the option letter to be
100793 separated from its argument, and the options –**e**, –**i**, and –**n** require that both arguments, if
100794 present, not be separated from the option letter.

100795 The following options shall be supported. In the following option descriptions, *column*, *lines*,
100796 *offset*, *page*, and *width* are positive decimal integers; *gap* is a non-negative decimal integer.

100797 **+***page* Begin output at page number *page* of the formatted input.

100798 –*column* Produce multi-column output that is arranged in *column* columns (the default shall
100799 be 1) and is written down each column in the order in which the text is received
100800 from the input file. This option should not be used with –**m**. The options –**e** and –**i**
100801 shall be assumed for multiple text-column output. Whether or not text columns are
100802 produced with identical vertical lengths is unspecified, but a text column shall
100803 never exceed the length of the page (see the –**l** option). When used with –**t**, use the
100804 minimum number of lines to write the output.

100805 –**a** Modify the effect of the –*column* option so that the columns are filled across the
100806 page in a round-robin order (for example, when *column* is 2, the first input line
100807 heads column 1, the second heads column 2, the third is the second line in column
100808 1, and so on).

100809 –**d** Produce output that is double-spaced; append an extra <newline> following every
100810 <newline> found in the input.

100811 –**e**[*char*][*gap*]

100812 Expand each input <tab> to the next greater column position specified by the
100813 formula *n***gap*+1, where *n* is an integer > 0. If *gap* is zero or is omitted, it shall
100814 default to 8. All <tab> characters in the input shall be expanded into the
100815 appropriate number of <space> characters. If any non-digit character, *char*, is
100816 specified, it shall be used as the input <tab>. If the first character of the –**e** option-

argument is a digit, the entire option-argument shall be assumed to be *gap*.

XSI **–f** Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline> characters. Pause before beginning the first page if the standard output is associated with a terminal.

–F Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline> characters.

–h *header* Use the string *header* to replace the contents of the *file* operand in the page header.

–i[*char*][*gap*] In output, replace <space> characters with <tab> characters wherever one or more adjacent <space> characters reach column positions *gap*+1, 2* *gap*+1, 3* *gap*+1, and so on. If *gap* is zero or is omitted, default tab settings at every eighth column position shall be assumed. If any non-digit character, *char*, is specified, it shall be used as the output <tab>. If the first character of the **–i** option-argument is a digit, the entire option-argument shall be assumed to be *gap*.

–l *lines* Override the 66-line default and reset the page length to *lines*. If *lines* is not greater than the sum of both the header and trailer depths (in lines), the *pr* utility shall suppress both the header and trailer, as if the **–t** option were in effect.

–m Merge files. Standard output shall be formatted so the *pr* utility writes one line from each file specified by a *file* operand, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations shall support merging of at least nine *file* operands.

–n[*char*][*width*]
Provide *width*-digit line numbering (default for *width* shall be 5). The number shall occupy the first *width* column positions of each text column of default output or each line of **–m** output. If *char* (any non-digit character) is given, it shall be appended to the line number to separate it from whatever follows (default for *char* is a <tab>).

–o *offset* Each line of output shall be preceded by offset <space> characters. If the **–o** option is not specified, the default offset shall be zero. The space taken is in addition to the output line width (see the **–w** option below).

–p Pause before beginning each page if the standard output is directed to a terminal (*pr* shall write an <alert> to standard error and wait for a <carriage-return> to be read on **/dev/tty**).

–r Write no diagnostic reports on failure to open files.

–s[*char*] Separate text columns by the single character *char* instead of by the appropriate number of <space> characters (default for *char* shall be <tab>).

–t Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.

–w *width* Set the width of the line to *width* column positions for multiple text-column output only. If the **–w** option is not specified and the **–s** option is not specified, the default width shall be 72. If the **–w** option is not specified and the **–s** option is specified, the default width shall be 512.

For single column output, input lines shall not be truncated.

OPERANDS

The following operand shall be supported:

file A pathname of a file to be written. If no *file* operands are specified, or if a *file* operand is `'-'`, the standard input shall be used.

STDIN

The standard input shall be used only if no *file* operands are specified, or if a *file* operand is `'-'`. See the INPUT FILES section.

INPUT FILES

The input files shall be text files.

The file **/dev/tty** shall be used to read responses required by the **-p** option.

ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of *pr*:

LANG Provide a default value for the internationalization variables that are unset or null. (See XBD Section 8.2 (on page 174) the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as printable (character class **print**). Non-printable characters are still written to standard output, but are not counted for the purpose for column-width and line-length calculations.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format of the date and time for use in writing header lines.

XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC_MESSAGES*.

TZ Determine the timezone used to calculate date and time strings written in header lines. If *TZ* is unset or null, an unspecified default timezone shall be used.

ASYNCHRONOUS EVENTS

If *pr* receives an interrupt while writing to a terminal, it shall flush all accumulated error messages to the screen before terminating.

STDOUT

The *pr* utility output shall be a paginated version of the original file (or files). This pagination shall be accomplished using either <form-feed> characters or a sequence of <newline> characters, as controlled by the **-F** or **-f** option. Page headers shall be generated unless the **-t** option is specified. The page headers shall be of the form:

XSI

```
"\n\n%s %s Page %d\n\n\n", <output of date>, <file>, <page number>
```

In the POSIX locale, the <*output of date*> field, representing the date and time of last modification of the input file (or the current date and time if the input file is standard input), shall be equivalent to the output of the following command as it would appear if executed at the given time:

```
date "+%b %e %H:%M %Y"
```

without the trailing <newline>, if the page being written is from standard input. If the page being written is not from standard input, in the POSIX locale, the same format shall be used, but the time used shall be the modification time of the file corresponding to *file* instead of the current time. When the *LC_TIME* locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the standard input is used instead of a *file* operand, the <*file*> field shall be replaced by a null string.

If the –**h** option is specified, the <*file*> field shall be replaced by the *header* argument.

STDERR

The standard error shall be used for diagnostic messages and for alerting the terminal when –**p** is specified.

OUTPUT FILES

None.

EXTENDED DESCRIPTION

None.

EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

CONSEQUENCES OF ERRORS

Default.

APPLICATION USAGE

A conforming application must protect its first operand, if it starts with a <plus-sign>, by preceding it with the "`--`" argument that denotes the end of the options. For example, *pr+x* could be interpreted as an invalid page number or a *file* operand.

EXAMPLES

1. Print a numbered list of all files in the current directory:

   ```
   ls –a | pr –n –h "Files in $(pwd)."
   ```

2. Print **file1** and **file2** as a double-spaced, three-column listing headed by "file list":

   ```
   pr –3d –h "file list" file1 file2
   ```

3. Write **file1** on **file2**, expanding tabs to columns 10, 19, 28, . . .:

   ```
   pr –e9 –t <file1 >file2
   ```

RATIONALE

This utility is one of those that does not follow the Utility Syntax Guidelines because of its historical origins. The standard developers could have added new options that obeyed the guidelines (and marked the old options obsolescent) or devised an entirely new utility; there are examples of both actions in this volume of POSIX.1-200x. Because of its widespread use by historical applications, the standard developers decided to exempt this version of *pr* from many of the guidelines.
