# THE MINERAL INDUSTRY OF GERMANY

### By Steven T. Anderson

#### Import and export tables were prepared by Glenn J. Wallace, international data coordinator.

In 2004, the mineral industry of Germany continued to depend heavily on imports of raw mineral materials to support the country's extensive mineral-processing capacity, although this capacity has been decreasing steadily for more than a decade. In turn, much of the processed mineral commodity output, especially in the metals sector, was exported. Germany's ability to continue to add sufficient value in processing minerals that originate outside of the country depends on the country's efficient, highly skilled labor force; technological advances, especially in recycling; retaining, improving, and expanding free trade alliances; and keeping input costs, especially with respect to labor and energy expenditures, as low as possible. In 2004, German exporters were also slightly more competitive in all manufacturing industries as a consequence of the country's lower inflation rate compared with that of most of the rest of the members of the European Union (EU), which were the primary consumers of mineral commodity exports from Germany (Deutsches Institut für Wirtschaftsforschung, 2004, p. 6).

In 2004, Germany's gross domestic product (GDP) based on purchasing power parity was about \$2,392 billion (International Monetary Fund, 2005§1). Mine production of minerals contributes only about 1% to the nominal GDP annually, but Germany still ranked as the world's leading producer of lignite and its third-leading producer of potash. The country also was the second-leading producer of kaolin in the EU and one of the leading European producers of crude gypsum, feldspar, and salt. The country exports about 30% of its total mine production, annually. For the most part, no metal is directly mined in Germany. A well-developed steel and nonferrous metals processing industry depended upon imports of raw metal minerals and accounted for about 6% to 7% of the GDP. The production levels of some of these metals and that of some industrial minerals were very significant on a worldwide scale. In 2004, Germany was the leading producer of crude steel in the EU and the sixth ranked producer in the world. Recycling of minerals from secondary sources to produce a growing set of metal commodities was not separately included in the officially recorded share of the GDP accounted for by production of the metal processing sector, but it was the most rapidly growing component of Germany's mineral industry in 2004 (Gwosdz and others, 2004; Mildner, undated§; Stahl-Zentrum, 2005§; Thomson Corporation, 2005§).

Continuing dependence on trade for the German mineral industry was consistent with a reliance on trade for the German economy, overall. One-third of the jobs in Germany were expected to be either directly or indirectly dependent on exports by 2005 (Bundesverband der Deutschen Industrie e.V., 2005a§). In 2004, exports accounted for more than one-third of Germany's GDP and reached a record annual value in euros (Deutsches Institut für Wirtschaftsforschung, 2004, p. 5). The euro exchange rate, which, relative to the U.S. dollar, remained high in 2004, helped shield the mineral industry in Germany from paying higher costs for the necessary imports of mineral raw materials, especially metals, which were valued in U.S. dollars (RAG-Magazin, 2005). The downside of the high exchange rate was that Germany's mineral commodity products, which were valued in euros, were harder to price competitively for export outside of the EU. In 2004, international access to more raw minerals and scrap metal (particularly from Poland) was improved by the official expansion of the EU to include 10 additional countries (mostly in Eastern Europe) on May 1. This EU expansion provides additional markets where the German mineral industry will have a more-competitive position for its exports (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 26, 78). In 2004, the growth rate of the real GDP was about 1.6% compared with an approximately 0.2% decrease in 2003 (International Monetary Fund, 2005§). This increased growth in economic output was primarily owing to an increase of about 8.7% in the real value of German exports during the same time period (International Monetary Fund, 2004§).

In 2004, many important concerns with the German economy, which included sluggish domestic demand, weak investment spending, and a persistent crisis in the construction sector, were also of concern to the country's mineral industry. Excess residential construction in the 1990s was most frequently blamed for the construction slowdown during the past 5 years, but residential construction was reported to have recovered somewhat in 2004. There still appeared to be a shortage of other construction, particularly public construction projects, however (HeidelbergCement AG, 2005, p. 19). Structural reforms of the German economy, which were aimed at alleviating the increasing economic pressure on major manufacturing firms (including major producers in the minerals industry) to shift production or more processing overseas, appeared to make some progress in 2004. These reforms included reducing inflexibility and overregulation in labor markets, alleviating some of the tax burden on these manufacturing firms, encouraging the establishment of new businesses in Germany, and enacting some measures to limit high social insurance costs. Domestically, however, such measures have limited efficacy when the economy depends so profoundly on exports and consumption trends in foreign countries. Also, technological advances and greater efficiencies in the labor force, as Germany has exhibited in its mineral industry, can result in greater unemployment, even with deregulation. Persistent high unemployment remained Germany's most sensitive political and economic issue in 2004. The mining and primary metal-processing sectors of the mineral

<sup>&</sup>lt;sup>1</sup>References that include a section mark (§) are found in the Internet References Cited section.

industry combined to employ about 1.1 million out of an officially eligible labor force of about 43.1 million people in the country (International Monetary Fund, 2004, p. 34, 45; Mildner, undated§; U.S. Commercial Service, 2005§).

#### **Government Policies and Programs**

In 2004, German concern with shortages of coke to supply its steel manufacturing sector and a growing concern with securing a consistent energy supply and supply of many other raw mineral materials led German authorities to renew debates on appropriate trade policy, environmental restrictions, energy resource diversification, and subsidizing hard coal production. Like the rest of the industrial world, Germany's ability to compete for mineral resources has been most recently perturbed by considerable growth in mineral resource consumption by Brazil, Russia, India, and China (BRIC); as much as 5% annual growth in resource consumption in these countries during the next 30 years is expected (Bundesanstalt für Geowissenschaften und Rohstoffe, 2004a). Given the economic dependence of Germany (and most fully industrialized countries) on imports of raw materials, the country has had to revise its energy and raw materials security policy repeatedly since the early 1970s. This strategy emphasizes maintaining a secure supply of mineral and other raw materials from countries where these materials are more abundant. The basic principles and rationale of this strategy have been basically unchanged since 1997, but changes to energy, trade, and raw materials policies as components of this overall strategy were being proposed in Germany toward the end of 2004 (Adamowitsch, 2004§; Bundesverband der Deutschen Industrie e.V., 2005a§).

Germany has few deposits of hydrocarbons or metallic and industrial minerals, but the country does contain large deposits of hard (bituminous) coal, lignite, and salt. Only the mining of hard coal in Germany was still directly subsidized in 2004, and one goal set in 1997 as part of the raw materials policy was to gradually phase out that subsidy by 2005. In 2003, however, this coal subsidy program was actually extended through 2012, although the Government has targeted regular decreases in the real value of the subsidy during that time (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 66). The trade policy component of the raw materials security strategy is basically aimed at further multilateral and bilateral reduction of tariffs in all countries, starting with German tariffs on imports of the raw materials necessary for the survival of the country's industries. Because Germany imports extensive quantities of raw materials from all over the world, the Government is concerned with securing imports from the mineral-producing countries, which supply ores, concentrates, and ferroalloys and other industrial countries, which also have processing industries (foundries, refineries) but can export unrefined metals and semifinished products to Germany (Adamowitsch, 2004§).

Germany's minerals policies have also traditionally emphasized the growing importance of recycling used domestic mineral-containing materials and imported scrap in the country. Germany also has a long history of applying the latest advances in materials research and development through which the use of raw mineral material can be optimized. Germany's raw materials strategy has been described by the following basic objectives since 1997:

• Maintain the efficiency of and further opening of the world's minerals markets;

• Stabilize commodity export earnings, especially in the less developed countries, with the aim of ensuring continuous supplies of raw mineral materials;

• Accelerate the industrialization process in and facilitate the transfer of technology to developing countries;

• Open the markets of all industrial countries to imports of manufactures and semimanufactures from the developing countries;

• Promote the flow of capital to the developing countries and protect investors from expropriation; and

• Explore new mineral deposits by means of cooperative projects (German Embassy, Washington, DC, 2005§).

In 2004, tighter markets for many mineral commodities, especially metals, and the expectation of normal lags in development of additional global mineral production capacity encouraged the German Government to contemplate adjusting this raw materials security strategy. For example, to maintain diversity in the energy supply, the Government could phase out the use of nuclear power less rapidly than was set out in 1997. Other proposed adjustments included decreasing domestic tariffs on raw materials, increasing support of multilateral tariff reduction through the World Trade Organization (WTO), and decreasing trade barriers bilaterally with countries that export raw materials to Germany, but are not part of the WTO. Additionally, the Government encouraged universal agreement on environmental standards, such as those set out in the Kyoto Protocol, to maintain the international competitiveness of Germany's mineral-using industries and support a sustainable global allocation of the consumption and use of minerals (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 70; Bundesverband der Deutschen Industrie e.V., 2005b§). Toward the end of 2004, some German officials also considered that it may be necessary to solicit the EU to protect against increasing exports of metal scrap to China and elsewhere by classifying scrap metal as a strategically important economic resource (Köhl, 2004).

#### **Environmental Issues**

In 2004, industry officials expressed concern that the raw materials debate in Germany and the EU had focused too much on the environmental costs of intensive mineral use and on plans for divesting Germany of industrial and consumer reliance on certain types of natural resources, such as uranium, and that too little emphasis had been placed on German industry's economic dependency on imports of raw materials, which included metals, industrial minerals, and mineral fuels. With respect to mineral fuels, industrial leaders in Germany claimed that there is an essential compatibility between Germany's obligation to protect the climate and environment and a strategy to maintain diversity in the country's energy supply (Bundesverband der Deutschen Industrie e.V., 2005, 2005b§).

In 2002, the Government adopted a new National Sustainability Strategy, which has many components directly

relevant to the mining industry. The first progress report on this Strategy was published in autumn 2004 and stated that the productivity of raw mineral materials had increased by about 28% since 1994. This increase was partly owing to the reduction of mineral waste, more recycling of mineralcontaining products, and substitution of regenerative technologies for some less efficient mineral uses. It was also partly owing to a decrease in the of use of mineral materials in end-use construction and other nonrecyclable use, as well as decreased production and use of hard coal and lignite in Germany's energy mix. Germany has used many of the latest technologies to burn coal with low emissions of toxic substances; as a result, the social and environmental costs of burning coal are estimated to be not much higher (and may even be lower) than using other energy sources. The costeffectiveness of coal use is hampered, however, by the high costs of developing, installing, and using the cleaner technologies. Additionally, production of hard coal is even less cost-effective than production and use of lignite because exploitable hard coal is available only very far underground in Germany (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 68-69).

The National Sustainability Strategy also aimed to reduce emissions of the six greenhouse gases named in the Kyoto Protocol by 21% from the base years 1990 to 1995 as soon as 2008 and no later than 2012. Germany had already come close to this goal with the reduction of 18.5% achieved by the end of 2003, which was achieved mainly by reducing emissions in the energy sector, which included lowering coal usage, and in the manufacturing industries, which included mineral processing. Reports of excessive carbon dioxide emissions by the energy industry have been noted again in recent years, however, mainly owing to some reclassifications of acceptable limits in the energy sector and to some coal-fired power stations starting up operations. Germany has also implemented an emissions permit trading policy as an efficient method to comply with the Kyoto Protocol (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 69-70).

Another part of the National Sustainability Strategy that is directly relevant to the mining industry is the German Government's joint position on a draft proposal for a uniform EU system for the registration, evaluation, and authorization of chemicals in conjunction with the Chemical Industry Association and the Mining, Chemicals, and Energy Union, which represent the branches of German industry that will be most affected by the proposal. This draft regulation would provide for registration of production of all chemical substances that exceed 1 metric ton per year (t/yr), greater responsibility for industry to control substances of concern, and a possible approvals procedure for some particularly dangerous chemical substances (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 70-71).

The Bundesministerium für Umwelt, Naturschutz und Reaktorsicherheit (BMU) is responsible for protecting the environment in Germany and for the following main relevant Federal agencies: the Umweltbundesamt (UBA), in Dessau, whose mission is to provide scientific and technical support for the Ministry; the Bundesamt für Naturschutz (BfN), in Bonn, which advises the Ministry on all issues that relate to national and international nature conservation and landscape management, promotes nature conservation activities, supports research projects, and acts as the authority permitting the import and export of protected species of animals and plants; and the Bundesamt für Strahlenschutz (BfS), in Salzgitter, which is a Federal scientific agency that specializes in developing advanced methods and policies in the fields of radiation protection, nuclear safety, transport and custody of nuclear fuels, and final disposal of radioactive waste (Bundesministerium für Umwelt, Naturschutz und Reaktorsicherheit, 2005§).

EU environmental directives require that the member nations (such as Germany) reach certain environmental objectives by a set date, and that the provisions of the directives have to be included as part of the national laws of all members. These EU directives usually outline general rules but seldom set out any detailed requirements and do not regulate how the directive is to be implemented. Directives are the most frequently used policy instruments in EU environmental policy.

After reunification of the former German Democratic Republic (GDR) and the former Federal Republic of Germany (FRG), Germany's most costly environmental problems have often involved reducing waste and counteracting environmental damage done by the mining industry of the former GDR. The largest challenges have been related to achieving a publicly acceptable and cost-effective environmental decommissioning of the former GDR's uranium mining and processing industry (Bundesministerium für Wirtschaft und Arbeit, 2004, p. 20).

The ongoing cleanup of the former state-owned Wismut GmbH uranium mining operations in Saxony and Thuringia (in the former GDR) was viewed as Europe's biggest mine rehabilitation project. According to German environmental policy, the costs to remediate contamination at mining sites, such as coal mining sites, are funded 60% out of Federal funds and 40% out of State government funds. In the case of Wismut, 100% of the costs are being funded by the Federal Government because of the urgency of the problem, which is complicated by the close proximity of large populations. At various sites, 48 waste rock piles contained about 311 million cubic meters of waste material and covered a surface area of about 15 square kilometers (km<sup>2</sup>). In addition, 14 tailings ponds contained 160 million cubic meters of residues from uranium-ore-processing plants and covered a surface area of 7 km<sup>2</sup>. As of 2002, more than one-half of the remediation was completed, and the rest of the initial cleanup work was scheduled to be completed in the next 6 to 8 years. Post-cleanup work will continue for quite some time after that, and the governments of Saxony and Thuringia are expected to bear some of the financial burden for those operations. The initial cleanup work in 2004 focused on decommissioning facilities and immobilizing contaminated material in a manner that would limit long-term hazards to humans and the environment (Bundesministerium für Umwelt, Naturschutz und Reaktorsicherheit, 2002, p. 37; Bundesministerium für Wirtschaft und Arbeit, 2004, p. 20-21).

Additional environmental concerns that relate to new mining projects and compliance with EU directives are addressed under the German mining law and its provisions for environmental impact assessments that must be completed before mining can start. The requirements of these assessments for mining were revised to comply with EU directives in 1990. The objective is to identify and evaluate all environmental consequences of a planned mining project by taking into account various design options. The environmental evaluation process in Germany presents a risk for the company involved because project approval is not guaranteed even after completion of the assessment, which usually involves considerable time and resources (UWS Umweltmanagement GmbH, 2005§).

#### Production

Even without strong domestic demand, increased international prices for most metals in 2004 helped spur increased annual production of many ferrous and nonferrous metals in Germany. Germany produced many of these metals as byproducts of other metal or industrial mineral ore (mostly imported) that was processed in Germany. From ore that was mined domestically, the quantity of copper-silver concentrate recovered as a byproduct of fluorspar and barite mining was very small in 2004. The high costs of production in Germany compared with those of competing foreign producers and the problems caused by trying to balance production in the reunified Germany continued to constrain production. In 2004, Germany was still one of the world's leading producers of aluminum metal, barite, bentonite, cement, feldspar, kaolin, lignite, pig iron and steel, potash, and salt (Gwosdz and others, 2004).

#### Trade

In 2004, other member countries of the newly expanded EU were the leading recipients of exports from Germany's mineral industry. In 2003, German trade relationships with the newest members of the EU were already established. Outside the EU, Japan and the United States were Germany's major trading partners, although China has also recently become a moreprominent recipient of Germany's mineral exports. Besides importing raw minerals, processing them, and then exporting more-finished mineral products, the ports of Germany have also traditionally made Germany an important transshipper of ores and concentrates to other EU countries, especially to the south and east of Germany. In the past few years, Germany has successfully extended this role to provide transshipments of raw mineral commodities to many countries in Asia, especially China. For example, almost all Germany's exports of lead ore and concentrate and molybdenum ore and concentrate went to China in 2003. Germany's other notable metal exports to China were arsenic metal, copper oxides and scrap, nickel oxides, platinum-group metals (PGM), titanium oxide, and zinc scrap and semimanufactures (table 3).

EU countries imported mostly refined metal products from Germany but also significant quantities of cement, coal briquets, dimension stone, feldspar, fertilizers, gypsum and plaster, kaolin, lignite, lime, limestone, peat, quartz, refractory-grade dolomite, salt and brine, and silica sand. Particularly in the steel sector, German firms have had successful mineral joint ventures, cooperative projects, and foreign direct investment (FDI) ventures in China since the beginning of China's reforms to "open" certain areas of commercial interest to the rest of the world. For example, a joint group of two German companies and Wuhan Iron and Steel Corporation (became Wuhan Iron and Steel Group in 2004) cooperated to create two large-scale steel facilities in China early in the 1970s. The Chinese city of Wuhan also became a sister city with the German city of Duisberg in 1982, and the Lower Rhine Chamber of Commerce set up an office in Wuhan in 1996. This is one of many examples of the long-term cooperative economic relationships between the Chinese and the German Governments that continue to allow German automobile components manufacturers, steel and other metal processing firms, and, more recently, engineering and financial firms to pursue foreign ventures in China with less political risk than many foreign rivals (Berry, 1997§; Pengxi, 2002§).

In 2004, Germany relied heavily on imports to feed the metals-processing industry. Some of the more-prominent suppliers of the critical raw minerals were Brazil for iron ore and concentrate; Chile for copper and molybdenum ores and concentrates; China for antimony oxides, magnesium oxides, and manganese metal; Guinea and Jamaica for bauxite and alumina; Russia for unwrought nickel metal; and South Africa for chromium, ferrochromium, and PGM. Germany also relied on imports of wrought metal, semimanufactures, and scrap for its large recycling capacity and secondary metal production. Imports of finished products, semifinished products, and scrap came mostly from EU countries, although some neighboring countries also functioned as transshippers to Germany of ores and concentrates from less developed countries. For example, Germany imported significant amounts of zinc ore and concentrate from Belgium in 2003. The nonferrous metal industry in Germany also imported a significant proportion of its raw materials requirements (mostly mineral fuels), semiprocessed mineral commodities, and scrap from many Eastern European countries, particularly Russia (table 4).

With respect to trade in industrial minerals, Germany was a major supplier of many mineral commodities to the rest of the (pre-expansion) EU in 2003. It imported significant quantities of barite from China; boron from Turkey; clays from the Czech Republic; fluorspar from China, Namibia, and South Africa; and phosphates from Israel. Germany also relied on imports of coal from Poland, Russia, and South Africa; coke from China and Poland; and crude petroleum from Russia (table 4). In 2004, the Government considered an extremely wide variety of minerals in its negotiations with the Governments of industrialized and developing countries in seeking to modernize Germany's trade policy and thereby increase the security of the country's supply of minerals for industrial and consumer use.

#### Structure of the Mineral Industry

The mineral industry in Germany is structured around trade. Toward the end of 2004, the mineral industry of Germany experienced import shortages of some critical raw materials. In the steel industry, international competition for iron ore and coke, mostly from China, meant that imports of scrap into Germany increased, but not enough to cover German domestic and export demand for steel in 2004. Germany ranked fifth in the world in apparent steel consumption in 2004; China was first. Also, Germany depended on imports for about 90% of the steel alloy metals (ores, concentrates, oxides, and ferroalloys) annually required by the country's steel industry (Bundesanstalt für Geowissenschaften und Rohstoffe, 2004b). In 2004, despite increasing costs of minerals on most markets, Germany still spent, in euros, only slightly more for imports of minerals (metals, nonmetals, precious metals, gemstones, and energy resources) even during times of significant price increases for oil (Bundesanstalt für Geowissenschaften und Rohstoffe, 2004b). This was largely owing to the strength of the euro relative to the U.S. dollar (Christian and Fels, 2004§).

The nonferrous metal sector relied heavily on imports for its raw materials as well, although this sector obtained a higher proportion of its overall output from the reprocessing of scrap and waste material than the ferrous metal sector. Technological advances have allowed Germany to be more efficient in using these secondary materials and recycling in the production of metals and nonmetals. In 2004, Germany continued to lead the EU in secondary production of metals and continued to make advances in recycling technology. New capacity to recycle electrical and electronic scrap served to boost secondary production of ferrous and nonferrous metals in 2004. At least one plant was able to obtain 67% of the weight of waste electrical and electronic equipment (WEEE) in metal, of which 43% was ferrous metal, and 24%, nonferrous. According to the managing director of this German plant, aluminum constituted only from 3% to 5% of the WEEE, but the aluminum output of the plant had a 90% pure aluminum content. Also, the plant required about 14 metric tons (t) of WEEE to produce 1 t of copper and about 70,000 t of electronic scrap to produce 1 t of gold, which was a better production ratio than that for the 200,000 t of ore typically required to produce the same amount of pure gold (Vollrath, 2004). Byproducts from German nonferrous metal refineries, German scrap production, and some imports of metal and scrap were responsible for supplying all the domestic demand for precious metals (Bundesanstalt für Geowissenschaften und Rohstoffe, 2004b).

Most of the mines and associated mineral processing plants in Germany that were still in operation in 2004 were small compared with those in the former FRG, except for mining operations to produce lignite and potash. Germany was the world's fourth leading producer of potash in 2004 and the third leading producer of salt. Domestic demand for most mineral commodities has been consistently very weak since the mid-1990s, which has led to an even greater dependence on exports to generate revenues for the mineral industry (Christian and Fels, 2004§). Because production of many industrial minerals is subject to lower profit margins and higher transportation costs per metric ton, the decline in the German construction industry during the same time period has encouraged lower production of cement, crushed stone, sand and gravel, and other industrial minerals and metals that are not as attractive on the export market. German use of refined aluminum, copper, lead, tin, and zinc amounted to more than 4 million metric tons (Mt) in 2003 (Bundesanstalt für Geowissenschaften und Rohstoffe, 2004b). In 2004, about 6 million people were employed in the mineral and manufacturing industries, combined, which was 1.9% less than in 2003 (Statistisches Bundesamt Deutschland, 2005§).

#### **Commodity Review**

#### **Metals**

Aluminum.-In 2004, rising energy costs were of the greatest concern to Germany's primary aluminum smelting and alumina refining industry. Norsk Hydro ASA accounted for more than 75% of the country's primary aluminum production with a 100% interest each in two primary plants in Neuss and Stade and a 33% interest in a third primary smelter in Hamburg. Hydro wrote down the book value of these three primary aluminum plants at the end of 2004 mainly because of higher-than-expected energy costs and also partially because their revenues (in euros) were insufficient to support their book values as long as the euro remained strong (as measured against the U.S. dollar). The energy contracts for these plants were set in 2002 when Hydro acquired VAW Aluminium AG. Those contracts were due to expire at the end of 2005, and Hydro expected an even higher increase in energy costs by that time than was budgeted into the book value of these plants in 2002 (Norsk Hydro ASA, 2004§).

A strong euro is expected to help buffer the costs of producing aluminum because the raw materials, such as bauxite and alumina, that are imported into Germany are valued in U.S. dollars. Hydro divested itself of some of VAW's previously owned interests in Germany and abroad, which were used to help ensure a supply of metal for VAW's former downstream fabricating operations. On June 30, 2004, Hydro finished divesting itself of any alumina production capacity in Germany by selling its 50% interest in Aluminium Oxid Stade GmbH (AOS), which had been acquired from VAW in 2002. DADCO Alumina & Chemicals Ltd. (based in the United Kingdom) obtained sole control over AOS by acquiring Hydro's 50% interest in 2004. DADCO already controlled the other 50% after acquiring it from Alcoa Inc. in 2001. In 2004, DADCO's ability to control sales prices for alumina in the United Kingdom and the EU was investigated before the acquisition was finally cleared by the United Kingdom's Office of Fair Trading on October 29, 2004. Another fair trading concern was that DADCO would substantially control the supply of bauxite into the EU as a result of the company's long-term contract with Alcoa to purchase bauxite from Jamaica and the acquisition of Hydro's 10% interest in Halco Mining Inc. as part of DADCO's acquisition of Hydro's interest in AOS. Halco was a participant in a Guinea bauxite mining joint venture, but DADCO's interest was not deemed to constitute sufficient control of this necessary input into alumina and aluminum metal production to warrant EU sanctions on the deal. Still, AOS did essentially remain an alumina monopoly in Germany, and the company's (and Germany's) access to foreign sources of bauxite was solidified through the DADCO acquisition (Office of Fair Trading, 2004§).

Secondary aluminum production continued to flourish in 2004, but increased competition for scrap metal, especially from China, caused some German authorities and other interested Europeans to call for trade protection on exports of nonferrous scrap metal, which included aluminum, toward the end of the year. Legal grounds for limiting the export of scrap metal from many European countries may rely upon the redefinition of scrap as an essential raw material or resource for the EU (Köhl, 2004). German demand for secondary aluminum, especially from major car manufacturers, increased in 2004, which encouraged Metallhüttenwerke Bruch GmbH to increase capacity by 30,000 t/yr in 2005, and reinforced the decision by VAW-IMCO Guss und Recycling GmbH to build a new aluminum recycling plant by 2006 (Metal Bulletin, 2004c; IMCO Recycling Inc., 2004§).

Copper.—Norddeutsche Affinerie AG (NA) operated the custom smelter and refinery at Hamburg and was the world's fifth ranked custom copper smelter with a production capacity of about 500,000 t/yr of copper cathode, 320,000 t/yr of copper rod, and 176,000 t/yr of copper billets and cake. Since its acquisition of Hüttenwerk Kayser AG (HK) in 2000, NA has essentially become a monopoly with respect to copper metal production in Germany and controls much of the secondary, as well as primary, production of the metal. As a result of higher metal prices, the global supply of copper concentrate increased substantially in 2004 but at a substantially higher cost to companies like NA. Therefore, NA decided to close down and refurbish parts of its main smelting facilities for part of the year, and annual production of custom copper metal products by NA decreased slightly in 2004 compared with that of 2003, although the company's production of cathodes from the refinery portion of the operation increased during the same timeframe (Norddeutsche Affinerie AG, 2005, p. 40-43).

NA faced strong competition from Chinese buyers for German scrap metal, but that competitive pressure appeared to relent somewhat toward the end of 2004 as China attempted to slow down its rapidly increasing demand for copper. Secondary smelter production of copper by NA was nonetheless lower in 2004 compared with that of 2003 because the international price of copper scrap was bid up above an economical level for German processing. Germany also did not have much domestic supply of scrap to direct toward domestic secondary smelters because the moribund German construction industry did not replace many existing copper-containing structures in 2004. More sources of copper scrap are expected to be available to NA in 2005 because the company developed a more-advanced recycling technology in 2004 that will allow it to recover an increased proportion of the potential copper contained in a wide set of sources, including the automotive, electronics, and engineering industries (Norddeutsche Affinerie AG, 2005, p. 42-43).

In 2003 and through the first quarter of 2004, NA went through a major restructuring to lower production costs and to coordinate production in the face of increasing costs for copper concentrate and scrap. This involved reducing secondary production at HK's Lünen plant and HK's workforce by about 30%. Among other restructuring steps were the streamlining of the Kayser Recycling System (KRS) and the eventual amalgamation of HK into NA as NA's main recycling center on March 1, 2004. The KRS was developed by HK, which claimed that it would be the most advanced copper recycling system in the world with high levels of environmental and energy efficiencies and the ability to process alternate feed, such as electronic scrap products. This new technology increased the capacity of the Lünen plant to process 40% more input from a much wider set of sources. The new system also improved the recovery of complex materials to convert more of the byproducts, such as gold, lead, nickel, palladium, platinum, selenium, and silver, in the copper concentrates and secondary raw materials into high-grade products (Norddeutsche Affinerie AG, 2005, p. 23, 53).

Magnesium.-VAW-IMCO Guss und Recycling GmbH (a subsidiary of U.S.-based IMCO Recycling Inc.) was on schedule to start producing magnesium in December 2004. This production was to come from a new facility that would produce magnesium out of scrap next to VAW-IMCO's secondary aluminum refining plant in Töging. It was not completed by the end of 2004, and only 5,000 t of the designed capacity of 15,000 t/yr of magnesium was expected to be produced in 2005. About 90% of the cast magnesium ingots from the plant were expected to be sold to the European automobile industry, and IMCO obtained an initial contract to recycle BMW engine blocks for reuse by BMW (IMCO Recycling Inc., 2004§). On December 9, 2004, Aleris International Inc. was formed through a merger of Commonwealth Industries, Inc. with IMCO Recycling Inc., and VAW-IMCO became a wholly owned subsidiary of Aleris (Aleris International Inc., 2004§). In 2004, the price of magnesium surged owing to shortages of supply out of China, and this encouraged an increase in German recycling that resulted in an increase of slightly greater than 6% in production of magnesium castings (Köhl, 2004).

Iron and Steel.—Europe's steel industry has become increasingly consolidated since the privatization and closure of many Eastern European steel plants. This sector of the EU economy was dominated by a few large steel producers, which included the leading German-based steal producer ThyssenKrupp Group. In 2004, ThyssenKrupp had a global production capacity of about 19 million metric tons per year (Mt/yr) of crude steel and it was the 10th ranked crude steel producer in the world. ThyssenKrupp Stahl AG controlled German production for ThyssenKrupp Group and was the leading steel producer with an estimated production capacity within Germany of about 12 Mt/yr (ThyssenKrupp Stahl AG, 2005, p. 16-17). The Luxembourg-based Arcelor Group was the leading crude steel producer in the world (44-Mt/yr capacity) and was the second ranked producer in Germany with subsidiaries that included Stahlwerke Bremen GmbH (4-Mt/yr capacity) and EKO Stahl GmbH (2.5-Mt/yr capacity) (Stahlwerke Bremen GmbH, 2005§).

Theoretically, the latest wave of increased consolidation in the steel industry that began globally at the end of the 1990s was expected to help stabilize steel prices because fewer firms will have better control over supply (MEPS International Ltd., 2005§). In 2004, however, increased demand, primarily in Germany's steel export market, put pressure on German steel producers to increase domestic production capacity rather than to continue to import an increasing amount of raw materials, scrap, and finished steel. In 2004, the increasing German reliance on imports for the country's steel production sector was mostly met by other EU countries, which included many of the new Eastern European members that officially became a part of the EU on May 1, but it also needed to import materials from outside of the EU, which were only sporadically available (Stahl-Zentrum, 2005§). Therefore, there were occasional shortages of raw materials, especially coke, and long delays in fulfilling orders for German steel products in 2004 (ThyssenKrupp Stahl AG, 2005, p. 11, 22). Germany's leading coke producer RAG Aktiengesellschaft reported that German steelmakers could face coke shortages of between 2 and 4 Mt/yr for the next 10 years if German coke-making capacity does not expand (Metal Bulletin, 2004b). In addition, Chinese imports of ferrous scrap from worldwide markets have more than doubled since 2000, and the increased competition for this raw material severely affected the minimills in Germany (Metal Bulletin, 2004a).

In the second half of 2004, production of crude steel by ThyssenKrupp Stahl was constrained by the restricted availability of sufficient coke of the required quality in Germany. Still, steel production facilities throughout Germany operated at near full capacity as demand increased following 2 years of decreases in steel consumption in Germany. Throughout 2004, the cost of energy and imported raw materials continued to increase in Germany although increasing global prices of iron ore and raw materials mostly produced outside of the EU were somewhat buffered by the strong exchange rate of the euro versus the U.S. dollar. To meet increased demand for steel in Western Europe, ThyssenKrupp Stahl and other German steel producers reduced inventories of finished and unfinished steel products and imported slabs of steel from outside the expanded EU (ThyssenKrupp Stahl AG, 2005, p.17).

After ThyssenKrupp Group, the Arcelor Group controlled the second largest amount of crude steel production capacity in Germany. Arcelor announced plans to decommission the smaller blast furnace (1.23-Mt/yr capacity) at Stahlwerke Bremen by 2012 but might stop production at this furnace much sooner because of the necessity to reline it in 2005 or 2006 and a coinciding expiration of Bremen's coke contract with RAG at the end of 2005. In 2004, Bremen sourced about two-thirds of its coke requirements from RAG and the rest from an Arcelor coke operation in Spain. High coke prices and shortages of coke in 2004 were reportedly responsible for delaying a contract extension beyond 2005 between Arcelor and RAG (Glasson, 2004a). Arcelor's German subsidiaries were still producing at nearly full capacity to serve increased export demand, mostly to the rest of the expanded EU, and their 2004 production of crude steel exceeded that of 2002 after having declined in 2003. Arcelor's German subsidiaries also increased steel shipments to China by about 6% above those of 2003. Like ThyssenKrupp Group, Arcelor focused on strategies to improve service to the expanding customer markets in the United States (North American Free Trade Agreement region) and Asia, particularly China (Arcelor S.A., 2005, p. 33).

In 2004, the German subsidiaries of Arcelor and ThyssenKrupp Groups were very concerned with the filing of an appeal by U.S. steel producers against an International Trade Commission (ITC) ruling that U.S. imports of cold flatrolled products from 20 countries, which included Germany, had not harmed the U.S. steel industry and that the U.S. Government was not justified in attempting to levy antidumping or antisubsidy duties on U.S. imports from these countries. This appeal was filed in the U.S. Court of International Trade (CIT); a decision was still pending at the end of 2004. If the ITC ruling is overturned, then these products produced by German steelmakers for export to the U.S. could be subject to new antidumping and antisubsidy duties. In retaliation, the European Commission (EC) imposed provisional antidumping duties on imports of certain U.S. cold-rolled flat stainless steels (20.6% on imports from AK Steel Corporation and 25% on imports from other companies). The EC cancelled this antidumping retaliation in March 2004, however, following a petition from the European Confederation of Iron and Steel Industries (Arcelor S.A., 2005, p. 129).

The third ranked steelmaker in Germany was Salzgitter AG, which was the leading seamless tube and pipe producer in Western Europe. On July 28, 2004, Salzgitter announced that it was to acquire the ThyssenKrupp Group's remaining 0.7% stake in Mannesmannröhren-Werke GmbH, which concluded another in a series of deals that have led to more consolidation in the steel sector of the EU and Germany. In response to increased export demand in 2004, Salzgitter was able to increase crude steel production despite high raw materials costs and shortages of coke in Germany (Salzgitter AG, 2005, p. 7). Salzgitter commissioned a new blast furnace and increased its hot metal production capacity by about 500,000 t/yr in November 2004. In 2004, Salzgitter had to import between 400,000 to 700,000 t of iron content to raise crude steel production to 8.69 Mt from 8.56 Mt in 2003. Modernization efforts and the additional capacity were expected to reduce Salzgitter's dependence on imports of iron to about 200,000 t in 2005 (Glasson, 2004b). In addition, Salzgitter received approval from the EU to build a plant to recycle steel and other scrap metals from cars supplied by Volkswagen AG (Metal Bulletin, 2004d). By the end of 2004, Salzgitter's share of the tubes unit at Mannesmannröhren-Werke had already helped Salzgitter to obtain a leading global position in the manufacture of steel tubes. Salzgitter was also among the top five producers of flat-rolled products and section segments in Europe (Salzgitter AG, 2005, p. 11).

The fourth ranked German steel producer, in terms of crude steel production capacity, was Saarstahl AG. In 2004, Saarstahl produced 2.72 Mt of crude steel and 2.52 Mt of rolled products, which represented the company's highest levels of production in more than 10 years. As with other German steel producers, Saarstahl increased production substantially in 2004 compared with that of 2003 in response to strong export demand, but it was more reliant on production of specialty steel products (Saarstahl AG, 2005a§). Saarstahl was one of the leading high-quality wire rod producers in Western Europe and specialized in the production of wire rod, steel bars, and semifinished products, which were targeted for sale to the automotive industry and its suppliers, the construction industry, power industry companies, the aerospace industry, and general mechanical engineering companies. The European automotive and automotive supplier industry represented Saarstahl's main sales market in 2004, and the company benefited from increased demand for its products from the construction and automotive sectors in the new Eastern European members of the EU and China (Saarstahl AG, 2005b§).

**Zinc.**—In 2004, Sudamin MHD GmbH controlled the zinc smelter and refinery in Duisburg, which had an annual

production of about 100,000 t of zinc (itelligence AG, 2004). Since purchasing the operation in 2002, Sudamin has undertaken a process to convert the smelter into a more-modern processing facility that can produce high-quality zinc and other minor metals from 100% recycled sources of feed; this meant that the company recovered other metals, such as cadmium and lead, in addition to its main line of secondary zinc production. This modernization process was expected to be completed by the end of June 2005 (Deutschen Zentrum für Luft-und Raumfahrt, 2005§). To improve the logistics for transporting the additional lead- and zinc-containing scrap, Sudamin set up a joint venture with Duisburger Hafen AG in 2004 that allowed better integration of the Duisburg Harbor's infrastructure into Sudamin's transportation network (Duisburger Hafen AG, 2004§).

In 2004, the leading zinc producer in Germany was the Nordenham zinc smelter, which was run by a subsidiary of Xstrata plc. This smelter produced more than 154,446 t of zinc metal in 2004, which was 10% more than its 2002 listed capacity. Xstrata acquired the Nordenham zinc smelter from Metaleurop SA at the end of 2002. Production at the smelter was expected to increase even more in 2005 owing to continuing operational improvements. Xstrata has contracts at least through 2005 with Glencore International AG to receive technical consultation concerning improvements to the Nordenham smelter, to purchase zinc concentrate from Glencore to feed the smelter, and to supply Glencore with a market-based proportion of zinc slabs and ingots produced at the smelter (Xstrata plc, 2005, p. 6, 62, 147).

#### Industrial Minerals

Bentonite.-In 2004, Süd-Chemie AG was the leading bentonite producer in Europe, with operations in France, Greece, Germany, Poland, Sardinia, Spain, Sweden, and Turkey, and was the world's leading producer of acid-activated bentonite, which is used in oil refining (Industrial Minerals, 2004). Süd-Chemie was serving the Asian market, which included China, with companies located in Indonesia and the Republic of Korea. In 2002, the company acquired a leading Chinese producer to improve service to China, which had the fastest-growing demand for Süd-Chemie's bentonite products, especially in the construction sector. In 2004, after acquiring SKW Gießerei-Technik GmbH & Co. KG of Germany and Tecpro Corp. of Atlanta, Georgia, in April, Süd-Chemie became the only full-service supplier of foundry chemicals for iron castings in Europe. The German and international foundry industries have been the main customers for bentonite products from Süd-Chemie (Süd-Chemie AG, 2005, p. 4, 21, 35).

**Cement.**—Despite HeidelbergCement AG being a large multinational producer, it shared the German and European market with at least two other large cement producers— Dyckerhoff AG and SCHWENK Zement KG. Germany exported cement to neighboring countries in 2004 mostly because of the weak domestic construction market. Dyckerhoff, in which Italian cement producer Buzzi Unicem SpA acquired a majority interest in 2004, benefited during the year from lowering some of its excess capacity in 2003; this included selling Anneliese Zementwerke AG to HeidelburgCement. HeidelburgCement retained Anneliese through 2004 and maintained a considerable amount of its other production capacity. This strategy was partially blamed for its financial losses in 2004 (Rawlinson, 2004).

HeidelburgCement did rid itself of some clinker capacity by closing a kiln at its Mainz-Weisenau plant at the beginning of 2004 but added attributable capacity via the acquisition of a majority share in Teutonia Zementwerk AG. The company claimed that its strategy was based upon an expected recovery in the domestic construction sector. An improvement in cement demand from residential construction, however, was offset by a lack of recovery in other domestic markets for cement, especially in public works projects. Owing to its substantial capacity, HeidelburgCement increased production in 2004 compared with that of 2003 but sold much of its product to Asian countries (HeidelburgCement AG, 2005, p. 20, 22, 23). The revenues from these sales were lower than expected owing to lower prices in Asia as a result of a price war in Indonesia. In an attempt to control production costs at its plant in Germany, HeidelbergCement started a legal challenge to the German Government and EU laws on emissions trading. In 2004, cement prices did gradually increase in Germany as a result of the big German producers' (especially HeidelbergCement's) reluctance to produce up to capacity (World Cement, 2004).

After 2004, German-based cement companies expected that growth in the new EU accession states, mostly in Eastern Europe, will provide enough demand to warrant more fully utilizing the country's cement production capacity. During 2004, HeidelburgCement was not the only company that experienced losses in Germany. The German subsidiaries of foreign multinationals, such as Holcim Ltd. and Lafarge Company S.A., also recorded losses because the German construction industry continued to languish with Germany's population (demand) continuing to decrease slowly in 2004. The cement producers in Germany claimed to have made some adjustments to this situation, but much more restructuring in these companies, especially at HeidelburgCement, was expected after 2004. The German cement market remained the largest in the EU, and most of these companies expected to make profits in 2005 after becoming more efficient through restructuring in 2004. The realization of any profits will depend on whether cement prices can keep pace with increasing energy costs, however (Rawlinson, 2004).

**Clay and Shale.**—In 2004, Germany was one of the leading producers of kaolin in Western Europe. Amberger Kaolinwerke GmbH produced kaolin, mostly for sale as a paper additive, and significant amounts of feldspar, mostly for the EU ceramic industry. Amberger Kaolinwerke mined these materials, as well as quartz and other industrial minerals, in Hirschau and Schnaittenbach, Bavaria, and Caminau and Kemmlitz, Saxony. In 2004, European demand for kaolin continued to increase because paper treated with kaolin products was increasingly demanded for use with more-modern computers, printers, copiers, and other technology (Amberger Kaolinwerke GmbH, 2005§). In Western Europe, demand for kaolin products and mineral paper additives has increased at an annual rate of 9% since 1982, although substitution of calcium carbonate for kaolin products in EU high-quality paper production has meant that demand for kaolin has been increasing at a much lower rate since the early 1990s. Still, EU demand and German production of kaolin was expected to continue to increase steadily through 2010 (Hieber, 2000§).

Graphite and Silicon.-In 2004, Graphit Kropfmühl AG was the only company that mined and processed natural graphite in Germany. The company operated graphite manufacturing plants in Bad Godesberg, Kropfmühl, and Wedel and was the only German producer of high-grade silicon metal after acquiring RW Silicium GmbH in Pocking, Germany, in 1998. In 2004, Graphit Kropfmühl controlled and secured supplies of raw materials for its graphite production through majority or 100% ownership of subsidiaries in China, the Czech Republic, Sri Lanka, and the United Kingdom. The company increased sales of silicon metal in the second half of 2004 largely owing to the official EU accession of the leading silicon consumers Slovakia and Slovenia. In 2004, however, higher energy costs continued to drag down the profitability of both product lines for the company, especially for silicon metal production (Graphit Kropfmühl AG, 2005, p. 18, 29, 53).

In 2004, about one-half of Graphit Kropfmühl's graphite production went into the European refractory industry. Demand for high-quality graphite products in Europe, which was the company's primary market, continued to grow, and China demanded significant high-quality graphite products for the first time in 2004. China almost exclusively demanded only commodity graphite products until 2004 and still was not viewed as having an influence on the European or German market for silicon metal (Graphitwerk Kropfmühl AG, 2005, p. 12, 52).

**Gypsum.**—Germany was a major European producer of crude gypsum. In 2004, the leading German producer was VG-ORTH GmbH & Co. KG, which was formed through the merger of Kurhessischen Gipswerke Peter Orth GmbH & Co. KG, which was based in Witzenhausen, and Vereinigten Gipswerken Stadtoldendorf GmbH & Co. KG, which was based in Stadtoldendorf. The company's primary production facilities were located in the Lower Saxony area, and the leading export markets for its products included Austria, Belgium, the Czech Republic, France, Hungary, Ireland, the Netherlands, Poland, Scandinavia, Switzerland, and the United Kingdom (Baustoffmarkt, 2004§).

**Potash.**—K+S Kali GmbH was the German mining subsidiary of K+S Aktiengesellschaft and operated six mines from which it extracts about 38 Mt/yr of potash and magnesium salts annually. In 2004, K+S Aktiengesellschaft was the fourth ranked producer of potash products in the world and the leading producer in Europe. K+S Aktiengesellschaft was the second ranked supplier of specialty and agricultural fertilizers in Europe. K+S Kali expected to begin processing 1.5 Mt/yr of sylvinite in 2005 from the deposits at Unterbreizbach at the Wintershall production facility within the company's Werra plant. The Werra plant annually produces more than 40% of K+S Kali's total output. The project was expected to increase capacity at the plant by about 250,000 t/yr of K<sub>2</sub>O content by increasing the specialty product range at Wintershall and fully utilizing the Unterbreizbach mine (K+S Aktiengesellschaft, 2004§).

**Salt.**—On June 9, 2004, K+S Kali acquired the remaining 38% interest in Europe's leading salt provider esco GmbH, from

Solvay S.A. esco had production capacities of about 5.8 Mt/yr of rock salt, 2.3 Mt/yr of vacuum salt, and 1.7 Mt/yr of brine. After this acquisition, K+S Kali accounted for all the rock salt and salt brine produced in Germany (esco GmbH, 2004§).

#### **Mineral Fuels**

Relative to its consumption, Germany has relatively insignificant domestic energy sources, other than coal, and must rely on imports to meet its energy needs. Oil was expected to remain the primary energy source, but Germany planned to reduce import reliance and reliance on nuclear energy by increasing the energy consumption share of renewable sources (mostly wind-generated energy and some biomass projects) sources to 20% by 2020. In 2004, the share of Germany's primary energy consumption that was provided by oil was about 36% followed by natural gas (23%), hard coal (14%), nuclear power (13%), and lignite (11%); the rest was provided by nonmineral-fuel energy sources (U.S. Energy Information Administration, 2004§).

Coal.—Bituminous and Anthracite.—The share of hard coal used in generating the total amount of electricity consumed in Germany in 2004 was estimated to be about 23% (RWE Aktiengesellschaft, 2005b, p. 75). In 2003, the Government passed a followup regulation to the Hard Coal Agreement of 1997, which was an agreement to continue mining subsidies but gradually lower them to provide financial support for just enough hard coal production capacity as is deemed critical to Germany's energy security. The 1997 agreement stipulated that the ceiling on hard coal subsidies needed to be reduced gradually by about 50% from 1998 to 2005. The 2003 extension of the agreement mandated that this ceiling should be reduced by another 50% from 2006 to 2012. In 2004, the Government expected that hard coal production will be reduced to about 16 Mt by 2012 as a result of this decrease in financial support from the German hard coal subsidy (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 66). Hard coal mining is centered in the Ibbenbüren, the Ruhr, and the Saar coalfields in Germany and is uneconomical without subsidies because the current resources lie prohibitively far underground (SPG Media Limited, 2005b§).

Because the EU policy was to eliminate completely subsidies to industries, individual country member exceptions must be approved by the EC. This broad policy objective has resulted in the gradual phaseout of subsidies (in some EU countries more rapidly than in others) that have supported Western Europe's coal industry for many years. In 2004, the German Government presented its long-term restructuring plan for German hard coal mining to the EC for approval. According to this plan, output in Warndt-Luisenthal would be stopped, and the Lohberg-Osterfeld mine would be closed in 2006; the Walsum and the Lippe Mines would then be closed in 2009 and 2010, respectively. Germany expected that further downward adjustments to hard coal mining capacities would be needed by 2012 to reduce production. In 2004, the Government estimated that a workforce of about 36,000 would produce about 26 Mt of hard coal in 2005 (Bundesministerium für Wirtschaft und Arbeit, 2005, p. 66).

In 2004, RAG sold off its foreign hard coal mining activities, but it retained some international activities, such as coal

trading and mining equipment manufacturing. In Germany, the company continued with hard coal mining and coke production for the steel industry through its mining division, which was controlled by Deutsche Steinkohle AG (DSK). RAG was also involved in related energy projects through its new energy division, which was controlled by STEAG AG; STEAG was the fifth ranked producer of electricity in Germay. In 2004, STEAG planned to begin construction of a new coal-fired powerplant in Germany (RAG Aktiengesellschaft, 2005, p. 5-10). By the end of 2004, RAG had just nine coal mines left, and the Government expected the company to close two in 2006, one in 2009, and one in 2010. DSK announced, however, that it had obtained Government approval to develop the company's new underground mine, Donar, which could produce 3 Mt/y of coking coal. RAG continued to negotiate with the Government to increase the capacity of its coking plant in Bottrop by 2 Mt/yr of coke. Members of Germany's steel industry indicated that they would share the costs of the expansion in Bottrop, and two-thirds of any additional coke production at the plant would be reserved for use by ThyssenKrupp Stahl (SBS Corporation, 2004§; SPG Media Limited, 2005b§).

Lignite.—In 2004, Germany was the world's leading producer of lignite. Lignite-fired powerplants were the second ranked supplier of electricity in Germany, and about 90% of Germany's total output of lignite was used in electricity generation (U.S. Energy Information Administration, 2004§). Including hardcoal-fired powerplants, coal was responsible for slightly more than one-half of all electricity produced in Germany; lignite was estimated to be responsible for about 26% of total electricity generation. The leading German producer of lignite was RWE Power Aktiengesellschaft, which was formed by the merger of RWE Rheinbraun with other interests of RWE Aktiengesellschaft (RWE) in 2003. RWE Power operated four large open pit mines (Bergheim, Garzweiler II, Hambach, and Inden) in the Rhenish area to the west of Cologne. These mines produced a total of 100.3 Mt of lignite in 2004. RWE Power planned to continue producing a total of about 100 Mt/yr from these mines after 2004 (RWE Aktiengesellschaft, 2005a, p. 21; 2005b, p. 75; SPG Media Limited, 2005a§).

**Petroleum.**—Although Germany's demand for petroleum continued to decrease slightly (by 1.2%) in 2004 compared with that of 2003, petroleum still comprised a 36% share of the country's primary energy consumption (RWE Aktiengesellschaft, 2005b, p. 75). German production also decreased by about 8% during the same timeframe; production was negligible compared to the country's level of consumption. The decrease in production was largely owing to lower production out of the Mittelplate oilfield owing to adverse weather conditions and technical difficulties (Niedersächisches Landesamt für Bodenforschung, 2005§). Mittelplate was Germany's largest producing field and is located in the Wattenmeer tidal flatlands off the western coast of Schleswig-Holstein. RWE and Wintershall AG each have a 50% interest in the Mittelplate joint venture.

Germany was the third ranked petroleum importer in the world and its main suppliers were Libya, Norway, Russia, and the United Kingdom. Russia was Germany's leading supplier and a longstanding proposal to extend the main Druzhba oil pipeline to the German Port of Wilhelmshaven was discussed in 2004. The pipeline extension would improve service to Germany through Poland and allow Russia to export oil to the U.S. and other markets without risking an environmental accident with tankers on the Baltic or the Black Sea. In 2004, however, negotiations were still ongoing because the tariff that Germany would have to charge on the oil transported through the pipeline extension to operate the German portion of the pipeline and the associated pumping stations profitably would be about 30% higher than that of Poland. An adequate costsharing agreement had not been reached by the end of the year (Soria and Gray, 2004).

Uranium.—In 2004, uranium was the leading source of German electricity generation with an estimated 27.5% share of the total (RWE Aktiengesellschaft, 2005b, p. 75). In 2002, Germany was the fourth ranked country in terms of installed nuclear capacity to generate electricity, but the country passed an amended Atomic Energy Act in April 2002 that legalized the planned phaseout of Germany's nuclear power production by 2021, although production from some plants could be extended. The powerplant in Stade was the first German nuclear plant to be decommissioned on November 14, 2003, and Germany's oldest nuclear powerplant, Obrigheim, will be closed in 2005. German industry, which included the mineral industry, has opposed the Government's nuclear phaseout program, and if the current ruling coalition (Social Democrats and Green Party) loses the expected 2005 election, the policy could be overturned (Gwosdz and others, 2004; U.S. Energy Information Administration, 2004§). The mining of uranium has been abandoned, but the country continues to recover trace amounts of uranium from the Wismut cleanup project each year. As the cleanup progresses, less uranium is expected to be recovered annually. The total amount of uranium recovered during 2004 was reported to be 77 t in U<sub>2</sub>O<sub>6</sub> content compared to 104 t in 2003 (Bundesministerium für Wirtschaft und Arbeit, 2004, p. 38).

#### Outlook

The export-led boom that has provided a boost to the mineral industry of Germany since the end of 2002 was believed to have run its course by the second half of 2004, and exports of mineral commodities, particularly metal commodities, may continue to suffer if the euro exchange rate remains strong against currencies in important export markets for Germany, such as China, which used a U.S. dollar-based currency in 2004 (Christian and Fels, 2004§). In the short run, higher input costs for the country's mineral processing industries could potentially force more domestic mergers, closures, and outsourcing of mineral processing to be closer to the sources of the minerals (outside of Germany). In the long run, expectations are that Germany's share of global resource use in mineral industry production and consumption could decline steadily as global consumption of minerals shifts proportionally more toward the emerging economies of the world (Bundesanstalt für Geowissenschaften und Rohstoffe, 2004a).

On the input side of Germany's mineral industry, the costs of raw materials increased enough in 2004 to cause great concern among the leaders of German industry that supplies of these materials may not be secure enough. These cost increases are especially alarming for the mineral industry because the strong euro exchange rate has thus far been a substantial buffer to higher prices for minerals currently being imported from countries outside of the EU (RAG-Magazin, 2005). Looking forward, dependence of the mineral industry and much of the German economy on trade is not going to change much in the near future, although rapid technological improvements in renewable domestic energy provision, recycling, and secondary production are keys to easing many of the uncertainties associated with this dependence on external markets. Also on the brighter side, the accession of 10 new markets into the EU in 2004 is expected to reduce some uncertainty with respect to the supplies of certain mineral raw materials and provide expanded markets where German mineral commodity exporters can be more competitive regardless of external fluctuations in the euro exchange rate.

German domestic consumption, which included consumption of mineral commodities and high-mineral content products, was still down in 2004. For the mineral industry, the most important sector that failed to pick up its consumption was construction. With about zero population growth and an aging population, the future prospects for domestic consumer-led boosts to the German mineral industry are not very promising. These problems were not new to the industry in 2004, however, and many restructuring efforts within the mineral industry were completed during the year. In steel production, global capacity consolidated substantially from 1997 through 2004, and the remaining German steel producers should benefit from more regional market power and price stability (MEPS International Ltd., 2005§). In cement production, German producers have pushed hard to reduce capacity and consolidate so that they can better control the quantity being produced and keep prices at profitable levels.

Any future growth in the mineral industry of Germany is likely to be led by exports. European-based (including Germanbased) mineral commodity producers have had to operate internationally for a longer period of time than producers based in other continents because they have relatively smaller home markets. The German Government and firms in the mineral industry appear to benefit from a long history of contributing exceptional operations, technology, quality, and labor and management skills to international joint ventures. Significant organizational skills are also necessary to coordinate capabilities effectively around the world; companies within the German mineral industry have traditionally proven to be very adept in successfully developing the international relationships necessary to maintain a secure supply of minerals and other raw materials into Germany (Wagner, 1998§). In 2004, many German mineral industry firms were benefiting from long-term contracts with raw materials suppliers and finished mineral product buyers within and especially outside of the EU. This international competitive advantage has been carefully cultivated, and most of these contracts should be in effect through 2010.

To improve benefits from some first-mover advantages that German firms enjoy with respect to technological advances in mineral processing development and recycling and access to some difficult export markets, the Government has traditionally supported multilateral trade agreements and globally inclusive environmental regulations. The more progress that the WTO agreements make in limiting multilateral tariff and nontariff barriers to trade and the more successful international environmental regulations are at leveling competition based on costs of production internationally, the more the German mineral companies will be able to benefit from the extensive investments that they have already made in international commercial relationships and domestic production technology (Bundesverband der Deutschen Industrie e.V., 2005).

		,,	,,.=~	,,=	, ,	, ,

<sup>e</sup>Estimated; estimated data are rounded to no more than three significant digits; may not add to totals shown. <sup>p</sup>Preliminary. <sup>r</sup>Revised. -- Zero.

<sup>1</sup>Table includes data available through January 2006.

<sup>2</sup>Iron ore is used domestically as an additive in cement and other construction materials but is of too low grade to use in the steel industry.

<sup>3</sup>Includes spiegeleisen, unspecified crude iron, and blast furnace ferromanganese with 2% or more carbon.

<sup>4</sup>Reported figure.

<sup>5</sup>Rounded to one significant digit.

### TABLE 2--Continued GERMANY: STRUCTURE OF THE MINERAL INDUSTRY IN $2004^1$

#### (Thousand metric tons unless otherwise specified)

	Major operating companies and		Annual
Commodity	major equity owners <sup>2</sup>	Location of main facilities	capacity
Steel	About 22 companies, of which the major		
	ones were:		
Do.	ThyssenKrupp Stahl AG	Plants mostly in the Westphalia Region	12,000
Do.	Hüttenwerke Krupp Mannesmann GmbH	Plant at Duisberg	6,000
	(Thyssen Krupp Stahl AG, 50%; Vallourec		
	& Mannesmann Tubes SA, 30%;		
	Mannesmannröhren-Werke AG, 20%)		
Do.	Salzgitter AG	Plants at Peine and Salzgitter	9,000
Do.	Stahlwerke Bremen GmbH (Arcelor S.A.,	Plant at Bremen	4,000
	100%)		
Do.	Saarstahl AG (Montan-Stiftung Saar, 74.9%)	Plants at Völkingen, Burbach, und Neunkirchen	3,000
Zinc	Ruhr-Zink GmbH	Refinery at Datteln	140
Do.	Sudamin MHD GmbH	Smelter at Duisburg	100
Do.	Xstrata plc	Smelter at Nordenham	155 °

<sup>e</sup>Estimated; estimated data are rounded to no more than three significant digits.

<sup>1</sup>Table includes data available through October 2004.

<sup>2</sup>Many more industrial minerals companies are listed in the Industrial Minerals Directory, 2004.

# TABLE 3 GERMANY: EXPORTS OF SELECTED MINERAL COMMODITIES IN $2003^1$

#### (Kilograms unless otherwise specified)

				Destinations
Commodity		Total	United States	Other (principal)
METALS				
Alkali and alkaline-earth metals:				
Alkali metals valu	e, thousands	\$12,458	\$716	Switzerland \$6,395; France \$822; unspecified Asia \$3,306.
Alkaline-earth metals		548,270		Spain 221,101; United Kingdom 101,601; Netherlands 79,699.
Aluminum:				
Ore and concentrate		26,666,205		France 9,629,000; Netherlands 1,819,187; Italy 1,789,687.
Oxides and hydroxides	metric tons	780,300	48,669	Italy 133,688; Netherlands 121,282; United Kingdom 108,686.
Ash and residue containing aluminum		23,307,446		Austria 7,508,699; Norway 7,356,500; Spain 5,146,800.
Metal, including alloys:				· · · · ·
Scrap	metric tons	556,405	72	Italy 123,872; Austria 101,597; Netherlands 82,001.
Unwrought	do.	389,343	396	Austria 114,476; France 58,781; Italy 41,182.
Semimanufactures:				·
Powders and flakes		14,552,711	550,288	Austria 1,957,074; Italy 1,675,875; Sierra Leone 1,164,625.
Rods, bars, profiles	metric tons	185,389	3,486	Austria 25,295; France 21,866; Netherlands 13,277.
Wire		10,028,730	13,687	Austria 2,421,163; United Kingdom 1,103,101; Italy 824,421.
Plates, sheets, strips	metric tons	947,103	61,487	United Kingdom 126,356; Italy 121,371; France 82,871.
Foil	do.	294,000	26,935	Switzerland 38,758; France 35,151; Netherlands 26,935.
Tubes and pipes		24,480,558	2,285,773	Czech Republic 3,897,124; France 2,462,250; Spain 2,081,187.
Tube or pipe fittings		20,089		Macedonia 13,750; Cyprus 5,500; Albania 742.
Antimony:				· · ·
Ore and concentrate	value	\$8,000		All to Switzerland.
Oxides		682,809	15,812	Switzerland 195,101; Austria 125,398; Poland 53,101.
Metal, including alloys, all forms		29,917	500	Austria 12,000; Belgium 5,065; Sweden 3,375.
Arsenic, metal, including alloys, all forms		8,515	2,812	Japan 2,000; China 1,687; United Kingdom 1,000.
Beryllium, metal, including alloys, all forms	value	\$248,000	\$169,000	Hungary \$34,000; Switzerland \$31,000; United Kingdom \$14,000.
Bismuth, metal, including alloys, all forms		154,594	22,101	Czech Republic 46,601; France 21,101; Netherlands 12,687.
				Switzerland \$11,000; United Kingdom \$7,000; South Africa
Cadmium, metal, including alloys, all forms	value	\$29,000		\$3,000.
Chromium:				
Ore and concentrate		3,666,520	19,500	Austria 714,875; France 697,812; Czech Republic 452,125.
Metal, including alloys, all forms		2,095,906	46,913	Netherlands 1,001,687; France 149,000; Belgium 109,897.
Cobalt:				
Oxides and hydroxides		151,464	3,000	France 66,199; Spain 17,601; Czech Republic 13,187.
Metal, including alloys, all forms		1,120,212	125,472	United Kingdom 189,198; France 155,999; Sweden 143,198.
Columbium (niobium) and tantalum, metal, inc	luding alloys,			
all forms, tantalum		324,172	3,687	Czech Republic 12,375; Portugal 2,500; unspecified 303,025.
Copper:				
Ore and concentrate		48,673,545		Sweden 44,745,398; Canada 3,549,375; Slovakia 183,601.
Matte and speiss, including cement copper		899,187		Canada 896,500; Sudan 2,687.
Oxides and hydroxides		3,955,804	4,312	United Kingdom 1,032,000; China 463,875; Netherlands 436,687.
Sulfate		2,159,877	20,398	France 532,312; United Kingdom 412,187; Denmark 279,187.
Ash and residue containing copper		11,772,758		Belgium 6,703,898; Slovakia 2,299,687; Austria 1,565,187.
Metal, including alloys:				
Scrap	metric tons	363,762	5,981	China 100,749; Netherlands 73,736; Belgium 38,163.
Unwrought	do.	140,580	8,741	France 40,501; Italy 21,690; Austria 10,954.
Semimanufactures:				
Powders and flakes		8,441,750	588,124	Italy 1,570,726; France 1,120,699; Austria 522,886.
Rods, bars, profiles	metric tons	117,199	4,526	France 17,336; Italy 15,795; United Kingdom 11,255.

Worked, including agglomerated splittings	654,173	7,187	France 154,824; Italy 113,125; Czech Republic 112,601.
Nitrates, crude	19,137,101		Unspecified 19,137,101.
Phosphates, crude	77,328		Poland 39,672; Uzbekistan 21,199; Russia 11,625.
Phosphorus, elemental	583,634	36,898	Poland 96,000; Japan 54,898; Indonesia 49,601.
Pigments, mineral, iron oxides and hydroxides,			
processedmetric tons	163,335		France 10; Italy 1; unspecified 163,324.
Precious and semiprecious stones other than			
diamond:	_		
Natural value, thousands	\$129,393	\$52,729	Switzerland \$17,806; Hong Kong, China \$10,893; Japan \$8,478.
Synthetic do.	\$19,964	\$12,415	Hong Kong, China \$668; Austria \$529; Italy \$476.
Pyrite, unroasted	389,486	3,000	Poland 119,300; France 99,898; Saudi Arabia 40,000.
Quartz crystal, piezoelectric value	\$3,090,000	\$80,000	Switzerland \$968,000; Singapore \$563,000; Slovakia \$491,000.
Salt and brine metric tons	3,695,084	2,572	Belgium 1,063,140; Netherlands 597,670; Denmark 384,793.
Sodium compounds, n.e.s., natural and/or			
manufactured:	-		
Soda ash do.	457,061	74	Netherlands 31,040; Denmark 28,616; unspecified 298,602.
Sulfate do.	39,078	8	Czech Republic 11,584; Hungary 7,804; Austria 4,998.
Stone, sand and gravel:	-		
Dimension stone:	-		
Crude and partly worked do.	252,980	388	Switzerland 116,513; Austria 81,281; Netherlands 20,662.
Worked do.	186,650	6,095	France 41,897; Switzerland 32,366; Austria 27,894.
Dolomite, chiefly refractory-grade do.	524,469	138	Luxembourg 379,656; Netherlands 71,162; Belgium 31,751.
Gravel and crushed rock thousand metric tons	12,355	1	Netherlands 8,897; Switzerland 1,146; Belgium 1,034.
Limestone other than dimension metric tons	101,169		Luxembourg 74,644; France 10,039; Netherlands 7,791.
Quartz and quartzite	71,573,577	147,999	Netherlands 49,487,574; Austria 5,447,648; Belgium 2,879,812.
Sand other than metal-bearing metric tons	9,484,210	836	Netherlands 6,621,700; Belgium 1,898,127; Switzerland 413,306.
Sand and gravel thousand metric tons	21,839	2	Netherlands 15,519; Belgium 2,932; Switzerland 1,559.
Sulfur:	-		
Elemental:	-		
Crude, including native and byproduct metric tons	897,870	4	Belgium 145,484; Morocco 132,218; France 89,217.
Colloidal, precipitated, sublimed	4,020,820	3,125	Belgium 2,885,500; Denmark 519,687; France 230,800.
Dioxide	27,988,942		Austria 15,319,500; Spain 4,750,101; Netherlands 2,218,812.
Sulfuric acid metric tons	1,007,523	87,067	Belgium 419,748; Norway 94,973; United Kingdom 71,343.
Talc, steatite, soapstone, pyrophyllite	5,284,598	47,574	Netherlands 1,055,875; Belgium 629,625; France 571,312.
Vermiculite, perlite, chlorite	1,619,069		Belgium 517,875; Poland 317,812; Luxembourg 130,800.
Other, slag and dross, not metal-bearing metric tons	2,679,240	2,704	France 1,168,384; Netherlands 779,771; Belgium 219,979.
MINERAL FUELS AND RELATED MATERIALS	-		
Asphalt and bitumen, natural metric tons	6,557		Denmark 5,348; Switzerland 537; Hong Kong, China 220.
Carbon black do.	118,956	2,982	France 29,160; Belgium 12,221; Italy 9,697.
<u>Coal:</u>	-		
Briquets of anthracite and bituminous coal	47,724,497		France 41,951,101; Belgium 4,242,699; Switzerland 587,625.
Lignite, including briquets metric tons	180,232		Austria /0,593; Belgium 49,408; France 17,394.
All grades, including briquets do.	410,189		France 130,231; Belgium 117,976; Austria 94,629.
