# Analysis of Total Food Intake and Composition of Individual's Diet Based on USDA's 1994-1996, 1998 Continuing Survey of Food Intakes by Individuals (CSFII) 

## DISCLAIMER

This document has been reviewed in accordance with U.S. Environmental Protection Agency policy and approved for publication. Mention of trade names or commercial products does not constituted endorsement or recommendation for use.

#### Abstract

The American food supply is generally considered to be one of the safest in the world. The U.S. Department of Agriculture has been protecting the nation's food supply for over a century through a number of food safety programs that monitor chemical and biological contaminants and rank the quality of various food items. Nevertheless, contamination of foods may occur through environmental pollution of air, water, and soil or through intentional use of chemicals such as pesticides or other agrochemical products. To assess chemical exposure through this pathway, information on food ingestion rates is needed. The National Center for Environmental Assessment (NCEA) conducted an analysis to provide an updated characterization of food consumption habits of individuals in the United States. The analysis was conducted using the data from the U.S. Department of Agriculture’s 1994-96 Continuing Survey of Food Intakes by Individuals (CSFII) and its 1998 Supplemental Children's Survey and the EPA's Food Commodity Intake Database (FCID). Distributions were derived to characterize (1) total food intake among various groups in the U.S. population, subdivided by age, race, geographic region, and urbanization; (2) intake of various food categories (e.g., meats, grains, and vegetables) by different age groups within the U.S. population; and (3) intake of various food categories of individuals exhibiting high end consumption patterns of one specific food category (e.g., individuals above the 90th percentile for meat consumption).

## PREFACE

The Exposure Factors Program of the National Center for Environmental Assessment (NCEA) of the U.S. Environmental Protection Agency's (EPA's) Office of Research and Development (ORD) has three main goals: (1) provide updates to the Exposure Factors Handbook (U.S. EPA, 1997) and the Child-Specific Exposure Factors Handbook (U.S. EPA, 2002); (2) identify exposure factors data gaps and needs in consultation with clients; and (3) develop companion documents to assist clients in the use of exposure factors data. The activities under each goal are supported by and respond to the needs of the various program offices.

Although the American food supply is generally considered to be one of the safest in the world, contamination of foods may occur through environmental pollution. To assess chemical exposure through this pathway, information on food ingestion rates is needed. For this reason, a thorough analysis of the dietary habits of the American public would aid in the identification of potential exposure pathways. Data on food consumption rates reported in the Exposure Factors Handbook and the Child-Specific Exposure Factors Handbook were collected by the U.S. Department of Agriculture through national surveys. These surveys are conducted periodically. Updating food consumption data in the handbooks is necessary to reflect changes in people's diets. To that end, EPA developed per capita food intake rates for various food item and food categories using databases developed by the U.S. Department of Agriculture (USDA). These intake rates were published in CSFII Analysis of Food Intake Distributions (U.S. EPA, 2003).

EPA has expanded the analysis of food intake in order to examine the food consumption habits of individuals in greater detail. This report presents the results of an analysis of the total food intake using data from the USDA’s 1994-1996, 1998 Continuing Survey of Food Intakes by Individuals (CSFII) and EPA’s Food Commodity Intake Database (FCID) (U.S. EPA, 2000). This analysis will assist exposure and risk assessors in identifying target populations forintensive study and food-specific exposure pathways for the general population or for individual groups. However, this analysis was conducted before EPA published the guidance document entitled Selecting Age Groups for Monitoring and Assessing Childhood Exposures to Environmental Contaminants (U.S. EPA, 2005). Therefore, the age groups used for children in this analysis are not entirely consistent with the age groups recommended in the 2005 guidance document. Some of the data will be reanalyzed in the future update to the Child-Specific Exposure Factors Handbook to conform with EPA's recommended age groups for children.

## AUTHORS, CONTRIBUTORS, AND REVIEWERS

The National Center for Environmental Assessment (NCEA) of EPA's Office of Research and Development was responsible for preparing this report. The report was compiled by the Exposure Assessment Division of Versar, Inc., in Springfield, Virginia, under EPA Contract No. 68-D5-0051. Jacqueline Moya served as the EPA Work Assignment Manager, providing overall direction and technical assistance, as well as Contributing Author.

## ACKNOWLEDGMENT

The project manager would like to acknowledge USDA for providing the data files. The project manager would also like to acknowledge the contributions of the following individuals: Terri Konoza of NCEA who managed the document production activities, Patricia von Brook of KBM Group who provided editing support, and Rita Harding of KBM Group who designed the front cover.

## 1. INTRODUCTION

The American food supply is generally considered to be one of the safest in the world. The U.S. Department of Agriculture has been protecting the nation's food supply for over a century through a number of food safety programs that monitor chemical and biological contaminants and rank the quality of various food items. However, contamination of foods may occur through environmental pollution of air, water, and soil or through intentional use of chemicals such as pesticides or other agrochemical products. A thorough analysis of the dietary habits of the American public would aid in identifying potential exposure pathways. To this end, the U.S. Environmental Protection Agency (EPA) developed per capita food intake rates for various food items and food categories using databases developed by the U. S. Department of Agriculture (USDA). These intake rates were incorporated into EPA's 1997 Exposure Factors Handbook (U.S. EPA, 1997). EPA has since recommended that the food intake study be updated and expanded. Thus, a more comprehensive analysis is presented in this document.

The purpose of this study was to characterize the consumption of food by the people of the United States. This characterization includes the quantification of (1) total food intake among various subgroups of the U.S. population, subdivided on the basis of age, race, geographic region, and urbanization; (2) the consumption of various food categories (e.g., meats, grains, and vegetables) by different age groups within the U.S. population; and (3) the consumption of various food categories of individuals exhibiting unusual consumption patterns of one specific food category, e.g., consumption behavior of individuals above the 90th percentile for meat consumption.

The results of the analysis, presented in a series of tables, provide a tool for examining food consumption at a high level of detail. They allow exposure assessors and risk analysts to identify target populations for intensive study and to identify food-specific exposure pathways for the general population or for individual groups. Please note that, due to their size, all the tables mentioned in this report are presented at the end of the text.

## 2. SOURCES OF FOOD CONSUMPTION DATA

### 2.1. FOOD CONSUMPTION SURVEYS

Food consumption data were acquired from two separate surveys of food intake conducted by USDA’s Agricultural Research Service (USDA, 2000): the 1994-96 Continuing Survey of Food Intakes by Individuals (CSFII) and its 1998 Supplemental Children’s Survey. These two surveys were designed to obtain data from a statistically representative sample of noninstitutionalized persons living in the United States. Survey participants were selected using a multistage process described in Attachment 1, Appendix B, Section 3.1.1 which contains documentation provided with the CSFII databases. The 1998 Supplemental Children's Survey was conducted in order to expand the number of children in the database for the purpose of conducting child- and infant-specific exposure studies. It was carried out using a multistage process similar to that of the 1994-96 study (see Attachment 1, Appendix B, Section 3.1.1). The two surveys are hereinafter referred to jointly as CSFII 1994-96, 1998.

Respondents to CSFII 1994-96, 1998 were contacted multiple times to obtain a wide range of demographic information, including physical (gender, age, weight), economic (income, household size), cultural (race, ethnicity), and geographical (urban, regional) data. The respondents were interviewed twice to collect information on food consumption during two nonconsecutive days. The Day 1 interviews were conducted in person. Day 2 interviews typically took place 3 to 10 days after Day 1 interviews, but not on the same day of the week. Five percent of the Day 2 interviews were conducted via telephone; 95\% were conducted in person in a manner similar to the Day 1 interviews. Interview days were chosen in such a way that, across the sample population, each day of the week was represented in at least $10 \%$ of the interviews. For further discussion on how the survey was conducted, refer to Attachment 1, Appendix B, Section 3.1.1.

On the first interview day, respondents were asked to recall all food and drink consumed between midnight and midnight on the previous day. Following the respondent's initial listing of food consumption, he or she was asked to add any additional items forgotten during the first listing and to identify the eating occasion (e.g., lunch, snack, breakfast) and approximate time associated with each food consumed. Interviewers also asked for details such as brand names of foods, cooking methods, seasonings added to cooked food, and ingredients included in food
mixtures such as salads and casseroles. The quantity of food consumed was estimated by the survey respondent; interviewers carried measurement guides such as bowls, measuring cups, and pictures of fish and chicken parts to assist in the estimation.

### 2.2. SAMPLE WEIGHTS

Each individual in the CSFII 1994-96, 1998 was assigned a personal weighting factor. These weighting factors vary from person to person due to demographic differences between the sampled population and the total U.S. population, and serve to compensate for variability in the survey response rate, the timing of the survey, and other factors inherent in such a large-scale survey. The weighting factors were calculated in such a way that the sum of weighting factors for the entire survey population would approximate the population of the United States. Because the demographic makeup of the population in the original 1994-96 CSFII changed with the addition of the 1998 data, each individual has a weighting factor for the 1994-96 study alone and another factor for the combined 1994-96 and 1998 data sets. Similarly, each individual has different weighting factors for one-day consumption data and two-day average consumption data because the characteristics of the entire survey population and the portion that completed both days of the survey are slightly different. Because the present study used only combined two-day average consumption data from both the original 1994-96 survey and the 1998 children's supplement, the weighting factor for the two-day average using the combined 1994-96 and 1998 data sets was used in this study.

Annual person-level data sets for each of the four years of the study $(1994,1995,1996$, and 1998) were assigned sample weights as follows. Each individual in the sample was assigned a "base weight equal to the reciprocal of the probability of selection." Individuals were selected for participation in the survey through a multi-stage process involving the selection of a "primary sampling unit" (PSU), a population segment within any given PSU, an individual household within a segment, and an individual within a household. Each of these stages has a probability of selection that may be calculated from the known number of units available and the number selected; the product of these four probabilities equals the probability of selection for an individual and was used to calculate each individual's base weight. Following this, base weights were adjusted to account for the non-response rate; for this step, respondents were classified into groups based on characteristics that were determined to be positively correlated with the response
rate. In the final step, the sample weights were adjusted based on U.S. Census Bureau population estimates for March of the year being assessed, using a process known as "ranking ration weighting." In this process, individual sample weights were adjusted in such a manner that the sum of all weights for certain demographic groups, e.g., males, females, persons in specific age categories, urbanization, employment status, etc., would equal the total United States population estimate for that demographic group. By statistically compensating for anomalies in sampling, this multi-step process of determining sample weights served to make the survey population as representative of the overall United States population as possible. For further discussion of the sample weighting process, the reader is referred to Appendix C of the CSFII 1994-96, 1998 documentation (USDA, 2000).

Each individual's weighting factor was used in calculating percentile values of food consumption for the various demographic cohorts that were analyzed in the study. Conceptually, the calculation of percentiles was analogous to sorting the individuals in ascending order on the basis of consumption of food and, knowing the total number of individuals, identifying the desired percentile values by counting the appropriate distance down the sorted list. However, in order to account for differences in sample weight from one individual to the next, the conceptual "sorted list" was modified so that each individual had a number of entries on the list that corresponded to his or her weighting factor. Thus, the sorted list may have 1,000 entries for one individual and 2,000 for another, based on their weighting factors. In this way, each individual would tend to "stretch" the histogram of food consumption values to a degree proportional to his or her weighting factor, and the percentiles would reflect that stretching. A simplified example of how this process works is shown in Table 1. The two sorted lists-one weighted and one unweighted-show the $50^{\text {th }}$ percentile value, which by definition lies at the midpoint of each sorted list. The unweighted and weighted lists result in different values for the 50th percentile because, as shown in the example, the weighting factors happen to favor the individuals with lower consumption. In the actual data set used in this study, the same process, occurring for much larger population sizes, was used to increase or decrease the relative significance of each individual's contribution in order to more accurately represent the entire U.S. population.

Table 1. Hypothetical Example of the Effect of Weighting Factors

| Individual | Consumption <br> g/day | Weighting <br> Factors | 50 <br> unwerighted <br> unwercentile <br> g/day | $\mathbf{5 0}^{\text {th }}$ percentile <br> weighted <br> g/day |

|  |  |  |  | F 60 |
|  |  |  |  | E 70 |
|  |  |  |  | B 80 |
|  |  |  |  | A 90 |

### 2.3. CONVERSION OF USDA FOOD CODES TO EPA COMMODITY CODES

Intakes of food expressed in CSFII 1994-96, 1998 were converted to EPA food commodity codes using data provided in EPA's Food Commodity Intake Database (FCID) (U.S. EPA, 2000). The FCID contains a "translation file" that broke down the USDA food codes used in the CSFII into the EPA commodity codes listed in Table 2. A single food item in CSFII may be associated with several EPA commodity codes. The method used to translate USDA food codes into EPA commodity codes is discussed in detail in the documentation included in CSFII 1994-96, 1998 (Attachment 1). The EPA commodity codes used in this study are documented in EPA’s Food Commodity Vocabulary (Attachment 2).

### 2.4. IDENTIFICATION OF FOOD CATEGORIES

The 548 EPA commodity codes were assigned to 10 food categories for use in the analysis, and "other" category that was not included in the analysis (Table 2). The categories are Dairy, Meat, Eggs, Fish, Grain, Vegetables, Fruits, Fats, Soy Products, and Nuts. Water, coffee, tea, sugar, vinegar, and a few other foods that were not appropriate for any other category were

Table 2. EPA Commodity Codes, by Food Category

| Meats |  |
| :---: | :---: |
| 21000470 | Beef, fat |
| 21000471 | Beef,fat- babyfood |

not included in the analysis. Some EPA commodity codes are listed under more than one food category. For example, the code for beef fat, which represents only the nutrient fat from beef, is included in the Fats category as well as the Meats category because the nutrient fat in beef would be a part of any prepared food product containing beef. Soybean oil appears in the Fats category as well as in the Soy Products category. For this reason, in the results tables, the intakes for each individual food category do not necessarily add up to the figure given for total food intake.

Some food products were classified on the basis of their pattern of use in the human diet rather than on a strict horticultural definition. For example, tomatoes and avocados meet the biological definition of a fruit, but were classified as vegetables, based on their customary use.

## 3. DATA ANALYSIS

### 3.1. PREPARATION OF DATA

CSFII 1994-96, 1998 contains 3,173,197 records of food consumption for 21,662 individuals. This database was subjected to a series of filters to produce an operating data set for use in calculating food consumption.

The full database contains three types of food consumption data: Day 1 consumption, Day 2 consumption, and average consumption (the arithmetic mean consumption for days 1 and 2.) If an individual completed the food consumption survey for both days, an average consumption was calculated for each food item consumed by each individual, whether the item was consumed on Day 1, Day 2, or both days. An average was not calculated if the individual completed the food consumption survey for only one day. The consumption of any given food code by any given survey respondent may therefore appear in one, two, or three records in the database. For example, if an individual ate a food item on one day of the survey and did not complete the survey for the second day, only one record was added to the database. If an individual ate a food item on only one of the two days and completed the survey for both days, the consumption appears as a Day 1 or Day 2 consumption and as an average consumption. If an individual ate a food item on both days, the consumption appears as one Day 1 consumption, one Day 2 consumption, and one average consumption. An example based on two individuals from the database is provided in Table 3.

Table 3. Listing of Food Consumption Events in Database

|  | Person's ID code | $\begin{gathered} \text { Day Code: } \\ \text { 1=day } 1 \\ \text { 2=day } 2 \\ \text { 4=2-day avg. } \end{gathered}$ | EPA <br> commodity code consumed | Amount Consumed g/day | Comments |

|  | 1000101 | 2 | 3002370 | 0.120856 |  |
|  | 1000101 | 4 | 3002370 | 0.275048 |  |

| $\begin{aligned} & \text { Individual that completed } \\ & \text { day } 1 \text { only } \end{aligned}$ | 1010801 | 1 | 1010520 | 0.047479 | Only one day of data; no Day <br> 2 or Average recorded |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1010801 | 1 | 1010780 | 0.144031 | Only one day of data; no Day 2 or Average recorded |
|  | 1010801 | 1 | 1012980 | 0.071958 | Only one day of data; no Day 2 or Average recorded |

The first person listed in Table 3 (ID code 1000101) completed surveys for both days, so EPA commodity codes are listed for the day the food was consumed and are listed as a two-day average (even if the commodity was consumed on only one of the two days). The second person in Table 3 (ID code 1010801) only completed the survey for Day 1, so all the commodities consumed are listed only as Day 1 records.

In this analysis, only two-day average consumption records were used. This was done because the sample person weighting factors for each survey respondent were different for Day 1 consumption, Day 2 consumption, and average consumption. Because average consumption represented a larger data set for each survey respondent, it was used in the analysis. By removing all the Day 1 and Day 2 records, the 3,173,197 records in the CSFII were reduced to 1,286,953 two-day average consumption records. Note that in the example above, the second individual in Table 3 (ID Code 1010801) would be removed from the analysis because no Day 2 data were available.

The decision to use only complete, two-day records for the analysis resulted in the removal from the database of 1,055 persons who completed only the first day of the food consumption survey. In addition, 808 persons were flagged for removal from the study because they did not provide a body weight on their survey form. Without a body weight, the weightnormalized intake values in this study cannot be calculated. Fifty-one of the individuals in the survey had both an invalid body weight and only one day of food consumption data. Therefore, these two selection criteria reduced the number of persons in the database by 1,812 , leaving an operating survey population of 19,850 individuals who submitted complete intake data for both days and provided a valid body weight. This population of 19,850 was the starting point for all demographic cohorts discussed in this study and presented in the data tables.

When the database of $1,286,953$ two-day average consumption records was filtered to include only the 19,850 individuals in the demographic database, 45,772 records were removed, leaving $1,241,181$ consumption records in the consumption database. These records contain consumption data for 19,731 individuals.

The remaining 119 individuals in the total cohort of 19,850 were valid persons (in the sense that they provided a body weight and completed the survey for both days), but they do not appear in the consumption database because they did not consume any food items that have valid EPA commodity codes. This is not an error, but rather a reflection of a population segment that
consumed only human milk during the survey period. All 119 individuals were 7 months old or younger, and 107 were 4 months old or younger. All 119 had a data element in their survey indicating that they were breastfeeding. Because the EPA commodity code list did not include human milk, these individuals have no entries in the food consumption database. At the other end of the spectrum, there were several individuals in CSFII 1994-96, 1998 whose food consumption data were unusually high. The highest reported food consumption was $8,840 \mathrm{~g} / \mathrm{day}$ from a 19-year-old white male from the rural Midwest. The 99th percentile of total food consumption among the entire survey population was 2,650 grams.

Because challenging or verifying reported food consumption in CSFII 1994-96, 1998 was beyond the scope of this project, data were assumed to be correct as presented in the CSFII, even in the case of these extremely high food consumption rates.

### 3.2. IDENTIFICATION OF DEMOGRAPHIC COHORTS

The 19,850 individuals in the working database were divided into cohorts on the basis of four demographic characteristics included in the surveys completed by the study participants (Table 4). Individuals were grouped on the basis of age, race, urbanization, and geographic region. Except in the case of age, the level of detail in identifying the demographic categories was determined by the constraints of the source data and is the same as in CSFII 1994-96, 1998.

Age. The selection of age categories was based on previous food consumption studies. For the calculation of total food intake, there were eight age categories: less than 1 year, 1-2 years, $3-5$ years, $6-11$ years, $12-19$ years, $20-39$ years, $40-69$ years, and greater than 70 years. For the analysis of low-end, mid-range, and high-end consumers, the oldest three categories were combined into a single category containing all individuals aged 20 years or older.

Race. Survey respondents were asked to indicate their race from a list of five choices: White, Black, Asian/Pacific Islander, American Indian, or Other.

Urbanization. Survey respondents were asked to indicate whether they lived in the central part of a Metropolitan Statistical Area (MSA), the outer portions of an MSA, or not in any MSA. These designations are listed in the study results as Central City, Suburban, and Nonmetropolitan, respectively

Geographic region. Survey respondents were asked to identify their geographic region (Northeast, Midwest, South, or West, as defined in Figure 1).

Figure 1. Geographic regions as defined in CSFII.

### 3.3. USE OF WEIGHTING FACTORS

Weighting factors (see Section 2.2) for the two-day average consumption values were provided in CSFII 1994-96, 1998. These weighting factors are based on a population of 20,607 individuals who provided two days of food consumption data. This number of individuals is slightly higher than the 19,850 used in the present study because 757 individuals with two days of consumption data were removed from the present study because they did not provide a body weight (see Preparation of Data, Section 3.1). The effect of this discrepancy was expected to be minor relative to the other variables in the study, such as estimation of an individual's portion size based on a survey and conversion of food items to individual commodities.

## 4. RESULTS

### 4.1. TOTAL DIETARY INTAKE: WHOLE POPULATION AND POPULATION SUBGROUPS

Total dietary intake was calculated for the whole population and for each of the demographic categories. For the purposes of this study, total dietary intake is defined as consumption of food that corresponds to any of the EPA commodity codes in Table 2, except those listed as "other/not classified." Percent consuming, mean, standard error, and a range of percentile values were calculated for each demographic group. The calculations were performed on the basis of grams of food per kilogram of body weight per day (Table 5A) and on the basis of grams per day (Table 5B.)

### 4.2. INTAKE OF INDIVIDUAL FOOD GROUPS, CATEGORIZED BY AGE

Total intake of each of the 10 food categories listed in Table 1 and total dietary intake were calculated for the whole population and for five age categories: $0-1$ years, $1-2$ years, $3-5$ years, 6-11 years, and 12-19 years, and 20 years old and above. Percent consuming, mean, standard error, and a range of percentile values were calculated for each food type. Table numbers for each age group and type of intake are presented in Table 6. Tables 7A through 7N present the results. For each age category, two tables are presented: one with intakes on the basis of grams of food per kilogram of body weight per day, and one with intakes on the basis of grams per day.

### 4.3. IDENTIFICATION OF HIGH-END, MID-RANGE, AND LOW-END DECILES OF FOOD INTAKE

In order to compare patterns of food intake among groups with unusually high or low rates of intake of certain foods, subgroups were isolated from the total survey population of 19,850 individuals. The bottom, middle, and upper deciles of consumption were identified for six decile target foods: total foods, meats, meat and dairy, fish, fruits and vegetables, and dairy. The calculation of food intake by age group for each of the 10 food categories was repeated for each decile.

Table 6. Table Numbers for Each Age Group and Type of Intake

| Age <br> (years) | Intakes <br> (g/kg/d) | Intakes <br> (g/d) |
| :---: | :---: | :---: |
| All ages <br> combined | 7 A | 7 B |
| $20+$ | 7 C | 7 D |
| $<1$ | 7 E | 7 F |
| $1-2$ | 7 G | 7 H |
| $3-5$ | 7 K | 7 J |
| $6-11$ | 7 M | 7 L |
| $12-19$ |  | 7 N |

Deciles were identified as follows. For each of the six age groups, consumption of the decile target food was calculated for each individual. The individuals were sorted by consumption, and a weighted percentile value was calculated for each individual using the weighting factors described in Section 2.2, with the lowest consumption approximately equal to zero and the highest equal to one. The low-consuming decile was defined as all persons with a consumption less than the 10th percentile. The mid-range decile was defined as all persons with a consumption falling between the 45th and 55th percentile. The high-consuming decile was defined as all persons with a consumption greater than the 90th percentile. This identification was repeated for each age category and for the entire survey population. The identification of deciles resulted in lists of high-, mid-range-, and low-consuming individuals for each age group for each of the six target foods. Note that due to differences in weighting factors, the high, midrange, or low decile for a given age group does not necessarily contain exactly $10 \%$ of the individuals in the group.

As an aid to the reader, the table numbers are listed in Table 8. The results of the decile analysis are presented in Tables 9A through 14N. In each of these tables, the number denotes the decile target food, and the letter denotes the age group and the basis of the intake calculation (g/kg/day or g/day).
