**EXPLANATION** Map showing hazard zones, faults, and volcanic vents in the Crater Lake region. Data sources for faults and vents: Sherrod (1991), Sherrod and MacLeod (1992), Sherrod and Pickthorn (1992), Smith (1988), Smith and others (1982), C. R. Bacon (unpublished mapping, 1996), and M. A. Lanphere (unpublished K-Ar ages, 1006) 1996).

## Hazard Zones

Proximal Hazard Zone A -- Area bounded by Crater Lake caldera rim; subject to pyroclastic surges and ballistics from explosive eruptions anywhere within the caldera

Proximal Hazard Zone B -- Area outside of Proximal Hazard Zone A that may be affected by pyroclastic surges and ballistics from explosive eruptions from vents within the lake and close to the shoreline; boundaries defined by height/runout ratio of 0.1 and source of surges up to 500 m above lake surface 

Regional Hazard Zone RH -- Zone of relatively high probability of a volcanic eruption; contains volcanic vents less than 100,000 yrs in age. Annual probability of eruption from a new vent estimated to be  $\sim$ 1 in 5,000 (2x10 exp -4); 30-year probability  $\sim$ 1 in 170 (6x10 exp-3).

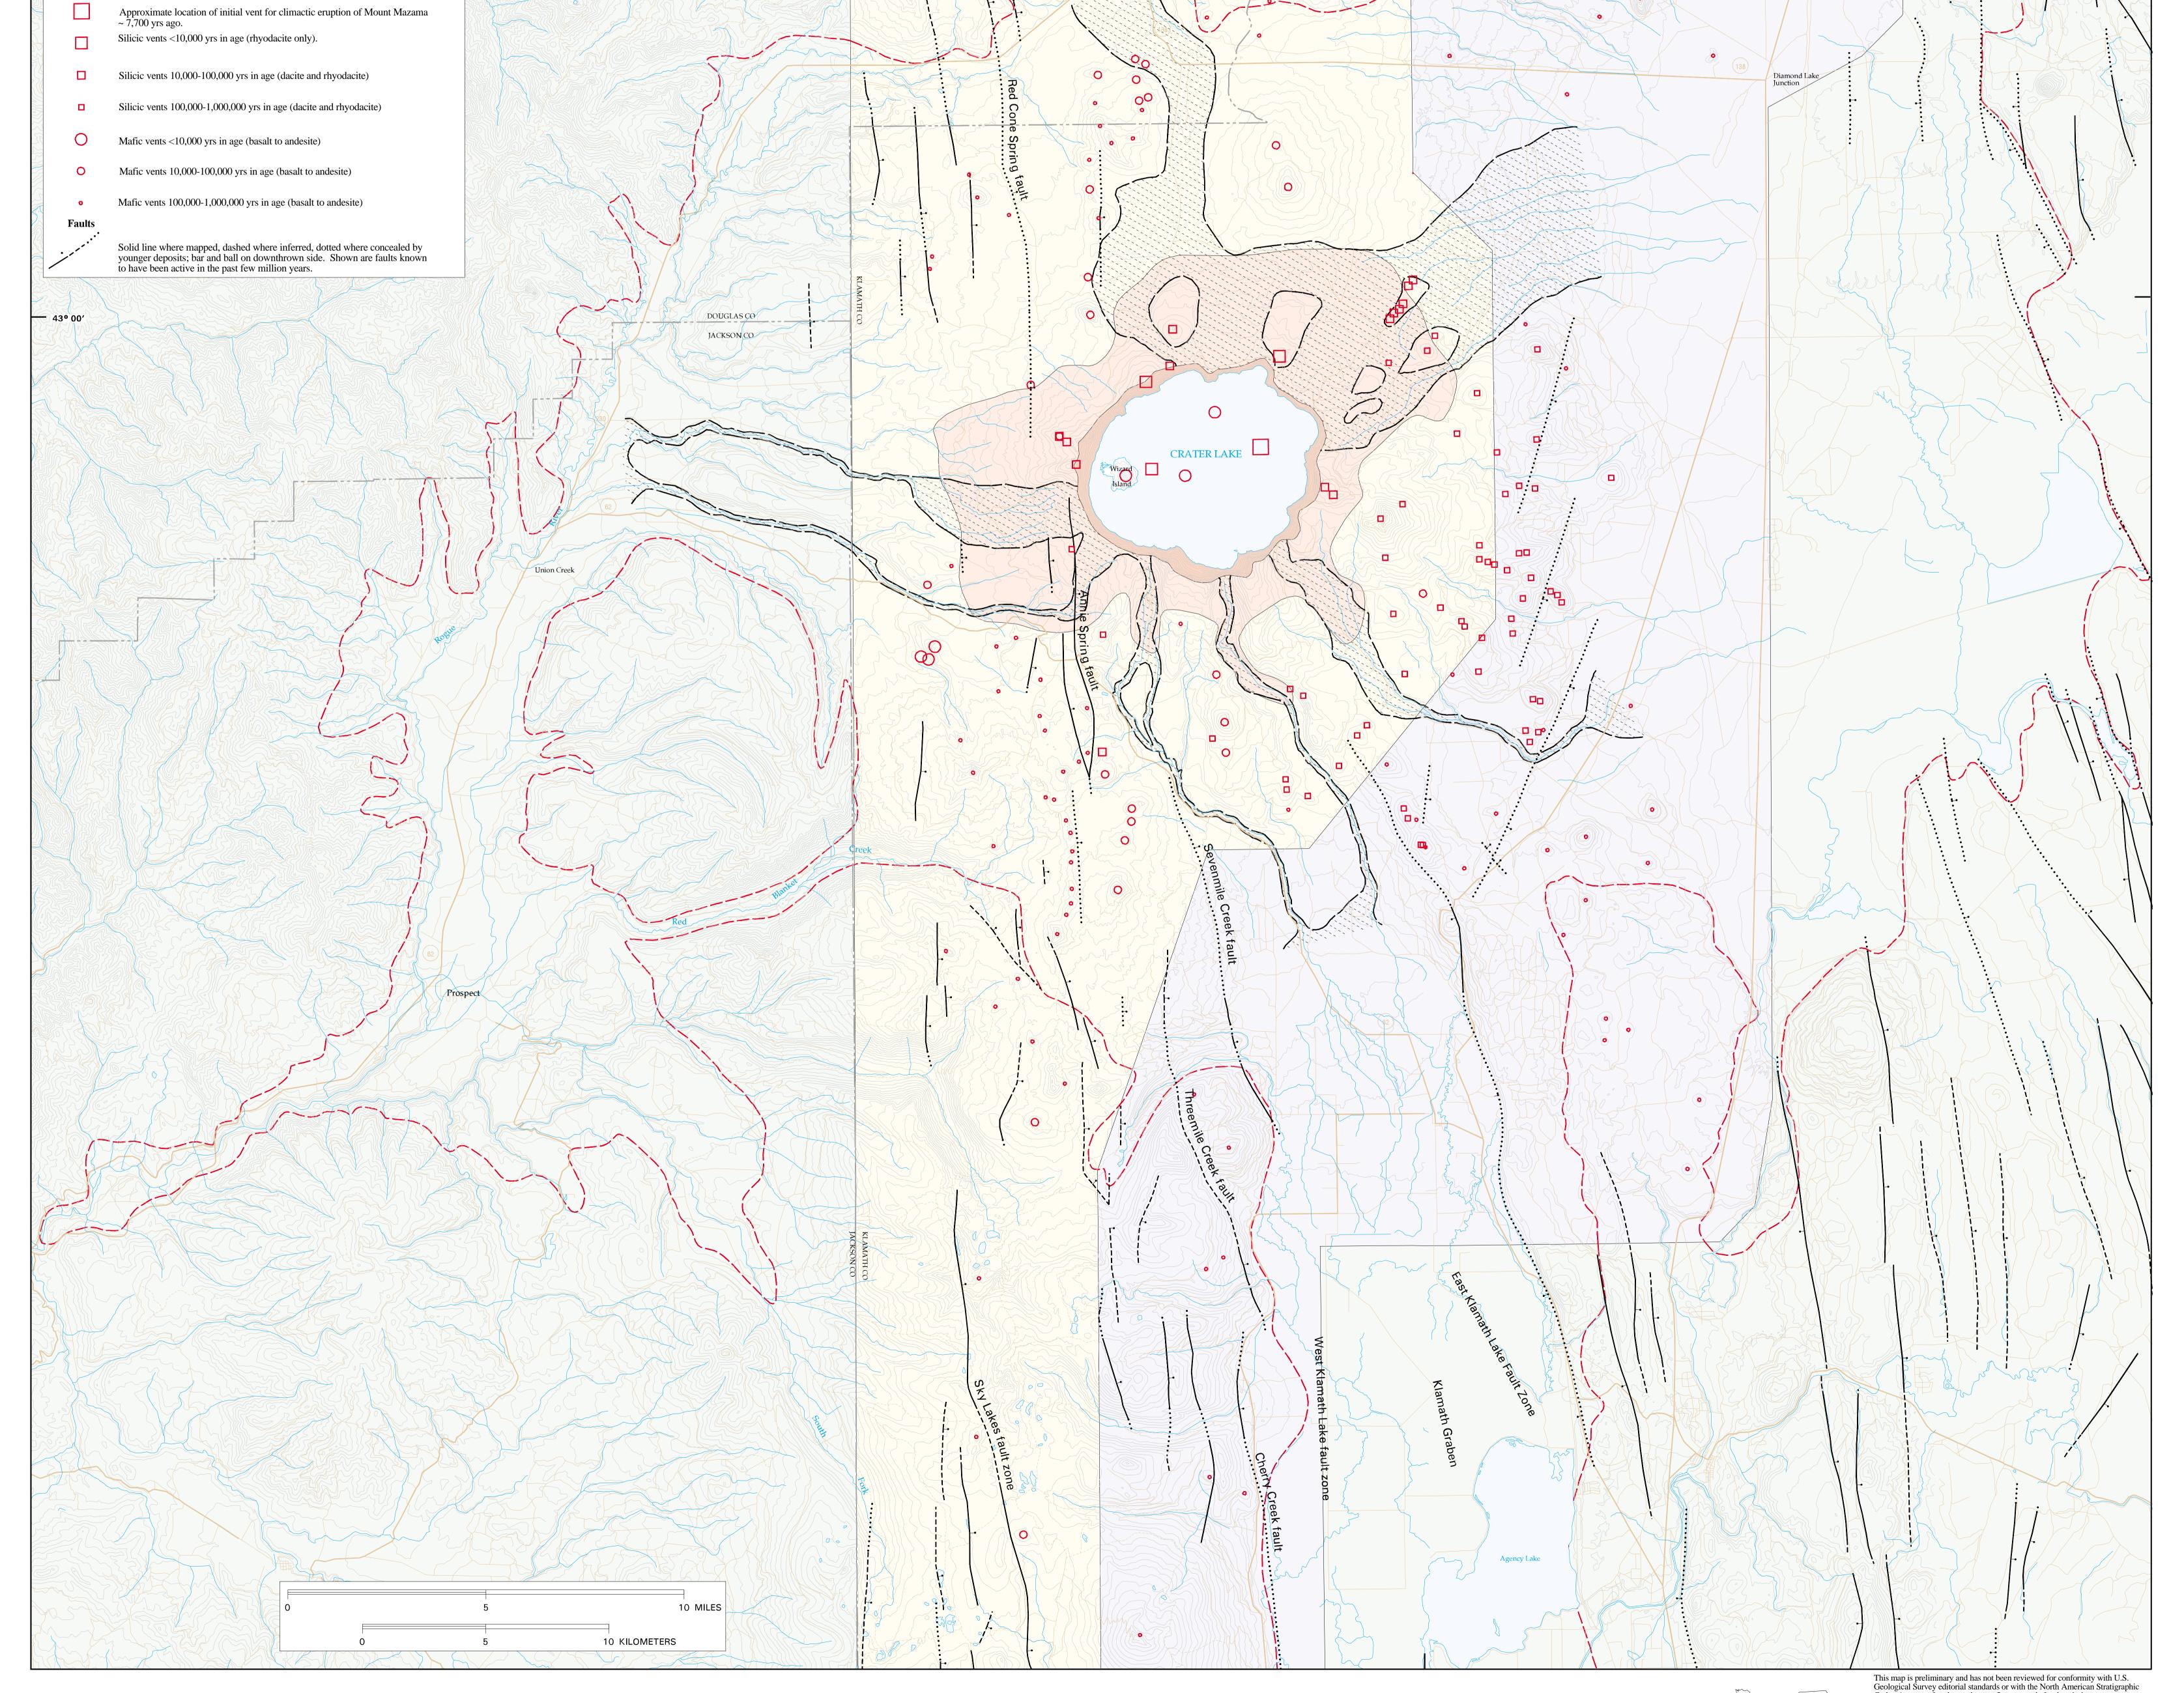

Regional Hazard Zone RL -- Zone of relatively low probability of a volcanic eruption; contains volcanic vents 100,000-1,000,000 yrs in age. Annual probability of eruption from a new vent estimated to be  $\sim$ 1 in 100,000 (10 exp-5) 30-year probability  $\sim$ 1 in 3,000 (3x10 exp-4). The probability of an eruption from a new vent outside this zone is considered insignificant.

Lahar Hazard Zone -- Areas potentially inundated by lahars (volcanic debris flows) caused by volcanic eruptions within Crater Lake caldera. 

Maximum extent of pumiceous pyroclastic-flow deposits of climactic eruption of Mount Mazama (~7,700 yrs ago). Area devastated by pyroclastic flows and ash fall exceeds limits of pumiceous pyroclastic-flow deposits. \_\_\_\_
