

FLORISTIC DATA FOR 96 PALUSTRINE EMERGENT WETLANDS IN PORTLAND, OREGON

SUPPLEMENTARY DATA FOR:

Teresa K. Magee¹, Ted L. Ernst¹, Mary E. Kentula², and Kathleen A. Dwire^{1,3}. 1999. Floristic Comparison of Freshwater Wetlands in an Urbanizing Environment. *Wetlands* 19(3): 517-534.

Abstract: We evaluated the floristic condition of freshwater palustrine wetlands dominated by wet meadow, emergent marsh, aquatic vegetation, or open water within the rapidly urbanizing area of Portland, Oregon, by (1) characterizing plant species richness (presence/absence) and composition of naturally occurring wetlands (NOWs) and mitigation wetlands (MWs), and (2) identifying relationships between floristic characteristics and variables describing land use, site conditions, and mitigation activities. Data were collected on 45 NOWs and 51 MWs. Overall species richness was high (365 plant taxa), but more than 50% of the species present on both NOWs and MWs were introduced. Only 14 species occurred on more than half the sites and nine of these were invasive nonindigenous species. The mean number of native species per site did not differ between land use categories (ANOVA, $p=0.6031$), however, wetlands surrounded by agricultural and commercial/industrial/transportation corridor uses had more introduced species per site than wetlands surrounded by undeveloped land ($p \leq 0.05$). Although overlapping in floristic composition, NOWs and MWs had significantly different (MRPP, $p < 0.0001$) species assemblages that were identified using TWINSPAN. MRPP analyses for all sites showed that watershed, land use, HGM class, percent cover of water and MW age were significantly related to the floristic composition of the study wetlands. Canonical correspondence analyses further revealed that the primary gradient for species distribution in NOWs was related to moisture; the secondary gradient was related to land use. The primary gradient also described a strong relationship between percent cover of water and HGM class. For MWs, the primary gradient was related to watershed location and surrounding land use; the secondary gradient was related to percent cover of water and MW age. Most MWs (44 out of 51 sites) were depressions in various settings, so while HGM class separates NOWs from MWs, it does little to distinguish MW assemblages. Our results show wetlands in the urbanizing study area are floristically degraded. Further, current wetland management practices are replacing natural marsh and wet meadow systems with ponds, resulting in changes in the composition of plant species assemblages.

Keywords: biodiversity, canonical correspondence analysis (CCA), hydrogeomorphic classes (HGM), introduced species, mean similarity dendograms, multiple response permutation procedures (MRPP), native species, nonindigenous species, Oregon, USA, TWINSPAN, wetland mitigation, urban ecosystems.

SUPPLEMENTARY DATA. Ecological status of taxa found in study sites in the Portland, Oregon metropolitan area and the number of naturally occurring wetlands (NOW) or mitigation wetlands (MW) on which they occur. Species are listed as native, introduced, or unknown origin[§]. Each species was assigned to an United States Fish and Wildlife Service Wetland Indicator Category (IND): OBL = obligate wetland, FACW = facultative wetland, FAC = facultative, FACU = facultative upland, UPL = obligate upland, NI = no-indicator, UNK = absent from the indicator list (Reed 1988, 1993). Species that were identified in the literature and through field observation as invasive[†] are indicated by a star (*); superscript numbers indicate sources for invasive designation. Trees and shrubs of horticultural origin found only on MWs are indicated by a diamond (◆). Nomenclature based on BONAP (1996); Synonyms from regional floras (Hitchcock and Cronquist. 1973 or Hickman 1993) are included in parentheses.

[§]Determination of native/introduced status for vascular taxa was based on Hitchcock & Cronquist (1973), with the exception of *Phalaris arundinacea* and *Festuca rubra*. *Phalaris arundinacea* has historically been considered to have some native genotypes, however, currently much of its extent on the landscape is believed to be represented by aggressively spreading cultivars introduced for forage and erosion control (Guard 1995, Naglich 1994). In the study area, *Festuca rubra* is represented by a complex of native and introduced varieties (personal communication Barbara Wilson, Oregon State University) so, here, its native/introduced status is listed as unknown. For taxa identified only to genus, native or introduced status was usually listed as unknown. However, if a particular specimen could be identified to one of a small group of species known to be either introduced or native, it was assigned the appropriate status.

[†]Plant species characterized as invasive or noxious weeds were identified using information from local floras, and noxious weed lists or floras describing widespread introduced species: ¹Hitchcock & Cronquist (1973), ²Hawkes et al. (1989), ³Taylor (1990), ⁴Washington State Department of Agriculture (1992), ⁵U.S. Congress, Office of Technology Assessment (1993), ⁶Oregon State Department of Agriculture (1994), ⁷Guard (1995), ⁸Houck (1996) and ⁹Whitson et al. (1996).
