# ARROWTOOTH FLOUNDER 

## by

Thomas K. Wilderbuer and Terrance M. Sample

## EXECUTIVE SUMMARY

The following changes have been made to this assessment relative to the November 1998 SAFE.

## Changes to the input data

1) 1999 survey size composition
2) 1999 survey biomass point-estimate and-standard error.
3) Estimate of catch and discards through I8, September 1999.
4) Estimate of retained and discarded portion of the 1998 catch.

## Assessment results

1) The projected age $1+$ total biomass for 2000 is $784,630 \mathrm{t}$.
2) The projected female spawning biomass for 2000 is $496,000 \mathrm{t}$.
3) The recommended 2000 ABC is $130,500 t$ based on an $\mathbf{F}_{0.40}(0.22)$ harvest level.
4) The 2000 overfishing level is $160,200 t$ based on a $F_{0.35}(0.27)$ harvest level.

| 1999 Assessment recommendation for 2000 harvest | 1998 Assessment recommendation for 1999 harvest |
| :---: | :---: |

Total biomass 784,630 t 819,250 t
ABC 130,500 t 140,000 t
Overfishing $\quad 160,200 \mathrm{t} \quad 219,100 \mathrm{t}$

| FABC | $\mathrm{F}_{0.4 \overline{0}}=0.22$ | $\mathrm{~F}_{0.4 \bar{\sigma}}=0.23$ |
| :--- | :--- | :--- |

$\mathrm{F}_{\text {overifing }} \quad \mathrm{F}_{0.35}=0.27 \quad \mathrm{~F}_{0.30}=0.36$

## INTRODUCTION

The arrowtooth flounder (Atheresthes stomias) is a relatively large flatfish which occupies continental shelf waters almost exclusively until age 4, but at older ages occupies both shelf and slope waters. Two species of Atheresthes occur in the Bering Sea. Arrowtooth flounder and Kamchatka flounder (A. evermanni) are very similar in appearance and are not usually distinguished in the commercial catches. In past years, these species were not consistently separated in trawl survey catches and are combined in this assessment to maintain the comparability of the trawl survey time series. Arrowtooth flounder ranges into the Aleutian Islands region where their abundance is lower than in the eastern Bering Sea. The resource in the EBS and the Aleutians are managed as a single stock although the stock structure has not been studied.

Arrowtooth flounder was managed with Greenland turbot as a species complex until 1985 because of similarities in their life history characteristics, distribution and exploitation. Greenland turbot has been the target species of the fisheries whereas arrowtooth flounder are taken as bycatch. Because the stock condition of the two species have differed markedly in recent years, management since 1986 has been by individual species.

Arrowtooth flounder begin to recruit to the continental slope at about age 4. Based on age data from the 1982 U.S.-Japan cooperative survey, recruitment to the slope gradually increases at older ages and reaches a maximum at age 9 . However, greater than $50 \%$ of age groups 9 and older continue to occupy continental shelf waters. The low proportion of the overall biomass on the slope during the 1988 and 1991 surveys, relative to that of earlier surveys, indicates that the proportion of the population occupying slope waters may vary considerably from year to year depending on the age structure of the population.

## CATCH HISTORY

Catch records of arrow-tooth flounder and Greenland turbot were combined during the 1960s. The fisheries for Greenland turbot intensified during the 1970s and the bycatch of arrowtooth flounder is assumed to have also increased. In 1974-76, total catches of arrow-tooth flounder reached peak levels ranging from 19,000 to $25,000 \mathrm{t}$ (Table 5.1). Catches decreased after implementation of the MFCMA and the resource has remained lightly exploited with catches averaging 12,200 t from 1977-99. This decline resulted from catch restrictions placed on the fishery for Greenland turbot and phasing out of the foreign fishery in the U.S. EEZ. Total catch reported through 18 September, 1999 is $9,152 \mathrm{t}$ (well below the ABC of $140,000 \mathrm{t}$ ). NMFS Regional Office reports indicate that bottom trawling accounted for $85 \%$ of the 1999 catch.

Although research is being conducted on their commercial utilization (Greene and Babbitt 1990, Wasson et al. 1992, Porter et al. 1993, Reppond et al. 1993, Cullenberg 1995), arrowtooth flounder currently have a low perceived commercial value as they are captured primarily in pursuit of other high value species and most are discarded.. The catch information in Table 5.1 reports the annual total catch tonnage for the foreign, JV, and DAP fisheries. The proportion of retained and discarded arrow-tooth flounder in Bering Sea fisheries can be estimated from observer sampling applied to the 'blend' estimate of reported and observed retained catch as follows:

| Year' | Retained | Discarded | Total | \% Retained |
| :---: | :---: | :---: | :---: | :---: |
| 1985 | 17 t | 72t | 89t | 19 |
| 1986 | 65t | 277t | 342t | 19 |
| 1987 | 75t | 320t | 395t | 19 |
| 1988 | 3,309 t | 14,107 t | 17,416 t | 19 |
| 1989 | 958t | 4,084 t | 5,042 t | 19 |
| 1990 | 2,356 t | 10,042 t | 12,398 t | 19 |
| 1991 | 3,211 t | 18,841 t | 22,052 t | 15 |
| 1992 | 675t | 9,707 t | 10, 382 t | 7 |
| 1993 | 403t | 6,775 t | 7,178 t | 6 |
| 1994 | 626t | 13,641 t | 14,267 t | 4 |
| 1995 | 509t | 8,772 t | 9,281 t | 5 |
| 1996 | 1,372 t | 13,280 t | 14,652 t | 9 |
| 1997 | 1,029 t | 9,024 t | 10,054 t | 10 |
| 1998 | 2.896 t | 12,345 t | 15.241 t | 19 |

' 1990 \% retained rate applied to the $1985-89$ reported retained DAP catch.
Substantial amounts of arrowtooth flounder are discarded overboard in the various trawl and longline target fisheries. Largest discard amounts occurred in the Pacific cod, rock sole, 'other flatfish' and Greenland turbot fisheries.

## DATA

The data used in this assessment include estimates oftotal catch, trawl survey biomass estimates and standard error from shelf and slope surveys, sex-specific trawl survey size composition and available fishery lengthfrequencies from observers.

Fishery Catch and Catch-at-Age
Fishery catch data are available from 1970 . September 18, 1999 and fishery length-frequency data from 1978-91.

## SurveyCPUE

The relative abundance of arrow-tooth flounder increased substantially on the continental shelf from 1982 to 1990 as the CPUE from AFSC surveys on the shelf increased steadily from 1.6 to $9.9 \mathrm{~kg} / \mathrm{ha}$ (Fig. 5.1). The overall shelf catch rate decreased slightly to $7.1 \mathrm{~kg} / \mathrm{ha}$ during 1991 but increased to $9.5 \mathrm{~kg} / \mathrm{ha}$ during the 1992 bottom trawl survey. The CPUE continued to increase through 1996 to $12.0 \mathrm{~kg} / \mathrm{ha}$. These increases in CPUE were also observed on the slope from 1981 to 1986 as CPUE from the Japanese landbased fishery increased from 1.5 to 21.0 thr (Bakkala and Wilderbuer 1990). The CPUE declined in 1997 to $10.3 \mathrm{~kg} / \mathrm{ha}$ and continued to decline over the next two years to $5.7 \mathrm{~kg} / \mathrm{ha}$ in 1999.

## Absolute Abundance from Trawl Surveys

Biomass estimates (t) for arrow-tooth flounder from U.S. and U.S.-Japanese cooperative surveys in the eastern Bering Sea and Aleutian Islands region are as follows:

*The 1988 and 1991 slope estimates were from the depth ranges of $200-800 \mathrm{~m}$ while earlier slope estimates were from 200-1,000 m.

Although the standard sampling trawl changed in 1982 to a more efficient trawl which may have caused an overestimate of the biomass increase in the pre-1982 part of the time-series, biomass estimates from AFSC surveys on the continental shelf have shown a consistent increasing trend since 1975. Since 1982, biomass point -estimates indicate that arrowtooth abundance has increased eight-fold to a high of $570,600 \mathrm{t}$ in 1994. The population biomass remained at a high level from 1992-97. Results of the 1998 and 1999 bottom trawl surveys indicate the Bering Sea shelf population biomass has since declined to $243,800 \mathrm{t}$, half of the 1997 biomass point estimate.

Arrowtooth flounder absolute abundance estimates are based on "area-swept" bottom trawl survey methods. These methods require several assumptions which can add to the uncertainty of the estimates. For example, it is assumed that the sampling plan covers the distribution of the species and that all fish in the path of the trawl are captured (no losses due to escape or gains due to herding). Due to sampling variability alone, the $95 \%$ confidence intervals for the 1999 point estimate are $112,200-375,400 \mathrm{t}$.

Trawl surveys on the continental slope estimate that arrow-tooth flounder biomass increased significantly from 1982 to 1985. The biomass estimate in 1988 and 1991 were lower. However, sampling in 1988 and 1991 ( $200-800 \mathrm{~m}$ ) was not as deep as in 1985 and earlier years ( $200-1,000 \mathrm{~m}$ ). Based on slope surveys conducted between 1979 and 1985, 67 to $100 \%$ of the arrowtooth flounder biomass on the slope were found at depths less than 800 m . These data suggest that less than $20 \%$ of the total EBS population occupied slope waters in 1988 and 199 1, a period of high arrowtooth flounder abundance. Surveys conducted during periods of low and increasing arrow-tooth abundance (1979-85) indicate that $27 \%$ to $51 \%$ of the population weight occupied slope waters.

The combined arrowtooth/Kamchatka flounder abundance estimated from the 1997 Aleutian Islands trawl survey is $94,100 \mathrm{t}$, which is a continuation of the increasing trend observed in the Aleutian Islands since 1991.

## Weight-at-age. Length-at-age and Maturitv-at-age

Parameters of the von Bertalanffy growth curve for arrow-tooth flounder from age data collected during the 1982 U.S.-Japan cooperative survey and the 1991 slope survey (Zimmermann and Goddard 1995) are as follows:

| Sex | Sample size | $\begin{aligned} & \text { Age } \\ & \text { range } \end{aligned}$ | $\mathrm{L}_{\text {inf }}{ }^{-}$ | k | $\mathrm{t}_{0}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1982 age sample |  |  |  |  |  |
| Male | 528 | 2-14 | 45.9 | 0.23 | -0.70 |
| Female | 706 | 2-14 | 73.8 | 0.14 | -0.20 |
| Sexes Combined | 1,234 | 2-14 | 59.0 | 0.17 | -0.50 |
| 1991 age sample |  |  |  |  |  |
| Male | 53 | 3-9 | 57.9 | 0.17 | -2.17 |
| Female | 134 | 4-12. | 85.0 | 0.16 | -0.81 |

Based on 282 observations during a AFSC survey in 1976, the length (mm)-weight (gm) relationship for arrow-tooth flounder (sexes combined) is described by the equation:

$$
\mathrm{W}=5.682 \times 10^{-6} * \mathrm{~L} * * 3.1028
$$

Maturity information from a histological examination of arrowtooth flounder in the Gulf of Alaska (Zimmerman 1997) indicate that male and female fish become $50 \%$ mature at 46.9 and 42.2 cm , respectively.

## ANALYTIC APPROACH

## Model Structure

The abundance, mortality, recruitment and selectivity of arrowtooth flounder were assessed with a split-sex, length-based version of the stock synthesis assessment model (Methot 1990). The model is a separable catchage analysis that uses survey estimates of biomass and size composition estimates as auxiliary information. The model simulates the dynamics of the population and compares the expected values of the population characteristics to the those observed from surveys and fishery sampling programs. This is accomplished by the simultaneous estimation of the parameters in the model using the maximum likelihood estimation
procedure. The fit of the simulation values to the observed characteristics is optimized by maximizing the $\log$ (likelihood) function.

The suite of parameters estimated by the model are classified by three likelihood components:

| Data Component Distribution assumption |
| :--- | :--- |

Trawl fishery size composition
Trawl survey population size composition
Trawl survey biomass estimates and S.E.

Multinomial
Muitinomial
Log normal

The total $\log$ likelihood is the sum of the likelihoods for each data component (see Table 6-6). The model allows for the individual likelihood components to be weighted by an emphasis factor. The parameters estimated by the model are presented below:

$\left.\begin{array}{ccccc}\hline \text { Fishing mortality } & \text { Selectivity } & & \text { Year class } & \text { strength }\end{array}\right]$ Total | 30 | 12 | $=$ | 52 | 94 |
| :---: | :---: | :---: | :---: | :---: |

Natural mortality and survey catchability were estimated independently of the model. The increase in the number of parameters estimated in this assessment compared to last year can be accounted for by the input of another year of fishery catch data and the entry of another year class into the observed population.

We assume that the shelf and slope surveys measure non-overlapping segments of the arrowtooth flounder stock. The model was configured with the Bering Sea shelf comprising $87 \%$ of the population, calculated from the average proportion of shelf/shelf+slope biomass from the trawl survey time-series. In this assessment we did not attempt to incorporate the Aleutian Islands biomass estimate. For Bering Sea shelf flatfish, the accepted belief is that the trawl survey is a good indicator of the flatfish abundance level. Thus, it is desirable to obtain a reasonable fit to this data component and the model was configured with an emphasis of 5.0 was placed on fitting the shelf survey biomass trend. This resulted in a better fit to the abundance trend without degrading the fit to the other primary data components.

The most reliable and consistent data for modeling the arrowtooth flounder population are the shelf survey biomass and size composition time-series. Consequently, results are most closely linked to fitting the general trend of increasing shelf survey biomass estimates during the 1980s to its peak level in the mid- 1990s, and to fitting the male and female size compositions from the shelf survey (Fig. 5.2).

## Parameters Estimated Independently

## Natural mortality

The natural mortality of arrowtooth flounder is assumed to be 0.20 . This estimate was used because it is similar to that of other species of flatfish with approximately the same age range as arrow-tooth flounder and is the same estimate used by Okada et al. (1980).

Aging by both U.S. and Japanese scientists from samples collected in the EBS during U.S.-Japanese cooperative surveys has shown age 15 to be the maximum age of arrow-tooth flounder.

## Catchability

A past assessment (Wilderbuer and Sample 1995) also analyzed the value of Q or catchability of the research trawl by examining fits of the models' various likelihood components over a range of fixed Q values. The results indicated that $\mathrm{Q}=2.0$ which suggests that more fish are caught in the survey trawl than are present in the "effective" fishing width of the trawl (ie. some herding may occur or the "effective" fishing width of the trawl may be the distance between the doors instead of between the wingtips of the survey trawl).

In the case of the fit to the slope survey abundance estimates, Q is less than 1.0 as the fit to this likelihood component degrades with increasing Q . This is consistent with the Q profiling presented in the Greenland turbot assessment (Ianelli et al., section 4) and our belief that the Noreastem trawl is a poor sampling tool on the Bering Sea slope (Bakkala and Wilderbuer 1990).

## Parameters Estimated Conditionally

Year class strengths
The population simulation specifies the number-at-age in the beginning year of the simulation, the number of recruits in subsequent year, and the survival rate for each cohort as it moves through the population calculated from the population dynamics equations (see Table 6-6).

## Selectivity and sex ratio

Survey results indicate that fish less than about 4 years old ( $<30 \mathrm{~cm}$ ) are found only on the Bering Sea shelf. Males from $30-50 \mathrm{~cm}$ and females $30-70 \mathrm{~cm}$ are found in shelf and slope waters, and males $>50 \mathrm{~cm}$ and females $>70 \mathrm{~cm}$ are found exclusively on the slope. Sex specific "domed-shaped" selectivity was freely estimated for the shelf survey; for the slope survey we assumed an asymptotic selectivity pattern.

At the present time there is no arrowtooth flounder directed fishery. Length measurements collected from the fishery represent opportunistic samples of arrowtooth flounder taken as bycatch. This results in sample size problems which make estimates of fishery selectivity unreliable. Also, we felt that a directed fishery would likely target a different segment of the stock. Accordingly, the shape of the selectivity curve was fixed asymptotic for older fish in the fishery since a directed fishery would presumably target on larger fish. This also allowed for a realistic calculation of exploitable biomass from the model estimate of total biomass.

Examination of the shelf and slope survey population estimates indicate that females are consistently estimated to be in higher abundance than males (Fig. 5.3). This difference was also evident in the Gulf of Alaska from triennial surveys conducted from 1984-96 (Tumock et al. 1998). This information was incorporated into last years' assessment by adjusting the size composition data input into the model by the sex ratio proportion observed in shelf and slope trawl surveys and fishery data. This resulted in unsatisfactory results as the model gave low estimates of male selectivity which has the undesirable result ofartificially increasing population estimates. This assessment assumes an equal population sex composition.

Possible reasons for the higher estimates of females in the survey observations may be: 1) there is a spatial separation of males and females where males are less available to the survey trawl, 2) there is a higher natural mortality for males than females, 3) there are some sampling problems, or 4) there is a genetic predisposition to produce more females than males.

Growth
The length-based synthesis model allows flexibility on the relationship between length and age. The model was configured to estimate the $\mathrm{L}_{\text {inf }}$ and K parameters by sex as was described in a past asssessment (Wilderbuer and Sample 1995). These estimates of the growth parameters provided the best fit to the slope and shelf size compositions.

## Fishing mortality

The fishing mortality rates (Fj for each age and year are calculated to exactly match the catch weight by solving for F as follows:

$$
\sum_{a}\left[N_{a y} \hat{W}_{a}\left(\frac{f_{y} S_{a}}{f_{y} S_{a}+M}\right) 1-\exp ^{\left(-f_{y} S_{a}+M\right)}\right]-\sum_{a} C_{a y} \hat{W}_{a}=0
$$

where $\mathbf{F}_{a y}=\mathbf{f} S_{y^{a}}, N_{a y}=$ numbers of fish age a in year $\mathrm{y}, \hat{W}_{z}=$ average weight-at-age, M is the natural mortality rate, $C_{a y}=$ catch weight of age a fish in year $y, S$, is the fishery selectivity at age and $f_{y}$ is the fishing effort in year $y$.

## MODEL RESULTS

## Fishing mortality and selectivity

The stock synthesis model estimates of the annual fishing mortality on fully selected ages and the estimated annual exploitation rates (catch/total biomass) are given in Table 5.2. The exploitation rate has been at a low level, $4 \%$, from 1977-1999 due to the undesirability of arrowtooth flounder as a commercial product. Agespecific selectivity estimated by the model (Table 5.3, Fig. 5.4) indicate that arrow-tooth flounder are $50 \%$ selected by the fishery at about 8 and 7 years of age and are fully selected by ages 17 and 11 , for males and females, respectively.

## Abundance Trend

Model estimates indicate that arrow-tooth flounder total biomass increased more than 5 fold from 1980 to its' most abundant level in 1995 at $915,230 \mathrm{t}$ (Fig. 5.5, Table 5.4). The biomass has declined $10 \%$ since then to the 1999 estimate of $823,435 \mathrm{t}$. Female spawning biomass is also estimated at a high level, projected at nearly $481,000 \mathrm{t}$ in 2000 (Table 5.4). Model estimates of population numbers by age, year and sex and total biomass are given in Table 5.5.

The model fit to the shelf survey (emphasis 5.0) tracks the abundance trend well through 1990. The model estimate of survey biomass is less than the observed values from 1993-97 and does not provide a godd fit to the declining estimates from the 1998 and 1999 shelf surveys. The model indicates an increasing biomass trend on the slope which fits the slope survey estimates poorly (Fig. 5.5). The slope biomass represents a smaller fraction of the total stock and is not well estimated by the survey, particularly the 1991 point estimate which is considered to be an underestimate of the slope survey biomass due to the reduction in sampling depth relative to earlier surveys.

The model provided a good fit to the survey shelf size compositions for the past 10 years for males and females (1989-99) and are shown in the Appendix. Reasonable fits also resulted for slope survey size composition observations.

## Recruitment Trends

Increases in abundance from 1983-95 were the result of 5 strong year-classes spawned in 1981, 1984, 1986, 1987 and 1988 (Fig. 5.6, Table 5.6). Recruitment since 1990 is estimated to be near average in 1990-92, weak in 1993 and 1994, but stronger than average in 1995.

Otoliths for aging arrowtooth flounder have been routinely collected during AFSC surveys in the EBS, but they have been infrequently aged because of higher priority for aging other species. However, an examination of length-frequency data shows that modes formed by age groups 1 to 3 are reasonably well separated so that fish less than 25 cm can be used as a measure of recruitment for age 2 fish; some age 1 fish are also included, but they are poorly recruited to the survey trawls. Population estimates (in millions) for fish less than 25 cm are as follows:

| Year |  | 1982 | 1983 | 1984 | 1985 | 7986 | 1987 | 1988 | 1989 | 1990 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Population | estimates | 86.1 | 290.2 | 57.9 | 62.4 | 150.3 | 94.3 | 200.6 | 273.8 | 105.2 |
| Year |  | $\underline{1991}$ | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 |
| Population | estimates | 71.7 | 79.4 | 96.8 | 126.6 | 75.1 | 55.6 | 108.8 | 93.6 | 92.1 |

Over this period, population estimates for this size group have averaged 120 million. Above average recruitment has occurred in 1983, 1986, 1988, 1989 and 1994. Since the estimates primarily represent age 2 fish, the year-classes producing the strong recruitment are 198 1, 1984, 1986, 1987 and 1992 (Fig. 5.6). Estimates of age 2 recruitment from the synthesis model agree well with the trawl survey population estimates and also indicate average to above average recruitment for the four years following the large '1986 and 1987 year-classes. The past five surveys indicate recruitment below the 1982-99 average.

## ACCEPTABLE BIOLOGICAL CATCH

Arrow-tooth flounder have a wide-spread bathymetric distribution in the Bering Sea/Aleutian Islands region and are believed to be at a high level, primarily as a resuit of five strong year-classes spawned during the 1980s and minimal commercial harvest. They are estimated to have declined $10 \%$ since a peak population biomass in 1995. The estimate of 2000 total biomass from stock synthesis is $\mathbf{7 8 4 , 6 0 0} \mathrm{t}$ and the female spawning biomass is estimated at 496,000 t .

The reference fishing mortality rate for arrowtooth flounder is determined by the amount of reliable population information available (Amendment 44 of the Fishery Management Plan for the groundfish fishery of the Bering Sea/Aleutian Islands). Equilibrium female spawning biomass is calculated by applying the female spawning biomass per recruit resulting from a constant $F_{0.40}$ harvest to an estimate of average equilibrium recruitment. For the 1999 assessment, the Alaska Fisheries Science Center policy is to use only year classes spawned in 1977 or later to calculate the average equilibrium recruitment. Using the time-series
of recruitment from 1978-98 from the stock assessment model results in an estimate of $\mathrm{B}_{0.40}=194,600 \mathrm{t}$. The stock synthesis model estimates the 2000 level of female spawning biomass at $496,000 \mathrm{t}$ (B). Since reliable estimates of $\mathrm{B}, \mathrm{B}_{0.40}, \mathrm{~F}_{0.40}$, and $\mathrm{F}_{0.50}$ exist and $\mathrm{B}>\mathrm{B}_{0.40}(496,000>194,600)$, arrowtooth flounder reference fishing mortality is defined in tier 3a. For the 2000 harvest: $F_{A B C} \leq F_{0.40}=0.22$ and $F_{\text {overfisting }}=F_{0.35}=0.27$ (full selection F values).

Acceptable biological catch is estimated for 2000 by applying the $\mathrm{F}_{0.40}$ fishing mortality rate and age-specific fishery selectivities to the projected 2000 estimate of age-specific total biomass as follows:

$$
\left.\left.A B C=\Sigma \sum_{a=a_{r}}^{a} \bar{w}_{a} n_{a}\left(\frac{F s_{a}}{M+F s_{a}}\right)\right]=e^{-M-F s_{a}}\right)
$$

where S , is the selectivity at age, M is natural mortality, $\mathrm{W}_{\mathrm{a}}$ is the mean weight at age, and n , is the beginning of the year numbers at age. This results in a 2000 ABC of $\mathbf{1 3 0 , 5 0 0} \mathrm{t}$.

The potential yield of arrowtooth flounder for 2000 at various levels of fishing mortality (full selection) are as follows:

Fevel Exploitation rate Potential vield

| $\mathrm{F}_{\text {overisthing }}$ | 0.27 |  |
| :--- | :---: | :---: |
| $\mathrm{~F}_{\mathbf{0 . 4 0}}$ | 0.22 |  |
|  | $160,200 \mathrm{t}$ |  |
|  | $\mathbf{1 3 0 , 5 0 0} \mathrm{t}$ |  |

Please note that these values are estimated assuming that the "area-swept" survey estimates of biomass are unbiased (ie. " Q " $=1.0$ ). Preliminary results suggest that " Q " $>1.0$ which would result in lower biomass and ABC estimates (for the Bering Sea shelf and slope).

## PROJECTED BIOMASS

This year, a standard set of projections is required for each stock managed under Tiers 1,2, or 3 of Amendment 56. This set of projections encompasses seven harvest scenarios designed to satisfy the requirements of Amendment 56, the National Environmental Protection Act, and the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA).

For each scenario, the projections begin with the vector of 1999 numbers at age estimated in the assessment. This vector is then projected forward to the beginning of 2000 using the schedules of natural mortality and selectivity described in the assessment and the best available estimate of total (year-end) catch for 1999. In each subsequent year, the fishing mortality rate is prescribed on the basis of the spawning biomass in that year and the respective harvest scenario. In each year, recruitment is drawn from an inverse Gaussian distribution whose parameters consist of maximum likelihood estimates determined from recruitments estimated in the assessment. Spawning biomass is computed in each year based on the time of peak spawning and the maturity and weight schedules described in the assessment. Total catch is assumed to equal the catch associated with the respective harvest scenario in all years. This projection scheme is run 1000 times to obtain distributions of possible future stock sizes, fishing mortality rates, and catches.

Five of the seven standard scenarios will be used in an Environmental Assessment prepared in conjunction with the final SAFE. These five scenarios, which are designed to provide a range of harvest alternatives that
are likely to bracket the final TAC for 2000, are as follow ("max $F_{A B C}$ " refers to the maximum permissible value of $F_{A B C}$ under Amendment 56):

Scenario I: In all future years, $F$ is set equal to $\max F_{A B C}$. (Rationale: Historically, TAC has been constrained by ABC , so this scenario provides a likely upper limit on future TACs.)

Scenario 2: In all future years, $F$ is set equal to a constant fraction of $\max F_{A B C}$, where this fraction is equal to the ratio of the $F_{A B C}$ value for 2000 recommended in the assessment to the max $F_{A B C}$ for 2000. (Rationale: When $F_{A B C}$ is set at a value below $\max F_{A B C}$, it is often set at the value recommended in the stock assessment.)

Scenario 3: In all future years, $F$ is set equal to $50 \%$ of $\max F_{A B C}$. (Rationale: This scenario provides a likely lower bound on $F_{A B C}$ that still allows future harvest rates to be adjusted downward when stocks fall below reference levels.)

Scenario 4: In all future years, $F$ is set equal to the 1994-1998 average $F$. (Rationale: For some stocks, TAC can be well below ABC , and recent average $F$ may provide a better indicator of $F_{T A C}$ than $F_{A B C}$.)

Scenario 5 : In all future years, $F$ is set equal to zero. (Rationale: In extreme cases, TAC may be set at a level close to zero.)

Two other scenarios are needed to satisfy the MSFCMA's requirement to determine whether a stock is currently in an overfished condition or is approaching an overfished condition. These two scenarios are as follow (for Tier 3 stocks, the MSY level is defined as $B_{35 \%}$ ):

Scenario 6: In all future years, $F$ is set equal to $F_{O F L}$. (Rationale: This scenario determines whether a stock is overfished. If the stock is expected to be above $1 / 2$ of its MSY level in 2000 and above its MSY level in 2010 under this scenario, then the stock is not overfished.)

Scenario 7: In 2000 and $2001, F$ is set equal to $\max F_{A B C}$, and in all subsequent years, $F$ is set equal to $F_{\text {ofL }}$. (Rationale: This scenario determines whether a stock is approaching an overfished condition. If the stock is expected to be above its MSY level in 2012 under this scenario, then the stock is not approaching an overfished condition.)

Simulation results (Table 5.7) indicate that arrowtooth flounder are not currently overfished and the stock is not considered to be approaching an overfished condition.

## OTHER CONSIDERATIONS

Arrow-tooth flounder are currently of limited economic importance as a fisheries product, however, trophic studies (Lang et al. 1991, Livingston et al. 1993) indicate they are an important predator and may be an important component in understanding the dynamics of the Bering Sea benthic ecosystem. This is particularly relevant as the Council begins to consider shifting emphasis from single species to multi-species fisheries management of the Bering Sea and Aleutian Islands (Ecosystem Considerations, 1994 SAFE). Trophic studies indicate that the main food item in the diet of arrowtooth flounder is fish, particularly for arrow-tooth larger than 30 cm . Pollock are a major component of the diet as well as other fish such as zoarcids. Invertebrates are also important and include cephalopods, euphausids and pandalid and crangonid shrimp. Preadators of arrowtooth flounder include Pacific cod and large pollock, mostly on juvenile fish.

2012 179, 465 46, $776 \quad 0.24$

Figure 5.1-Catch per unit effort (CPUE) of arrowtooth flounder on the eastern Bering Sea continental shelf as shown by Alaska Fisheries Science Center (AFSC) survey data.

Figure 5.3-Proportion of the estimated male population from Bering Sea bottom trawl surveys on the shelf and the continental slope.

Figure 5.4-Age-specific shelf and slope survey selectivity (top panel) and fishery selectivity (bottom panel) by sex, estimated from the stock synthesis model.

Figure 5.5-Stock synthesis model estimates of begin year biomass, mid-year biomass and spawning biomass (top panel), model fit to shelf survey biomass (middle panel) and model fit to the slope survey biomass (bottom panel).

Figure 5-6-Estimates of arrowtooth flounder age 2 recruitment from the synthesis model (top panel) and from the shelf trawl survey (bottom panel).

## APPENDIX

Figures show the fit of the stock synthesis model to the time-series of shelf and slope survey size composition data by sex (estimated values are the dotted lines) and the fishery size composition data from 1978-90.

Table of arrowtooth flounder catch during research activities by the Alaska Fisheries Science Center, 1977-99.

| helf survey females | survey females | Shelf survey females |
| :---: | :---: | :---: |
|  |  |  |
|  |  |  |
|  |  |  |
|  |  |  |
|  |  |  |
|  |  |  |
