---

Experiment 787 is a search for reactions of the type  $K^+ \rightarrow 6 B^+ X$ , where X is a weakly interacting light neutral particle. The experiment is sensitive to such decays at the  $10^{-10}$  level. The prime candidate is  $K^+ \rightarrow 6 B^+ \llcorner$  which provides a uniquely stringent test of the Standard Model and its parameters because it is the only experimentally accessible process that is dominated by an unambiguously calculable higher order weak interaction. Two body decays  $K^+ \rightarrow 6 B^+ X$  are also searched for to place constraints on the existence of a variety of hypothetical particles such as axions, familons, hyperphotons and supersymmetric neutrals predicted by extensions to the SM. Several other rare decays including  $K^+ \rightarrow 6 B^+ \llcorner$ ,  $K^+ \rightarrow 6 B^+ \mu^+ \mu^-$ ,  $B^0 \rightarrow 6 \llcorner$ , and  $B^0 \rightarrow 6 \llcorner$  are also being investigated. The former two,  $K^+ \rightarrow 6 B^+ \llcorner$  and  $K^+ \rightarrow 6 B^+ \mu^+ \mu^-$ , were discovered by this experiment. Recently a candidate for  $K^+ \rightarrow 6 B^+ \llcorner$  was observed by E787.

---

Motivated by Jaffe's 1977 prediction of a six-quark object with strangeness -2 and  $J^P = 0^+$  at a mass of 2150, this experiment proposed to study the strangeness of -2 two-baryon mass spectrum from 100 MeV below the mass of the lightest known two-baryon strangeness -2 system, 77 mass. This particle, called the "H," has been predicted by later bag models as well. Although the mass calculation is model dependent, the predictions are considered within the expected range of sensitivity. The possibility of resonances near the 77 mass due to conventional meson exchange forces can also be explored using the experiment covers the region both above and below the 77 mass.

## EXPERIMENT 821

---

The anomalous gyromagnetic ratio of the muon ( $g-2$ ) will be measured to 0.35 ppm or a factor of 20 times better than it is currently known. The predicted contribution to ( $g-2$ ) from the first and second order  $W^\pm$  and  $Z^0$  radiative corrections is predicted to be 1.3 ppm, so this experiment will provide a direct test of the electroweak radiative corrections, and hence of the renormalizability of the Glashow-Weinberg-Salam theory. Since  $a_\mu$  is sensitive to a wide range of non-standard model effects there is a window in which to search for new physics.  $W$  or muon substructure, super-symmetry and the existence of new gauge bosons are several possibilities. A 14 m diameter superferric muon storage ring is now operational. Data collection will begin in FY 1997.

**EXPERIMENT 850**

Home Page • <http://www.phys.psu.edu/LEPS/EVA/eva.html>

---

**EVA, A SOLENOIDAL DETECTOR FOR LARGE ANGLE EXCLUSIVE REACTIONS**  
**EXPERIMENT 850 - DETERMINING COLOR TRANSPARENCY**  
**Spokesmen: A.S. Carroll and S. Heppelmann**

- **Brookhaven National Laboratory**

E. Piasetzky
- **University of Auckland** - N. Christensen
- **University of Massachusetts-Dartmouth** - J.J. Russell

---

In order to extend the range and sensitivity of measurements of large angle exclusive reactions, a new solenoidal detector, EVA, has been built. This detector increases the solid angle acceptance by over a factor of 20 over the existing dipole detector of E834, and provides for momentum measurements of all outgoing particles. The initial experiment, E850, has made new determinations of color transparency for carbon nuclei. Also measurements of carbon spectral functions at large momentum transfers were made. With a neutron detector, the correlations of neutrons associated with quasi-elastic (p,2p) reactions were determined. The solenoidal magnet which has not had reliable operation, has been substantially rebuilt, and now performs in a satisfactory manner.

- **Rensselaer Polytechnic Institute** - G. Adams, J P. Cummings, J Kuhn, J Napolitano, M. Nozar, J Smith, D. White, M. Witkowski

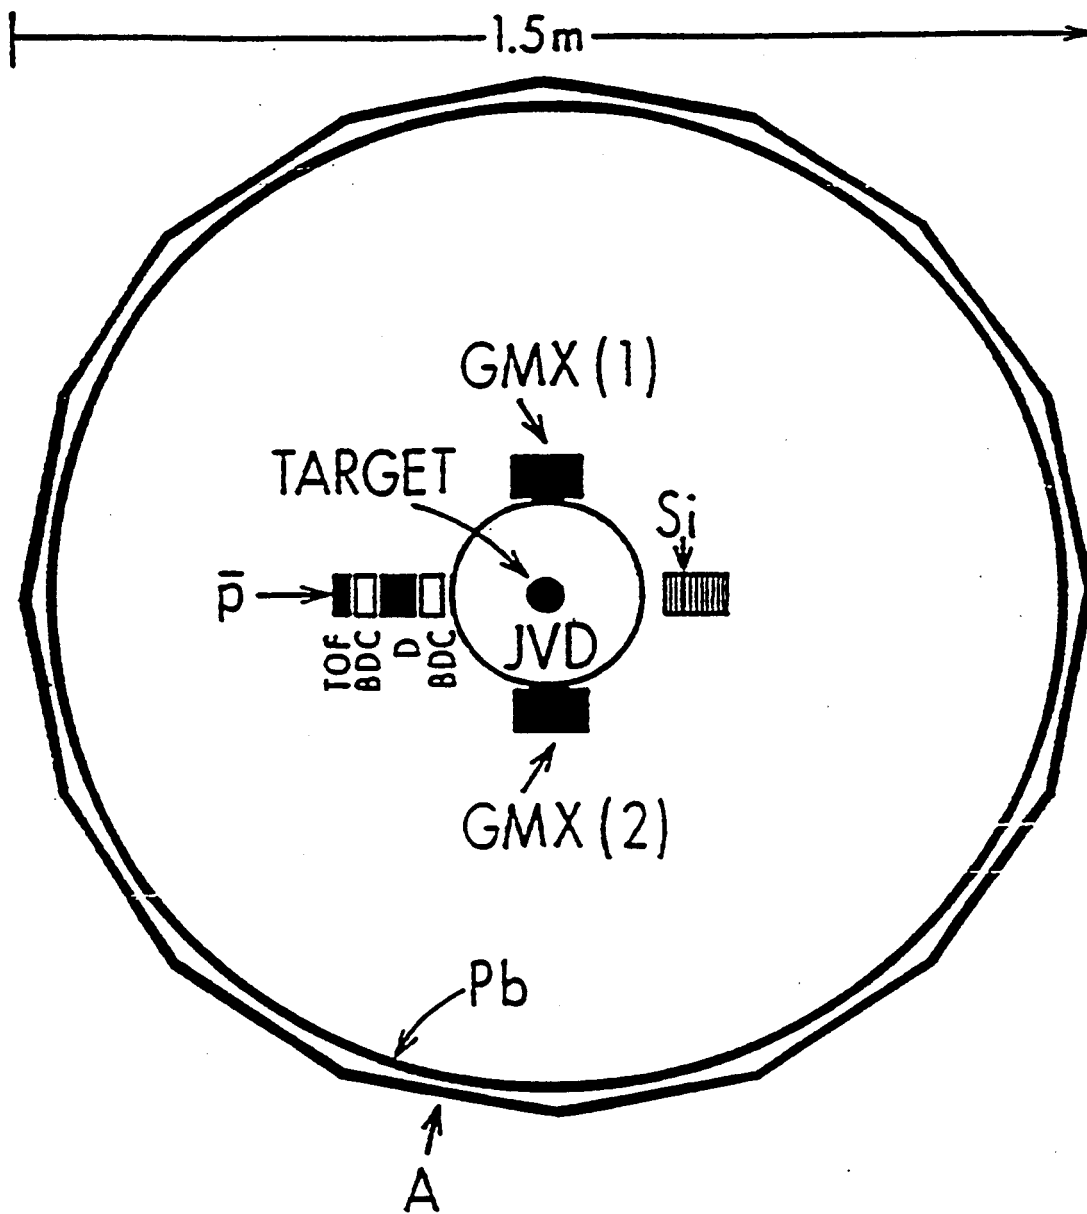

---

Despite a number of experimental searches there is still no unambiguous candidate for a glueball, hybrid or four-quark state, although QCD predicts such objects. However, there are some tantalizing states, among them the ME(1405) which has exotic  $J^C = 1^+$  and the scalar G(1590) which has unusual branching ratios for a quark-antiquark state.

The experimenters will study these and other states, concentrating on decay modes of mesons with multi-photons and 0, 1 or 2 charged particles. The detector is built around the MPS. The target will be surrounded by a CsI veto, charged particle detectors and a scintillation counter. The target will be followed by charged particle detectors, a Cerenkov counter and a 3000-element lead glass calorimeter to detect photons from meson decays.

The potential of antiprotons for practical applications within present antiproton collection capabilities is promising. Suggested applications include direct 3D electron density imaging, 3D multi-elemental imaging, guiding precise and easy delivery of ion beams to targets, and radiation therapy.

In this initial phase of the research, the following physics questions will be addressed: (a) Comparison of antiproton capture rates in complex targets with the Z-law; (b) Studies of the annihilation mechanism in nuclei. These studies of physics are interesting on their own right and will provide basic information in evaluating the proposed applications as well.

The experimenters have begun to carry out a systematic set of measurements and searches for "composite" objects produced in high energy heavy ion collisions. These measurements are aimed at studies utilizing the heaviest ions available at the AGS, including gold ions. A major focus of the experiment is on charged composites; however, studies of neutral systems are also considered significant in the study. The experiment is designed to study particles produced in the central region of rapidity which are produced in central collisions. Since composite systems must be produced by the overlap of particles produced in the collision, it is expected that composites will be made mostly in the central rapidity region where overlaps would be most probable.

E865, a second generation search for  $K^+ \rightarrow 6 B^+ \mu^+ e^-$  at the branching ratio level of  $\sim 3 \times 10^{-12}$ , a factor of 70 improvement over the previous limit of  $2.1 \times 10^{-10}$ . Data obtained in the FY95 run show a clear  $K^+ \rightarrow 6 B^+ \mu^+ e^-$  signal above background visible on one data tape or about one shift of running. The branching ratio for this decay was measured to be  $2.8 \times 10^{-7}$  in E851 and a few hours of running gathers more events than the world sample of 41 events that existed prior to the BNL rare kaon decay program. From this rate and those for  $K^+ \rightarrow 6 B^+ B^+ B^-$  and  $K^+ \rightarrow 6 B^+ B^0$  followed by  $B^0 \rightarrow 6 e^+ e^-$  (we estimate our current branching ratio sensitivity to be  $< 5 \times 10^{-11}$  for  $K^+ \rightarrow 6 B^+ \mu^+ e^-$ , well beyond  $2.2 \times 10^{-10}$  obtained in E777).

An upgrade of the data acquisition system should result in a factor of two increase in data rate in FY96. Additions to the experiment include special triggering electronics for the decay  $K^+ \rightarrow 6 B^+ \mu^+ \mu^-$  and a beam tracking detector in order to improve vertex reconstruction and sensitivity to rare decays with missing energy.

In keeping with the original purpose of E802 and E859, this experiment will continue the investigation of semi-inclusive single particle spectra using the gold beam: (1) to measure the particle momentum spectra as a function of  $p_t$  and  $y'$  (2) to find how these cross sections vary with "central" or "peripheral" collisions as taken from the event characterizing detectors; (3) to measure two-particle correlations; (4) to look for systemic variations in the cross sections with different beams and targets so as to clarify the reaction dynamics; and (5) to seek evidence in this measurement for the production of very dense nuclear matter, or ultimately, the quark-gluon plasma.

The Krakow-Louisiana-Minnesota (KLMM) collaboration has previously exposed small stacks of nuclear emulsions to the light nuclei beams available from the AGS, Exp. 808. The results of this work, when combined with similar exposures of stacks and chambers made at CERN to higher energy beams, EMU07, have been reported in a number of published papers. In April 1992, when beams of heavier nuclei became available with the commissioning of the Booster, the collaboration exposed stacks and chambers of nuclear emulsions to a beam of gold nuclei with a nominal energy of 10.6 GeV/nucleon. Excellent exposures were obtained and the emulsions successfully processed at Dubna. Analysis by Minnesota and Krakow of the interactions in these emulsions has been completed and some of the results published. Further analysis of specific aspects is continuing and further publications can be expected.

Another exposure, conducted by Minnesota, was made in January 1996 to a beam of 4.0 GeV/n gold nuclei. These emulsions have been processed in Dubna and returned to Krakow, where they will be analyzed. No analysis will be possible in Minnesota due to a lack of funding. Inspection of these emulsions show that they were successfully exposed but are characterized by a heavy background.

# 1992 BNL layout Exp 869

Schematic diagram of the detector setup used for the April 1992 AGS gold run. Ion chambers I - 0 to 4 are four gap parallel plate chambers filled with P10 gas. Cherenkov counters C - 0 to 3 contain radiators of Pilot 425 plastic mounted in white diffusion boxes. The multiwire proportional counters MW have 1 mm wire spacing. The target holder can place any of the targets in the beam by remote command. Thirty-two channels of data are recorded for each event at rates of up to 1,000 events/sec.

This experiment was proposed in order to continue a study of the fragmentation of ultra heavy, UH, nuclei begun at the Bevalac as part of a program of cosmic ray studies. It required additional experiments using the new Booster facility at the Brookhaven AGS. The experiments at the AGS would extend the energy range of the measurements upwards to match the energies of the majority of observed cosmic ray nuclei. These measurements would improve our ability to predict the partial cross sections for the production of fragments and allow better calculations of the abundances of the cosmic ray UH nuclei at the sources by taking account of the effects of propagation on the observed abundances. These measurements would also extend our current studies of the nuclear physics topics of factorization, limiting fragmentation, charge pickup, Coulomb dissociation and fission.

The detector array used during exposures to the AGS gold beam in April 1992 and January 1996 is shown. It consists of a combination of ion chambers and Cherenkov counters which identify the particles entering a target and then measure the sum of the charges emitted from interactions in the targets. During the 1992 exposure, 10.6 GeV/n gold projectiles were allowed to fall on targets of polyethylene, carbon, aluminum, copper, tin and lead. In each case sufficient data was taken to determine partial cross sections of 10 mb with better than 10% accuracy. In addition, a fragmentor was placed in the primary beam, generating secondary beams of fragments. Sufficient of these fragments were generated to allow partial cross sections to be determined in the targets for all projectiles between  $Z = 79$  and  $70$ . The excellent resolution of the detector array allows the identification of fragments with charges as low as  $Z = 50$  coming from gold projectiles.

In January 1996 a beam of 4.0 GeV/n gold nuclei was used in a similar set-up. In addition, data were taken at seven other lower energies using a combination of internal and external degraders. These results will allow a determination of the energy dependence of the partial cross sections, which will be very important in modeling the propagation of the heavy cosmic ray nuclei through the interstellar medium. The analysis of these data has only just begun.

This group is carrying out a new search for the decays  $K_L^0 \rightarrow 6 \mu e$  and  $K_L^0 \rightarrow 6 ee$ , building on the experience from the recently completed experiment, E791. The  $K_L \rightarrow 6 \mu \mu$  branching ratio measurement will also be improved. The final E791 single event sensitivity for  $K_L^0 \rightarrow 6 \mu e$  was about  $1-2 \times 10^{-11}$ . The new experiment will reach a single event sensitivity below  $10^{-12}$ , and if no events are observed, will set an upper limit of about  $2 \times 10^{-12}$ . About 10,000  $K_L^0 \rightarrow 6 \mu \mu$  decays will also be observed.

The experiment takes the novel approach of stopping the neutral beam in a beam stop near the upstream end of the spectrometer.

This group has built a 4.7 Tesla-meter room temperature solenoid which will be installed in a 10-foot long AGS straight section. AGS polarized proton beam time is used to perform *partial snake experiments*. These experiments tested successfully the idea of using a partial snake to correct all depolarizing imperfection resonances. Intrinsic depolarizing resonances are successfully overcome by using an AC vertical dipole to generate coherent betatron oscillation.

The existence and properties of 77 hypernuclei are intimately related to the H particle, a proposed six quark state (uuddss) and the question of strange matter and strangelets. If the H exists and is sufficiently bound, two 7s in a hypernucleus will fuse to form an H. The collaboration has built an experiment to form and detect 77 hypernuclei by stopping many more P than in any previous attempt.

Running of the experiment to date has primarily utilized a diamond target for high stopping rate of short-lived P. K at 1.8 GeV/c incident on a diamond target form P which stop in the diamond and K<sup>+</sup> which are detected in the spectrometer. Capture of P by carbon nuclei form 77 hypernuclei. A scintillating fiber array tracks hypernuclear decay products, and a large TOF array detects the

formation neutron. If H particles are formed, their decays can be detected.  $S = -2$  systems formed in the initial  $K^-$  interaction will also be studied.

---

The experimenters have measured the ratio of  $O^0$  production on deuterium by positive and negative pions over the momentum range from 640 MeV/c to 755 MeV/c. This range spans the onset of the  $S_{11}(1535)$  resonance, which has a very large branching ratio for  $O^0$  decay. The  $O^0$ s are observed by detection of the photons from the neutral decay of the  $O^0$  into two photons.

The measurement of this ratio is a direct test of the validity of charge symmetry in this unexplored domain of nuclear physics. Violations of the symmetry are to be expected because of  $B^0$ - $O^0$  mixing.

The experiments showed large asymmetries, ranging up to over 10% at the highest momentum pions.

A preliminary fit of the data to a model of  $O^0$  production which includes  $BE$ - $O^0$  mixing as the only adjustable parameter requires a value for the mixing angle of  $\sim 1$ - $2^\circ$ . This is the first direct evidence of  $BE$ - $O^0$  mixing in a nuclear environment.

The experiment also demonstrated the power of the AGS as a potent source of O mesons.

**EXPERIMENT 891**

---

A program is underway to study Au-Au collisions at the AGS by measuring the angles and momenta of charged tracks,  $K^0$ 's and  $\gamma$ 's using the TPC's and trigger detectors from E810. In order to handle the higher track multiplicities produced by Au beams, a modified geometric arrangement of the TPC modules is used. This program allows the experimenters to look for anomalous behavior in rapidities (or pseudorapidities), multiplicity, strangeness enhancements,  $P_z$  ( $E_z$ ), energy flow; possibly observe Hanbury-Brown and Twiss effects and other new phenomena. These observations are on an event-by-event basis so that particularly interesting classes of events can be selected and added together to search for new effects (like strangelets) implying a QGP or other new states of matter in a manner which tends to maximize signal-to-background ratios.

\* Also associated with Brookhaven National Laboratory

## EXPERIMENT 892

Home Page • <http://www/ags.bnl.gov/~e892/>

---

Schematic diagram of the apparatus. The adiabatically decreasing solenoid field (shown schematically by the coil height) transports and focuses the positrons. Small dipoles at either end deflect the positrons and electrons into the scintillator detectors. These detectors measure the positron energy and, from time of flight, determine the emission angle of the positron. Positrons are verified by the 511 keV annihilation radiation detected in the gamma detectors. A large dipole magnet(s) located downstream from the APS separates the charge states of the emerging ions.

**EXPERIMENT 892 - CAPTURE FROM PAIR PRODUCTION**  
**Spokesman: H. Gould**

- **Lawrence Berkeley Laboratory** - A. Belkacem, N. Claytor, T. Dinneen, B. Feinberg, H. Gould

---

The experiment measures the cross section for capture from pair production and free pair production of 10 GeV/n Au<sup>79+</sup> on Au collisions. This provides the first measurement of capture from pair production at energies above the 1 GeV/n region. The results are essential to understand the process, to guide ongoing efforts, to develop a nonperturbative theory, and to supply important data for the operations of RHIC. Capture from pair production is the process in which an electron-positron pair is produced by the transient electromagnetic field from a relativistic heavy-ion atomic collision (no nuclear contact) and the electron emerges bound to the projectile ion. It is unique because it is the only recombination process in which the cross section *increases* with energy at relativistic energies. At sufficiently high energies it is predicted to become the dominant re-combination mechanism.

The experimenters are carrying out a systematic and exclusive measurement of the energy (2-10 A GeV) and mass dependence of particle production, correlations, and collective flow effects in Au+ Au collisions. They seek to determine the highest compression achievable in nuclear matter and to study its properties and they will search for evidence for an exotic Equation of State, that is, new physics such as Resonance Matter, Exotica, and QGP. The experimenters are also interested in signatures of critical phenomena in dilute nuclear matter.

It is proposed to measure the four-momentum of light mass particles ( $B^\pm$ ,  $K_s^0$ ,  $K^\pm$ ,  $\gamma$ , n, p, d,  $^3\text{He}$ ,  $^4\text{He}$ ,  $^6\text{He}$ , and the isotopes of Li and Be), projectile fragments from  $Z = 6$  to  $Z = 79$ , and anti-proton production. The majority of the data will be acquired, on an event by event basis, from a state-of-the-art Time Projection Chamber

(EOSTPC) built and used at LBL by the E0S collaboration. The TPC provides continuous tracking, almost 4 $\pi$  acceptance and particle identification for the light mass particles.

\* Deputy at the AGS

The experiment is a search for the  $H_0$  di-baryon and for new states of nuclear matter produced in nucleus-nucleus (AA) collisions at the AGS. The experiment enhances the existing AA program by extending the search into regions of shorter lifetime and complements the existing double-strangeness-exchange program by offering access to a new, more probable doorway channel, the coalescence of two  $\Lambda$ 's into a bound di- $\Lambda$ . The detector is capable of unambiguously identifying the topological signature of unstable particle decays as well

as the rigidity of each particle produced, affording a sensitive search for new metastable states and investigation of the properties of known strange particles such as the  $\Lambda$  polarization and  $\Sigma$  potential.

This experiment studies effects produced by heavy ions (principally 1 GeV/u<sup>56</sup>Fe) in a hierarchy of biological systems. The biological effects of densely ionizing radiation are studied for a number of genetic and cellular endpoints, constituting a broad range of quantifiable endpoints for the molecular to the whole animal level, in some cases including genetic responses over several generations. The biology experiments are supported by physics components designed to provide basic dosimetric information as well as the detailed characterization of the radiation field essential for the accurate interpretation of biological data.

E898 differs from a typical AGS experiment in that it actually consists of a number of more or less independent biology and physics experiments. The list of experiments and PI's may vary from year

to year. Please contact Dr. Marcelo Vazquez (BNL x 3443) for a list of investigators for 1995-1996.

---

Exclusive studies of target fragmentation in 2 - 24 GeV/c hadron ( $p$ ,  $\bar{p}$  and  $B^-$ )-induced reactions have started. Measurements are performed with the Indiana Silicon Sphere 4B detector array, capable of identifying H and He isotopes and  $Z = 3 - 20$  fragments for target rapidity ejectiles over a wide dynamic range. The primary physics objectives are twofold: (1) to improve the understanding of energy dissipation phenomena for central collisions in the  $h + A$  reaction at relativistic energies, and (2) to examine the decay modes of hot nuclear matter excited by simple hadron probes. The bombarding energy regime is chosen to overlap the region in which previous inclusive measurements at AGS have been interpreted in terms of a liquid-gas phase transition in hot finite nuclei. It is in this energy region that the excitation of  $\Delta$ ,  $N^*$  and higher resonances provide an effective means of dissipating projectile energy into internal excitation energy of the target nucleus. Thus, these data will place fresh constraints on the new generation of transport codes, as well as current models of multifragmentation. During the 1996 proton cycle, studies were successfully completed on the  $p + {}^{197}\text{Au}$  system at 6.0, 10.0, 12.0 and 14.6 GeV/c and  $B^- + {}^{197}\text{Au}$  at 5.0, 9.2 and 11.0 GeV/c. These measurements demonstrated an independence of energy deposition on projectile momentum and type for these reactions. In 1998 it is intended to measure the 7 GeV/c  $\bar{p} + {}^{197}\text{Au}$  reaction to search for enhanced energy deposition with antiproton beams.

---

The experimenters proposed to irradiate specimens of permanent-magnet materials so that the defect pinning of magnetic domain walls due to particle tracks can be evaluated.

An assortment of 10 samples ranging in thickness from 0.1 to 1.0 mm, each being about 1 mm square were used. The most interesting spacing for the damage tracks is in the range of 10 to 100 nm which implies irradiation to a dose of about  $10^{10}$  ions per  $\text{cm}^2$ . After the samples had been irradiated and characterized, annealing experiments were carried out to determine the microstructural changes induced by the annealing and the corresponding changes in domain wall pinning and performance characteristics of the material. Some samples were irradiated parallel to the c-axis and others at 45° to the c-axis.

The above has been completed.

The experimenters will irradiate several stacks of YBCO tiles. The chemistry ( $Y_{1.7}Ba_2Cu_3Pt_{0.01}$ ) of these tiles, and their heat processing and oxygen annealing, are the best known at present for field trapping. One set of tiles will each be 20 mm in diameter and 8 mm thick. A stack of several such tiles will be used. As the Au ions penetrate,  $dE/dx$  increases. The ions will first form string-of-beads defects. This experiment will provide a string-of-beads test for the first time and will provide the materials to produce a trapped field magnet (TFM) of greater field than any previously achieved. The experimenters estimate that the field will be 5 Tesla at 77K, and 12.5 Tesla at 65K.

In addition, 4 sets of smaller tiles (3.7 mm in diameter and 2 mm thick) will also be irradiated. The small size of the tiles in these runs is suitable to VSM or SQUID measurement of the magnetic moment and hence  $J_c$ . These runs will provide a desirable cross check on the large scale analysis of  $J_c$  via trapped field. In order to get the same fluence as in the case of 20 mm diameter tiles, these smaller tiles require 1/16 of the beam x time. The 4 sets of tiles will be run at 4 values of fluence.

## EXPERIMENT 905

Home Page • <http://www.phy.bnl.gov/~bnlhyp/e905.html>

A comparison of the in-flight (BNL) observations of the G-structure in  ${}^4\text{He}$  and the stopped kaon experiments at KEK. In both sets, the structure is present in  $(K^-, B^-)$  reactions, but not for  $(K^-, B^+)$ .

---

The evidence for the existence of E (bound)-nuclei derives from three experiments: the first in a  $^4\text{He}$  bubble chamber at the AGS, the second at KEK with stopped  $\text{K}^-$  in  $^4\text{He}$ , and the third, BNL experiment E774. The purpose of E905 is to remeasure helium, using in-flight reactions to verify the existence of a bound state and to obtain the binding energy and width with high precision. This will be accomplished by making use of experience gained in BNL's E774 and E887 to get better control of systematic errors, suppress backgrounds due to electrons and muons and to obtain increased statistics. The precise measurement of the position and width of the postulated bound state may allow a definite allocation of the structure observed in these experiments to a bound state or to a threshold cusp, which is an alternative explanation. The precise measurement of the E-production cross sections in the bound and unbound regions will allow a choice between competing model explanations.

---

The experimenters propose a new way to produce and to identify several hundred double-7 hypernuclei by observing two (successive) mesonic-decay pions with about 1.7 MeV resolution. The rate is larger by two orders of magnitude than other experiments done so far and will enable us to open a new spectroscopy of double-7 hypernuclei.

Double-7 hypernuclei will be produced at the ( $K^-$ ,  $K^+$ ) reaction point through multi-step processes and successive mesonic-decay pions will be detected by a cylindrical detector system and solenoidal magnetic spectrometer (CDS) surrounding the target. The 2 GeV/c kaon beam line and the same experimental setup used for E813 and E836 (with some minor modifications), will be used for this experiment.

---

The threshold for O production in the reactions B<sup>-</sup>p 6 On and K<sup>-</sup>p 67 O is close to the mass of the S<sub>11</sub>(N\*(1535) and S<sub>01</sub>(7\*(1670) resonances, respectively. The cross section for O production in both reactions is unexpectedly large as are other O threshold production cross sections. Better quality data, particularly angular distributions which are currently lacking, in both the K<sup>-</sup>p and B<sup>-</sup>p reactions are needed to understand the role of these resonances near the O threshold. There is a factor of four discrepancy in the determination of the ON scattering length and the O<sup>7</sup> scattering length is unknown due to a lack of precise threshold cross section data. New, precision data at threshold would allow better determinations of these scattering lengths.

The experimenters propose to measure total cross section, as well as angular distributions for O production in both of these reactions from threshold ( $P_B = 685$  MeV/c, and  $P_K = 723$  MeV/c) up to 760 MeV/c. The O particles are detected via the 2( decay mode using the improved O spectrometer currently in operation on the C8 beam line.

The experimenters are studying proton-nucleus (p-A) and heavy ion collisions at the AGS using a large-acceptance detector. The main focus of the experiment is measurement of strange particle production and a search for  $H^0$  dibaryon formation in p-A collisions. The strange-particle production measurements will provide data for comparison to recent measurements in heavy-ion collisions and also allow more detailed studies of the mechanisms that are responsible for strangeness enhancement in p-A and heavy-ion collisions. The main component of the proposed detector is the EOS TPC, a part of Exp. 895. The TPC will be augmented with downstream tracking, a high-resolution time-of-flight wall and a second-level trigger capable of triggering on kaons in the final state. The apparatus will provide a dedicated facility for the EOS TPC which would allow the detector to be employed during all modes of AGS running.

---

This is a comprehensive experimental program in baryon spectroscopy using the SLAC Crystal Ball detector to make precision measurements of total and differential cross sections for neutral final states in B

interactions using pion beams in the momentum range 0.4 - 1.9 GeV/c. The angular distributions of all the neutral final states such as (n, B<sup>0</sup>) are measured simultaneously. The purpose is to improve the mass, width, and neutral branching fractions for the N\* resonances in this energy region. The Crystal Ball detector is a nearly 4B multi-photon spectrometer which is used to analyze events by reconstructing the invariant mass and, in conjunction with the measured beam momentum, the missing mass of the produced ( rays.

# EXPERIMENT 914

Home Page • <http://ucla5.phy.bnl.gov/htdocs/e913-914/e913-914.html>

**EXPERIMENT 914 - NEUTRAL HYPERON SPECTROSCOPY**

- **University of Regina** - N. Knecht, G. Lolos, Z. Papandreou

This experiment proposes to investigate the spectrum of  $\Sigma^*$  and  $\Sigma^*$  resonances via their neutral decays in the reactions:

$K^- p \Sigma^+ \Sigma^0$	600-1800 MeV/c ( $p_{lab}$ )
$K^- p \Sigma^+ \Sigma^0$	"
$K^- p \Sigma^+ \Sigma^0$	"
$K^- p \Sigma^+ \Sigma^0$	720-1800 MeV/c ( $p_{lab}$ )
$K^- p \Sigma^+ \Sigma^0$	600-1800 MeV/c ( $p_{lab}$ )
$K^- p \Sigma^+ \Sigma^0$	"
$K^- p \Sigma^+ \Sigma^0$	"
$K^- p \Sigma^+ \Sigma^0$	890-1800 MeV/c ( $p_{lab}$ )

Measurements of total and differential cross sections of these reactions will be made simultaneously over the full angular range, using the Crystal Ball multi photon spectrometer and a LH2 target. The Crystal Ball has a 94% solid angle coverage and good energy and angular resolution. The incident beam momentum is varied in steps of 25-50 MeV/c from 600 MeV/c in the C-line to the maximum momentum of 1.8 GeV/c in the D-line.

---

The Trek Collaboration proposes to use the 11.4 A GeVAu beam at the AGS to calibrate the large collector of the Trek experiment. Trek is a collaborative experiment consisting of the physicists at Berkeley and at the Space Research Institute in Moscow. Trek consists of two detectors. The small detector (0.09 m<sup>2</sup> in area) was mounted on an outside wall of the living quarters of the space station and has already been returned to earth for analysis. Its goal is to measure the isotopic abundances of iron-group elements in the galactic cosmic-rays. A large collector for ultraheavy galactic cosmic rays was mounted on the outside of the Kvant-2 module for the Mir Space Station to two cosmonauts in an EVA in June 1991. The goals of the large Trek collector are to resolve and measure the composition of both odd-Z and even-Z cosmic-ray nuclei from tin (Z = 50) through uranium (Z = 92) and to search for transuranic nuclei and exotic particles such as strangelets. The experimenters propose to calibrate the detectors with a highly relativistic gold beam at the AGS at the first opportunity after recovery.

**EXPERIMENT 916 - STUDY OF PROJECTILE FRAGMENTATION FOR  $^{197}\text{Au}$  IONS AT  $\sim 4\text{A GeV}$   
IN VARIOUS TARGETS  
Spokesman: Y. D. He**

- **University of California - Berkeley** - Y. D. He, P. B. Price

---

This is a small-scale experiment with  $^{197}\text{Au}$  ions at  $\sim 4\text{A GeV}$ . We exposed 10 BP-1 glass detectors interleaved with targets ranging from C to Pb to a defocused low intensity beam over an area of  $5\text{ cm} \times 5\text{ cm}$  at a density of  $1200 \pm 200\text{ cm}^{-2}$ . Using our automated scanning system, the charge resolution from one single measurement is found to be  $\sim 0.14$  charge unit. The charge resolution for beam particles and projectile fragments obtained from 5 plates of detectors is  $\sim 0.06$  charge unit (see figure). This charge resolution is more than adequate to identify fragments and hence to measure cross sections for charge-changing interactions. With this experiment, we hope to accomplish the following:

1. **Fragmentation Study:**

We will study nuclear reactions that we have previously studied at  $\sim 1\text{A GeV}$  at BEVALAC and  $\sim 11\text{A GeV}$  at AGS. In particular, we will measure cross sections at  $\sim 4\text{A GeV}$  for fragmentation both nuclear and electromagnetic, for charge pickup reaction, and for other processes in collisions of  $\sim 4\text{A GeV}$  on various targets. We hope to establish the energy dependence of these cross sections, which may enable us to understand the physics in peripheral collisions of relativistic heavy ions.

2. **Detector Response Study:**

Another interesting topic is the study of the response of BP-1 glass detectors to relativistic heavy ions with different energies. We have previously established the dependence of the detector response on charge  $Z$  for a given velocity  $\beta c$ . The response is empirically known to be a complicated function of  $(Z/\beta)^2$ , to a good approximation, for a limited range of  $\beta$  tested. However, the dependence of the response on Lorentz factor  $\gamma$  for a wide range of  $\beta$  remains unknown. With this experiment, we expect to study the dependence of the detector response on  $\beta$  for a given  $Z$ . This set of data will permit an interesting examination of the dependence of restricted energy loss on  $\gamma$  (in addition to  $(Z/\beta)^2$  term).

---

This is a NASA effort in the AGS to study the genetic and epigenetic effects produced by high energy heavy ions. There will be two runs labeled BNL-3, 4 (E919) for the period of October 1, 1996 to September 31, 1998. Each run provides 150 hours of 1 GeV/nucleon Fe ions.

Schematic of a MCS radiographic detector system. The beam is first prepared with a diffuser and matching lens to meet optics requirements. It then passes through the object to be radiographed. The transmitted beam passes through an iris, or aperture, is focused on the first detector, then passes through a smaller diameter iris and is focused on a second detector. The ratio of the first and second detector intensities provides both the density profile and material composition of the object.

Beam : A1  
Status: Complete 1996  
Hours Charged: 197

**EXPERIMENT 920 - LENS TEST FOR PROTON RADIOGRAPHY**  
**Spokesman: J Zumbro**

- **Los Alamos National Laboratory** - G. Hogan, K. Morley, C. Morris, K. Mueller, J Sarracino, H. Z iock, J Z umbro
- 

The goal of this experiment is to provide data for standard test objects which can be benchmarked against models of proton transport and magnetic optics. Additionally the performance of proton radiography will be directly compared with X-ray measurements on the same set of objects.

**EXPERIMENT 922 - RADIATION TESTING OF NASA'S GLOBAL POSITIONING SYSTEM  
AND INERTIAL NAVIGATION SENSOR (GPS/INS)  
Spokesman: W. X. Culpepper**

- **National Aeronautics and Space Administration** - W. X. Culpepper

---

NASA has elected to pursue the development of an integrated global positioning system (GPS) and inertial navigation system (INS) (GPS/INS) for use as common hardware on the International Space Station (ISS), the Space Shuttle Orbiter and the ISS Crew Return Vehicle (CRV). NASA's Johnson Space Center (JSC) is the lead center for this activity. This GPS/INS will perform the prime state vector estimation and navigation functions for the flight vehicles involved and is considered a criticality 1 subsystem, *i.e.*, impacts crew safety, vehicle survivability and mission success.

A facility producing heavy ions with sufficient energy per nucleon is needed to perform system level tests with heavy ions similar to the IUCF proton tests to establish latchup susceptibility for the proposed hardware. The 10-11 GeV gold ion beam scheduled at the AGS in the fall/winter of 1996 is the only American resource known that can accomplish this special testing.

# EXPERIMENT 923

Home Page • <http://www.phy.bnl.gov/~E923/>

---

This experiment proposes a new search for the time reversal violating polarization of the muon normal to the decay plane of the  $K^0 \rightarrow \mu^+ B^0_{\mu}$  decay. The experiment will be performed with in-flight decays in an intense ( $2 \times 10^7$   $K^+$  per sec) 2 GeV/c separated kaon beam in an existing beam-line at the AGS. The center piece of the detector will be a new polarimeter which will consist of 128 carbon wedges, with active detector elements (either scintillator or wire chambers) between the wedges, arranged in a cylindrical manner around the kaon beam. More than  $10^9$  events are expected to be analyzed to obtain sensitivity to the T-violating polarization of  $\pm 0.0007$  to  $\langle Im \rangle$ , an improvement by approximately 40 over the previous best limit.

The experimenters propose to measure asymmetries in the inclusive reactions,

$$\begin{aligned} & p8p \ 6 \ B^+ \ \text{anything}, \ p8C \ 6 \ B^+ \ \text{anything}, \\ & p8p \ 6 \ B^- \ \text{anything}, \ p8C \ 6 \ B^- \ \text{anything} \end{aligned}$$

using a transversely polarized beam, a liquid hydrogen target, and a carbon target. The measurements would be made using the 23-GeV/c proton beam in an extracted beam line from the AGS, a spectrometer consisting of an analyzing magnet, scintillation hodoscopes, scintillation trigger counters, and a gas threshold Cerenkov counter. The kinematic range covered by the experiments would be  $p_T$  up to 1.0 GeV/c and  $x = p_L/p_{\max} \cdot 0.5 \text{ to } 0.8$ .

The purpose of this proposal is to obtain basic information in order to design a polarimeter for the RHIC polarized beams. The RHIC polarimeter is a crucial item for the success of the RHIC spin program.

- 

The experimenters propose a high-resolution ( $\gamma$ -ray spectroscopy measurement of several light hypernuclei employing a large-acceptance germanium detector system which is being constructed in Japan. Hypernuclei are produced by the ( $K^{\pm}, B^{\pm}$ ) reaction and their  $\gamma$  transitions are detected in coincidence. They will use  $K^{\pm}$  beam at C6 beam line together with the present spectrometer. The aim is to determine  $\gamma$  spin-dependent interactions through  $\gamma$  spectroscopy of some light hypernuclei. Data will be taken with  ${}^9\text{Be}$ ,  ${}^{16}\text{O}$ ,  ${}^{12}\text{C}$  and  ${}^7\text{Li}$  targets and to study  $\gamma$  transitions of  ${}^{15}_7\text{N}$ ,  ${}^9_7\text{Be}$ ,  ${}^{16}_7\text{O}$ ,  ${}^{12}_7\text{C}$ ,  ${}^7_7\text{Li}$ , which will give information on the spin-spin, spin-orbit, and tensor interactions between  $\gamma$  and nucleon.

This experiment addresses an unresolved, fundamental question of "why" and "when" to apply the  $I = \frac{1}{2}$  rule to the weak decay of strange hadrons. An opportunity now exists to determine if this apparently universal rule applies to the non-mesonic weak decay of a 7, by studying particle emission from an important problem which can only be addressed through the coupling of the NMS spectrometer to the C8 beam line.

---

The purpose of this proposed calibration run at Brookhaven is to test and calibrate detectors to determine if they are capable of making precision measurements of the elemental abundances and energy spectra of galactic cosmic rays with  $10 \leq Z \leq 92$ . The Advanced Cosmic Ray Composition Experiment for Space Station (ACCESS) has been approved by NASA for a Mission Concept Study over the next two years. The present concept includes detectors which will be used to precisely measure the charge of these ultra-heavy nuclei.

Experimental goals of the ultra-heavy portion of the mission are: to determine whether the chemical fractionation pattern of GCRs is better organized by FIP or volatility; test whether galactic cosmic rays originate from interstellar dust grains, mass loss from main sequence star, freshly synthesized supernova debris, special sources, such as Wolf-Rayet stars; determine whether  $Z > 30$  and  $Z \leq 30$  nuclei have a common source; test if r-processes that contributed to GCRs were driven further than those that formed the solar system mix by measuring the r/s-process mix as a function of charge.

The detectors are Li-drifted silicon wafer detectors for  $dE/dx$ , waveshifter readout plastic scintillators for  $dE/dx$ , scintillating fibers for time-of-flight, and waveshifter readout Cerenkov counters.

# EXPERIMENT 935

Home Page • <http://wmhcg1.physics.wm.edu/e935>

**EXPERIMENT 935 - A DECAY SEARCH FOR A LIGHT GLUINO BOUND STATE IN THE B5 LINE**  
**Spokesman: Y. Kuang**

- **University of Richmond** - P. Rubin

---

The experimenters propose to search at the AGS for the supersymmetry-based  $R^0$  hadron in terms of a decay channel involving a photino and two charged pions with a sensitivity in the product of production cross section and branching fraction of  $5 \times 10^{-36} \text{ cm}^2/\text{GeV}^2$ . A positive signal would be a first observation of a supersymmetric particle.

The detector facility assembled by the E871 collaboration to conduct rare kaon decay studies offers the highest flux neutral beam available and a detector that has acceptable sensitivity to the decay of the  $R^0$ -hadron. The E871 detector in its present configuration would be used to look for two-pion vertex events originating in the decay volume. Achieving an improved vacuum decay tank of  $< 10^{-6}$  torr is the main modification required for the detector system.

---

An experiment is proposed to search for T-violation in the  $K^0 \rightarrow B^0 \mu^+ \mu^-$  decay using a stopped beam method. The muon transverse polarization will be examined with high precision and with small systematic errors. The experimental setup will be transferred from the KEK E246 T-violation experiment after the completion of data taking early in 1999. After 3000 hours of running at AGS, the sensitivity of  $|P_T| \cdot 3.5 \times 10^4$  will be obtained corresponding to the sensitivity of  $|Im\epsilon| \cdot 1.5 \times 10^3$ .

**EXPERIMENT 937**  
**Home Page • <http://>**

Beam : D6  
Status: Complete in FY 1997  
Hours Charged/Approved: 16/48

**EXPERIMENT 937 - A STUDY OF THE OCCURRENCE OF RADIATION-INDUCED  
SOFT ERROR UPSETS (SEU)  
Spokesman: R. J. Peterson**

- **University of Colorado** - C. J. Gelderloos, R. J. Peterson
- 

We exposed one sample of a 16 Mbit high density memory chip to negative pion beams of 1.2 and 1.8 GeV/c on the D-line. A plastic scintillator with the same dimensions as the chip was used to monitor the pion fluence. Cross sections for soft errors, changing the bit content of the chip without permanent damage, were found to be much smaller than observed at lower pion momenta. The experiment was truncated by a major equipment problem, and will not be extended because the information obtained is sufficient for the needs to understand avionics failures in commercial aircraft.

**EXPERIMENT 938**

- **Paul Scherrer Institute** - G. Bauer

---

There is a worldwide effort in planning and designing the next generation neutron source; the focus is on spallation source with average power of up to 5 MW and single pulse energies of 100 kJoules. The design issues center around the heavy metal target; liquid mercury is the current first choice. The AGS is a unique resource to study in detail neutron production, pressure wave mitigation and other issues in target design. It is the **only** proton source in the world with the energy per pulse equal to the proposed future sources.

The experiment will initially measure the neutron production and energy deposition in liquid mercury as a function of incident proton energy. The pressure wave behavior under peak power loading will then be measured and proposed mitigation measures evaluated. Finally, the performance of a liquid mercury target in conjunction with a lead reflector and moderators will be measured to study the complete system performance. The total proton flux required at a given proton energy is minimal (typically a few times  $10^{14}$ ) for the first two proposed measurement periods.

**EXPERIMENT 939**  
**Home Page • <http://>**

Beam : U  
 Status: In Progress  
 Hours Charged: 51

**EXPERIMENT 939 - EXPERIMENTS FOR THE DOE ACCELERATOR PRODUCTION  
OF TRITIUM (APT) PROJECT  
Spokesmen: N. S.P. King and A. L. Hanson**

- **Bechtel Nevada** - R. Thompson, R. Liljestrand
- **Brookhaven National Laboratory** - G. Greene, A. L. Hanson, L. Snead, M. Todosow

- **U. S. Department of Energy** - T. Ward

---

The purpose of this experiment is to advance the R&D work for the accelerator production of tritium in the national program now underway in this subject. Using fast extracted protons, various materials will be exposed to proton beams of 800, 1200, 1600 and 2000 MeV to measure the production cross sections for  $^{27}\text{Al}(p,3n)^{24}\text{Na}$ .

- **University of Pennsylvania** - W. D. Wales

---

This experiment proposes to search for the process  $\mu N 6e N$  with a significantly improved sensitivity with respect to past and proposed future searches. Interest is in searching for violations of additive quantum numbers associated with each type of lepton. Violation of these quantum numbers is commonly referred to as lepton flavor violation (LFV). The process will provide direct evidence of muon and electron number violation.

The experiment will be conducted in a new  $\mu$  beam line produced using a pulsed proton beam. The proton energy will be chosen in the range 8-20 GeV to optimize the  $\mu$  flux per unit time and minimize operating costs of the experiment. The expected sensitivity, normalized to the kinematically similar process of  $\mu$  capture on the nucleus, is one event for a branching fraction of  $2 \times 10^{-17}$ .

**The E864 "Spectrometer" measures**

- Charge ( $Z$ ) and Mass ( $M$ )
- Strangelets from  $M > 7 \text{ GeV}/c^2$  with  $Z/M < 0.3 \text{ e}/\text{GeV}/c^2$

---

Although charged leading particles in p+ A collisions have been studied extensively at the beginning of the era for ultra-relativistic heavy ion collisions, neutral leading particles have not been measured accurately and systematically. Neutral leading particles represent a significant fraction of the cross sections for incident proton fragmentation. When the incident proton is described by its quark content and is broken up during nuclear collisions, the emerging leading particles can be combinations of neutron + B<sup>+</sup> or proton + B<sup>0</sup> in the framework of a diquark-quark breakup scenario. This experiment plans to measure both charged and neutral leading particles in p+ Pt, p+ Cu, p+ Al and p+ Be collisions at the beam momenta of 18 and 12 GeV/c with the E864 spectrometer.

The experiment will be conducted in a new  $\mu$  beam line produced using a pulsed proton beam. The proton energy will be chosen in the range 8-20 GeV to optimize the  $\mu$  flux per unit time and minimize operating costs of the experiment. The expected sensitivity, normalized to the kinematically similar process of  $\mu$  capture on the nucleus, is one event for a branching fraction of  $2 \times 10^{-17}$ .

### Publications - AGS Experiments 1982 - 1998

*This listing was originally prepared using the SLAC data base SPIRES; we now rely on the experimenters themselves to supply us with information. It is easy to miss publications in such a wide search and we apologize for any left out or misidentified. Please let us know about these as well as keeping us posted on your recent publications of AGS experiments.*

Wilkes, et al., *Scaled Factorial Moment Analysis of 200 A GeV Sulfur + Gold Interactions*, (EMU-01 Collaboration), Proc. of the Santa Fe Workshop, Intermittency in High Energy Collisions, Los Alamos National Laboratory, Los Alamos, USA, March 18-21, 1990, eds. F. Cooper, R.C. Hwa, I. Sarcevic, World Scientific, p. 145 (1991).

M.I. Adamovich, et al., *Energy, target, projectile and multiplicity dependence of Intermittency behavior in high-energy O(S)-emulsion interactions*, Z Phys. C49:395 (1991).

M.I. Adamovich, et al., *Stochastic Emission of Particles in Ultra-Relativistic Heavy Ion Collisions*, Modern Physics Letters A6:469 (1991).

M.I. Adamovich, et al. *Stochastic Emission of Particles in Ultra-Relativistic Heavy-Ion Collisions*, (EMU-01 Collab.), High Energy Physics and Nuclear Physics in China, 15, 131 (1991).

M.I. Adamovich, et al., *On the Systematic Behavior of the Intermittency-Indices in Nuclear Interactions*, (EMU-01 Collaboration) Phys. Lett. B, 263(3,4), 539-543 (1991).

M.I. Adamovich, et al., *Stochastic Emission of Particles in Ultra-Relativistic Heavy-Ion Collisions*, (EMU-01 Collaboration), Modern Phys. Lett. A. 6(6), 469-478 (1991).

R.J. Wilkes, et al., *Analysis of Fluctuations and Correlations in 200\*A GeV A-A Collisions*, (EMU-01 Collaboration), Proc. 22nd International Cosmic Ray Conference (Dublin, 1991), 4:21.

M.I. Adamovich, et al., *Energy, Target, Projectile and Multiplicity Dependencies of Intermittency Behavior in High Energy O(si,S) induced Interactions*, (EMU-01 Collaboration), Z. Phys. C - Particles and Fields 49, 395-399 (1991).

M.I. Adamovich, et al., *Multiplicities in <sup>16</sup>O-Induced Violent Heavy-Ion Collisions from 5A to 2 x 10<sup>5</sup> A MeV*, (EMU-01 Collab.), Phys. Rev. Lett. 67(10), 1201-1205 (1991).

T.C. Awes, et al., *Review of Recent Results on Particle Production from EMU-01*, R.J. Wilkes and the EMU-012 Collaboration, Nuclear Physics A544:153c, (1992), (invited talk at Quark Matter '91, ed., North Holland, 1992).

V. S. Bhatia, et al., *Emission Characteristics of Helium Fragments in S-Emulsion Interactions at 200 A GeV Energy*. Proc. XXI Int. Symp. on Multiparticle Dynamics, Wuhan, China, Sept. 23-27, 1991, p. 623-626. (World Scientific, Singapore, 1992, Eds.: Wu Yuanfang and Liu Lianshou.)

I. Otterlund, et al., *The Energy Dependence of Particle Densities and Multiplicities in Violent Nucleus-Nucleus Collisions*. Proc. XXI Int. Symp. on Multiparticle Dynamics, Wuhan, China, Sept. 23-27, 1991. p. 573-581. (World Scientific, Singapore, 1992, Eds.: Wu Yuanfang and Liu Lianshou).

R. J. Wilkes, et al., *Review of Recent Results on Particle Production from EMU01*. Proc. Quark Matter '91, Gatlinburg, Tennessee, November 11-15, 1991. Nucl. Phys. A544 (1992) 153c.

S. Garpman, et al., *Linear and Non-Linear Aspects of Relativistic Heavy-Ion Interactions from EMU01 results*. Proc. 7th Int. Symp. on Very High Energy Cosmic Ray Interactions, Ann Arbor, Michigan, USA, June 21-27, 1992.

**Publications**

I Otterlund, et al., *EMU01 Results from Oxygen, Silicon and Sulphur Induced Violent Interactions at BNL-AGS and CERN-SPS*. Proc. Int. Conf. on Hadron Structure '92, Stará Lesná, Czechoslovakia, Sept 6-11, 1992, p. 244- (Košice, 1992, eds.: D. Bruncko and J Urban).

M. I. Adamovich, et al., *A systematic study of the energy independent behavior of the fragmentation regions in 0-16 EM interactions from 3.7-A-GeV to 200-A-GeV*. Z. Phys. C55 (1992) 235-24.

M. I. Adamovich, et al., *A Systematic Investigation of Scaled Factorial Cumulant Moments for Nucleus-Nucleus Interactions*, (EMU-01 Collaboration) Physical Review D 47:3726 (1993).

M. I. Adamovich, et al., *On the jet-like and ring-like substructure in distributions of produced particles in central heavy ion collisions at ultrarelativistic energies*. J. Phys. G19:2035-2044, 1993.

E. Stenlund, et al., *Pseudorapidity Distributions and Azimuthal Substructure in Heavy Ion and Very Heavy Ion Collisions at Energies up to 200 A GeV*. Proc. 22nd Int. Symp. on Multiparticle Dynamics, Santiago de Compostella, Spain, July 13-17, 1992. p. 349-365. World Scientific, Singapore, 1993, Ed.: C.Pajares).

I. Otterlund, et al., *Gentle and Violent Gold Interactions from the BNL-AGS*. Proc. Heavy Ion Physics at the AGS, HIPAGS'93, Massachusetts Institute of Technology, Cambridge, MA, January 13-15, 1993. MITLNS-2157, pp. 1. (Eds. S. G. F. Stephans, S. G. Steadman and W. L. Kehoe).

J. Nystrand, et al., *Rapidity Density Distributions in  $^{16}O$ ,  $^{28}Si$ , and  $^{197}Au$  Induced High Energy Heavy Ion Interactions*, Proc. 2<sup>nd</sup> Int. Conf. on Physics and Astrophysics of Quark-Gluon Plasma, Calcutta, India, January 19-23, 1994. pp. 462 (World Scientific, Singapore, 1994), Eds.: B. Sinha, Y. P. Vijoyi and S. Raha).

E. Stenlund, et al., *Violent Au-Induced Collisions at the BNL-AGS and Comparisons with Expectations from Particle Densities and their Fluctuations in Collisions with Lighter Systems*. Proc. Cracow Workshop on Multiparticle Productions - Soft Physics and Fluctuations, Cracow, Poland, May 4-7, 1993. (World Scientific, Singapore, 1994, Eds.: A. Bialas, K. Fialkowski, K. Zalewski and R. C. Hwa.)

S. Garpman, et al., *Multiparticle Production in Energetic Nucleus-Nucleus Collisions*, Proc. Hadron Structure '93 Int. Conf., Banská Štiavnica, Slovakia, Sept 5-10, 1993. pp. 83. (Bratislava 1993, Eds.: S. Dubnicka and A. Z. Dubnickova).

S. Vokal, et al., *Interactions of 14.6 A GeV/c Silicon Nuclei in Nuclear Emulsion*, Proc. Hadron Structure '93 Int. Conf., Banská Štiavnica, Slovakia, Sept 5-10, 1993. pp. 93. (Bratislava 1993, Eds.: S. Dubnicka and A. Z. Dubnickova).

J. Nystrand, et al., *Rapidity Density Distributions in Au+ Au and Au+ Ag Interactions at 11.6 A GeV/c*. Proc. Quark Matter '93, Borlänge, Sweden, June 20-24, 1993. Nucl. Phys. A566 (1994) 419c.

R. J. Wilkes, et al., *Systematics of Pseudorapidity Distributions*. Proc. 23rd Int. Cosmic Ray Conf., Calgary, Canada, July 1993.

V. Navotny, et al., *Rapidity and Azimuthal Correlations in Relativistic Heavy-Ion Interactions at 4-200 GeV/Nucleon*. Proc. VIII Int. Symp. on , Japan, July 24-20, 1994, pp. 339.

L.X. Jan, L. Addessi, V. Castillo, L.H. Gong, J. Leskowitz, R. Meier, G. Miglionico, J. Scaduto, *Safety Design, Operation, and Control of a Liquid Hydrogen Target at BNL*. Presented at 1997 Cryogenic Engineering Conf., Portland, Oregon, July 28-August 1, 1997.

W. B. Tippens, (for 913 collaboration), *Hadron spectroscopy with the crystal ball at the AGS*, Presented at Hadron 97, S.U. Chung, ed. (to be published) 1997.

A. Starostin, *Eta production in the reaction  $BP$  to  $ON$  near threshold*, Presented at Hadron 97, S.U. Chung, ed. (to be published) 1997.

W. B. Tippens, (for the 913 collaboration) *Recent results from the crystal ball program at BNL*, proc. Of GW/TJNAF Workshop on  $N^*$  Physics, Oct. 30 - Nov. 1, 1997 (to be published).

**916** Y. D. He, P. B. Price, and M. Solarz, *Charge-changing cross sections for gold projectile at  $\sim 4$  A GeV in various targets*, in preparation (1997).

**917** C. Ogilvie (for the E917 collaboration), *E917 collaboration: Probing the dynamics of HI collisions plus searching for the QGP*, Proc. Of HIPAGS 96, WSU-NP-96-16, C. A. Pruneau, ed., Detroit, Mich., 1996.

J. Chang (for the E917 collaboration), *Multiplicity measurements at various AGS beam energies*, Proc. 13th Winter Workshop on Nuclear dynamics, Marathon, Fla., 1997.

J. Dunlop (for the E917 collaboration) *An excitation function of particle production at the AGS*, Proc. Of 6th conf. On Intersections of Particle and Nuclear Physics, Big Sky, MT., 1997.

B. Back, et al., *A beam vertex detector using scintillating fibers*, Accepted for publication in Nuclear Instru. And Meth A, 1997.

C. Ogilvie (for the E917 collaboration), *E802/859/866/917 report*, proc. Of 13th Intl. Conf. On Ultra-Relativistic Nucleus-Nucleus Collisions, Tsukuba, Japan, 1997.

R. Set and J. Dunlop (for the E917 collaboration), *An excitation function at the AGS: Probing the dynamics of heavy ion collisions*, Proc. Of 13th Intl. Conf. On Ultra-Relativistic Nucleus-Nucleus collisions, Tsukuba, Japan, 1997.

## Publications

---

**923** M. V. Diwan, et al., *Search for  $T$ -violation in  $KM\bar{U}3$  decay*, presented by Hong Ma, Div. Of Particles and Fields, APS 1996 Divisional Mtg., Minneapolis, MN., Aug. 10-15, 1996.

**924** D. W. Hertzog, P. T. Debevec, R. A. Eisenstein, M. A. Graham, S. A. Hughes, P. E. Reimer, and R. L. Tayloe, *A High Resolution Lead/Scintillating Fiber Electromagnetic Calorimeter*, University of Illinois at Urbana-Champaign, Nuclear Physics Laboratory Department of Physics P/90/3/41.

*Large Solid Angle Detector for Charged Particles from Photodisintegration of Light Nuclei*, University of Illinois at Urbana-Champaign, Nuclear Physics Laboratory Department of Physics P/90/3/41.

**MPS** S. Eisman, et al., *The MPS II Drift Chamber System*. Nuclear Instruments and Methods 217, 140-148 (1983).
