Fission Calculation Details

1. Fission Barriers of 5254 nuclei calculated for $170 < A \leq 330$
Several different parameterizations are used
2. 5D parameterization, energy for 5 000 000 different shapes are calculated for each nucleus
3. For small deformations a 3D parameterization is used
Elongation, neck and axial-asymmetry shape degrees of freedom.
4. An improved determination of the ground-state energy and shape is done in a 4D space
5. When multiple minima are present a special strategy is used to establish which minimum and saddle define the “barrier”.
(In practice this technique cannot be implemented in HFB)

6. Just the potential energies correspond to more than 250 Gb of information.
7. Saddles, minima, valleys are determined in a completely automated fashion. Compact result files are generated for each nucleus
8. Data sets, such as tables of barrier heights (Z, N, A, E_f) are generated, also by automated scripts.

Results will be made available at URL

Results more complete than can be published will be available here in due course.

Five Essential Fission Shape Coordinates

Fission-Barrier and Associated Shapes for ^{242}Am

Fission Barrier and Associated Shapes for ^{232}Th

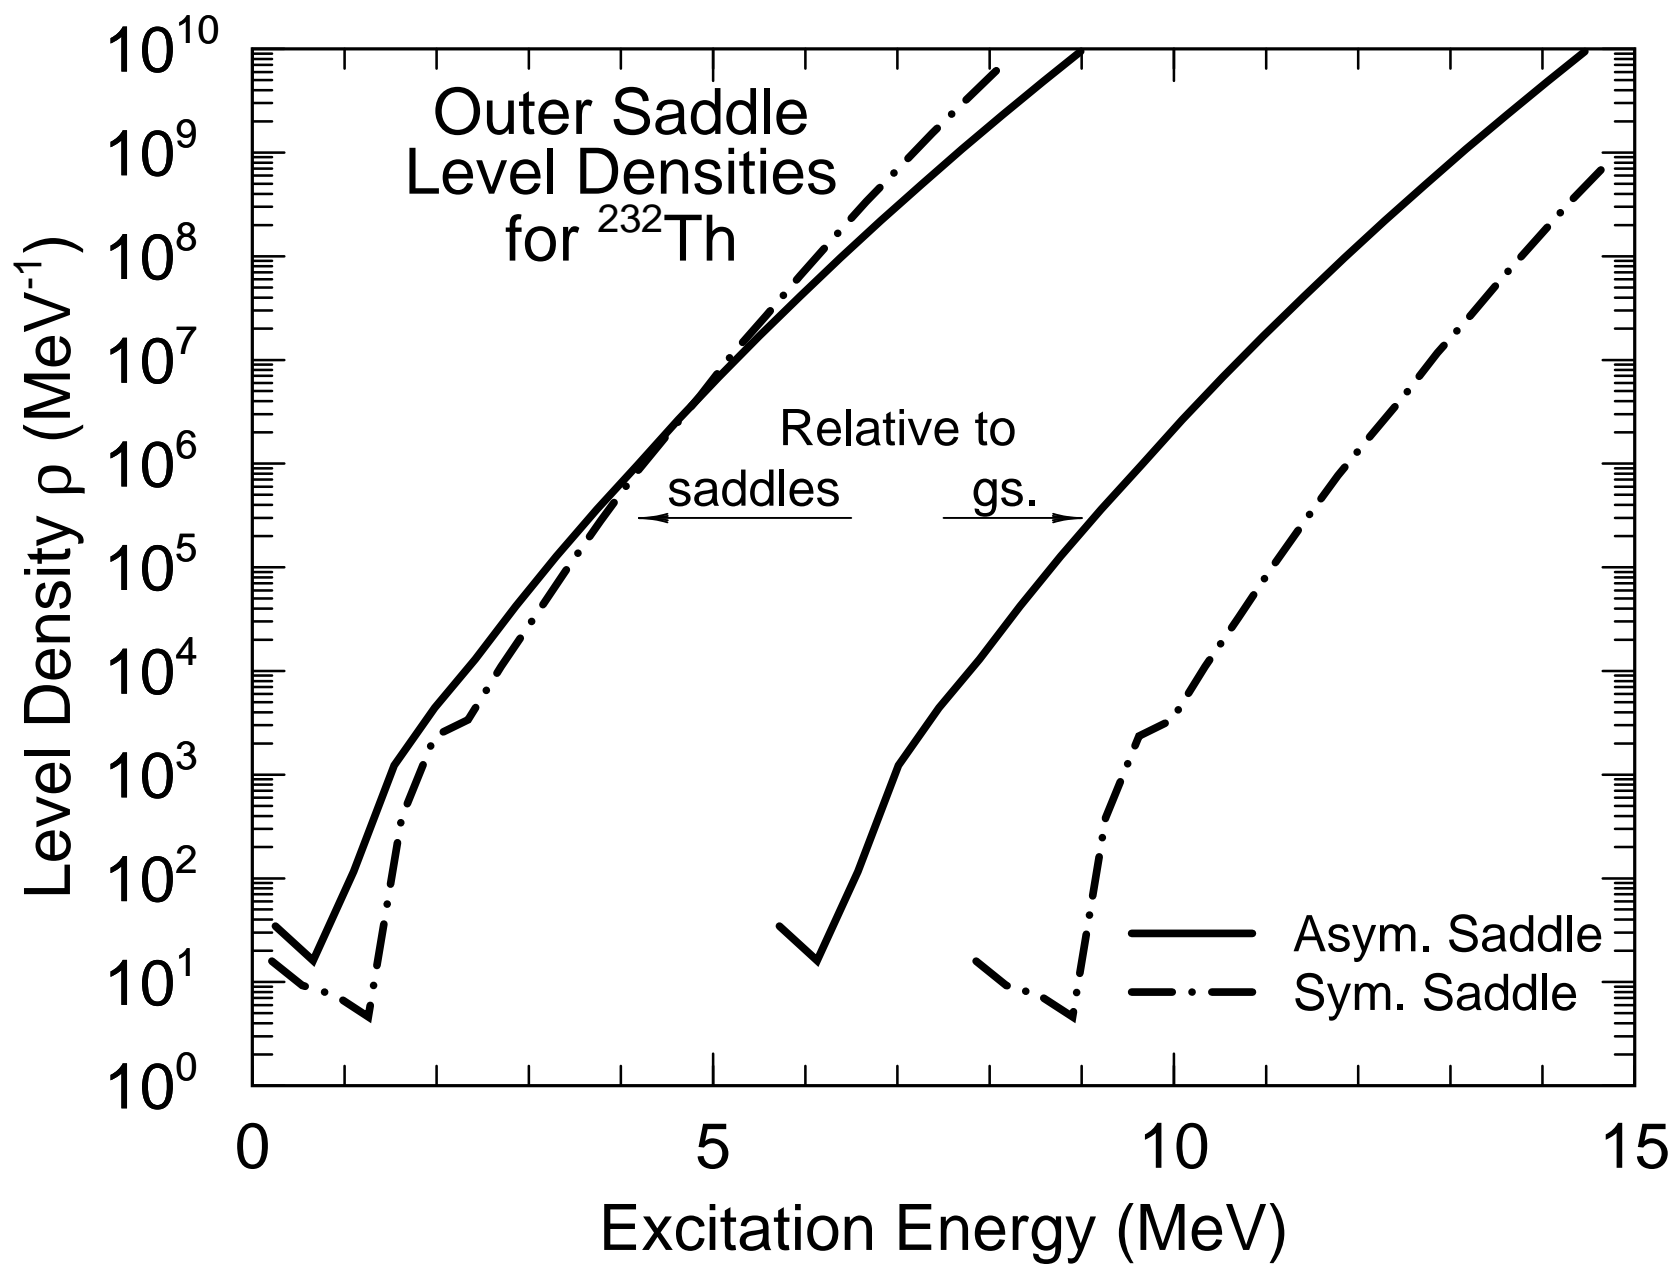

TABLE I: Fermi-gas level-density parameters determined from adjustments of parameters of the Fermi-gas model to microscopic calculations of intrinsic level densities. The numbers in parentheses are (1) for an asymmetric saddle, and (2) for a symmetric saddle. B and C refer to the second and third saddle, respectively, for a triple-humped barrier, see Fig. ??.
