## Table 6. Sun SPARCstation 2 Timings (cont.)

(a) All times are in seconds. CPU times are the sum of the "user + system" contributions. Wall clock times are given in parentheses. For the iterative methods (RHF, UHF, SD-CI, QCISD, and CASSCF), each entry consists of a trio of numbers: "CPU-time-per-iteration/total-CPU (total-wallclock)". The "CPU-time-per-iteration" for the conventional SCF methods was defined as the total run time (integrals +SCF ) divided by the number of iterations. These values are intended to facilitate comparison with direct HF methods. For other methods the leftmost entry corresponds to the incremental time for the method. For example, the MP2 entry preceding the slash is the total run time minus the time needed for the preliminary HF step.
Unless otherwise noted all SPARC 2 calculations were performed on a machine with 64 MB of memory, a 900 MB Seagate ST4766 disk and a 600 MB Fujitsu M2266 disk running under SunOS 4.1.1 with Release 1.4 of Sun Fortran. G90 was compiled with version 1.2 of the Fortran compiler because of problems encountered in getting it to run under 1.4. Runs were made on an otherwise quiet system.
NA: not available with this program.
FTC-ND: Failed to complete - not enough disk space.
FTC-unknown: Failed to complete for unknown reasons.
SCF calculations were converged to approximately 7-8 digits in the density.
(b) The ethylene UHF calculation treated the $\pi \rightarrow \pi^{*}\left({ }^{3} B_{1 u}\right)$ state. The ethylene ground state is ${ }^{1} A_{g}$. MP2, MP4, CISD and QCISD calculations involved all electrons (i.e., there were no "core" electrons). The CAS configuration list contains 8 CSFs in $D_{2 h}$ symmetry and was generated with 4 electrons in 4 orbitals ( $\left.3_{a g}, 1 b_{3 u}, 1 b_{2 g}, 2 b_{1 u}\right)$. This configuration list is sufficient to allow ethylene to dissociate into two triplet methylenes. The time reported includes the time required to compute the integrals and solve the CAS equations using the canonical orbitals as the starting guess. The default INDO initial guess used by Gaussian for ethylene's open shell calculations did not pick up the $\pi \rightarrow \pi^{*}{ }^{3} \mathrm{~B}_{1 \mathrm{u}}$ state. If the ordering of the initial guess orbitals was corrected using an ALTER command the calculation with Gaussian 90 died with a complaint that symmetry was being broken. Thus, it was necessary to run these calculations with the NOSYMM option, which ignored the available $\mathrm{D}_{2 \mathrm{~h}}$ symmetry. Gaussian 92 fixed this problem with the UHF benchmark and was run in full $D_{2 h}$ symmetry.
Gaussian 90 requires that RHF calculations that precede certain correlated methods be run in $\mathrm{C}_{1}$ symmetry. This results in an increase in the ethylene SCF times from 196 seconds ( $\mathrm{D}_{2} \mathrm{~h}$ ) to 441 seconds $\left(\mathrm{C}_{1}\right)$ for the $6-311 \mathrm{G}^{* *}$ basis; from 1900 seconds $\left(\mathrm{D}_{2}\right)$ to 5795 seconds $\left(\mathrm{C}_{1}\right)$ for the ccpVTZ basis; from 1969 seconds $\left(\mathrm{D}_{2} \mathrm{~h}\right)$ to 6657 seconds $\left(\mathrm{C}_{1}\right)$ for the $6-311++\mathrm{G}(3 \mathrm{df}, 3 \mathrm{pd})$ basis.
The caffeine RHF calculation was on the cation state of the molecule.
(c) The Gaussian CAS calculation using RHF canonical orbitals aborted with an error message saying that the initial guess was too poor. After massaging the initial guess, the calculation could be made to proceed, but the final energy was approximately 20 millihartrees too high. The total times reported have been increased by the amount necessary to perform a SCF calculation.
(d) GAMESS and HONDO could not do a combined RHF + SDCI or RHF + CAS in one job step. In order to make the total time comparable to what is reported for other programs, the time to perform the RHF calculation (exclusive of the 2-el. integral time) was simply added to the SDCI or CAS time.
(e) Failed to converge in 30 iterations. By iteration 11 the energy was within $10^{-7}$ hartree of the converged result, but the energy subsequently oscillated.
(f) This calculation died due to a lack of disk space in the middle of iteration 2. At that point the size of the "rwf" exceeded 900 MB , the size of the largest scratch partition available.
(g) The number of configurations in the SDCI calculations were 21,037 for $6-311++\mathrm{G}^{* *}$ ethylene; 50,741 for cc-pVTZ ethylene.
(h) This MOLPRO calculation failed to produce correct gradients.
(i) The MOLPRO gradient integral package is unable to handle generally contracted basis sets.
