# The CÆSAR Code Package
## (LA-UR–00-5568, LA-CC–06-027)

**Michael L. Hall**

February 3, 2009

The CÆSAR Code package was developed by Michael L. Hall. He can be reached at:

Los Alamos National Laboratory
P.O. Box 1663, MS-D413
Los Alamos, NM 87545
Email: `Hall@LANL.gov`

The release history of the CÆSAR Code Package is:

| | |
|---|---|
| Version: 1.1.1 | Date: 05/09/06, 10:51:41 (current version) |
| Version: 1.1 | Date: 03/22/06 (LA-CC–06-027) |
| Version: 1.0 | Date: 02/05/04 (LA-CC–04-009) |
| Version: 0.6 | Date: 10/02/03 |
| Version: 0.5 | Date: 11/13/00 (LA-UR–00-5568) |

# Preface

The CÆSAR Code Package is a computational physics development environment. In other words, it provides an environment where the physics of real systems can be modeled, by discretizing a set of partial differential equations on a mesh and solving the resultant algebraic system.

The CÆSAR Code Package does not by any means span this extremely large problem space. It does, however, provide a consistent means of incorporating new methods of attacking the computational physics problem. It is *extensible* – new equation sets, new discretizations, new meshes, new linear solvers, new communication libraries, etc., may be incorporated easily.

The emphasis in CÆSAR is on equation sets, discretizations, meshes, nonlinear solvers and preconditioners, which are all incorporated into the basic CÆSAR structure. In contrast, linear solvers, communications libraries, mesh generators and partitioners, and visualization tools are generally included as external packages developed elsewhere, but may be developed inside CÆSAR eventually.

The CÆSAR Code Package has these coding characteristics:

- It is written in Fortran-90, preprocessed by Gnu m4.
- It is written in an object-based fashion, and probably comes as close to being object-oriented as is possible in Fortran-90.
- It has both parallel and serial versions, designed in from the start of the project.
- It has a completely levelized design (Lakos, 1996); there are no dependency loops between classes or modules.
- It uses its own form of Design by Contract™ (Meyer, 1997) to verify the behavior of all procedures.
- It uses extensive unit testing to certify all classes.
- It uses the ideas of literate programming[1] (Knuth, 1992) to generate documentation (in HTML, PostScript and PDF) from comments included in the code, via the Document Package[2].

The CÆSAR Code Package has these computational physics characteristics:

- It allows for multiple mesh types. Currently, a multi-mesh class which can support many types of meshes is being developed. Among the meshes supported will be: uniform meshes, orthogonal meshes, structured meshes, unstructured meshes, adaptive mesh refinement (AMR) meshes, triangular/tetrahedral meshes, and quadrilateral/hexahedral meshes. Polygonal/polyhedral meshes may also be supported in the future.
- It allows for multiple dimensions – 1–D, 2–D and 3–D.
- It allows for multiple geometries – cartesian, cylindrical and spherical.
- It allows for multiple physics packages by allowing for various sets of partial differential equations. Future physics to be modeled may include diffusion, radiation transport (photonics), radiation hydrodynamics, fluid dynamics, magnetohydrodynamics and heat pipe thermal hydraulics.
- It allows for multiple discretizations of the same terms in the equations.
- It allows for multiple external packages for linear solvers, communications, visualization, etc.

[2] `http://www.lanl.gov/Document`

The CÆSAR Code Package is related to the earlier Augustus[3], Spartan[4], and THROHPUT[5] Code Packages.

The documentation is split into the following major parts:

- CÆSAR Package User's Manual (Part I, page 3)
- CÆSAR Package Code Manual (Part II, page 17)
- CÆSAR Package Methods Discussion (Part III, page 185)
- CÆSAR Package Code Listings (Part IV, page 193)

Additional documentation related to the CÆSAR project is listed in Presentations and Articles (Chapter 1, page 3).

# Presentations and Articles

The papers and presentations in this chapter are available online via the HTML-based version of this document.

Currently, the best general overview papers and presentations concerning the Cæsar Project are:

**Cæsar:**

**The Cæsar Code: Software Design Issues** A presentation by Michael L. Hall that was made to the X-Division External Review Committee on March 10th, 1999 is available in HTML, PDF and PostScript formats (LA-UR–99-1069). There is also a manager's version of this presentation in PDF and PostScript (LA-UR–99-1070).

**Spartan:**

**Spartan/Augustus Overview: Simplified Spherical Harmonics and Diffusion for Unstructured Hexahedral Lagrangian Meshes** A presentation by Michael L. Hall that was made to the Shavano working group on April 22nd, 1998 is available in HTML, PDF and PostScript formats (LA-UR–98-3766).

**Augustus:**

**Diffusion Discretization Schemes in Augustus: A New Hexahedral Symmetric Support Operator Method** A presentation by Michael L. Hall and Jim E. Morel which was given three times — to the ASCI PI meeting on July 14th, 1998 at Los Alamos National Laboratory; at an X-Division Work In Progress talk on July 29th, 1998; and at the Nuclear Explosives Code Development Conference in Las Vegas, NV on October 29th, 1998 — is available in HTML, PDF and PostScript formats (LA-UR–98-3146).

**A Local Support-Operators Diffusion Discretization Scheme for Hexahedral Meshes** A paper by J. E. Morel, Michael L. Hall, and Mikhail J. Shashkov which has been submitted to the *Journal of Computational Physics*, Summer 1999 — is available in HTML, PDF and PostScript formats (LA-UR–99-4358).

**A Second-Order Cell-Centered Diffusion Difference Scheme for Unstructured Hexahedral Lagrangian Meshes** A presentation by Michael L. Hall and Jim E. Morel which was given twice — at the International Congress On Computational And Applied Mathematics in Leuven, Belgium on July 26th, 1996; and at the Nuclear Explosives Code Developers Conference in San Diego, CA on October 24th, 1996 — is available in PostScript and PDF formats (LA-CP–97-7). It was presented with a video.

**A Second-Order Cell-Centered Diffusion Difference Scheme for Unstructured Hexahedral Lagrangian Meshes** A paper by Michael L. Hall and Jim E. Morel in the *Proceedings of the 1996 Nuclear Explosives Code Developers Conference (NECDC), UCRL-MI-124790* is available in HTML, PDF and PostScript formats (LA-CP–97-8).

A complete listing of presentations and papers that are related to the CÆSAR Project follows:

**Cæsar:**

**Progress Towards Higher-Fidelity Yet Efficient Modeling of Radiation Energy Transport Through Three-Dimensional Clouds** A poster presentation by Michael L. Hall and Anthony B. Davis that was made at the Atmospheric Radiation Measurement (ARM) Science Team Meeting in Daytona Beach, FL on March 14th–18th, 2005 is available in HTML, PDF and PostScript formats (LA-UR–05-2275).

**Three-Dimensional Radiative Transfer, Simplified . . . with Cloud Modeling and Remote Sensing in Mind** A presentation by Anthony B. Davis, Michael L. Hall and Igor N. Polonsky that was made at the Atmospheric Radiation Measurement (ARM) Science Team Meeting in Daytona Beach, FL on March 14th–18th, 2005 is available in PDF format (LA-UR–05-2282).

**The Cæsar Code: Software Design Issues** A presentation by Michael L. Hall that was made to the X-Division External Review Committee on March 10th, 1999 is available in HTML, PDF and PostScript formats (LA-UR–99-1069). There is also a manager's version of this presentation in PDF and PostScript (LA-UR–99-1070).

**Spartan:**

**Diffusion, $P_1$, and Other Approximate Forms of Radiation Transport** A paper by Gordon L. Olson, Larry H. Auer and Michael L. Hall, in the *Journal of Quantitative Spectroscopy and Radiative Transfer*, 64:6 (2000) pp. 619-634, is available in PDF format as both the submitted version and the JQSRT version (LA-UR–99-471).

**Analysis of Z Pinch Shock Wave Experiments** A Sandia report by Timothy G. Trucano, Kent G. Budge, Jeffery Lawrence, James Asay, Clint Hall, Kathleen Holland, Carl Konrad, Wayne Trott, Gordon Chandler, and Kevin Fleming is available in PDF format (SAND99-1255).

**Spartan Test Problem Results** A presentation by Michael L. Hall that was made on September 29th, 1998 to the Department of Energy is available in HTML, PDF and PostScript formats (LA-UR–98-3890). It was presented with a video.

**Aspects of Analysis of Z Machine Shock Wave Physics Experiments** A presentation by Timothy G. Trucano that was made on August 6, 1998 to the DOE Interlaboratory MHD Workshop at Los Alamos National Laboratory is available in PDF format.

**Spartan Parallelization and Augustus Time Dependent Results** A few slides prepared by Michael L. Hall as part of a larger presentation to Gil Weigand on June 1st, 1998 are available in HTML, PDF and PostScript formats (LA-UR–98-3750).

**Spartan/Augustus Overview: Simplified Spherical Harmonics and Diffusion for Unstructured Hexahedral Lagrangian Meshes** A presentation by Michael L. Hall that was made to the Shavano working group on April 22nd, 1998 is available in HTML, PDF and PostScript formats (LA-UR–98-3766).

**"Top Hat" problem (or "Pipe Flow" problem) Results From Spartan** Some results and graphs by Michael L. Hall from running Spartan on the "Top Hat" problem are available: Data Listing, Results Summary (PostScript) and compressed tarfile of whole directory.

**Augustus:**

**A Local Support Operator Diffusion Discretization Scheme for Hexahedral Meshes** A presentation by Michael L. Hall, Jim E. Morel and Mikhail J. Shashkov which was given at the JOWOG 42 meeting on October 21st, 1999 at Los Alamos National Laboratory — is available in HTML, PDF and PostScript formats (LA-UR–99-5834).

**A Local Support-Operators Diffusion Discretization Scheme for Hexahedral Meshes** A presentation by Jim Morel, Michael L. Hall, and Mikhail J. Shashkov which was presented at a CNLS Numerical Analysis Seminar on November 9th, 1999 at Los Alamos National Laboratory — is available in HTML, PDF and PostScript formats (LA-UR–99-6259).

**A Local Support-Operators Diffusion Discretization Scheme for Hexahedral Meshes** A paper by J. E. Morel, Michael L. Hall, and Mikhail J. Shashkov which has been submitted to the *Journal of Computational Physics*, Summer 1999 — is available in HTML, PDF and PostScript formats (LA-UR–99-4358).

**Diffusion Discretization Schemes in Augustus: A New Hexahedral Symmetric Support Operator Method** A presentation by Michael L. Hall and Jim E. Morel which was given three times — to the ASCI PI meeting on July 14th, 1998 at Los Alamos National Laboratory; at an X-Division Work In Progress talk on July 29th, 1998; and at the Nuclear Explosives Code Development Conference in Las Vegas, NV on October 29th, 1998 — is available in HTML, PDF and PostScript formats (LA-UR–98-3146).

**A Second-Order Cell-Centered Diffusion Difference Scheme for Unstructured Hexahedral Lagrangian Meshes** A presentation by Michael L. Hall and Jim E. Morel which was given twice — at the International Congress On Computational And Applied Mathematics in Leuven, Belgium on July 26th, 1996; and at the Nuclear Explosives Code Developers Conference in San Diego, CA on October 24th, 1996 — is available in PostScript and PDF formats (LA-CP–97-7). It was presented with a video.

**A Second-Order Cell-Centered Diffusion Difference Scheme for Unstructured Hexahedral Lagrangian Meshes** A paper by Michael L. Hall and Jim E. Morel in the *Proceedings of the 1996 Nuclear Explosives Code Developers Conference (NECDC), UCRL-MI-124790* is available in HTML, PDF and PostScript formats (LA-CP–97-8).

**Unique Linear Solver Needs of the Los Alamos Radiation Transport Team** A presentation by Michael L. Hall and John M. McGhee which discusses the peripheral issue of linear solvers with respect to two main code packages, DANTE and Augustus/Spartan, is available in PostScript and PDF formats (LA-UR–99-1225). It was presented at the Application Code Developers Meeting of the Accelerated Strategic Computing Initiative in Albuquerque, NM, August 28th, 1996.

**RAYHYD: An ICF Target Simulation Code Written in C++** A paper by Kent G. Budge, James S. Peery, Timothy G. Trucano, Mike K. Wong, Jim E. Morel and Michael L. Hall in the *Proceedings of the 1994 Nuclear Explosives Code Developers Conference (NECDC)* is available in PDF format.

**Augustus: Unstructured Quadrilateral Mesh Diffusion** A preliminary results presentation by Michael L. Hall and Jim E. Morel that was made very early in the development of Augustus, without much detail, is available in PostScript and PDF. It was presented internally at Sandia National Laboratory on May 6th, 1994.

# Chapter 2

# Installation

## 2.1 Requirements

In order to unpack the distribution file, you must have:

**GNU tar**[1] available and in your path. CÆSAR has recently been tested with gtar version 1.13.25.

**GNU zip**[2] available and in your path. CÆSAR has recently been tested with gzip version 1.3.3.

In order to build and run the program, you must also have:

**GNU make**[3] available and in your path. CÆSAR has recently been tested with gmake version 3.79.1.

**GNU m4**[4] available and in your path. CÆSAR has recently been tested with gm4 version 1.4.1.

**A Fortran 90/95 compiler** available and in your path. These compilers are currently supported:

**Lahey Compiler on Linux.**[5] CÆSAR has recently been tested with Lahey F95 version L6.20c.

**Absoft Compiler on Linux.**[6] CÆSAR has recently been tested with Absoft F95 version 8.2.

**Absoft Compiler on Darwin.**[7] CÆSAR has recently been tested with Absoft F95 version 8.2.

**Sun Workshop Compiler on Solaris.**[8] CÆSAR has recently been tested with Sun WorkShop 6 update 2 Fortran 95 6.2 on Solaris 6. (Yes, this is very old. Support will soon be removed from Solaris.)

These compilers have been supported in the past:

**MIPSpro Compiler on SGI/IRIX.**[9] CÆSAR was last tested with MIPSpro compiler version 7.4 on IRIX 6.5.

In order to generate the documentation yourself, you must also have:

---

[2] http://www.gzip.org/
[3] http://www.gnu.org/software/make/
[4] http://www.gnu.org/software/m4/
[5] http://www.lahey.com/
[6] http://www.absoft.com/
[7] http://www.absoft.com/
[8] http://www.sun.com/
[9] http://www.sgi.com/products/software/irix/tools/mipspro.html

**The Document Package**[10] available and in your path.

**2html**[11] installed on your system. The latex2html-2002.2.1-6.rpm version is sufficient.

**perl**[12] installed on your system and in your path. CÆSAR has recently been tested with perl version 5.8.0.

Alternately, you can retrieve the documentation from the web[13].

## 2.2 External Packages

CÆSAR makes use of several external packages to accomplish its goals.

In most cases, there are (or will be) multiple packages to perform any given function, so that CÆSAR may be compiled in many different configurations. For selected packages, optimization and debugging can be toggled as a group.

### 2.2.1 MPI Package

MPI, the Message Passing Interface standard, was developed by the MPI Forum to provide a standard for low-level interprocessor communication in a parallel environment. Several vendors have implementations of MPI and there is also a portable version of MPI called MPICH.

CÆSAR does not require MPI directly, but all parallel versions of CÆSAR use packages which require MPI. CÆSAR can be compiled with no MPI (a serial version), or with a vendor-supplied MPI, or with the included MPICH.

### 2.2.2 PGSLib Package

PGSLIB(Parallel Gather-Scatter Library) was developed by Robert Ferrell of Cambridge Power Computing Associates, Ltd.. It is used for high-level parallel communication in CÆSAR. PGSLib has both a serial version, which runs on a single processor, and a parallel version, which allows inter-processor communication.

The parallel version of PGSLIB requires an MPI package (see Section 2.2.1), which can be provided by the computer vendor or by MPICH (included with CÆSAR).

CÆSAR can be compiled without PGSLIB, or with the serial or parallel versions of PGSLIB.

### 2.2.3 LAPACK Package

LAPACK (Linear Algebra Package) provides routines for solving systems of simultaneous linear equations, least-squares solutions of linear systems of equations, eigenvalue problems, and singular value problems. The associated matrix factorizations (LU, Cholesky, QR, SVD, Schur, generalized Schur) are also provided, as are related computations such as reordering of the Schur factorizations and estimating condition numbers. Dense and banded matrices are handled, but not general sparse matrices. LAPACK routines are written so that as much as possible of the computation is performed by calls to the Basic Linear Algebra Subprograms (BLAS). LAPACK was developed by Jack Dongarra's LAPACK Project group at the University of Tennessee.

Highly efficient machine-specific implementations of LAPACK and the BLAS are available for many modern high-performance computers. If a vendor-supplied version is available, it is prefered.

[10] http://www.lanl.gov/Document
[11] http://tug.org/mailman/listinfo/latex2html
[12] http://www.perl.org/
[13] `http://www.lanl.gov/Caesar/`

CÆSAR does not currently use LAPACK directly, but it may in the future. CÆSAR currently requires the LAMG package, which may be compiled with LAPACK. CÆSAR can be compiled with no LAPACK or with a vendor-supplied LAPACK, or with the included LAPACK.

### 2.2.4 LAMG Package

LAMG (Los Alamos Algebraic Multigrid Code) was developed by the Parallel Architectures and Algorithms Team in the Scientific Computing Group (CIC-19) at LANL. It provides algebraic multigrid and Krylov solvers to the CÆSAR Project.

CÆSAR can not currently be compiled without LAMG because LAMG provides the only solvers in CÆSAR. Eventually, as other solver packages are added and developed within CÆSAR, this dependency will be removed.

# Chapter 5

# Design Decisions

- Documentation will be an integral part of the program, and will be done via my Document package. The documentation will be available in both HTML and PostScript form, via LaTeX and LaTeX2html.
- Assume `gmake` is available. This allows many coding constructions not found in vendor `make`s, and increases portability.
- "Design by Contract" coding methodology will be used, but some terminology may be changed to be more meaningful.
  - For instance, "assertions" will be used, but will be referred to as "verifications". To "assert" means to state that something is true, whereas to "verify" means to test to make sure that something is true. Other nomenclature that I considered and rejected includes: check, confirm, certify, warrant, ascertain, ensure, guarantee. All of these are better than "assert", but I considered "verify" to be the best.
  - Also, "invariant" will be referred to as "valid_state", because it is more indicative of the test being done. Other nomenclature that I considered and rejected includes: self-consistent, consistent, well-formed, valid.

  Granted, I may lose a small amount of understanding on the part of C programmers who are looking at my code (and are familiar with the terms "assert" and "invariant"), but I will gain a great deal of understanding from people that are new to the "Design by Contract" method.
- Assume `gm4` is available. This means that line numbers from the source code can be output as error messages from the verifications.
- Assume that all error line references are to the original, unprocessed files. This means that any header files can add blank lines, which means that the ubiquitous "dnl" can be eliminated, which will greatly increase readability.
- In addition to the VERIFY macros, I'm making a WARN_IF macro that generates a warning if a test fails but continues program execution.
- I considered using DejaGnu to automate testing, but ultimately rejected it. The reasons for rejection include:
  - It seems that DejaGnu's main thrust is testing on different platforms, and it requires Tcl and Expect to run. I don't want to require all three programs (Tcl, Expect and DejaGnu) to be able to test on other architectures.
  - It looks non-trivial to set up, especially since I don't know Tcl and Expect.
  - It's unclear what benefit, if any, would be derived from using it.

My current solution for testing, as far as modules are concerned, is to include a test routine at the end of each module which will only be activated if a gm4 flag is set. I'm including the "script" necessary to run each module test as Self-Documentation text that my perl script Document can pick out.

# Chapter 6

# m4 Preprocessing

The CÆSAR Code Package makes extensive use of the m4 preprocessor to modify the Fortran 90 source code. All Fortran 90 source is preprocessed by m4 before compilation. The Gnu version of m4 is required.

Some of the uses of the m4 preprocessor in CÆSAR include unit testing, verification and warning statements (which implement design by contract), intrinsic type definition, and code replication.

## 6.1 Global m4 Settings

The "settings" set of m4 commands defines the m4 environment that is used in the CÆSAR Code Package:

- The m4 quotation characters are changed to "[" and "]", to avoid interaction with standard F90 syntax.
- The m4 comment character is changed to "!", to coincide with the F90 comment character. Note that comments in m4 are echoed to the output with no macro expansion. To avoid echoing at all, the m4 command "dnl" must be used (this may change in future versions of Gnu m4).
- Builtin m4 macros must be called with a prefix of "m4_". For example, the "format" macro must be called via "m4_format". Therefore, all of the m4 preprocessing in the CÆSAR Code Package must be done with Gnu m4, using either the `-P` or `--prefix-builtins` option.
- Certain commonly used m4 builtins are defined to be usable without an "m4_" prefix.

In addition to these environmental settings, some globally useful macros are defined.

**m4 macros defined in the `include/settings.m4` file:**

| | |
|---|---|
| `__date__` | Date field (mm/dd/yy). |
| `__file__` | Unprefixed form of `m4___file__`. |
| `__line__` | Unprefixed form of `m4___line__`. |
| `__time__` | Time field (hh:mm:ss, 24-hour). |
| `define` | Unprefixed form of `m4_define`. |
| `dnl` | Unprefixed form of `m4_dnl`. |
| `expand` | Force macro expansion in words containing underscores. |
| `firstword` | Returns the first word from a space-delimited list of words. |
| `forloop` | A numerical text iterator (see code listing in section A.1 for input/output details). |
| `fortext` | A textual text iterator (see code listing in section A.1 for input/output details). |
| `ifdef` | Unprefixed form of `m4_ifdef`. |
| `ifelse` | Unprefixed form of `m4_ifelse`. |

| | |
|---|---|
| `include` | Unprefixed form of `m4_include`. |
| `m4_chop` | Removes last character of input string. |
| `m4_die` | Prints error message and terminates. |
| `popdef` | Unprefixed form of `m4_popdef`. |
| `pushdef` | Unprefixed form of `m4_pushdef`. |
| `tailwords` | Returns everything except the first word from a space-delimited list of words. |
| `undefine` | Unprefixed form of `m4_undefine`. |

The Settings m4 Macros code listing in section A.1 contains additional documentation.

## 6.2 Type m4 Macros

The "type" set of m4 macros allows intrinsic F90 types to be defined in a manner similar to defined types, making use of the kind parameter to ensure consistency and allow for double and single precision versions of the code. The type macros allow the following constructions to be used in the CÆSAR Code Package:

```
type(real) :: realvar1
type(real,0) :: realvar2
type(real,3) :: realvar3
type(integer,1), intent(out) :: intvar1
type(integer,4,np) :: intvar2
type(logical,1,np) :: logvar
type(character,8) :: charvar1
type(character,*,2,np) :: charvar2
type(defined) :: defvar

intvar = changetype(integer, variable)
realvar = changetype(real, variable)
```

This code is expanded by Gnu m4 into the following valid F90 code:

```
real (kind=KIND(1.0d0)) :: realvar1
real (kind=KIND(1.0d0)) :: realvar2
real (kind=KIND(1.0d0)), pointer, dimension(:,:,:) :: realvar3
integer (kind=KIND(1)), pointer, dimension(:), intent(out) :: intvar1
integer (kind=KIND(1)), dimension(:,:,:,:) :: intvar2
logical (kind=KIND(.true.)), dimension(:) :: logvar
character (len=8) :: charvar1
character (len=*), dimension(:,:) :: charvar2
type(defined) :: defvar

intvar = INT(variable, KIND(1))
realvar = REAL(variable, KIND(1.0d0))
```

Note that this set of m4 macros depends on the m4 commands in the `settings.m4` file (see section 6.1) and on the SINGLE and UNICOS macro definitions.

**m4 macros defined in the `include/types.m4` file:**

| | |
|---|---|
| `changetype` | Used for intrinsic type conversions. |
| `pnt$dim` | Private macro used in type. |
| `real$kind` | Private macro used in type and changetype. |
| `type` | Used for intrinsic type definition. (see code listing in section A.2 for input/output details). |

The Type m4 Macros code listing in section A.2 contains additional documentation.

## 6.3 Verify m4 Macros

*Power is not revealed by striking hard or often, but by striking true. – Honore de Balzac (1799-1850)*

The "verify" set of m4 macros enable the conditional compilation of the verification statements which are used to implement "Design by Contract" methodology in the CÆSAR Code Package. Verification statements[1] are simply logical tests on variables which can be conditionally compiled into the code, allowing for extreme error checking if they are compiled in and unfettered execution speed if they are compiled out. The "Design by Contract" methodology extends this idea slightly by specifying when these verifications are to be done: input requirements are verified upon entry into a routine and output guarantees are verified before routine exit.

The CÆSAR Code Package further extends this idea in two ways:

- In addition to VERIFY commands which *halt* execution if they are not satisfied, WARN_IF commands output a warning message and *continue* execution if they are not satisfied.
- Both VERIFY and WARN_IF commands are conditionally compiled in based on a level variable (`DEBUG_LEVEL` for VERIFY and `WARNING_LEVEL` for WARN_IF) which can be set for each instance of a command individually. This allows a great deal of user control.

The syntax for the VERIFY/WARN_IF macros is given by:

```
VERIFY(<logical expression>,<activation level>)
WARN_IF(<logical expression>,<activation level>)
```

where `<logical expression>` is the F90 test to be satisfied and `<activation level>` is the value of the appropriate LEVEL variable (`DEBUG_LEVEL` for VERIFY and `WARNING_LEVEL` for WARN_IF) at which the test is compiled into the executable program – for level values less than the `<activation level>`, the test is commented out. To reiterate, if the debug or warning level is not set high enough to activate a particular command, that command will be commented out and will not be executed by the code.

The level at which a particular command will activate should be set according to a combination of criteria: importance and cost. An expensive (in terms of cpu-time) command, ceteris paribus, should have a higher `<activation level>` than a cheaper command. Commands whose satisfaction is more important should have a lower `<activation level>`. Verification or warning commands that specify an `<activation level>` of -1 will always be executed.

Code compiled with lower debug or warning levels will necessarily be as fast as or faster than code compiled with higher levels, but will also include fewer checks for accuracy. A debug or warning level of zero should include only those checks that the code author thought were absolutely necessary. Setting the debug or warning level to -1 will eliminate all commands of the specified type (except those with activation levels of -1).

When a VERIFY/WARN_IF test is compiled into the code, an if-block is inserted which evaluates the test. If the test fails, an output message is printed which contains the text, filename, and line number of the failed test. VERIFY commands then abort program execution, while WARN_IF commands continue.

There is a slight difference in the coding for the Intrinsic Classes (see chapter 7), because they are lower level than the communication routines, and therefore require serial coding. To trigger this difference, the Intrinsic Classes specify "`define([VERIFY_COMMUNICATION],[Local])`" in their headers.

[1] C and C++ programmers call a similar concept "assertions", see B. W. Kernighan and D. M. Ritchie, *The C Programming Language*, 1988, page 253

As an example, assume that a file named `verify_example` contains these lines:

```
m4_include(settings.m4)
m4_include(verify.m4)

VERIFY( i < 1, 5)
VERIFY( j > 2, 6)
VERIFY( k < 4, 7)

define([DEBUG_LEVEL], 2)
VERIFY( Valid_State(matrix), 1)
VERIFY( Valid_State(matrix), 2)
VERIFY( Valid_State(matrix), 3)
```

When this file is processed by Gnu m4, it is expanded into the following valid F90 code, if the `DEBUG_LEVEL` variable is not set:

```
! if (.not. Global_ALL(i < 1)) then
!   if (this_is_IO_PE) then
!     write (6,*) "Verification failed: ", &
!                 "i < 1, ", &
!                 "file verify_example, ", &
!                 "line 4."
!   end if
!   call Abort
! end if
! if (.not. Global_ALL(j > 2)) then
!   if (this_is_IO_PE) then
!     write (6,*) "Verification failed: ", &
!                 "j > 2, ", &
!                 "file verify_example, ", &
!                 "line 5."
!   end if
!   call Abort
! end if
! if (.not. Global_ALL(k < 4)) then
!   if (this_is_IO_PE) then
!     write (6,*) "Verification failed: ", &
!                 "k < 4, ", &
!                 "file verify_example, ", &
!                 "line 6."
!   end if
!   call Abort
! end if

 if (.not. Global_ALL(Valid_State(matrix))) then
   if (this_is_IO_PE) then
     write (6,*) "Verification failed: ", &
                 "Valid_State(matrix), ", &
                 "file verify_example, ", &
                 "line 9."
   end if
   call Abort
 end if
 if (.not. Global_ALL(Valid_State(matrix))) then
```

```
    if (this_is_IO_PE) then
      write (6,*) "Verification failed: ", &
                  "Valid_State(matrix), ", &
                  "file verify_example, ", &
                  "line 10."
    end if
    call Abort
  end if
! if (.not. Global_ALL(Valid_State(matrix))) then
!   if (this_is_IO_PE) then
!     write (6,*) "Verification failed: ", &
!                 "Valid_State(matrix), ", &
!                 "file verify_example, ", &
!                 "line 11."
!   end if
!   call Abort
! end if
```

If the DEBUG_LEVEL m4 variable is set to a value of 6, via the command line option -DDEBUG_LEVEL=6, then the expansion becomes:

```
  if (.not. Global_ALL(i < 1)) then
    if (this_is_IO_PE) then
      write (6,*) "Verification failed: ", &
                  "i < 1, ", &
                  "file verify_example, ", &
                  "line 4."
    end if
    call Abort
  end if
  if (.not. Global_ALL(j > 2)) then
    if (this_is_IO_PE) then
      write (6,*) "Verification failed: ", &
                  "j > 2, ", &
                  "file verify_example, ", &
                  "line 5."
    end if
    call Abort
  end if
! if (.not. Global_ALL(k < 4)) then
!   if (this_is_IO_PE) then
!     write (6,*) "Verification failed: ", &
!                 "k < 4, ", &
!                 "file verify_example, ", &
!                 "line 6."
!   end if
!   call Abort
! end if

  if (.not. Global_ALL(Valid_State(matrix))) then
    if (this_is_IO_PE) then
      write (6,*) "Verification failed: ", &
                  "Valid_State(matrix), ", &
                  "file verify_example, ", &
                  "line 9."
```

```
    end if
    call Abort
  end if
  if (.not. Global_ALL(Valid_State(matrix))) then
    if (this_is_IO_PE) then
      write (6,*) "Verification failed: ", &
                  "Valid_State(matrix), ", &
                  "file verify_example, ", &
                  "line 10."
    end if
    call Abort
  end if
! if (.not. Global_ALL(Valid_State(matrix))) then
!   if (this_is_IO_PE) then
!     write (6,*) "Verification failed: ", &
!                 "Valid_State(matrix), ", &
!                 "file verify_example, ", &
!                 "line 11."
!   end if
!   call Abort
! end if
```

If the WARN_IF macro had been used instead of the VERIFY macro (and the `WARNING_LEVEL` were set instead of the `DEBUG_LEVEL`), then the only changes in the output of the above examples would be that the Abort call would not have appeared, the test would not have been negated, and a Global_ANY would have been used instead of a Global_ALL.

If the VERIFY_COMMUNICATION macro had been set to Local, then the Global_ALL call would not have been used, the IO_PE check would not have appeared, and the Abort call would have been replaced with a stop.

As an additional refinement, any quotation characters in the logical expression are removed from the output string to prevent confusion with quoting there. Quotation marks in the logical expression should therefore be paired.

Note that this set of m4 macros depends on the m4 commands in the `settings.m4` file (see section 6.1) and on the DEBUG_LEVEL and WARNING_LEVEL macro definitions.

**m4 macros defined in the `include/verify.m4` file:**

| | |
|---|---|
| `DEBUG_LEVEL` | Verification is turned on for VERIFY commands whose activation level is equal to or less than the `DEBUG_LEVEL`. |
| `VERIFY` | Compile in or comment out a test which halts execution if unsatisfied. |
| `WARNING_LEVEL` | Warnings are turned on for WARN_IF commands whose activation level is equal to or less than the `WARNING_LEVEL`. |
| `WARN_IF` | Compile in or comment out a test which prints a warning and continues execution if satisfied. |

The Verify m4 Macros code listing in section A.3 contains additional documentation.

## 6.4 Replicate m4 Macros

The "replicate" set of m4 macros is used to replicate a routine so that a version exists for every possible array dimensioning (scalars plus up to seven-dimensioned arrays, the maximum allowed in F90). To use the replicate macros in the CÆSAR Code Package,

- define the interface using the REPLICATE_INTERFACE macro,
- define the REPLICATE_ROUTINE, using the REP_EXPAND, ARRAY_ONLY and SCALAR_ONLY macros as needed,
- invoke the REPLICATE macro to generate multiple versions of the REPLICATE_ROUTINE for scalars and all array dimensions, or
- invoke the REPLICATE_ARRAYS macro to generate multiple versions of the REPLICATE_ROUTINE for all array dimensions only, and write a separate routine for scalars (sometimes useful if the array and scalar versions have little in common).

Take the following code segment as an example:

```
module test_replicate
  REPLICATE_INTERFACE([Generic_Routine], [Specific_Routine])
contains

define([REPLICATE_ROUTINE],[
  function Specific_Routine_$1 (R REP_ARGS([var[]i]))
    type(real,$1) :: R
    REP_DECLARE([type(integer)], [var[]i])
    REP_ALLOCATE(R, [var[]i], [status])
    ARRAY_ONLY DEALLOCATE(R)
    SCALAR_ONLY R = 999.
    <other routine contents>
  end function Specific_Routine_$1

])
REPLICATE
end module test_replicate
```

This code is expanded by Gnu m4 into the following valid F90 code:

```
module test_replicate
  interface Generic_Routine
    module procedure Specific_Routine_0
    module procedure Specific_Routine_1
    module procedure Specific_Routine_2
    module procedure Specific_Routine_3
    module procedure Specific_Routine_4
    module procedure Specific_Routine_5
    module procedure Specific_Routine_6
    module procedure Specific_Routine_7
  end interface
contains

  function Specific_Routine_0 (R)
    real (kind=KIND(1.0d0)) :: R
    ! DEALLOCATE(R)
    R = 999.
    <other routine contents>
  end function Specific_Routine_0

  function Specific_Routine_1 (R, var1)
    real (kind=KIND(1.0d0)), pointer, dimension(:) :: R
    integer (kind=KIND(1)) :: var1
```

```
  ALLOCATE(R(var1), stat=status)
  DEALLOCATE(R)
  ! R = 999.
  <other routine contents>
end function Specific_Routine_1

function Specific_Routine_2 (R, var1, var2)
  real (kind=KIND(1.0d0)), pointer, dimension(:,:) :: R
  integer (kind=KIND(1)) :: var1, var2
  ALLOCATE(R(var1, var2), stat=status)
  DEALLOCATE(R)
  ! R = 999.
  <other routine contents>
end function Specific_Routine_2

function Specific_Routine_3 (R, var1, var2, var3)
  real (kind=KIND(1.0d0)), pointer, dimension(:,:,:) :: R
  integer (kind=KIND(1)) :: var1, var2, var3
  ALLOCATE(R(var1, var2, var3), stat=status)
  DEALLOCATE(R)
  ! R = 999.
  <other routine contents>
end function Specific_Routine_3

function Specific_Routine_4 (R, var1, var2, var3, var4)
  real (kind=KIND(1.0d0)), pointer, dimension(:,:,:,:) :: R
  integer (kind=KIND(1)) :: var1, var2, var3, var4
  ALLOCATE(R(var1, var2, var3, var4), stat=status)
  DEALLOCATE(R)
  ! R = 999.
  <other routine contents>
end function Specific_Routine_4

function Specific_Routine_5 (R, var1, var2, var3, var4, var5)
  real (kind=KIND(1.0d0)), pointer, dimension(:,:,:,:,:) :: R
  integer (kind=KIND(1)) :: var1, var2, var3, var4, var5
  ALLOCATE(R(var1, var2, var3, var4, var5), stat=status)
  DEALLOCATE(R)
  ! R = 999.
  <other routine contents>
end function Specific_Routine_5

function Specific_Routine_6 (R, var1, var2, var3, var4, var5, var6)
  real (kind=KIND(1.0d0)), pointer, dimension(:,:,:,:,:,:) :: R
  integer (kind=KIND(1)) :: var1, var2, var3, var4, var5, var6
  ALLOCATE(R(var1, var2, var3, var4, var5, var6), stat=status)
  DEALLOCATE(R)
  ! R = 999.
  <other routine contents>
end function Specific_Routine_6

function Specific_Routine_7 (R, var1, var2, var3, var4, var5, var6, var7)
  real (kind=KIND(1.0d0)), pointer, dimension(:,:,:,:,:,:,:) :: R
  integer (kind=KIND(1)) :: var1, var2, var3, var4, var5, var6, var7
```

```
    ALLOCATE(R(var1, var2, var3, var4, var5, var6, var7), stat=status)
    DEALLOCATE(R)
    ! R = 999.
    <other routine contents>
  end function Specific_Routine_7

end module test_replicate
```

Note that this set of m4 macros depends on the m4 commands in the `settings.m4` file (see section 6.1) and on the `REPLICATE_ROUTINE` macro definition.

**m4 macros defined in the `include/replicate.m4` file:**

| | |
|---|---|
| `ARRAY_ONLY` | Used to comment out lines for scalars, but leave them untouched for arrays. |
| `REPLICATE` | Replicates a routine for all array dimensions and scalars. |
| `REPLICATE_ARRAYS` | Replicates a routine for all array dimensions only. |
| `REPLICATE_INTERFACE` | Defines the interface block for the replicated routine. |
| `REP_ALLOCATE` | Used to allocate a replicated variable. |
| `REP_ARGS` | Used to replicate an argument list. |
| `REP_DECLARE` | Used to decalre a replicated variable. |
| `REP_EXPAND` | Used in the `REPLICATE_ROUTINE` macro to expand to text that varies with the dimensioning (see code listing in section A.4 for input/output details). |
| `REP_NUMBER` | The number of the dimension of the current routine, used internally. |
| `SCALAR_ONLY` | Used to comment out lines for arrays, but leave them untouched for scalars. |
| `type(vartype,$1)` | A useful construction for replicated procedures which is defined by the types macros (see section 6.2). |

The Replicate m4 Macros code listing in section A.4 contains additional documentation.

## 6.5 Superclass m4 Macros

The "superclass" set of m4 macros is used to automatically create a superclass module that will dynamically dispatch superclass calls to the correct subclass routine or function. This achieves run-time polymorphism, which is commonly considered to be too much effort in Fortran 90, in an easily implemented fashion.

To use the "superclass" set of m4 macros certain naming and coding conventions must be followed. Assuming that the superclass name is "Matrix", that three subclasses exist named "One", "Two", and "Three", and that the routine to be dynamically dispatched is named "Solve", the following names must be used:

| | |
|---|---|
| superclass derived type: | Matrix_type |
| subclass derived types: | One_type, Two_type, Three_type |
| subclass module names: | One_Class, Two_Class, Three_Class |
| superclass module name: | Matrix_Class |
| superclass routine name: | Solve_Matrix |
| superclass interface name: | Solve |
| subclass routine names: | Solve_One, Solve_Two, Solve_Three |
| subclass interface name: | Solve |

In addition, the superclass derived type must be:

```
  type Matrix_type
```

```
    character (len=80) :: Subclass
    type(One_type) :: One
    type(Two_type) :: Two
    type(Three_type) :: Three
  end type Matrix_type
```

To use the superclass macros in the CÆSAR Code Package,

- define the superclass name in the SUPERCLASS macro,
- define the subclass names as a space-delimited list in the SUBCLASSES macro,
- use the SUPERCLASS_USE_ASSOCIATIONS, SUPERCLASS_TYPE, SUPERCLASS_ROUTINE and SUPERCLASS_-FUNCTION macros as needed to define the superclass module.

Take the following code segment as an example:

```
define([SUPERCLASS],[Matrix])
define([SUBCLASSES],[One Two Three])

module SUPERCLASS[]_Class

  SUPERCLASS_USE_ASSOCIATIONS
  SUPERCLASS_TYPE

contains

  SUPERCLASS_ROUTINE([Initialize],
                     [type(real)], [a], [The a variable],
                     [type(integer), intent(in)], [b], [The b variable])

  SUPERCLASS_FUNCTION([Verify_State], [type(logical)],
                      [type(real)], [b], [The b variable])

  SUPERCLASS_ROUTINE([Finalize],
                     [type(real)], [c], [The c variable],
                     [type(real)], [d], [The d variable])

end module SUPERCLASS[]_Class
```

This code is expanded by Gnu m4 into the following valid F90 code:

```
module Matrix_Class

  use One_Class
  use Two_Class
  use Three_Class

  type Matrix_type
    character (len=80) :: Subclass
    type(One_type) :: One
    type(Two_type) :: Two
    type(Three_type) :: Three
  end type Matrix_type

contains
```

```
subroutine Initialize_Matrix (Matrix, a, b)

  type(Matrix_type) Matrix
  real (kind=KIND(1.0d0)) :: a ! The a variable
  integer (kind=KIND(1)), intent(in) :: b ! The b variable

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  select case (Matrix%Subclass)
  case ("One")
    call Initialize (Matrix%One, a, b)
  case ("Two")
    call Initialize (Matrix%Two, a, b)
  case ("Three")
    call Initialize (Matrix%Three, a, b)
  case default
    write (6,*) 'Error: no ', Matrix%Subclass, ' in Matrix_Class.'
  end select

end subroutine Initialize_Matrix

function Verify_State_Matrix (Matrix, b)

  type(Matrix_type) Matrix
  logical (kind=KIND(.true.)) :: Verify_State, Verify_State_Matrix
  real (kind=KIND(1.0d0)) :: b ! The b variable

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  select case (Matrix%Subclass)
  case ("One")
    Verify_State_Matrix = Verify_State (Matrix%One, b)
  case ("Two")
    Verify_State_Matrix = Verify_State (Matrix%Two, b)
  case ("Three")
    Verify_State_Matrix = Verify_State (Matrix%Three, b)
  case default
    write (6,*) 'Error: no ', Matrix%Subclass, ' in Matrix_Class.'
  end select

end function Verify_State_Matrix

subroutine Finalize_Matrix (Matrix, c, d)

  type(Matrix_type) Matrix
  real (kind=KIND(1.0d0)) :: c ! The c variable
  real (kind=KIND(1.0d0)) :: d ! The d variable

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  select case (Matrix%Subclass)
  case ("One")
    call Finalize (Matrix%One, c, d)
```

```
    case ("Two")
      call Finalize (Matrix%Two, c, d)
    case ("Three")
      call Finalize (Matrix%Three, c, d)
    case default
      write (6,*) 'Error: no ', Matrix%Subclass, ' in Matrix_Class.'
    end select

  end subroutine Finalize_Matrix

end module Matrix_Class
```

Note that this set of m4 macros depends on the m4 commands in the `settings.m4` file (see section 6.1) and on the `SUPERCLASS` and `SUBCLASSES` macro definitions.

**m4 macros defined in the `include/superclass.m4` file:**

| | |
|---|---|
| `SUPERCLASS_ARGUMENTS` | Used internally by the `SUPERCLASS_ROUTINE` and `SUPERCLASS_-FUNCTION` macros. |
| `SUPERCLASS_DECLARATIONS` | Used internally by the `SUPERCLASS_ROUTINE` and `SUPERCLASS_-FUNCTION` macros. |
| `SUPERCLASS_FUNCTION` | Expands into a complete function for the superclass. This function dynamically dispatches calls to the superclass to the correct subclass function. |
| `SUPERCLASS_ROUTINE` | Expands into a complete subroutine for the superclass. This subroutine dynamically dispatches calls to the superclass to the correct subclass routine. |
| `SUPERCLASS_TYPE` | Outputs a standard superclass type definition. |
| `SUPERCLASS_USE_ASSOCIATIONS` | Outputs the correct use associations for the superclass. |

The Superclass m4 Macros code listing in section A.5 contains additional documentation.

## 6.6 Unit Test m4 Macros

> *We like to test things... No matter how good an idea sounds, test it first. – Henry Block, CEO, H&R Block*

The "unit test" set of m4 macros provides the capability to conditionally compile in F90 statements for use during unit testing. Unit testing is the ability to test a particular routine in isolation from the remainder of the code. Unit testing is accomplished by including a main program and necessary auxiliary routines at the end of the file containing the routine to be tested, in this manner:

```
ifdef([UNIT_TEST],[
program Unit_Test
  <program contents>
end
])
```

During a standard compilation, the Unit_Test program will not be present because UNIT_TEST is not defined. To do unit testing, the file is processed with "-DUNIT_TEST" defined on the m4 command line, and the Unit_Test program is compiled in.

In addition to those capabilities, which are provided in each F90 source file, the "unit test" set of m4 macros allows the following constructions to be used in the CÆSAR Code Package:

```
TESTWRITE (6,100) 'Output test variables ==>', &
  IF_UNIT_TEST x1, x2, x3
IF_UNIT_TEST 100 format (a, 3(1pe13.6))
IF_NOT_UNIT_TEST debug = 0
```

This code is expanded by Gnu m4 into the following valid F90 code:

```
! write (6,100) 'Output test variables ==>', &
  ! x1, x2, x3
! 100 format (a, 3(1pe13.6))
debug = 0
```

if UNIT_TEST is not defined. If UNIT_TEST is defined, then the same code is expanded by Gnu m4 into the following:

```
write (6,100) 'Output test variables ==>', &
  x1, x2, x3
100 format (a, 3(1pe13.6))
! debug = 0
```

which allows for statements to be conditionally compiled in when unit testing is being done.

Note that this set of m4 macros depends on the m4 commands in the `settings.m4` file (see section 6.1) and on the UNIT_TEST macro definition.

**m4 macros defined in the `include/unit_test.m4` file:**

| | |
|---|---|
| `TESTWRITE` | Write statement toggled by the UNIT_TEST macro. |
| `IF_UNIT_TEST` | Comments out code unless UNIT_TEST is defined. |
| `IF_NOT_UNIT_TEST` | Comments out code if UNIT_TEST is defined. |

The Unit Test m4 Macros code listing in section A.6 contains additional documentation.

## 6.7 Flags Module

The Flags Module is used to define flag constants that are used in the CÆSAR Code Package.

**Flags Module public parameters:**

**Intrinsic Initialization/Finalization Flags**

| | |
|---|---|
| `finalize_character_flag` | Value used to finalize characters. |
| `finalize_integer_flag` | Value used to finalize integers. |
| `finalize_logical_flag` | Value used to finalize logicals. |
| `finalize_real_flag` | Value used to finalize reals. |
| `initialize_character_flag` | Value used to initialize characters. |
| `initialize_integer_flag` | Value used to initialize integers. |
| `initialize_logical_flag` | Value used to initialize logicals. |
| `initialize_real_flag` | Value used to initialize reals. |

**Derived Type Initialization Flags**

| | |
|---|---|
| `initialized_flag` | Value used to signify derived type initialization. |
| `uninitialized_flag` | Value used to signify derived type lack of initialization (when a derived type is finalized). |

**Boundary Condition Face Flags**

| | |
|---|---|
| `AMR_Large_Cell_BC` | In an AMR mesh, this signifies an internal level-jump interface where the current cell is the larger cell. |
| `AMR_Small_Cell_BC` | In an AMR mesh, this signifies an internal level-jump interface where the current cell is the smaller cell. |
| `Dirichlet_BC` | Signifies a Dirichlet boundary condition. |
| `Homogeneous_BC` | Signifies a homogeneous boundary condition. |
| `Internal_or_Periodic_BC` | Signifies an internal face or a periodic boundary condition face. |
| `Neumann_BC` | Signifies a Neumann boundary condition. |
| `Reflective_BC` | Signifies a reflective boundary condition. |
| `Source_BC` | Signifies a source boundary condition. |
| `Vacuum_BC` | Signifies a vacuum boundary condition. |

The Flags Module code listing in § A.7 on page 208 contains additional documentation.

## 6.8 Numbers Module

The Numbers Module is used to define number constants that are used in the CÆSAR Code Package.

**Numbers Module public parameters:**

| **Numbers 0–9** | |
|---|---|
| `zero` | 0 |
| `one` | 1 |
| `two` | 2 |
| `three` | 3 |
| `four` | 4 |
| `five` | 5 |
| `six` | 6 |
| `seven` | 7 |
| `eight` | 8 |
| `nine` | 9 |

| **Numbers 10–19** | |
|---|---|
| `ten` | 10 |
| `eleven` | 11 |
| `twelve` | 12 |
| `thirteen` | 13 |
| `fourteen` | 14 |
| `fifteen` | 15 |
| `sixteen` | 16 |
| `seventeen` | 17 |
| `eighteen` | 18 |
| `nineteen` | 19 |

| **Numbers 20-100, by tens** | |
|---|---|
| `twenty` | 20 |
| `thirty` | 30 |
| `forty` | 40 |
| `fifty` | 50 |
| `sixty` | 60 |
| `seventy` | 70 |
| `eighty` | 80 |
| `ninety` | 90 |

| | |
|---|---|
| `hundred` | 100 |
| **Fractions** | |
| `half` | $\frac{1}{2}$ |
| `third` | $\frac{1}{3}$ |
| `fourth` | $\frac{1}{4}$ |
| `fifth` | $\frac{1}{5}$ |
| `sixth` | $\frac{1}{6}$ |
| `seventh` | $\frac{1}{7}$ |
| `eighth` | $\frac{1}{8}$ |
| `ninth` | $\frac{1}{9}$ |
| `tenth` | $\frac{1}{10}$ |
| **Forms of pi** | |
| `pi` | $\pi$ |
| `sqrtpi` | $\sqrt{\pi}$ |
| `invpi` | $\frac{1}{\pi}$ |
| `pisqr` | $\pi^2$ |
| `fourthirdspi` | $\frac{4\pi}{3}$ |
| `twopi` | $2\pi$ |
| `threepi` | $3\pi$ |
| `fourpi` | $4\pi$ |
| `halfpi` | $\frac{\pi}{2}$ |
| `thirdpi` | $\frac{\pi}{3}$ |
| `fourthpi` | $\frac{\pi}{4}$ |
| **Decimal multipliers** | |
| `deca` | $10^1$ |
| `hecto` | $10^2$ |
| `kilo` | $10^3$ |
| `mega` | $10^6$ |
| `giga` | $10^9$ |
| `tera` | $10^{12}$ |
| `peta` | $10^{15}$ |
| `exa` | $10^{18}$ |
| `zetta` | $10^{21}$ |
| `yotta` | $10^{24}$ |
| `deci` | $10^{-1}$ |
| `centi` | $10^{-2}$ |
| `milli` | $10^{-3}$ |
| `micro` | $10^{-6}$ |
| `nano` | $10^{-9}$ |
| `pico` | $10^{-12}$ |
| `femto` | $10^{-15}$ |
| `atto` | $10^{-18}$ |
| `zepto` | $10^{-21}$ |

| | |
|---|---|
| `yocto` | $10^{-24}$ |

The Numbers Module code listing in § A.8 on page 209 contains additional documentation.

# Chapter 7

# Intrinsics Module

*The Greek word for leisure was scholê ($\sigma\chi o\lambda\eta$), whence our school. For leisure meant to them opportunity for pursuits of intrinsic worth, such as a man would choose for his own sake – De Burgh*

The Intrinsics Module provides a thin wrapper for the standard F90 intrinsic types (Integer, Real, Character, and Logical), giving them the fundamental procedures necessary to be considered a class (in the CÆSAR sense). These fundamental procedures are `Initialize`, `Finalize`, and `Valid_State`. The CÆSAR intrinsic types are the pointered versions of standard F90 intrinsic types for multi-dimensional arrays, and non-pointered (static) scalars. The `Valid_State` procedures also have a version for non-pointered arrays, which can be accessed by the name `Valid_State_NP`.

In addition to the fundamental class procedures, the Intrinsics Module provides some functions that are "missing" in F90:

| Function | Intrinsic Type |
|---|---|
| ALL | Logical Scalars |
| ANY | Logical Scalars |
| COUNT | Integer/Logical Scalars |
| MaxVal | Real and Integer Scalars |
| MinVal | Real and Integer Scalars |
| SUM | Real and Integer Scalars |

and some useful functions involving intrinsics:

| Function | Description |
|---|---|
| .InInterval. | True if argument is in the specified interval. |
| .InSet. | True if argument is in the specified set. |
| .NotInInterval. | True if argument is not in the specified interval. |
| .NotInSet. | True if argument is not in the specified set. |
| .VeryClose. | True if arguments are within 10 times the local spacing distance between variables. |

In addition to the F90 standard intrinsic types, the Status Class is defined here. The Status Class is, in a way, even more basic than the intrinsic types, as it is used in the Initialization and Finalization of the intrinsic types themselves. Several procedures associated with the manipulation of Status objects are included.

The Intrinsics Module code listing in § B on page 211 contains additional documentation.

## 7.1 Status Class

The Status Class is used to handle status flags in the CÆSAR Code Package.

**Status public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a status variable (vector or scalar). |
| `Finalize` | Finalizes a status variable (vector or scalar). |
| `Valid_State` | Returns false iff a status variable (vector or scalar) is in an invalid state. |
| **Operations** | |
| `Consolidate` | Consolidates a vector status variable into a scalar status variable (also has an assignment interface). |
| `Equal` | Returns true when its arguments are equal. Versions of this function for Status-Status and Status-Character comparisons are available. |
| `Error` | Returns true if the severity level of a scalar status variable is 'Error'. |
| `Get` | Gets an output character string according to the specified status variable (also has an assignment interface). |
| `Normal` | Returns true if the severity level of a scalar status variable is 'Normal'. |
| `Not_Equal` | Returns true when its arguments are not equal. Versions of this function for Status-Status and Status-Character comparisons are available. |
| `Set` | Sets a scalar status variable according to the specified selector character value (also has an assignment interface). |
| `Warning` | Returns true if the severity level of a scalar status variable is 'Warning'. |

**Status public defined types:**

| | |
|---|---|
| `Status_type` | The Status Class variable type. |

The Status Class code listing in § B.1 on page 211 contains additional documentation. The Status Class also contains a Unit Test Program which is listed in § B.1.19 on page 229.

### 7.1.1 Initialize_Status Procedure

The Initialize_Status procedure initializes a status variable.

**Calling syntax:**

```
call Initialize (S)
```

**Output variable:**

`S` The status, which has been initialized to a value of "Unset".

The Initialize_Status code listing in § B.1.1 on page 215 contains additional documentation.

### 7.1.2 Initialize_Status_Vector Procedure

The Initialize_Status_Vector procedure initializes a vector of status variables.

**Calling syntax:**

```
call Initialize (S)
```

**Output variable:**

`S` The status vector, which has been initialized to a value of "Unset".

The Initialize_Status_Vector code listing in § B.1.2 on page 215 contains additional documentation.

### 7.1.3 Finalize_Status Procedure

The Finalize_Status procedure finalizes a status variable.

**Calling syntax:**

```
call Finalize (S)
```

**Input/Output variable:**

`S` The status, which has been finalized.

The Finalize_Status code listing in § B.1.3 on page 216 contains additional documentation.

### 7.1.4 Finalize_Status_Vector Procedure

The Finalize_Status_Vector procedure finalizes a vector of status variables.

**Calling syntax:**

```
call Finalize (S)
```

**Input/Output variable:**

`S` The status vector, which has been finalized.

The Finalize_Status_Vector code listing in § B.1.4 on page 217 contains additional documentation.

### 7.1.5 Valid_State_Status Procedure

The Valid_State_Status procedure returns true iff the status is in a valid state – that is, iff the status passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(S)
```

**Input variable:**

`S` The status variable to be checked.

**Output variable:**

`Valid_State` True iff the status is in a valid state.

The Valid_State_Status code listing in § B.1.5 on page 217 contains additional documentation.

### 7.1.6 Valid_State_Status_Vector Procedure

The Valid_State_Status_Vector procedure returns true iff the status is in a valid state – that is, iff the status passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(S)
```

**Input variable:**

| | |
|---|---|
| `S` | The status vector to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the entire status vector is in a valid state. |

The Valid_State_Status_Vector code listing in § B.1.6 on page 218 contains additional documentation.

### 7.1.7 Character_Equal_Status Procedure

The Character_Equal_Status procedure returns a logical value which is true when the status variable is the same state specified by the input character string, used as a selector flag (see Set_Status procedure in section 7.1.13 for a list of valid flags). It has an operator (== or `.eq.`) interface.

**Calling syntax:**

```
Logical = C == SS          or
Logical = Equal(C, SS)
```

**Input variable:**

| | |
|---|---|
| `C` | The selector flag string to be compared. |
| `SS` | The status variable to be compared. |

**Output variable:**

| | |
|---|---|
| `Equal` | True iff the status variable and the selector flag string match. |

The Character_Equal_Status code listing in § B.1.7 on page 219 contains additional documentation.

### 7.1.8 Character_Not_Equal_Status Procedure

The Character_Not_Equal_Status procedure returns a logical value which is true when the status variable is not equal to the state specified by the input character string, used as a selector flag (see Set_Status procedure in section 7.1.13 for a list of valid flags). It has an operator (/= or `.ne.`) interface.

**Calling syntax:**

```
Logical = C /= SS              or
Logical = Not_Equal(C, SS)
```

**Input variable:**

| | |
|---|---|
| `C` | The selector flag string to be compared. |
| `SS` | The status variable to be compared. |

**Output variable:**

`Not_Equal` True iff the two status variables have different states.

The Character_Not_Equal_Status code listing in § B.1.8 on page 219 contains additional documentation.

### 7.1.9 Consolidate_Status Procedure

The Consolidate_Status procedure returns a single status variable that is the result of consolidating an input status vector. It has an assignment interface so that it may be called by assigning a vector Status_type variable to a scalar Status_type variable.

The input status vector (Multiple_S) is combined into the output status variable (Consolidated_S) by looping over each input status variable. The following table shows the value of Consolidated_S after it has been combined with a single value from the vector Multiple_S, based on the previous value of Consolidated_S:

| Consolidated_S | Multiple_S(i) | | | | | |
|---|---|---|---|---|---|---|
| (previous) | Unset | Success | ME | MW | Error | Warning |
| Unset | Unset | Success | ME | MW | Error | Warning |
| Success | Success | Success | ME | MW | Error | Warning |
| ME | ME | ME | ME | ME | ME | ME |
| MW | MW | MW | ME | MW | ME | MW |
| Error | Error | Error | ME | ME | ME† | ME |
| Warning | Warning | Warning | ME | MW | ME | MW† |

where ME stands for 'Multiple Error', MW stands for 'Multiple Warning' and † signifies that ME or MW is set only if the two errors or warnings are different from each other.

**Calling syntax:**

```
Consolidated_S = Multiple_S                    or
call Consolidate (Consolidated_S, Multiple_S)
```

**Input variable:**

`Multiple_S` A vector of status variables to be consolidated.

**Output variable:**

`Consolidated_S` The status that is a result of consolidating the input status vector.

The Consolidate_Status code listing in § B.1.9 on page 220 contains additional documentation.

### 7.1.10 Error_Status Procedure

The Error_Status procedure returns true iff the status is an error status – that is, iff the status severity level is 'error'.

**Calling syntax:**

```
Logical = Error(S)
```

**Input variable:**

`S` The status variable to be examined.

**Output variable:**

| | |
|---|---|
| `Error` | True iff the status is an error status. |

The Error_Status code listing in § B.1.10 on page 223 contains additional documentation.

### 7.1.11 Get_Status_Output Procedure

The Get_Status_Output procedure returns the output string from a status variable. It has an assignment interface so that it may be called by assigning a Status_type variable to a character variable.

**Calling syntax:**

```
Status_String = S              or
call Get (Status_String, S)
```

**Input variable:**

| | |
|---|---|
| `S` | The status to be examined. |

**Output variable:**

| | |
|---|---|
| `Status_String` | Output string for this status variable. |

The Get_Status_Output code listing in § B.1.11 on page 224 contains additional documentation.

### 7.1.12 Normal_Status Procedure

The Normal_Status procedure returns true iff the status is a normal status – that is, iff the status severity level is 'normal'.

**Calling syntax:**

```
Logical = Normal(S)
```

**Input variable:**

| | |
|---|---|
| `S` | The status variable to be examined. |

**Output variable:**

| | |
|---|---|
| `Normal` | True iff the status is a normal status. |

The Normal_Status code listing in § B.1.12 on page 224 contains additional documentation.

### 7.1.13 Set_Status Procedure

The Set_Status procedure assigns a value to a status variable. It has an assignment interface so that it may be called by assigning a character variable to a Status_type variable.

**Calling syntax:**

```
S = Selector_Flag              or
call Set (S, Selector_Flag)
```

**Input variable:**

`Selector_Flag` String to select status flag. Possible values are: 'Unset', 'Success', 'Multiple Error', 'Multiple Warning', 'Memory Warning', 'Memory Error', 'File Error', 'CGNS Error', 'CGNS No Node', 'CGNS Bad Path'.

**Output variable:**

`S` The status, which is now set.

The Set_Status code listing in § B.1.13 on page 225 contains additional documentation.

### 7.1.14 Status_Equal_Character Procedure

The Status_Equal_Character procedure returns a logical value which is true when the status variable is the same state specified by the input character string, used as a selector flag (see Set_Status procedure in section 7.1.13 for a list of valid flags). It has an operator (== or `.eq.`) interface.

**Calling syntax:**

```
Logical = S == C          or
Logical = Equal(S, C)
```

**Input variable:**

`C` The selector flag string to be compared.
`S` The status variable to be compared.

**Output variable:**

`Equal` True iff the status variable and the selector flag string match.

The Status_Equal_Character code listing in § B.1.14 on page 226 contains additional documentation.

### 7.1.15 Status_Equal_Status Procedure

The Status_Equal_Status procedure returns a logical value which is true when the two status variable inputs are equal (i.e. have the same state). It has an operator (== or `.eq.`) interface.

**Calling syntax:**

```
Logical = S1 == S2          or
Logical = Equal(S1, S2)
```

**Input variable:**

`S1, S2` The status variables to be compared.

**Output variable:**

`Equal` True iff the two status variables have the same state.

The Status_Equal_Status code listing in § B.1.15 on page 226 contains additional documentation.

### 7.1.16 Status_Not_Equal_Character Procedure

The Status_Not_Equal_Character procedure returns a logical value which is true when the status variable is not equal to the state specified by the input character string, used as a selector flag (see Set_Status procedure in section 7.1.13 for a list of valid flags). It has an operator (`/=` or `.ne.`) interface.

**Calling syntax:**

```
Logical = S /= C              or
Logical = Not_Equal(S, C)
```

**Input variable:**

| | |
|---|---|
| `C` | The selector flag string to be compared. |
| `S` | The status variable to be compared. |

**Output variable:**

| | |
|---|---|
| `Not_Equal` | True iff the two status variables have different states. |

The Status_Not_Equal_Character code listing in § B.1.16 on page 227 contains additional documentation.

### 7.1.17 Status_Not_Equal_Status Procedure

The Status_Not_Equal_Status procedure returns a logical value which is true when the two status variable inputs are not equal (i.e. have different states). It has an operator (`/=` or `.ne.`) interface.

**Calling syntax:**

```
Logical = S1 /= S2            or
Logical = Not_Equal(S1, S2)
```

**Input variable:**

| | |
|---|---|
| `S1, S2` | The status variables to be compared. |

**Output variable:**

| | |
|---|---|
| `Not_Equal` | True iff the two status variables have different states. |

The Status_Not_Equal_Status code listing in § B.1.17 on page 228 contains additional documentation.

### 7.1.18 Warning_Status Procedure

The Warning_Status procedure returns true iff the status is a warning status – that is, iff the status severity level is 'warning'.

**Calling syntax:**

```
Logical = Warning(S)
```

**Input variable:**

`S` The status variable to be examined.

**Output variable:**

`Warning` True iff the status is a warning status.

The Warning_Status code listing in § B.1.18 on page 228 contains additional documentation.

## 7.2 Real Class

The Real Class is used to describe a real scalar or array in the CÆSAR Code Package. The Real Class does not use a user-defined type – it is the class for the F90 intrinsic type "real".

**Real public procedures:**

**Fundamental procedures**

| | |
|---|---|
| `Initialize` | Initializes a real scalar or array variable. |
| `Finalize` | Finalizes a real scalar or array variable. |
| `Valid_State` | Returns false iff a real scalar or array variable is in an invalid state. |

**Operations**

| | |
|---|---|
| `MaxVal` | Extends the F90 intrinsic procedure MaxVal to scalar arguments. |
| `MinVal` | Extends the F90 intrinsic procedure MinVal to scalar arguments. |
| `SUM` | Extends the F90 intrinsic procedure SUM to scalar arguments. |
| `VeryClose` | Returns true if input values are almost equal. |

The Real Class code listing in § B.2 on page 231 contains additional documentation. The Real Class also contains a Unit Test Program which is listed in § B.2.8 on page 242.

### 7.2.1 Initialize_Real Procedure

The Initialize_Real procedure allocates and initializes a real scalar or array variable.

**Calling syntax:**

```
call Initialize (R, [dim1, ..., dimn,] status)
```

**Input variables:**

| | |
|---|---|
| `R` | A real scalar variable or a pointer to an unallocated real array variable. |
| `dim1, ..., dimn` | Extents of the dimensions for the array R. Only as many dimensions as are needed should be entered. |

**Output variables:**

| | |
|---|---|
| `R` | The R variable has been allocated (if it is an array) and initialized to `initialize_real_flag`. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |

The Initialize_Real code listing in § B.2.1 on page 232 contains additional documentation.

### 7.2.2 Finalize_Real Procedure

The Finalize_Real procedure deallocates and finalizes a real scalar or array variable.

**Calling syntax:**

```
call Finalize (R, status)
```

**Input variable:**

| | |
|---|---|
| `R` | A real scalar variable or a pointer to an allocated real array variable. |

**Output variables:**

| | |
|---|---|
| `R` | The R variable has been deallocated and nullified, if it is an array, or set to a flag value (`finalize_real_flag`), if it is a scalar. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `deallocate_status` | Deallocation Status. |

The Finalize_Real code listing in § B.2.2 on page 234 contains additional documentation.

### 7.2.3 Valid_State_Real Procedure

The Valid_State_Real procedure returns true iff the real scalar or array variable is in a valid state – that is, iff the variable passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(R)      or
Logical = Valid_State_NP(R)
```

**Input variable:**

| | |
|---|---|
| `R` | A real scalar variable or a pointer to an allocated real array variable. A non-pointered variable may be used with the Valid_State_NP version of the call. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the real scalar or array variable is in a valid state. |

The Valid_State_Real code listing in § B.2.3 on page 236 contains additional documentation.

### 7.2.4 MaxVal_Real_Scalar Procedure

The MaxVal_Real_Scalar procedure provides a function equivalent to the MaxVal() intrinsic function for real scalars. It returns a value equal to the input value.

**Calling syntax:**

```
Real = MaxVal(R)
```

**Input variable:**

`R` Input real scalar variable.

**Output variable:**

`MaxVal` MaxVal is equal to R.

The MaxVal_Real_Scalar code listing in § B.2.4 on page 240 contains additional documentation.

### 7.2.5 MinVal_Real_Scalar Procedure

The MinVal_Real_Scalar procedure provides a function equivalent to the MinVal() intrinsic function for real scalars. It returns a value equal to the input value.

**Calling syntax:**

```
Real = MinVal(R)
```

**Input variable:**

`R` Input real scalar variable.

**Output variable:**

`MinVal` MinVal is equal to R.

The MinVal_Real_Scalar code listing in § B.2.5 on page 240 contains additional documentation.

### 7.2.6 SUM_Real_Scalar Procedure

The SUM_Real_Scalar procedure provides a function equivalent to the SUM() intrinsic function for real scalars. It returns a value equal to the input value.

**Calling syntax:**

```
Real = SUM(R)
```

**Input variable:**

`R` Input real scalar variable.

**Output variable:**

`SUM` SUM is equal to R.

The SUM_Real_Scalar code listing in § B.2.6 on page 241 contains additional documentation.

### 7.2.7 VeryClose_Real Procedure

The VeryClose procedure provides a way to check whether or not two variables are "Very Close" to each other. The definition of "Very CLose" that is used is "within 10 times the internumeral spacing distance in the vicinity of the numbers". This test should be used instead of equality tests for reals. For array-valued X and Y, all the values must satisfy the condition for the result to be true.

Note that I would rather call this routine "Very_Close", but the F90 standard does not allow underscores in defined operator names (i.e. ".Very_Close." is not allowed).

**Calling syntax:**

```
Logical = X .VeryClose.  Y    ,
Logical = VeryClose(X, Y)     or
```

**Input variables:**

| | |
|---|---|
| `X, Y` | Input real, scalar or array variables to test. |

**Output variable:**

| | |
|---|---|
| `VeryClose` | Logical which is true if X and Y are within 10 times the spacing distance between variables at (X+Y)/2. |

The VeryClose_Real code listing in § B.2.7 on page 241 contains additional documentation.

## 7.3 Integer Class

The Integer Class is used to describe an integer scalar or array in the CÆSAR Code Package. The Integer Class does not use a user-defined type – it is the class for the F90 intrinsic type "integer".

**Integer public procedures:**

**Fundamental procedures**

| | |
|---|---|
| `Initialize` | Initializes an integer scalar or array variable. |
| `Finalize` | Finalizes an integer scalar or array variable. |
| `Valid_State` | Returns false iff an integer scalar or array variable is in an invalid state. |

**Operations**

| | |
|---|---|
| `MaxVal` | Extends the F90 intrinsic procedure MaxVal to scalar arguments. |
| `MinVal` | Extends the F90 intrinsic procedure MinVal to scalar arguments. |
| `SUM` | Extends the F90 intrinsic procedure SUM to scalar arguments. |

The Integer Class code listing in § B.3 on page 244 contains additional documentation. The Integer Class also contains a Unit Test Program which is listed in § B.3.7 on page 252.

### 7.3.1 Initialize_Integer Procedure

The Initialize_Integer procedure allocates and initializes an integer scalar or array variable.

**Calling syntax:**

```
call Initialize (I, [dim1, ..., dimn,] status)
```

**Input variables:**

| | |
|---|---|
| `I` | An integer scalar variable or a pointer to an unallocated integer array variable. |
| `dim1, ..., dimn` | Extents of the dimensions for the array I. Only as many dimensions as are needed should be entered. |

**Output variables:**

| | |
|---|---|
| `I` | The I variable has been allocated (if it is an array) and initialized to `initialize_-integer_flag`. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |

The Initialize_Integer code listing in § B.3.1 on page 246 contains additional documentation.

### 7.3.2 Finalize_Integer Procedure

The Finalize_Integer procedure deallocates and finalizes an integer scalar or array variable.

**Calling syntax:**

```
call Finalize (I, status)
```

**Input variable:**

| | |
|---|---|
| `I` | An integer scalar variable or a pointer to an allocated integer array variable. |

**Output variable:**

| | |
|---|---|
| `I` | The I variable has been deallocated and nullified, if it is an array, or set to a flag value (`finalize_integer_flag`), if it is a scalar. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `deallocate_status` | Deallocation Status. |

The Finalize_Integer code listing in § B.3.2 on page 247 contains additional documentation.

### 7.3.3 Valid_State_Integer Procedure

The Valid_State_Integer procedure returns true iff the integer scalar or array variable is in a valid state – that is, iff the variable passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(I)      or
Logical = Valid_State_NP(I)
```

**Input variable:**

`I` An integer scalar variable or a pointer to an allocated integer array variable. A non-pointered variable may be used with the Valid_State_NP version of the call.

**Output variable:**

`Valid_State` True iff the integer scalar or array variable is in a valid state.

The Valid_State_Integer code listing in § B.3.3 on page 249 contains additional documentation.

### 7.3.4 MaxVal_Integer_Scalar Procedure

The MaxVal_Integer_Scalar procedure provides a function equivalent to the MaxVal() intrinsic function for integer scalars. It returns a value equal to the input value.

**Calling syntax:**

```
Integer = MaxVal(I)
```

**Input variable:**

`I` Input integer scalar variable.

**Output variable:**

`MaxVal` MaxVal is equal to I.

The MaxVal_Integer_Scalar code listing in § B.3.4 on page 250 contains additional documentation.

### 7.3.5 MinVal_Integer_Scalar Procedure

The MinVal_Integer_Scalar procedure provides a function equivalent to the MinVal() intrinsic function for integer scalars. It returns a value equal to the input value.

**Calling syntax:**

```
Integer = MinVal(I)
```

**Input variable:**

`I` Input integer scalar variable.

**Output variable:**

`MinVal` MinVal is equal to I.

The MinVal_Integer_Scalar code listing in § B.3.5 on page 251 contains additional documentation.

### 7.3.6 SUM_Integer_Scalar Procedure

The SUM_Integer_Scalar procedure provides a function equivalent to the SUM() intrinsic function for integer scalars. It returns a value equal to the input value.

**Calling syntax:**

```
Integer = SUM(I)
```

**Input variable:**

`I` Input integer scalar variable.

**Output variable:**

`SUM` SUM is equal to I.

The SUM_Integer_Scalar code listing in § B.3.6 on page 251 contains additional documentation.

## 7.4 Logical Class

The Logical Class is used to describe a logical scalar or array in the CÆSAR Code Package. The Logical Class does not use a user-defined type – it is the class for the F90 intrinsic type "logical".

**Logical public procedures:**

**Fundamental procedures**

| | |
|---|---|
| `Initialize` | Initializes a logical scalar or array variable. |
| `Finalize` | Finalizes a logical scalar or array variable. |
| `Valid_State` | Returns false iff a logical scalar or array variable is in an invalid state. |

**Operations**

| | |
|---|---|
| `ALL` | Extends the F90 intrinsic procedure ALL to scalar arguments. |
| `ANY` | Extends the F90 intrinsic procedure ANY to scalar arguments. |
| `COUNT` | Extends the F90 intrinsic procedure COUNT to scalar arguments. |
| `InInterval` | Returns true iff the argument is in the specified interval. |
| `InSet` | Returns true iff the argument is in the specified set. |
| `NotInInterval` | Returns true iff the argument is not in the specified interval. |
| `NotInSet` | Returns true iff the argument is not in the specified set. |

The Logical Class code listing in § B.4 on page 254 contains additional documentation. The Logical Class also contains a Unit Test Program which is listed in § B.4.11 on page 266.

### 7.4.1 Initialize_Logical Procedure

The Initialize_Logical procedure allocates and initializes a logical scalar or array variable.

**Calling syntax:**

```
call Initialize (L, [dim1, ..., dimn,] status)
```

**Input variables:**

| | |
|---|---|
| `L` | A logical scalar variable or a pointer to an unallocated logical array variable. |
| `dim1, ..., dimn` | Extents of the dimensions for the array L. Only as many dimensions as are needed should be entered. |

**Output variables:**

| | |
|---|---|
| `L` | The L variable has been allocated (if it is an array) and initialized to `initialize_logical_flag`. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |

The Initialize_Logical code listing in § B.4.1 on page 256 contains additional documentation.

### 7.4.2 Finalize_Logical Procedure

The Finalize_Logical procedure deallocates and finalizes a logical scalar or array variable.

**Calling syntax:**

```
call Finalize (L, status)
```

**Input variable:**

| | |
|---|---|
| `L` | A logical scalar variable or a pointer to an allocated logical array variable. |

**Output variable:**

| | |
|---|---|
| `L` | The L variable has been deallocated and nullified, if it is an array, or set to a flag value (`finalize_logical_flag`), if it is a scalar. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `deallocate_status` | Deallocation Status. |

The Finalize_Logical code listing in § B.4.2 on page 258 contains additional documentation.

### 7.4.3 Valid_State_Logical Procedure

The Valid_State_Logical procedure returns true iff the logical scalar or array variable is in a valid state – that is, iff the variable passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(L)      or
Logical = Valid_State_NP(L)
```

**Input variable:**

`L` A logical scalar variable or a pointer to an allocated logical array variable. A non-pointered variable may be used with the Valid_State_NP version of the call.

**Output variable:**

`Valid_State` True iff the logical scalar or array variable is in a valid state.

The Valid_State_Logical code listing in § B.4.3 on page 259 contains additional documentation.

### 7.4.4 ALL_Scalar Procedure

The ALL_Scalar procedure provides a function equivalent to the ALL() intrinsic function for logical scalars. It returns true iff its input is true.

**Calling syntax:**

```
Logical = ALL(L)
```

**Input variable:**

`L` Input logical scalar variable.

**Output variable:**

`ALL` ALL is true iff L is true.

The ALL_Scalar code listing in § B.4.4 on page 260 contains additional documentation.

### 7.4.5 ANY_Scalar Procedure

The ANY_Scalar procedure provides a function equivalent to the ANY() intrinsic function for logical scalars. It returns true iff its input is true.

**Calling syntax:**

```
Logical = ANY(L)
```

**Input variable:**

`L` Input logical scalar variable.

**Output variable:**

| | |
|---|---|
| `ANY` | ANY is true iff L is true. |

The ANY_Scalar code listing in § B.4.5 on page 261 contains additional documentation.

### 7.4.6 COUNT_Scalar Procedure

The COUNT_Scalar procedure provides a function equivalent to the COUNT() intrinsic function for logical scalars. It returns the number of trues in the input, so it is 1 if the input scalar is true and 0 if the input scalar is false.

**Calling syntax:**

```
Integer = COUNT(L)
```

**Input variable:**

| | |
|---|---|
| `L` | Input logical scalar variable. |

**Output variable:**

| | |
|---|---|
| `COUNT_Scalar` | Set to the number of trues in the input (either 0 or 1). |

The COUNT_Scalar code listing in § B.4.6 on page 261 contains additional documentation.

### 7.4.7 InInterval Procedure

The InInterval procedure provides a way to check whether or not a value lies within a specified interval. The interval is considered to be a closed interval that includes the end-points. For an array-valued X, all the values must satisfy the condition for the result to be true.

Note that I would rather call this routine "In_Interval", but the F90 standard does not allow underscores in defined operator names (i.e. ".In_Interval." is not allowed).

**Calling syntax:**

```
Logical = X .InInterval.  (/Int1, Int2/)    ,
Logical = X .InInterval.  Interval          or
Logical = InInterval(X, Interval)
```

**Input variables:**

| | |
|---|---|
| `X` | Input integer or real, scalar or array variable. |
| `Interval` | A vector of length 2 that specifies the extents of the interval to be checked. |
| `(/Int1, Int2/)` | A means of expressing an interval without declaring a vector. |

**Output variable:**

| | |
|---|---|
| `InInterval` | Logical which is true if X is in the closed interval, which includes the end-points. |

The InInterval code listing in § B.4.7 on page 262 contains additional documentation.

### 7.4.8 InSet Procedure

The InSet procedure provides a way to check whether or not a value lies within a specified set.

Note that I would rather call this routine "In_Set", but the F90 standard does not allow underscores in defined operator names (i.e. ".In_Set." is not allowed).

**Calling syntax:**

```
Logical = X .InSet.  (/Elem1, Elem2, .../)    ,
Logical = X .InSet.  Set                      or
Logical = InSet(X, Set)
```

**Input variables:**

| | |
|---|---|
| `X` | Input integer, real or character scalar variable. |
| `Set` | A vector containing the elements of the set to be checked. |
| `(/Elem1, Elem2, .../)` | A means of expressing a set without declaring a vector. |

**Output variable:**

| | |
|---|---|
| `InSet` | Logical which is true if X is an element of the set. |

The InSet code listing in § B.4.8 on page 263 contains additional documentation.

### 7.4.9 NotInInterval Procedure

The NotInInterval procedure provides a way to check whether or not a value lies outside of a specified interval. The interval is considered to be a closed interval that includes the end-points. For an array-valued X, all the values must satisfy the condition for the result to be true.

Note that I would rather call this routine "Not_In_Interval", but the F90 standard does not allow underscores in defined operator names (i.e. ".Not_In_Interval." is not allowed).

**Calling syntax:**

```
Logical = X .NotInInterval.  (/Int1, Int2/)    ,
Logical = X .NotInInterval.  Interval          or
Logical = NotInInterval(X, Interval)
```

**Input variables:**

| | |
|---|---|
| `X` | Input integer or real, scalar or array variable. |
| `Interval` | A vector of length 2 that specifies the extents of the interval to be checked. |
| `(/Int1, Int2/)` | A means of expressing an interval without declaring a vector. |

**Output variable:**

| | |
|---|---|
| `NotInInterval` | Logical which is true if X is in the closed interval, which includes the end-points. |

The NotInInterval code listing in § B.4.9 on page 264 contains additional documentation.

### 7.4.10 NotInSet Procedure

The NotInSet procedure provides a way to check whether or not a value lies within a specified set.

Note that I would rather call this routine "Not_In_Set", but the F90 standard does not allow underscores in defined operator names (i.e. ".Not_In_Set." is not allowed).

**Calling syntax:**

```
Logical = X .NotInSet.  (/Elem1, Elem2, .../)    ,
Logical = X .NotInSet.  Set                      or
Logical = NotInSet(X, Set)
```

**Input variables:**

| | |
|---|---|
| `X` | Input integer, real or character scalar variable. |
| `Set` | A vector containing the elements of the set to be checked. |
| `(/Elem1, Elem2, .../)` | A means of expressing a set without declaring a vector. |

**Output variable:**

| | |
|---|---|
| `NotInSet` | Logical which is true if X is not an element of the set. |

The NotInSet code listing in § B.4.10 on page 265 contains additional documentation.

## 7.5 Character Class

The Character Class is used to describe a character scalar or array in the CÆSAR Code Package. The Character Class does not use a user-defined type – it is the class for the F90 intrinsic type "character".

**Character public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a character scalar or array variable. |
| `Finalize` | Finalizes a character scalar or array variable. |
| `Valid_State` | Returns false iff a character scalar or array variable is in an invalid state. |

The Character Class code listing in § B.5 on page 267 contains additional documentation. The Character Class also contains a Unit Test Program which is listed in § B.5.4 on page 273.

### 7.5.1 Initialize_Character Procedure

The Initialize_Character procedure allocates and initializes a character scalar or array variable.

**Calling syntax:**

```
call Initialize (C, [dim1, ..., dimn,] status)
```

**Input variables:**

| | |
|---|---|
| `C` | A character scalar variable or a pointer to an unallocated character array variable. |
| `dim1, ..., dimn` | Extents of the dimensions for the array C. Only as many dimensions as are needed should be entered. |

**Output variables:**

| | |
|---|---|
| `C` | The C variable has been allocated (if it is an array) and initialized to `initialize_character_flag`. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variable:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |

The Initialize_Character code listing in § B.5.1 on page 268 contains additional documentation.

### 7.5.2 Finalize_Character Procedure

The Finalize_Character procedure deallocates and finalizes a character scalar or array variable.

**Calling syntax:**

```
call Finalize (C, status)
```

**Input variable:**

| | |
|---|---|
| `C` | A character scalar variable or a pointer to an allocated character array variable. |

**Output variable:**

| | |
|---|---|
| `C` | The C variable has been deallocated and nullified, if it is an array, or set to a flag value (`finalize_character_flag`), if it is a scalar. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `deallocate_status` | Deallocation Status. |

The Finalize_Character code listing in § B.5.2 on page 270 contains additional documentation.

### 7.5.3 Valid_State_Character Procedure

The Valid_State_Character procedure returns true iff the character scalar or array variable is in a valid state – that is, iff the variable passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(C)       or
Logical = Valid_State_NP(C)
```

**Input variable:**

`C` A character scalar variable or a pointer to an allocated character array variable. A non-pointered variable may be used with the Valid_State_NP version of the call.

**Output variable:**

`Valid_State` True iff the character scalar or array variable is in a valid state.

The Valid_State_Character code listing in § B.5.3 on page 272 contains additional documentation.

# Chapter 8

# Utilities Module

Robin: *Where'd you get a live fish, Batman?*
Batman: *The true crimefighter always carries everything he needs in his utility belt, Robin.*

There are some procedures in CÆSAR that do not belong to a particular class, yet are still generally useful. It does not make sense to develop a class around these procedures unless one wishes to be pedantic about object-oriented programming, so they are collected in the Utilities Module.

They are grouped by function, with three of the groups, Shell_Utils, File_Utils and Text_Utils, based on duplicating the Gnu shell functions in Fortran95 code. As of April 4, 2003, these three Gnu shell function groupings were combined into a package called Core_Utils, but they will continue to be grouped separately here.

The Utilities Module code listing in § C on page 275 contains additional documentation.

## 8.1 F2003_Utils Module

The F2003_Utils Module provides intrinsic procedures that conform to the Fortran 2003 standard[1]. The procedures provided are similar, but may not behave exactly the same as the F2003 versions. These functions should be replaced by F2003 calls as compilers become available.

**F2003_Utils public procedures:**

| | |
|---|---|
| `Command_Argument_Count` | Returns the number of arguments on the command line. |
| `Get_Command_Argument` | Returns a particular argument number from the command line. |

The F2003_Utils Module code listing in § C.1 on page 275 contains additional documentation. The F2003_-Utils Module also contains a Unit Test Program which is listed in § C.1.3 on page 278.

### 8.1.1 Command_Argument_Count_F2003 Procedure

The Command_Argument_Count_F2003 returns the number of command-line arguments used for this invocation of the executable. It is modeled after the Fortran 2003 function so that it can be replaced by that function eventually.

**Calling syntax:**

[1] `http://j3-fortran.org/`

```
Integer = COMMAND_ARGUMENT_COUNT()
```

(This is capitalized because it is an intrinsic in Fortran 2003.)

**Output variable:**

| | |
|---|---|
| `Command_Argument_Count` | Returns the number of command arguments. |

The Command_Argument_Count_F2003 code listing in § C.1.1 on page 276 contains additional documentation.

### 8.1.2 Get_Command_Argument_F2003 Procedure

The Get_Command_Argument_F2003 procedure returns a particular command-line argument used for this invocation of the executable. It is modeled after the Fortran 2003 function so that it can be replaced by that function eventually.

**Calling syntax:**

```
call GET_COMMAND_ARGUMENT(Number, Argument)
```

(This is capitalized because it is an intrinsic in Fortran 2003.)

**Input variables:**

| | |
|---|---|
| `Number` | The number of the argument to be queried. |

**Output variable:**

| | |
|---|---|
| `Argument` | The character value of the argument. |

The Get_Command_Argument_F2003 code listing in § C.1.2 on page 277 contains additional documentation.

## 8.2 Shell_Utils Module

The Shell_Utils Module provides utility routines that mimic those found in the Gnu shell-utils package for use inside Fortran routines. The routines provided are similar, but may not behave exactly the same as the Gnu versions.

Candidates for inclusion in this module (i.e., the utilities in the Gnu version) are: basename, chroot, date, dirname, echo, env, expr, factor, false, groups, hostname, id, logname, nice, nohup, pathchk, printenv, printf, pwd, seq, sleep, stty, su, tee, test, true, tty, uname, users, who, whoami, and yes.

**Shell_Utils public procedures:**

| | |
|---|---|
| `Basename` | Removes the path prefix and optionally the suffix from a given pathname. |
| `Dirname` | Strips off the filename or last level and returns only the directory name from a given pathname. |

The Shell_Utils Module code listing in § C.2 on page 278 contains additional documentation. The Shell_Utils Module also contains a Unit Test Program which is listed in § C.2.3 on page 281.

### 8.2.1 Basename_Shell_Utils Procedure

The Basename_Shell_Utils procedure strips off the path prefix and optionally the suffix from a given pathname. Note that the suffix behavior is slightly different from the standard basename function.

**Calling syntax:**

```
Character = Basename(Filename, Suffix)
```

**Input variables:**

| | |
|---|---|
| `Filename` | The Filename to be modified. |
| `Suffix_Strip` | Toggle for removing suffix. Default is true. [Optional] |

**Output variable:**

| | |
|---|---|
| `Basename` | The Filename with any leadin pathname and (optionally) any suffix stripped off. |

**Internal variables:**

| | |
|---|---|
| `basename_left` | Leftmost character of stripped name. |
| `basename_right` | Rightmost character of stripped name. |

The Basename_Shell_Utils code listing in § C.2.1 on page 279 contains additional documentation.

### 8.2.2 Dirname_Shell_Utils Procedure

The Dirname_Shell_Utils procedure strips off the filename and returns only the directory name from a given pathname.

**Calling syntax:**

```
Character = Dirname(Filename)
```

**Input variables:**

| | |
|---|---|
| `Filename` | The Filename to be modified. |

**Output variable:**

| | |
|---|---|
| `Dirname` | The directory part of the input Filename. Note that '.' is returned if there is no directory part. |

**Internal variables:**

| | |
|---|---|
| `dirname_right` | Rightmost character of directory name. |

The Dirname_Shell_Utils code listing in § C.2.2 on page 281 contains additional documentation.

## 8.3 Text_Utils Module

*Change changing places*
*Root yourself to the ground*
*Capitalize on this good fortune*
*One word can bring you round*
*Changes*
*– Yes, 90125, "Changes"*

The Text_Utils Module provides utility routines that mimic those found in the Gnu text-utils package for use inside Fortran routines. The routines provided are similar, but may not behave exactly the same as the Gnu versions. The Text_Utils Module also provides various other functions to manipulate text.

Candidates for inclusion in this module (i.e., the utilities in the Gnu version) are: cat, cksum, comm, csplit, cut, expand, fmt, fold, head, join, md5sum, nl, od, paste, ptx, pr, sort, split, sum, tac, tail, tr, tsort, unexpand, uniq, and wc.

**Text_Utils public procedures:**

| | |
|---|---|
| `Capitalize` | Converts a string to lowercase with uppercase at the beginning of words. |
| `Lowercase` | Converts a string to all lowercase. |
| `Uppercase` | Converts a string to all uppercase. |

The Text_Utils Module code listing in § C.3 on page 283 contains additional documentation. The Text_Utils Module also contains a Unit Test Program which is listed in § C.3.4 on page 287.

### 8.3.1 Capitalize_Text_Utils Procedure

The Capitalize_Text_Utils procedure returns a capitalized version of the input string. That is, the string is all in lowercase except for the first letter of every word, which is uppercase. Words are defined as contiguous strings of letters, and all non-letter characters define word boundaries.

**Calling syntax:**

```
Character = Capitalize(String)
```

**Input variables:**

| | |
|---|---|
| `String` | The String to be capitalized. |

**Output variable:**

| | |
|---|---|
| `Capitalize` | The capitalized version of the input String. |

The Capitalize_Text_Utils code listing in § C.3.1 on page 284 contains additional documentation.

### 8.3.2 Lowercase_Text_Utils Procedure

The Lowercase_Text_Utils procedure returns a lowercased version of the input string.

**Calling syntax:**

```
Character = Lowercase(String)
```

**Input variables:**

`String` The String to be lowercased.

**Output variable:**

`Lowercase` The lowercase version of the input String.

The Lowercase_Text_Utils code listing in § C.3.2 on page 285 contains additional documentation.

### 8.3.3 Uppercase_Text_Utils Procedure

The Uppercase_Text_Utils procedure returns an uppercased version of the input string.

**Calling syntax:**

```
Character = Uppercase(String)
```

**Input variables:**

`String` The String to be uppercased.

**Output variable:**

`Uppercase` The uppercase version of the input String.

The Uppercase_Text_Utils code listing in § C.3.3 on page 286 contains additional documentation.

# Chapter 9

# Data_Structures Module

*Get your data structures correct first, and the rest of the program will write itself. – David Jones*

*The secret of life is data structures. – Elizabeth Schwarzin*

Data structures are important. Programs with less than optimal data structures experience problems reaching their full potential, and programs with poor data structures can fail completely. Parallel data structures are even more important, and even more complex. Ideally, this complexity should be hidden from the casual user.

The Data_Structures Module implements the fundamental parallel data structures in the CÆSAR Code Package, and addresses the following issues:

- Input/Output on a single processor
- Data distribution over all the PEs
- Indirect addressing – gather/scatters
- Encapsulation – hiding the tricky operations
- Data access and storage
- User-specified base structures
- Memory/communication time trade-offs

The rest of this section explains how this is accomplished.

**Communication and Trace Classes**

First, all of the low-level communication calls in CÆSAR are wrapped by the Communication Class (described in § 9.2 on page 73). These calls currently use the PGSLib Package (described in § 2.2.2 on page 8), but they could be rewritten to use UPS or even bare calls from the MPI Package (described in § 2.2.1 on page 8). The Communication Class also includes a serial version. Another data structure auxiliary type, which contains the information associated with a gather-scatter operation, is the Trace Class (described in § 9.1 on page 69).

**Strategy**

Every data structure in the Data Structures Module can be thought of as a multi-dimensional array, with one dimension spread across the processors. The dimension that is spread across the processors is referred

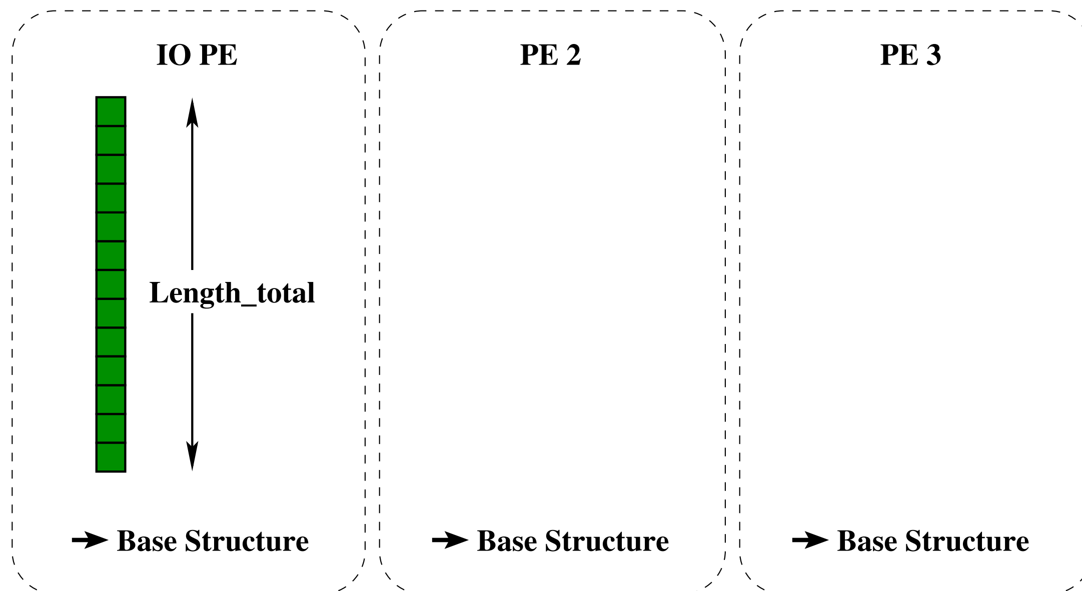

Figure 9.1: A Schematic Diagram of the Assembled Vector data structure. The data has been *assembled* on the IO PE.

to as the distributed (or parallel) dimension (or axis). [1] The remaining serial axes are contained on a given processor, and are treated like standard Fortran 95 arrays. In the rest of this discussion the serial axes will be ignored and arrays will be described as vectors, with the understanding that a "vector" may actually have several serial axes in addition to its single parallel or distributed axis. Note also that the PEs are assumed to contain contiguous pieces of the vector, with the first section being on PE=1, the second section being on PE=2, etc.

**Base_Structure Class**

Information about the basic distribution of an axis across the PEs is contained in the Base_Structure Class (described in § 9.3 on page 79). This information includes items such as the total length of the vector, the length of the vector on this PE, the starting and ending indices for this PE, and the locus (or name) for the axis. For example, a user might specify a Base Structure for the nodes in a mesh (locus = 'Nodes'), another one for the cells, and another one for the faces. Or equivalently, Base Structures could be defined for equations or variables. The actual locus is not specified by the Data_Structures Module, so the user may easily define new ones as needed.

**Assembled_Vector Class**

The simplest CÆSAR data structure, the Assembled_Vector Class (described in § 9.5 on page 88), is not parallel at all, but exists only on a single processor (see Figure 9.1). These vectors can be thought of as parallel data structures that have been "assembled" on a single PE (the IO processor). The primary use for an Assembled Vector is input and output, although there may certainly be times when a given parallel data structure is too large to be assembled on the IO PE. An Assembled Vector contains a pointer to a Base Structure which determines its structure.

**Distributed_Vector Class**

The basic parallel data structure is defined by the Distributed_Vector Class (described in § 9.6 on page 94). A Distributed Vector is a true parallel data structure, with data spread across the processors according to its Base Structure, a different amount on each PE (see Figure 9.2). A Distributed Vector contains a pointer to a Base Structure which determines its structure. The conversions between Assembled Vectors

[1] This is a similar idea to the distribution specified by a CMF array with a layout containing a single :NEWS (parallel) axis (*CM Fortran Reference Manual*, 1989).

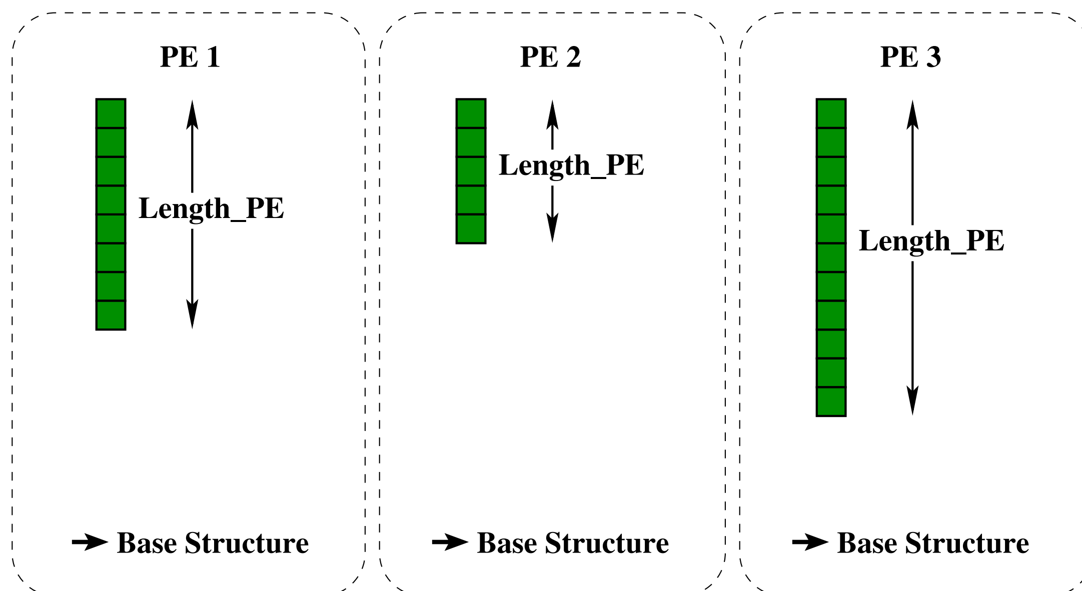

Figure 9.2: A Schematic Diagram of the Distributed Vector data structure. The data has been *distributed* to all of the PEs, a different amount on each one.

and Distributed Vectors (based on the same Base Structure) can be accomplished with an equals sign (via operator overloading). The operation changing a Distributed Vector to an Assembled Vector is known as *assemble*; the opposite operation is called *distribute*.

Assembled and Distributed Vectors, and the Base Structures that they are based upon, satisfy the input/output and parallel distribution needs of CÆSAR. There is also a need for the *association* of two different distributions. This is used to define, for example, the nodes that correspond to each cell in a mesh. The association between two data distributions can also be thought of as *indirection*, which is very useful for unstructured mesh operations (or parallel distributed mesh operations).

**Data_Index Class**

Association between two Base Structures in CÆSAR is accomplished via the Data_Index Class (described in § 9.4 on page 83). This association is considered to be a many-of-one relationship – "many" entries in the first Base Structure correspond to "one" entry in the second Base Structure. For example, many nodes in a node Base Structure correspond to each cell in a cell Base Structure. A Data Index therefore contains a Many (Base) Structure, a One (Base) Structure, and an index array to relate the two. It also stores some information about the communication pattern necessary to gather the "many" entries for each "one" entry on the one axis.

Note that "many" need not be more than unity – for instance there could be one boundary face for each regular face. In this case, the index array would be one-dimensional. If "many" is a constant number (for instance, there are always six faces on each cell), then the index array is a two-dimensional array (in this example, six by the number of cells on each PE). If "many" is a variable number (for instance, a polyhedral mesh where the number of faces per cell may vary), then a ragged-right index array is used. Ragged-right index arrays are not yet implemented, but one- and two-dimensional arrays are.

**Overlapped_Vector Class**

The Overlapped_Vector Class (described in § 9.7 on page 100) defines a data structure that represents an intermediate step in performing a gather and collect operation. The data in an Overlapped Vector has been gathered from a Distributed Vector with a Many Structure according to a specified One Structure, but has not been collected into place. An Overlapped Vector contains a Many (Base) Structure, a One (Base) Structure, a Many-of-One (Data) Index, and a Distributed Vector with a Many Structure (see Figure 9.3). It

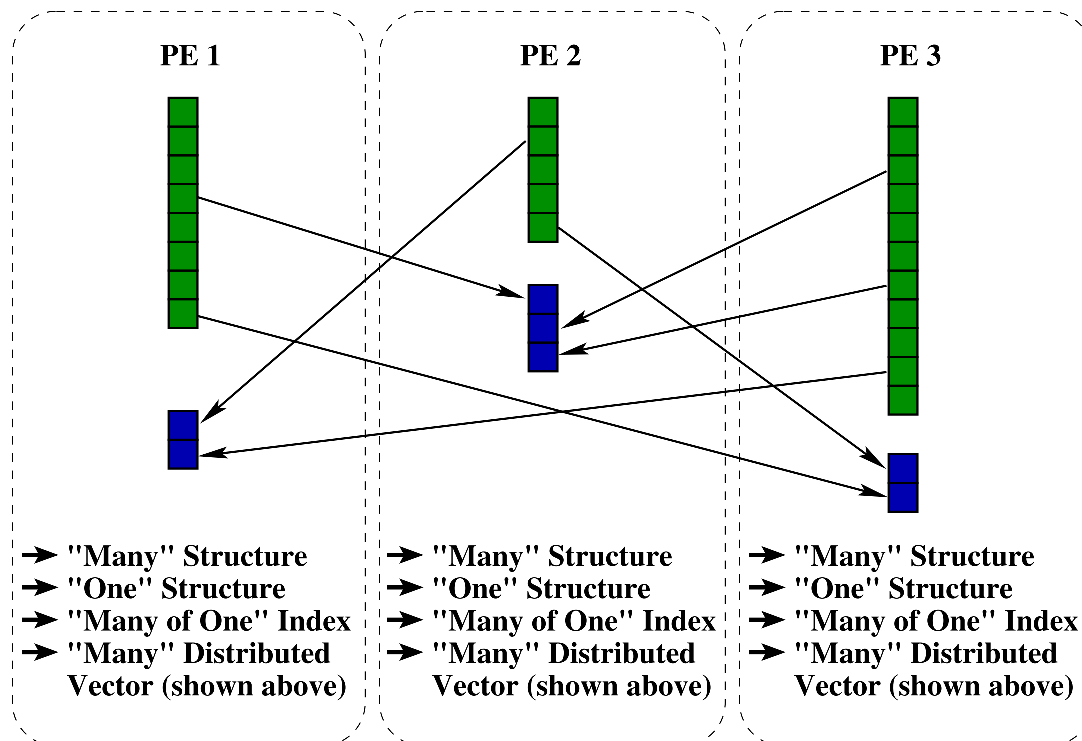

Figure 9.3: A Schematic Diagram of the Overlapped Vector data structure. The green blocks represent the Distributed Vector that the Overlapped Vector includes. The blue blocks represent off-processor data necessary for a gather operation that has been stored locally – the *overlapped* part of the vector.

also contains the entries from the Distributed Vector that would be needed for a gather and collect operation that are not local, and so some data is represented multiple times – but no more than once on a given PE. This *overlapped* data can represent the data from the boundary of a given processor that does not reside locally in the Distributed Vector. For example, an Overlapped Vector can contain the coordinates for all the nodes that correspond to cells on a given processor, even though some of the nodes on the boundary actually reside on other processors. Since it does not store the nodes twice on a given processor (even if more than one cell on that processor contains a specific node), the Overlapped Vector data structure uses a smaller amount of memory (compared to a Collected Array, which is described in the next subsection). Since it does not require interprocessor communication to generate the collected form of the data, an Overlapped Vector can save on run time (compared to gathering and collecting a Distributed Vector).

**Collected_Array Class**

The fully-evaluated "many-of-one" relationship between two distributions is described by the Collected_-Array Class (described in § 9.8 on page 107). In contrast to the other CÆSAR data structures, the Collected Array is an *array* rather than a vector (see Figure 9.4). It has *two* axes to represent the single parallel axis that has been discussed so far (in addition to the many possible serial axes whose discussion is being suppressed here). The vertical axis in Figure 9.4 is distributed across the processors according to the One Structure. The horizontal axis of the Collected Array has been formed by *collecting* all of the "many" items that correspond to each "one" (note that a Collected Array for a two-dimensional Many-of-One Index is shown).

A Collected Array is the final result of a gather and collect operation on a Distributed Vector according to a Many-of-One Index, or the result of simply *collecting* an Overlapped Vector (with no interprocessor communication). The data in a Collected Array is in a very useable form, so that access requires little run-time (as compared to collecting an Overlapped Vector or gathering and collecting a Distributed Vector). The data in a Collected Array takes up much more memory than an Overlapped Vector, since "many" items

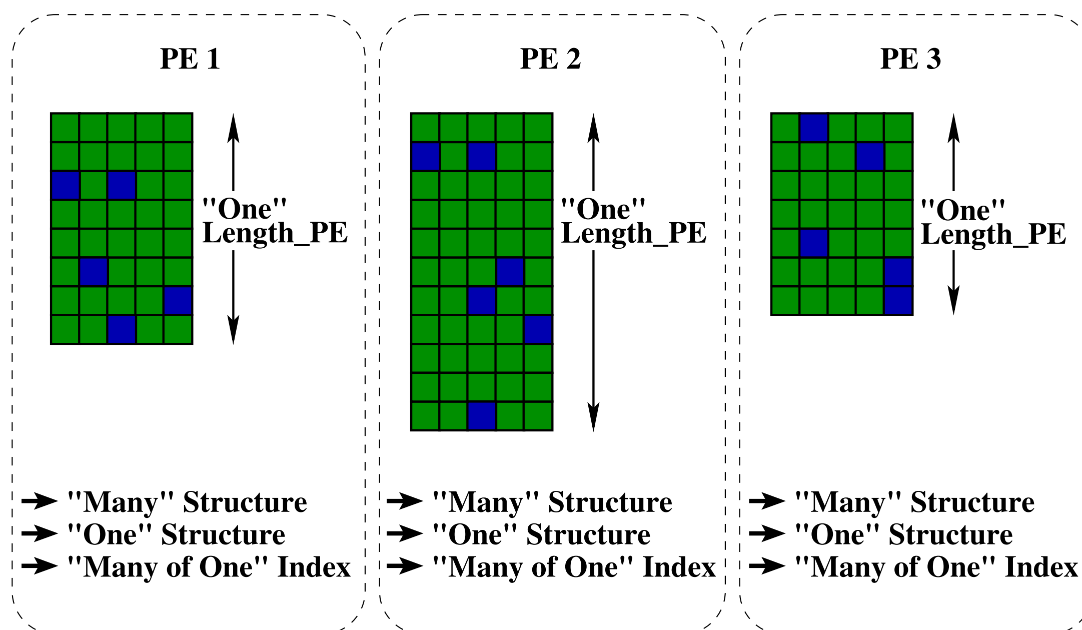

Figure 9.4: A Schematic Diagram of the Collected Array data structure. One way to form a Collected Array is to *collect* all of the “many” entries that correspond to each entry on the “one” axis. The green blocks represent data that was already on-processor when the data was distributed on the many axis in a Distributed Vector. The blue blocks represent off-processor data that was gathered and collected onto the one axis, which is the same as the blue overlapped blocks in an Overlapped Vector.

that belong to more than a single “one” item (for example, nodes belonging to more than one cell) are stored multiply, even if they exist on the same processor. Sometimes this behavior is not only useful from a run-time perspective, but is required – for instance, a physical property evaluated on each face of a cell may require a different value for the same face in different cells due to different materials in the cells. The “many” axis in a Collected Array can be *combined* using a specified combination operator to form a Distributed Vector with a One Structure.

**Bare Naked Vectors and Arrays**

In contrast to the communication, the calculations using data from the data structures are done using standard Fortran 95 arrays, pointered to allow dynamic memory allocation. This allows the compiler to make any optimizations possible with the Fortran 95 intrinsic array syntax. For the purpose of this discussion, to contrast these standard Fortran arrays with the other data structures described here, they are referred to as Bare Naked Vectors and Bare Naked Arrays, meaning that there is no encumbering derived type associated with them.

**Summary**

The CÆSAR data structures are very useful in coordinating the necessary communication for a parallel program. They provide a great deal of control over data layout, memory usage and cpu time, and enable CÆSAR to optimize in one direction or another depending on available resources (see Table 9.1). All of the complicated operations of converting from one data structure to another are hidden, and in fact can in most cases be accomplished with a simple equals sign, via operator overloading.

**An Example**

As an example, take the problem of reading in node coordinates, calculating cell center values, and writing them out. The steps to be taken are diagrammed in Figures 9.5 and 9.6. First, set-up information for the nodes is read in, in the form of the total number of nodes and the number on each PE, and a Base Structure for the nodes (referred to as the Node Structure) is initialized. A similar set up is done for the cells. Next,

Table 9.1: Relative Data Structure Memory and CPU Requirements. Assuming that information is stored in a Distributed Vector and needs to be accessed in a gathered and collected Bare Naked Array form, this table shows the memory / cpu time trade-offs for various CÆSAR data structures.

| Data Structure | Memory Usage | CPU Usage |
|---|---|---|
| Distributed Vector | Lowest | High, with communication |
| Overlapped Vector | Low (same as DV + off-PE entries) | Medium, no communication |
| Collected Array | High | Low, no communication |

an index array that tells which nodes are associated with which cells is read, and a Data Index called the Nodes of Cells Index is initialized using the index array and the Node and Cell Structures.

Now the necessary data structures can be easily initialized from the Node Structure, the Cell Structure, and the Nodes of Cells Index. These are, using acronyms for the data structures (i.e. AV: Assembled Vector, DV: Distributed Vector, OV: Overlapped Vector, CA: Collected Array, BNV: Bare Naked Vector, BNA: Bare Naked Array):

Coordinates_Nodes_BNV (IO PE only),
Coordinates_Nodes_AV,
Coordinates_Nodes_DV,
Coordinates_Nodes_of_Cells_OV,
Coordinates_Nodes_of_Cells_CA,
Centers_Cells_DV,
Centers_Cells_AV, and
Centers_Cells_BNV (IO PE only).

All of these data structures have a single serial axis in addition to the parallel axis, and it is dimensioned to the number of spatial dimensions in the problem (3 for 3-D).

The node coordinates are now read into a Bare Naked Vector called Coordinates_Nodes_BNV which is defined on the IO PE only. To store the coordinates in the Assembled Vector, a simple equals sign is used:

```
Coordinates_Nodes_AV = Coordinates_Nodes_BNV   .
```

To distribute the values across the processors, use another equals sign:

```
Coordinates_Nodes_DV = Coordinates_Nodes_AV   .
```

To gather the distributed node values to their respective cells, so that all nodes are on the same processor with their cells, in an Overlapped Vector, again use an equals sign:

```
Coordinates_Nodes_of_Cells_OV = Coordinates_Nodes_DV   .
```

To collect the node coordinates for each cell into an array, still an equals sign:

```
Coordinates_Nodes_of_Cells_CA = Coordinates_Nodes_of_Cells_OV   .
```

To calculate the cell center coordinates, combine the node coordinates for each cell using an "Average" operator. In this case, a subroutine call must be used to specify the combination operator:[2]

```
call Combine_with_Average (Centers_Cells_DV, Coordinates_Nodes_of_Cells_CA)   .
```

To assemble the cell center coordinates on the IO PE, use an equals sign:

```
Centers_Cells_AV = Centers_Cells_DV   .
```

To access the cell center coordinates on the IO PE, use a final equals sign:

```
Centers_Cells_BNV = Centers_Cells_AV   .
```

And then the cell center coordinates may be written to a file, completing our example.

[2] An equals sign could have been used if the combination operator had been a "SUM".

If the DEBUG_LEVEL is set high enough, copious error checking will be done to make sure that the left and right sides of the equals signs above are compatible.

Note that the solution given above is not unique. For example, to conserve memory, the Collected Array need not be formed, and a direct step around it may be taken:

```
call Collect_and_Average (Centers_Cells_DV, Coordinates_Nodes_of_Cells_OV)   .
```

Or, if the memory is available, the intermediate Overlapped Vector is superfluous and can be skipped:

```
Coordinates_Nodes_of_Cells_CA = Coordinates_Nodes_DV   .
```

Forming an Overlapped Vector does not use much more memory than the Distributed Vector it is based on, and saves much communication time.

The Data_Structures Module code listing in § D on page 289 contains additional documentation.

## 9.1 Trace Class

The Trace Class is used to describe a communication trace in the CÆSAR Code Package. A communication trace consists of the set-up information for a particular gather-scatter call.

**Trace public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a Trace object. |
| `Finalize` | Finalizes a Trace object. |
| `Valid_State` | Returns false iff a Trace object is in an invalid state. |
| **Operations** | |
| `Initialized` | Returns true iff a Trace object has been initialized. |

**Trace public defined type:**

| **Trace type** | |
|---|---|
| `Dimensionality` | The number of dimensions that the index has. |
| `Index1, Index2` | The index values, which may be modified by the communications package. |
| `Initialized` | Initialization status. |
| `Trace` | The trace for the communication associated with the index. |

The Trace Class code listing in § D.1 on page 290 contains additional documentation.

### 9.1.1 Initialize_Trace Procedure

The Initialize_Trace procedure allocates and initializes a Trace object.

**Calling syntax:**

```
call Initialize (Trace, Index, Length_PE, status)
```

**Input variables:**

| | |
|---|---|
| `Trace` | The Trace object to be initialized. |
| `Index` | The indirect index values for the specified communication pattern. |
| `Length_PE` | Length of the destination vector on this PE. This corresponds to the Many axis of a Many-to-One relationship. |

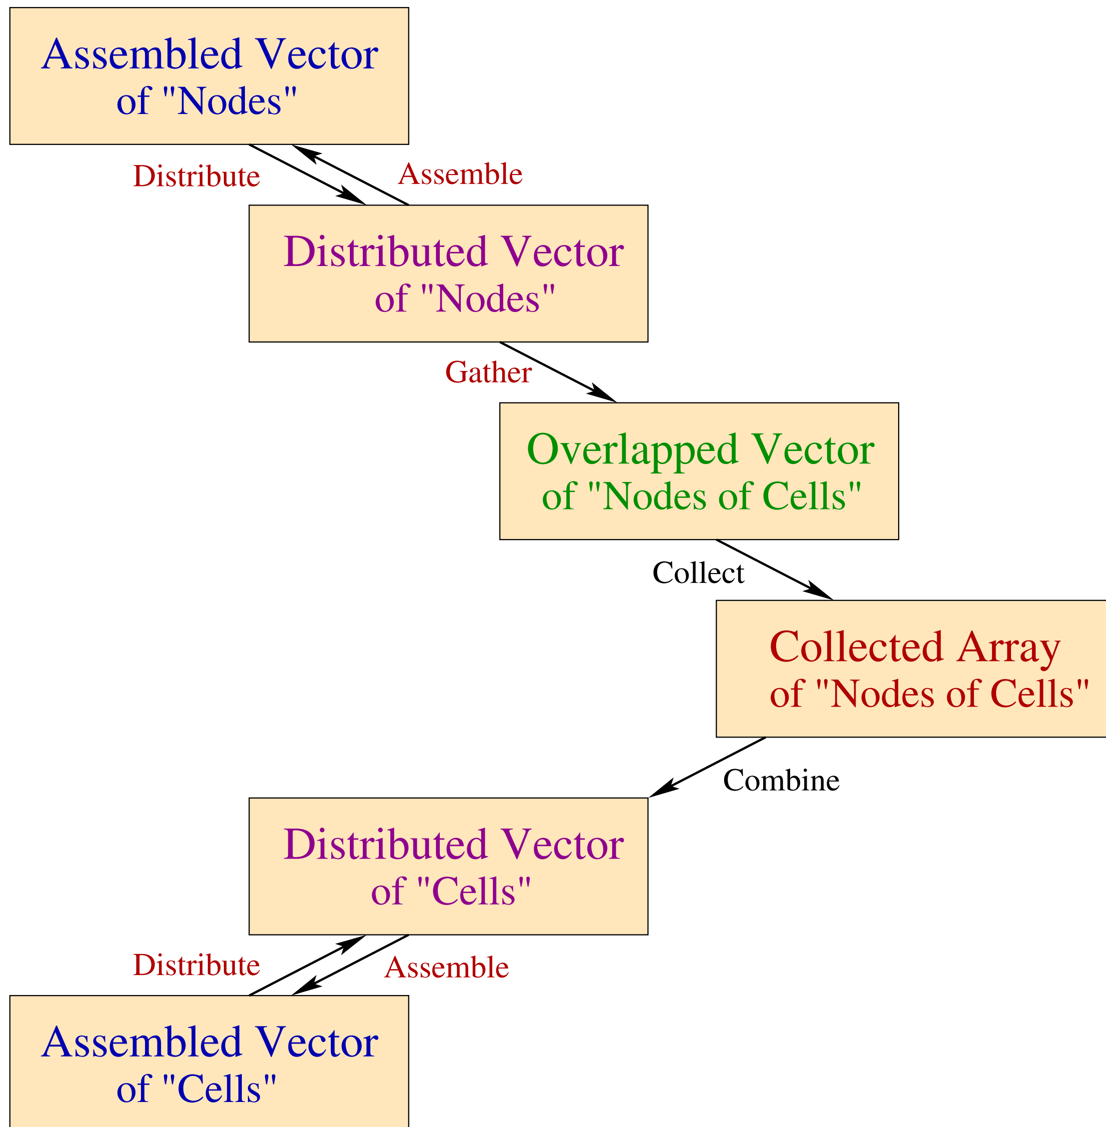

Figure 9.5: A flow chart showing the hierarchical relationships between CÆSAR Data Structures. Operations in red require global communication.

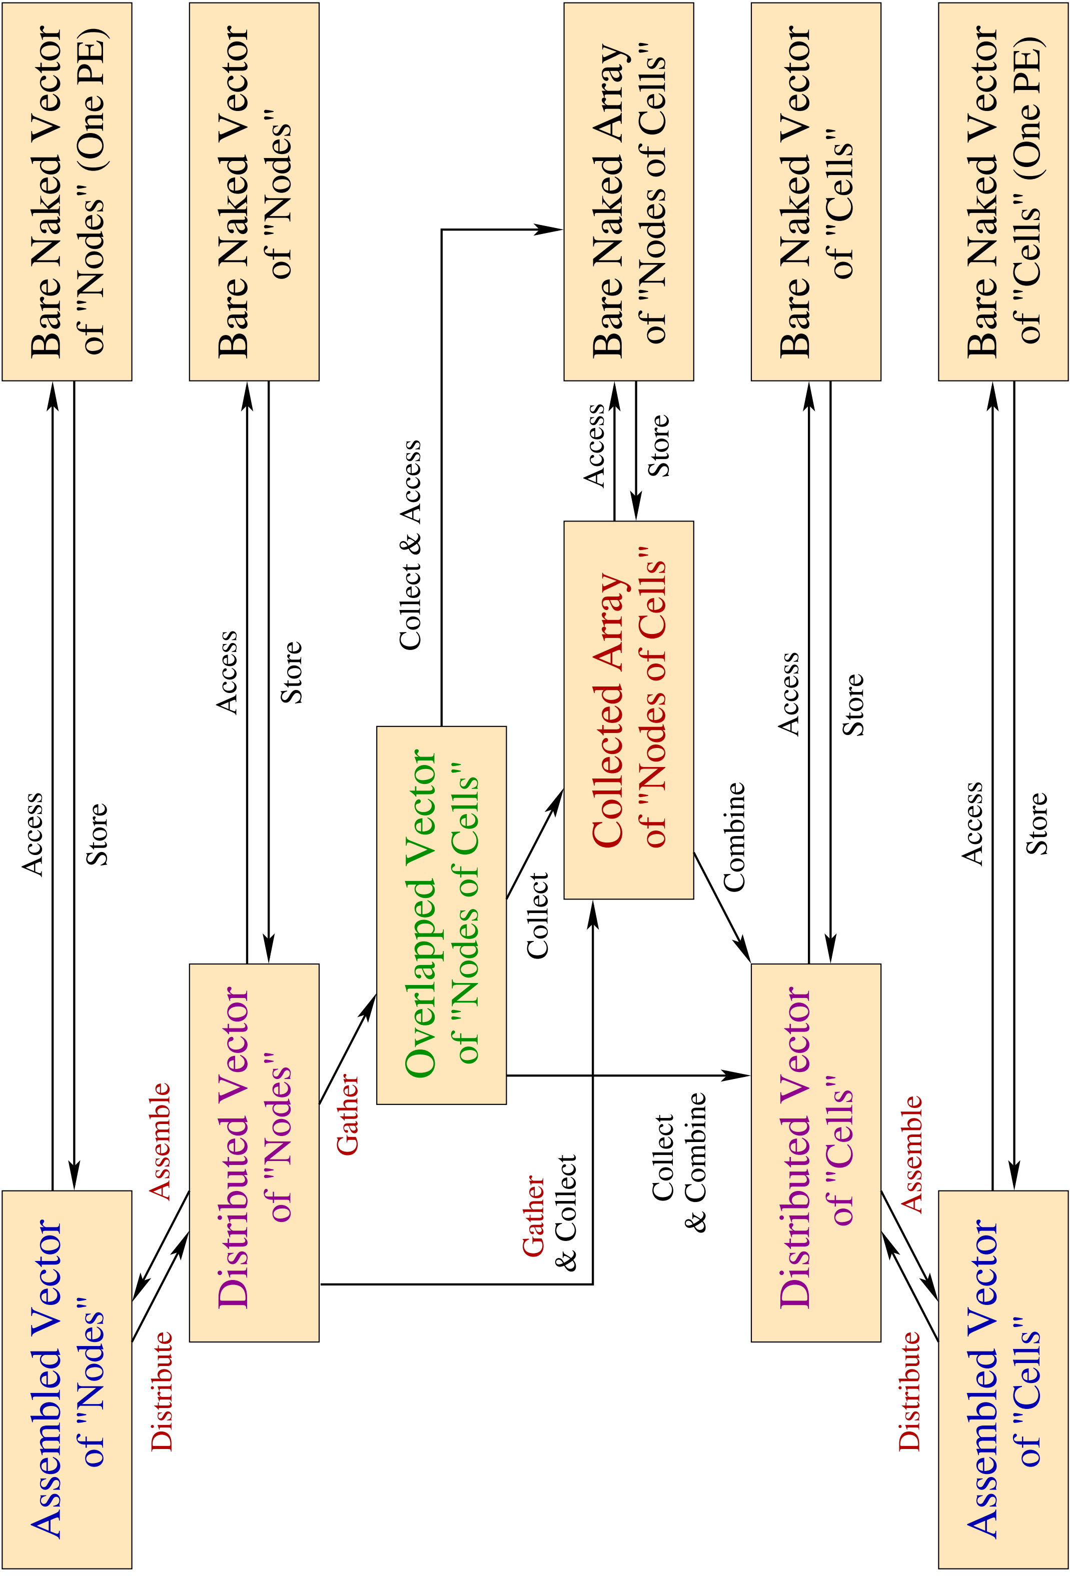

Figure 9.6: A flow chart showing operations that have been implemented for CÆSAR Data Structures. Operations in red require global communication.

**Output variables:**

| | |
|---|---|
| `Trace` | The Trace object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |

The Initialize_Trace code listing in § D.1.1 on page 291 contains additional documentation.

### 9.1.2 Finalize_Trace Procedure

The Finalize_Trace procedure deallocates and finalizes a Trace object.

**Calling syntax:**

```
call Finalize (Trace, status)
```

**Input variables:**

| | |
|---|---|
| `Trace` | The Trace object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Trace` | The Trace object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Trace code listing in § D.1.2 on page 293 contains additional documentation.

### 9.1.3 Valid_State_Trace Procedure

The Valid_State_Trace procedure returns true iff the Trace is in a valid state – that is, iff the Trace passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Trace)
```

**Input variables:**

| | |
|---|---|
| `Trace` | The Trace to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Trace is in a valid state. |

The Valid_State_Trace code listing in § D.1.3 on page 295 contains additional documentation.

### 9.1.4 Initialized_Trace Procedure

The Initialized_Trace procedure returns true iff the Trace object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Trace)
```

**Input variable:**

| | |
|---|---|
| `Trace` | The Trace object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Trace object has been initialized. |

The Initialized_Trace code listing in § D.1.4 on page 296 contains additional documentation.

## 9.2 Communication Class

The Communication Class is used to wrap the communication calls to other packages from the CÆSAR Code Package. It also contains serial versions of the routines so that CÆSAR may be run without any external packages on a serial platform.

**Communication public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes communication. |
| `Finalize` | Finalizes communication. |
| `Valid_State` | Returns false iff the communication is in an invalid state. |
| **Operations** | |
| `Abort` | Stops execution on all processors. |
| `Assemble` | Takes a variable that is distributed across all the processors and pulls it together (assembles it) on the IO PE. This is the opposite of the `Distribute` procedure. |
| `Broadcast` | Sets a variable on all the processors to a value on the IO PE. |
| `Distribute` | Takes a variable on the IO PE and divides it up (distributes it) among all the processors. This is the opposite of the `Assemble` procedure. |
| `Gather` | Transforms one distributed variable into another distributed variable, according to an indirection index. No collisions are possible, since this call is effectively pulling values out of a distributed variable, and there is a different location for each pulled value. This is the opposite of the `Scatter` procedure. |
| `Global Reductions` | Global operations that require communication with all the processors, such as SUM, ALL, etc. |
| `Output` | Outputs information about the communication set-up. |
| `Output_Test` | Outputs the result of a test. |
| `Parallel_Write` | Outputs data that is distributed across the processors. |

| | |
|---|---|
| `Scatter_OP` | Transforms one distributed variable into another distributed variable, according to an indirection index. Collisions are possible, since this call is effectively putting values into a distributed variable, and more than one value can go into the same location. Therefore, a combination operator, OP, must be specified. Allowed values for OP are: `AND`, `MAX`, `MIN`, `OR`, or `SUM`. This is the opposite of the `Gather` procedure. |

**Communication public defined types:**

| | |
|---|---|
| `Communication_type` | The Communication Class variable type. |

**Communication public variables:**

| | |
|---|---|
| `delta_PE_IO_PE` | Kronecker delta (PE, IO_PE). |
| `IO_PE` | The PE number which is allowed to do I/O. |
| `NPEs` | Total number of PEs (1 for serial runs). |
| `Parallel` | True for parallel runs, false for serial runs. |
| `Parallel_Library` | The name of the parallel communication library. |
| `Serial` | True for serial runs, false for parallel runs. |
| `Scope` | Global scope for PGSLib – not really utilized yet. |
| `this_is_IO_PE` | True on any PE which is allowed to perform I/O operations. |
| `this_is_not_IO_PE` | True on any PE which is not allowed to perform I/O operations. |
| `this_PE` | The PE number for this processor (in the range [1, `NPEs`]). |

The Communication Class code listing in § D.2 on page 296 contains additional documentation. The Communication Class also contains a Unit Test Program which is listed in § D.2.14 on page 321.

### 9.2.1 Initialize_Communication Procedure

The Initialize_Communication procedure sets up and initializes the communication scheme for the CÆSAR Code Package. Once it has been called, the global communication variables are defined and available via use association. This routine should be called whether or not a parallel run is being done.

**Calling syntax:**

```
call Initialize (Communication)
```

**Input/Output variable:**

| | |
|---|---|
| `Communication` | The Communication object to be initialized. |

The Initialize_Communication code listing in § D.2.1 on page 300 contains additional documentation.

### 9.2.2 Finalize_Communication Procedure

The Finalize_Communication procedure finalizes the communication scheme for the CÆSAR Code Package.

**Calling syntax:**

```
call Finalize (Communication, Output_Toggle)
```

**Input variable:**

| | |
|---|---|
| `Output_Toggle` | Toggles final output for this communication set-up. [Optional] |

**Input/Output variable:**

| | |
|---|---|
| `Communication` | The Communication object to be finalized. |

The Finalize_Communication code listing in § D.2.2 on page 301 contains additional documentation.

### 9.2.3 Valid_State_Communication Procedure

The Valid_State_Communication procedure returns true iff the communication is in a valid state – that is, iff the communication passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Communication)
```

**Input variable:**

| | |
|---|---|
| `Communication` | The Communication object to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the communication is in a valid state. |

The Valid_State_Communication code listing in § D.2.3 on page 303 contains additional documentation.

### 9.2.4 Abort Procedure

The Abort Procedure stops program execution. In parallel mode, Abort should stop execution on all processors.

**Calling syntax:**

```
call Abort
```

The Abort code listing in § D.2.4 on page 304 contains additional documentation.

### 9.2.5 Assemble Procedure

The Assemble Procedure takes an input vector or scalar that is distributed across all the processors and pulls it together (assembles it) on the IO processor. This is the opposite of the Distribute procedure.

**Calling syntax:**

```
call Assemble (Output, Input)
```

**Input variable:**

| | |
|---|---|
| `Input` | A real, integer, logical or character vector or scalar that is distributed across all the processors and which is to be assembled on the IO processor. |

**Output variable:**

| | |
|---|---|
| `Output` | The assembled version of the `Input` variable, existing only on the IO processor. |

The Assemble code listing in § D.2.5 on page 304 contains additional documentation.

### 9.2.6 Broadcast Procedure

The Broadcast Procedure takes an input value from the IO processor and sets the variable on all of the processors equal to that value.

**Calling syntax:**

```
call Broadcast (Variable)
```

**Input variable:**

`Variable` A real, integer, logical or character vector that is defined on the IO processor and which is to be broadcast over all of the processors.

**Output variable:**

`Variable` Every processor now has the same value for variable, equal to the input value on the IO processor.

The Broadcast code listing in § D.2.6 on page 305 contains additional documentation.

### 9.2.7 Distribute Procedure

The Distribute Procedure takes an input vector from the IO processor and divides it up (distributes it) across all of the processors. This is the opposite of the Assemble procedure.

**Calling syntax:**

```
call Distribute (Output, Input, Lengths)
```

**Input variable:**

`Input` A real, integer or logical vector that is defined on the IO processor and which is to be distributed over all of the processors.

`Lengths` An integer vector of dimension `NPEs` containing the number of elements of the input vector which are to be distributed to each PE. Lengths is only defined on the IO PE. In the special case of one element to each processor, this vector must not be included.

**Output variable:**

`Output` The distributed version of the `Input` vector, with a piece on every processor.

The Distribute code listing in § D.2.7 on page 306 contains additional documentation.

### 9.2.8 Gather Procedure

The Gather Procedure takes an input vector that is distributed across all the processors and gathers it into another distributed vector or array according to an indirect index vector or array. No collisions are possible, since this call is effectively pulling values out of a distributed variable, and there is a different location for

each pulled value. This is the opposite of the Scatter procedure.

**Calling syntax:**

```
call Gather (Output, Input, Index, Trace)
```

**Input variables:**

| | |
|---|---|
| `Index` | An optional integer vector or array of indirect references to positions in the `Input` vector. This must be included on the first call to this procedure with a given data structure, but may be omitted on subsequent calls if the `Trace` variable is present. [Optional] |
| `Input` | A real, integer or logical vector that is distributed across all the processors. |
| `Trace` | An optional structure that stores the setup from a previous Gather/Scatter call using the same `Index` variable and `Input` vector length. If `Trace` is present and uninitialized, it is set by this procedure. If Trace is present, it is used regardless of whether Index is present. [Optional] |

**Output variables:**

| | |
|---|---|
| `Output` | The gathered version of the `Input` vector, distributed across the processors. |
| `Trace` | If present, `Trace` is set to the setup information for this Gather/Scatter. [Optional] |

The Gather code listing in § D.2.8 on page 308 contains additional documentation.

### 9.2.9 Global Reduction Functions

The global reduction functions execute various global reductions on their input. Each global reduction function corresponds to a Fortran 90 intrinsic function with the same name, minus the "Global_" prefix. These functions require global all-to-all communication and are relatively computationally expensive. If the code is run in serial mode, then the global reduction functions are equivalent to the serial intrinsic functions.

**Calling syntax:**

```
Output = Global_ALL (Input)                    ,
Output = Global_ANY (Input)                    ,
Output = Global_MaxVal (Input)                 ,
Output = Global_MinVal (Input)                 ,
Output = Global_Sum (Input)                    or
Output = Global_Dot_Product (Input1, Input2)
```

**Input variables:**

| | |
|---|---|
| `Input` | A real or integer (in the case of Sum, MinVal and MaxVal) or a logical (in the case of ALL and ANY) scalar, vector or 2-D array that is defined on each processor and which is to be reduced over all of the processors. |
| `Input1, Input2` | The two real, integer or logical vectors that are defined on each processor and that are to be reduced via a dot product over all of the processors. |

**Output variable:**

| | |
|---|---|
| `Output` | The result of the global reduction. |

The Global Reduction code listing in § D.2.9 on page 311 contains additional documentation.

### 9.2.10 Output_Communication Procedure

The Output_Communication procedure writes out information about the communication set-up to the specified unit.

**Calling syntax:**

```
call Output (Communication, Unit)
```

**Input variables:**

| | |
|---|---|
| `Communication` | The Communication object to be output. |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Communication code listing in § D.2.10 on page 313 contains additional documentation.

### 9.2.11 Output_Test Procedure

The Output_Test procedure writes out the result of a test to the specified unit.

**Calling syntax:**

```
call Output_Test (Test_Name, Success, Unit)
```

**Input variables:**

| | |
|---|---|
| `Test_Name` | The name of the test that has been conducted. |
| `Success` | The result status of the test. |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Test code listing in § D.2.11 on page 314 contains additional documentation.

### 9.2.12 Parallel_Write Procedure

The Parallel_Write Procedure takes an input character scalar or vector that is distributed across all the processors and writes it to the specified unit number. If a specific PE number is specified, only the information for that PE is written; otherwise, the information for all the PEs is written in order.

**Calling syntax:**

```
call Parallel_Write (String, Unit, PE)
```

**Input variables:**

| | |
|---|---|
| `String` | The character string (scalar or vector) to be written out, defined differently on each processor. |
| `PE` | The processor number containing the data to be output. If not present, data from all of the processors will be output. [Optional] |
| `Unit` | The unit number for output. If not present, unit 6 (`stdout`) will be used. [Optional] |

The Parallel_Write code listing in § D.2.12 on page 315 contains additional documentation.

### 9.2.13 Scatter Procedure

The Scatter Procedure takes an input vector (bare naked vector) that is distributed across all the processors and scatters it into another distributed vector or array (bare naked vector or array) according to an indirect index vector or array. Collisions are possible, since this call is effectively putting values into a distributed variable, and more than one value can go into the same location. Therefore, a combination operator, OP, must be specified. This is the opposite of the Gather procedure.

**Calling syntax:**

```
call Scatter_AND (Output, Input, Index, Trace)   ,
call Scatter_MAX (Output, Input, Index, Trace)   ,
call Scatter_MIN (Output, Input, Index, Trace)   ,
call Scatter_OR (Output, Input, Index, Trace)    or
call Scatter_SUM (Output, Input, Index, Trace)
```

**Input variables:**

| | |
|---|---|
| `Index` | An optional integer vector or array of indirect references to positions in the `Output` vector. This must be included on the first call to this procedure with a given data structure, but may be omitted on subsequent calls if the `Trace` variable is present. [Optional] |
| `Input` | A real, integer or logical vector that is distributed across all the processors. |
| `Trace` | An optional structure that stores the setup from a previous Gather/Scatter call using the same `Index` variable and `Output` vector length. If `Trace` is present and uninitialized, it is set by this procedure. If Trace is present, it is used regardless of whether Index is present. [Optional] |

**Output variables:**

| | |
|---|---|
| `Output` | The scattered vector version of the `Input` vector, distributed across the processors. |
| `Trace` | If present, `Trace` is set to the setup information for this Gather/Scatter. [Optional] |

The Scatter code listing in § D.2.13 on page 318 contains additional documentation.

## 9.3 Base_Structure Class

The Base_Structure Class is used to describe a base structure in the CÆSAR Code Package. A Base_Structure is part of the overall data structure strategy in CÆSAR, which is made up of the following classes: Base_-Structure, Data_Index, Assembled_Vector, Distributed_Vector, Overlapped_Vector, and Collected_Array. A description of the overall data structure strategy can be found in the Data_Structures Module (described in chapter 9 on page 63).

**Base_Structure public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes a Base_Structure object. |
| `Finalize` | Finalizes a Base_Structure object. |
| `Valid_State` | Returns false iff a Base_Structure object is in an invalid state. |
| `Initialized` | Returns true iff a Base_Structure object has been initialized. |
| **Operations** | |
| `First_PE` | Returns the first global index number on this PE. |
| `Generate_Even_Distribution` | Returns an even distribution of items in a vector. |
| `Last_PE` | Returns the last global index number on this PE. |

| | |
|---|---|
| `Length_PE` | Returns the length of the distributed axis on this PE. |
| `Length_Total` | Returns the total the distributed axis of the entire vector (including all PEs). |
| `Length_Vector` | Returns a vector containing the length of the distributed axis for each PE. |
| `Locus` | Returns the locus of the Base_Structure object. |
| `Output` | Writes out the Base_Structure object. |
| `Range_PE` | Returns the range of global index numbers on this PE. |

**Base_Structure public variable:**

| | |
|---|---|
| `name_length` | Length of the character strings for names. |

**Base_Structure public defined type:**

**Base_Structure type**

| | |
|---|---|
| `First_PE` | First global index number for this PE. |
| `Initialized` | Initialization status. |
| `Last_PE` | Last global index number for this PE. |
| `Length_Total` | Total length of the distributed axis of the entire vector (including all PEs). |
| `Length_PE` | Length of the distributed axis on this PE. |
| `Length_Vector` | A vector containing the length of the distributed axis for each PE. |
| `Locus` | The location or variable name which is distributed over the processors (Cells, Nodes, Faces, Equations, Variables, etc.). |
| `Range_PE` | The range of global index numbers for this PE. |

The Base_Structure Class code listing in § D.3 on page 322 contains additional documentation. The Base_-Structure Class also contains a Unit Test Program which is listed in § D.3.8 on page 334.

### 9.3.1 Initialize_Base_Structure Procedure

The Initialize_Base_Structure procedure allocates and initializes a Base_Structure object.

**Calling syntax:**

```
call Initialize (Structure, Length_Vector, Locus, status)
```

**Input variables:**

| | |
|---|---|
| `Structure` | The Base_Structure object to be initialized. |
| `Length_Vector` | A vector containing the length of the distributed axis for each PE. |
| `Locus` | The location or variable name which is distributed over the processors (Cells, Nodes, Faces, Equations, Variables, etc.). [Optional] |

**Output variables:**

| | |
|---|---|
| `Structure` | The Base_Structure object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |

The Initialize_Base_Structure code listing in § D.3.1 on page 325 contains additional documentation.

### 9.3.2 Finalize_Base_Structure Procedure

The Finalize_Base_Structure procedure deallocates and finalizes a Base_Structure object.

**Calling syntax:**

```
call Finalize (Structure, status)
```

**Input variables:**

| | |
|---|---|
| `Structure` | The Base_Structure object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Structure` | The Base_Structure object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Base_Structure code listing in § D.3.2 on page 326 contains additional documentation.

### 9.3.3 Valid_State_Base_Structure Procedure

The Valid_State_Base_Structure procedure returns true iff the Base_Structure is in a valid state – that is, iff the Base_Structure passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Structure)
```

**Input variables:**

| | |
|---|---|
| `Structure` | The Base_Structure to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Base_Structure is in a valid state. |

The Valid_State_Base_Structure code listing in § D.3.3 on page 327 contains additional documentation.

### 9.3.4 Initialized_Base_Structure Procedure

The Initialized_Base_Structure procedure returns true iff the Base_Structure object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Structure)
```

**Input variable:**

| | |
|---|---|
| `Structure` | The Base_Structure object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Base_Structure object has been initialized. |

The Initialized_Base_Structure code listing in § D.3.4 on page 328 contains additional documentation.

### 9.3.5 Generate_Even_Distribution Procedure

The Generate_Even_Distribution procedure sets a short vector (on the order of NPEs) to the most even distribution of items possible, on every PE. It can be used to generate an even distribution for the Length_-Vector to initialize a Base_Structure object.

**Calling syntax:**

```
call Generate_Even_Distribution (Vector, NItems)
```

**Input variable:**

| | |
|---|---|
| `NItems` | The number of items to be distributed. |

**Output variable:**

| | |
|---|---|
| `Vector` | The vector with an even distribution of items. |

The Generate_Even_Distribution code listing in § D.3.5 on page 329 contains additional documentation.

### 9.3.6 Get Value Base_Structure Functions

The Get_Value_Structure functions return values from a Base_Structure object.

**Calling syntax:**

```
Output = First_PE (Structure)        ,
Output = Last_PE (Structure)         ,
Output = Length_PE (Structure)       ,
Output = Length_Total (Structure)    ,
Output = Length_Vector (Structure)   ,
Output = Locus (Structure)           or
Output = Range_PE (Structure)
```

**Input variables:**

| | |
|---|---|
| `Structure` | The Base_Structure object to be examined. |

**Output variable:**

`Output` For Locus, returns a character variable containing the locus assigned to the object upon initialization. For Range_PE, returns a dimension(2) integer containing the range of values on this PE. For Length_Vector, returns a dimension(NPEs) integer containing the number of values on all PEs. For all other functions, returns an integer variable with the named value for the Base_Structure object.

The Get Value Base_Structure code listing in § D.3.6 on page 330 contains additional documentation.

### 9.3.7 Output_Base_Structure Procedure

The Output_Base_Structure procedure writes out a Base Structure to the specified unit.

**Calling syntax:**

```
call Output (Structure, Unit, Type, Indent)
```

**Input variables:**

| | |
|---|---|
| `Structure` | The Base_Structure object to be queried. |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Type` | The structure type (e.g. Many, One). [Optional] |
| `Indent` | Number of indentation characters. [Optional] |

The Output_Base_Structure code listing in § D.3.7 on page 332 contains additional documentation.

## 9.4 Data_Index Class

The Data_Index Class is used to describe a data index in the CÆSAR Code Package. A Data_Index is part of the overall data structure strategy in CÆSAR, which is made up of the following classes: Base_Structure, Data_Index, Assembled_Vector, Distributed_Vector, Overlapped_Vector, and Collected_Array. A description of the overall data structure strategy can be found in the Data_Structures Module (described in chapter 9 on page 63).

The form of a Data_Index object is given by:

```
Array ( One_Axis [, Many_Axis] )
```

or

```
Array ( One_Axis [, Many_Axis_ragged_right] )
--> not implemented
```

where One_Axis refers to the axis which is spread across the processors.

**Data_Index public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes a Data_Index object. |
| `Finalize` | Finalizes a Data_Index object. |
| `Valid_State` | Returns false iff a Data_Index object is in an invalid state. |
| `Initialized` | Returns true iff a Data_Index object has been initialized. |
| **Operations** | |
| `Get_Values` | Gets the values from a Data_Index object and returns them in a bare naked vector (also has an assignment interface). |

| | |
|---|---|
| `Initialize_Shell_Partition` | Sets up the Base_Structure and Data_Index objects for a poor partitioning, used for testing. |
| `Output` | Writes out the Data_Index object. |

**Data_Index public defined type:**

| **Data_Index type** | |
|---|---|
| `Dimensionality` | The number of dimensions that the index has. "Ragged_Right" indices are signified by a Dimensionality of -1, and are equivalent to a Dimensionality of 2 where the number of columns per row varies. (Ragged_Right is not yet implemented.) |
| `Index1, Index2` | The index values, which are modified: 1. to reflect off-PE locations with a negative number corresponding to the location in Off_PE_Index of the original value; and 2. to have a local numbering instead of a global numbering. |
| `Initialized` | Initialization status. |
| `Many_Structure` | Basic data structure corresponding to the columns in the index array. The index array can be thought of as a "Many of One" relationship (e.g. Many Faces of Each Cell, or Faces_of_Cells), with each row of the array signifying all the "Many" items that correspond to that "One" row. |
| `NOff_PE` | The number of Off-PE values. |
| `Off_PE_Index` | The values of the index which are not local to this PE. |
| `Off_PE_Trace` | The trace for the communication associated with the Off_PE_Index. |
| `One_Structure` | Basic data structure corresponding to the rows in the index array. The index array can be thought of as a "Many of One" relationship (e.g. Many Faces of Each Cell, or Faces_of_Cells), with each row of the array signifying all the "Many" items that correspond to that "One" row. |
| `Trace` | The trace for the communication associated with the index. |

The Data_Index Class code listing in § D.4 on page 335 contains additional documentation. The Data_Index Class also contains a Unit Test Program which is listed in § D.4.9 on page 356.

### 9.4.1 Initialize_Data_Index Procedure

The Initialize_Data_Index procedure allocates and initializes a Data_Index object.

**Calling syntax:**

```
call Initialize (Index, Many_Structure, One_Structure, Many_of_One_Vector, Many_of_One_Array, Many_
```

**Input variables:**

| | |
|---|---|
| `Index` | The Data_Index object to be initialized. |
| `Many_of_One_Array` | The index vector, giving indices for the "Many" that correspond with each "One". Only the rows ("Ones") for this PE are included. Zero entries signify the lack of a reference. If this is specified, then Many_of_One_Vector and Many_of_One_Ragged should not be specified. [Optional] |
| `Many_of_One_Ragged` | The index vector, giving indices for the "Many" that correspond with each "One". Only the rows ("Ones") for this PE are included. Zero entries signify the lack of a reference. If this is specified, then Many_of_One_Vector and Many_of_One_Array should not be specified. [Optional] – NOT IMPLEMENTED YET. |
| `Many_of_One_Vector` | The index vector, giving indices for the "Many" that correspond with each "One". Only the rows ("Ones") for this PE are included. Zero entries signify the lack of a reference. If this is specified, then Many_of_One_Array and Many_of_One_Ragged should not be specified. [Optional] |
| `Many_Structure` | A data structure that corresponds to the columns in the index array. |

`One_Structure` A data structure that corresponds to the rows in the index array.

**Output variables:**

`Index` The Data_Index object has been allocated and initialized.
`status` If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough.

**Internal variables:**

`allocate_status` Allocation Status.

The Initialize_Data_Index code listing in § D.4.1 on page 338 contains additional documentation.

### 9.4.2 Finalize_Data_Index Procedure

The Finalize_Data_Index procedure deallocates and finalizes a Data_Index object.

**Calling syntax:**

```
call Finalize (Index, status)
```

**Input variables:**

`Index` The Data_Index object to be finalized.

**Output variables:**

`Index` The Data_Index object has been finalized and is no longer valid.
`status` If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough.

**Internal variables:**

`consolidated_status` Consolidated Status.
`deallocate_status` Deallocation Status vector.

The Finalize_Data_Index code listing in § D.4.2 on page 343 contains additional documentation.

### 9.4.3 Valid_State_Data_Index Procedure

The Valid_State_Data_Index procedure returns true iff the Data_Index is in a valid state – that is, iff the Data_Index passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Index)
```

**Input variables:**

`Index` The Data_Index to be checked.

**Output variable:**

`Valid_State` True iff the Data_Index is in a valid state.

The Valid_State_Data_Index code listing in § D.4.3 on page 344 contains additional documentation.

### 9.4.4 Initialized_Data_Index Procedure

The Initialized_Data_Index procedure returns true iff the Data_Index object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Index)
```

**Input variable:**

`Index` The Data_Index object to be examined.

**Output variable:**

`Initialized` True iff the Data_Index object has been initialized.

The Initialized_Data_Index code listing in § D.4.4 on page 346 contains additional documentation.

### 9.4.5 Generate_Shell_Partition Procedure

The Generate_Shell_Partition procedure returns the cell numbering for a "Shell Partitioning". That is, it returns an array giving cell number as a function of i, j, and k. It is called internally by the Initialize_Shell_-Partition procedure in section 9.4.7.

The idea behind a "Shell Partitioning" is to develop a numbering for a *very bad* partitioning. This can then be used to test algorithms to see how well they behave under adverse situations.

All the Shell Partitionings correspond to a structured, "linear", "square" or "cubic", mesh. The total size of the mesh is $\text{Size}^{\text{NDimensions}}$, where Size is any integer (and is equal to the number of processors) and NDimensions is 1, 2 or 3. Each processor then gets

$$\text{PE}^{\text{NDimensions}} - (\text{PE} - 1)^{\text{NDimensions}} \tag{9.1}$$

cells, where PE is the processor number. The following is a conceptual description of what is happening. In 1-D, each PE gets one cell – an even partitioning. In 2-D each PE gets the newly added last column and last row of a square, for example

```
XXXXX
    X
    X
    X
    X
```

for processor 5. In 3-D, each PE gets the newly added top and two sides (three sides total) of a cube.

This routine provides a functional relationship for cell numbers by (i,j,k) triplet. The cell numbers are contiguous for a PE, e.g. in 3-D the first PE has number 1, the second PE has numbers 2-8, the third PE has numbers 9-27, etc.

**Calling syntax:**

```
call Generate_Shell_Partition  (c, i_of_c, j_of_c, k_of_c,
                               NDimensions, NNodes_per_Side, Output)
```

**Input variables:**

| | |
|---|---|
| `NDimensions` | The number of dimensions (1=line, 2=square, 3=cube). |
| `NNodes_per_Side` | The number of nodes in the line, or on the edges of the square or cube. |
| `Output` | Output toggle. |

**Output variables:**

| | |
|---|---|
| `c` | The cell numbers as a function of i, j, and k. |
| `i_of_c, j_of_c, k_of_c` | The i, j, and k numbers for a particular cell number. |

The Generate_Shell_Partition code listing in § D.4.5 on page 346 contains additional documentation.

### 9.4.6 Get_Values_Data_Index Procedure

The Get_Values_Data_Index procedure gets the index values from a Data_Index object.

**Calling syntax:**

```
Values = Index                        or
call Get_Values (Values, Index)
```

**Input variable:**

| | |
|---|---|
| `Index` | The Data_Index object to be queried. |

**Output variable:**

| | |
|---|---|
| `Values` | The index values from the Data_Index object. |

The Get_Values_Data_Index code listing in § D.4.6 on page 348 contains additional documentation.

### 9.4.7 Initialize_Shell_Partition Procedure

The Initialize_Shell_Partition procedure sets up the Cell_Structure, the Node_Structure, and the Nodes_of_-Cells_Index for a "Shell Partitioning". The "Shell Partitioning" numbering scheme, which is designed to be a poorly distributed scheme for testing purposes, is described in the Generate_Shell_Partition procedure in section 9.4.5.

**Calling syntax:**

```
call Initialize_Shell_Partition  NDimensions, Cell_Structure, Node_Structure,
                                 Nodes_of_Cells_Index, Output
```

**Input variables:**

| | |
|---|---|
| `NDimensions` | The number of dimensions (1=line, 2=square, 3=cube). |
| `Output` | Output toggle. |

**Output variables:**

| | |
|---|---|
| `Cell_Structure` | The Cell Base_Structure object. |
| `Node_Structure` | The Node Base_Structure object. |
| `Nodes_of_Cells_Index` | The Nodes_of_Cells Data_Index object. |

The Initialize_Shell_Partition code listing in § D.4.7 on page 350 contains additional documentation.

### 9.4.8 Output_Data_Index Procedure

The Output_Data_Index procedure writes out a section of a Data Index to the specified unit.

**Calling syntax:**

```
call Output (Index, First, Last, Unit, Indent, Output_OPE)
```

**Input variables:**

| | |
|---|---|
| `Index` | The Data_Index object to be queried. |
| `First` | The first location to be output. [Optional] |
| `Last` | The last location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Indent` | Number of indentation characters. [Optional] |
| `Output_OPE` | Toggle for outputting the Off_PE_Index information. [Optional] |

The Output_Data_Index code listing in § D.4.8 on page 352 contains additional documentation.

## 9.5 Assembled_Vector Class

The Assembled_Vector Class is used to describe an assembled vector (existing only on a single processor) in the CÆSAR Code Package. An Assembled_Vector is part of the overall data structure strategy in CÆSAR, which is made up of the following classes: Base_Structure, Data_Index, Assembled_Vector, Distributed_Vector, Overlapped_Vector, and Collected_Array. A description of the overall data structure strategy can be found in the Data_Structures Module (described in chapter 9 on page 63).

**Assembled_Vector public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes an Assembled_Vector object. |
| `Finalize` | Finalizes an Assembled_Vector object. |
| `Valid_State` | Returns false iff an Assembled_Vector object is in an invalid state. |
| `Initialized` | Returns true iff an Assembled_Vector object has been initialized. |
| **Operations** | |
| `Get_Values` | Gets the values from an Assembled_Vector object and returns them in a bare naked vector (also has an assignment interface). |
| `Locus` | Returns the locus of the Assembled_Vector object. |
| `Name` | Returns the name of the Assembled_Vector object. |
| `Output` | Writes out the Assembled_Vector object. |

| | |
|---|---|
| `Set_Values` | Sets the values of the Assembled_Vector object to a bare naked vector (also has an assignment interface). |
| `Set_Version` | Sets the version number of the Assembled_Vector object (also has an assignment interface). |
| `Version` | Returns the version number of the Assembled_Vector object. |

**Assembled_Vector public defined type:**

**Assembled_Vector type**

| | |
|---|---|
| `Dimensionality` | The number of dimensions that the "vector" has, including the dimension that is spread over the processors. "Ragged_Right" indices are signified by a Dimensionality of -1. (Ragged_Right is not yet implemented.) |
| `Dimensions` | The extents of the dimensions that the "vector" has, including the dimension that is spread over the processors, which is last. |
| `Initialized` | Initialization status. |
| `Name` | The name for this variable (especially useful in a vector of Assembled Vectors). |
| `NValues_Total` | Total number of values in this vector. |
| `Structure` | Basic data structure for the axis that is spread over the processors. |
| `Values`{$n$} | Values in the vector, only defined on the IO PE. Values may have either 1, 2, 3, or 4 dimensions (n = 1, 2, 3, or 4), or be a ragged right array (n = RR). The last dimension is always the dimension to be spread across the processors. Only one of the variables will be allocated for a given object. Ragged right arrays have not been implemented yet. |
| `Version` | Version number which is incremented every time the vector is modified, or is synced with the version number of a data structure that it depends on when it is updated. |

The Assembled_Vector Class code listing in § D.5 on page 357 contains additional documentation. The Assembled_Vector Class also contains a Unit Test Program which is listed in § D.5.12 on page 373.

### 9.5.1 Initialize_Assembled_Vector Procedure

The Initialize_Assembled_Vector procedure allocates and initializes a Assembled_Vector object.

**Calling syntax:**

```
call Initialize (AV, Structure, Dimensionality, Name, status, dim1, dim2, dim3)
```

**Input variables:**

| | |
|---|---|
| `AV` | The Assembled_Vector object to be initialized. |
| `Structure` | The basic data structure for this Assembled_Vector. |
| `Dimensionality` | The number of dimensions that the "vector" has, including the dimension that is spread over the processors. "Ragged_Right" vectors are signified by a Dimensionality of -1. |
| `Name` | The name for this variable (especially useful in a vector of Assembled Vectors). [Optional] |
| `dim`{$n$} | The dimensions for this "vector". There must be dimensions specified up to a number one less than the Dimensionality. [Optional] |

**Output variables:**

| | |
|---|---|
| `AV` | The Assembled_Vector object has been allocated and initialized. |

| | |
|---|---|
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `Length_PE` | Length on this PE. |

The Initialize_Assembled_Vector code listing in § D.5.1 on page 361 contains additional documentation.

### 9.5.2 Finalize_Assembled_Vector Procedure

The Finalize_Assembled_Vector procedure deallocates and finalizes an Assembled_Vector object.

**Calling syntax:**

```
call Finalize (AV, status)
```

**Input variables:**

| | |
|---|---|
| `AV` | The Assembled_Vector object to be finalized. |

**Output variables:**

| | |
|---|---|
| `AV` | The Assembled_Vector object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Assembled_Vector code listing in § D.5.2 on page 363 contains additional documentation.

### 9.5.3 Valid_State_Assembled_Vector Procedure

The Valid_State_Assembled_Vector procedure returns true iff the Assembled_Vector is in a valid state – that is, iff the Assembled_Vector passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(AV)
```

**Input variables:**

| | |
|---|---|
| `AV` | The Assembled_Vector to be checked. |

**Output variable:**

`Valid_State` True iff the Assembled_Vector is in a valid state.

The Valid_State_Assembled_Vector code listing in § D.5.3 on page 364 contains additional documentation.

### 9.5.4 Initialized_Assembled_Vector Procedure

The Initialized_Assembled_Vector procedure returns true iff the Assembled_Vector object has been initialized.

**Calling syntax:**

```
Logical = Initialized(AV)
```

**Input variable:**

`AV` The Assembled_Vector object to be examined.

**Output variable:**

`Initialized` True iff the Assembled_Vector object has been initialized.

The Initialized_Assembled_Vector code listing in § D.5.4 on page 365 contains additional documentation.

### 9.5.5 Get_Locus_Assembled_Vector Procedure

The Get_Locus_Assembled_Vector procedure returns the locus of the Assembled Vector.

**Calling syntax:**

```
Character = Locus(AV)
```

**Input variable:**

`AV` The Assembled_Vector object to be queried.

**Output variable:**

`Locus` The locus of the Assembled_Vector object.

The Get_Locus_Assembled_Vector code listing in § D.5.5 on page 366 contains additional documentation.

### 9.5.6 Get_Name_Assembled_Vector Procedure

The Get_Name_Assembled_Vector procedure returns the name of the Assembled Vector.

**Calling syntax:**

```
Character = Name(AV)
```

**Input variable:**

`AV` The Assembled_Vector object to be queried.

**Output variable:**

`Name` The name of the Assembled_Vector object.

The Get_Name_Assembled_Vector code listing in § D.5.6 on page 367 contains additional documentation.

### 9.5.7 Get_Values_Assembled_Vector Procedure

The Get_Values_Assembled_Vector procedure gets the values from an Assembled Vector.

**Calling syntax:**

```
Values = AV                         or
call Get_Values (Values, AV)
```

**Input variable:**

`AV` The Assembled_Vector object to be queried.

**Output variable:**

`Values` The bare naked vector of values from the Assembled_Vector object, only defined on the IO PE.

The Get_Values_Assembled_Vector code listing in § D.5.7 on page 367 contains additional documentation.

### 9.5.8 Get_Version_Assembled_Vector Procedure

The Get_Version_Assembled_Vector procedure returns the version number for the Assembled Vector.

**Calling syntax:**

```
Integer = Version(AV)
```

**Input variables:**

`AV` The Assembled_Vector object to be queried.

**Output variable:**

`Version` The version number of the Assembled_Vector object.

The Get_Version_Assembled_Vector code listing in § D.5.8 on page 368 contains additional documentation.

### 9.5.9 Output_Assembled_Vector Procedure

The Output_Assembled_Vector procedure writes out a section of an Assembled Vector to the specified unit.

**Calling syntax:**

```
call Output (AV, First, Last, Unit)
```

**Input variables:**

| | |
|---|---|
| `AV` | The Assembled_Vector object to be queried. |
| `First` | The first location to be output. [Optional] |
| `Last` | The last location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Assembled_Vector code listing in § D.5.9 on page 369 contains additional documentation.

### 9.5.10 Set_Values_Assembled_Vector Procedure

The Set_Values_Assembled_Vector procedure sets the values for the Assembled Vector.

**Calling syntax:**

```
AV = Values                    or
call Set_Values (AV, Values)
```

**Input variable:**

| | |
|---|---|
| `Values` | The bare naked vector of values for the Assembled_Vector object, only defined on the IO PE. |

**Input/Output variable:**

| | |
|---|---|
| `AV` | The Assembled_Vector object to be set. |

**Internal variable:**

| | |
|---|---|
| `Version_Increment` | The amount that the version number is incremented, which is a global class variable. |

The Set_Values_Assembled_Vector code listing in § D.5.10 on page 371 contains additional documentation.

### 9.5.11 Set_Version_Assembled_Vector Procedure

The Set_Version_Assembled_Vector procedure sets the version number for the Assembled Vector.

**Calling syntax:**

```
AV = Version                    or
call Set_Version (AV, Version)
```

**Input variable:**

| | |
|---|---|
| `Version` | The version number for the Assembled_Vector object. |

**Input/Output variable:**

| | |
|---|---|
| `AV` | The Assembled_Vector object to be set. |

The Set_Version_Assembled_Vector code listing in § D.5.11 on page 372 contains additional documentation.

## 9.6 Distributed_Vector Class

The Distributed_Vector Class is used to describe a distributed vector (existing across all the processors) in the CÆSAR Code Package. A Distributed_Vector is part of the overall data structure strategy in CÆSAR, which is made up of the following classes: Base_Structure, Data_Index, Assembled_Vector, Distributed_Vector, Overlapped_Vector, and Collected_Array. A description of the overall data structure strategy can be found in the Data_Structures Module (described in chapter 9 on page 63).

The form of a Distributed_Vector object is given by:

```
Vector ( [dim1, [dim2, [dim3,]]] Structure_Axis )
```

or

```
Vector ( dim_ragged_right, Structure_Axis )
--> not implemented
```

where Structure_Axis refers to the axis which is spread across the processors.

**Distributed_Vector public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a Distributed_Vector object. |
| `Finalize` | Finalizes a Distributed_Vector object. |
| `Valid_State` | Returns false iff a Distributed_Vector object is in an invalid state. |
| `Initialized` | Returns true iff a Distributed_Vector object has been initialized. |
| **Operations** | |
| `Assemble` | Sets an Assembled_Vector object to a Distributed_Vector object by assembling the data on the IO PE (also has an assignment interface). |
| `Distribute` | Sets a Distributed_Vector object to an Assembled_Vector object by distributing the data from the IO PE to all the PEs (also has an assignment interface). |
| `Get_Values` | Gets the values from a Distributed_Vector object and returns them in a bare naked vector (also has an assignment interface). |
| `Locus` | Returns the locus of the Distributed_Vector object. |
| `Name` | Returns the name of the Distributed_Vector object. |
| `Output` | Writes out the Distributed_Vector object. |
| `Set_Values` | Sets the values of the Distributed_Vector object to a bare naked vector (also has an assignment interface). |
| `Set_Version` | Sets the version number of the Distributed_Vector object (also has an assignment interface). |
| `Version` | Returns the version number of the Distributed_Vector object. |

**Distributed_Vector public defined type:**

| **Distributed_Vector type** | |
|---|---|
| `Dimensionality` | The number of dimensions that the index"vector" has, including the dimension that is spread over the processors. "Ragged_Right" indices are signified by a Dimensionality of -1. (Ragged_Right is not yet implemented.) |
| `Dimensions` | The extents of the dimensions that the "vector" has, including the dimension that is spread over the processors, which is last. |
| `Initialized` | Initialization status. |
| `Name` | The name for this variable (especially useful in a vector of Distributed Vectors). |
| `NValues_PE` | Number of values on this PE. |
| `NValues_Total` | Total number of values in the entire vector (including all PEs). |
| `NValues_Vector` | A vector containing the number of values on each PE. |
| `Structure` | Basic data structure for the axis that is spread over the processors. |

| | |
|---|---|
| `Values{n}` | Values in the vector, with a different length on each PE. Values may have either 1, 2, 3, or 4 dimensions (n = 1, 2, 3, or 4), or be a ragged right array (n = RR). The last dimension is always the dimension to be spread across the processors. Only one of the variables will be allocated for a given object. Ragged right arrays have not been implemented yet. |
| `Version` | Version number which is incremented every time the vector is modified, or is synced with the version number of a data structure that it depends on when it is updated. |

The Distributed_Vector Class code listing in § D.6 on page 374 contains additional documentation. The Distributed_Vector Class also contains a Unit Test Program which is listed in § D.6.14 on page 396.

### 9.6.1 Initialize_Distributed_Vector Procedure

The Initialize_Distributed_Vector procedure allocates and initializes a Distributed_Vector object.

**Calling syntax:**

```
call Initialize (DV, Structure, Dimensionality, Name, status, dim1, dim2, dim3)
```

**Input variables:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be initialized. |
| `Structure` | The basic data structure for this Distributed_Vector. |
| `Dimensionality` | The number of dimensions that the "vector" has, including the dimension that is spread over the processors. "Ragged_Right" vectors are signified by a Dimensionality of -1. |
| `Name` | The name for this variable (especially useful in a vector of Distributed Vectors). [Optional] |
| `dim{n}` | The dimensions for this "vector". There must be dimensions specified up to a number one less than the Dimensionality. [Optional] |

**Output variables:**

| | |
|---|---|
| `DV` | The Distributed_Vector object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |
| `NSlice` | Number of values that are on one slice, given by a constant location on the distributed axis. |

The Initialize_Distributed_Vector code listing in § D.6.1 on page 378 contains additional documentation.

### 9.6.2 Finalize_Distributed_Vector Procedure

The Finalize_Distributed_Vector procedure deallocates and finalizes an Distributed_Vector object.

**Calling syntax:**

```
call Finalize (DV, status)
```

**Input variables:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be finalized. |

**Output variables:**

| | |
|---|---|
| `DV` | The Distributed_Vector object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Distributed_Vector code listing in § D.6.2 on page 381 contains additional documentation.

### 9.6.3 Valid_State_Distributed_Vector Procedure

The Valid_State_Distributed_Vector procedure returns true iff the Distributed_Vector is in a valid state – that is, iff the Distributed_Vector passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(DV)
```

**Input variables:**

| | |
|---|---|
| `DV` | The Distributed_Vector to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Distributed_Vector is in a valid state. |

The Valid_State_Distributed_Vector code listing in § D.6.3 on page 382 contains additional documentation.

### 9.6.4 Initialized_Distributed_Vector Procedure

The Initialized_Distributed_Vector procedure returns true iff the Distributed_Vector object has been initialized.

**Calling syntax:**

```
Logical = Initialized(DV)
```

**Input variable:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be examined. |

**Output variable:**

`Initialized` True iff the Distributed_Vector object has been initialized.

The Initialized_Distributed_Vector code listing in § D.6.4 on page 384 contains additional documentation.

### 9.6.5 Assemble_AV_from_DV Procedure

The Assemble_AV_from_DV procedure sets an Assembled Vector to a Distributed Vector by assembling the data on the IO PE.

**Calling syntax:**

```
AV = DV                    or
call Assemble (AV, DV)
```

**Input variable:**

`DV` The Distributed_Vector object to be assembled.

**Output variable:**

`AV` The Assembled_Vector object, completely on the IO PE.

The Assemble_AV_from_DV code listing in § D.6.5 on page 384 contains additional documentation.

### 9.6.6 Distribute_AV_to_DV Procedure

The Distribute_AV_to_DV procedure sets a Distributed Vector to an Assembled Vector by distributing the data from the IO PE to all the PEs.

**Calling syntax:**

```
DV = AV                    or
call Distribute (DV, AV)
```

**Input variable:**

`AV` The Assembled_Vector object to be distributed.

**Output variable:**

`DV` The Distributed_Vector object, distributed over all the PEs.

The Distribute_AV_to_DV code listing in § D.6.6 on page 386 contains additional documentation.

### 9.6.7 Get_Locus_Distributed_Vector Procedure

The Get_Locus_Distributed_Vector procedure returns the locus of the Distributed Vector.

**Calling syntax:**

```
Character = Locus(DV)
```

**Input variable:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be queried. |

**Output variable:**

| | |
|---|---|
| `Locus` | The locus of the Distributed_Vector object. |

The Get_Locus_Distributed_Vector code listing in § D.6.7 on page 387 contains additional documentation.

### 9.6.8 Get_Name_Distributed_Vector Procedure

The Get_Name_Distributed_Vector procedure returns the name of the Distributed Vector.

**Calling syntax:**

```
Character = Name(DV)
```

**Input variable:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be queried. |

**Output variable:**

| | |
|---|---|
| `Name` | The name of the Distributed_Vector object. |

The Get_Name_Distributed_Vector code listing in § D.6.8 on page 388 contains additional documentation.

### 9.6.9 Get_Values_Distributed_Vector Procedure

The Get_Values_Distributed_Vector procedure gets the values from a Distributed Vector.

**Calling syntax:**

```
Values = DV                     or
call Get_Values (Values, DV)
```

**Input variable:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be queried. |

**Output variable:**

| | |
|---|---|
| `Values` | The bare naked vector of values from the Distributed_Vector object, defined differently on each PE. |

The Get_Values_Distributed_Vector code listing in § D.6.9 on page 388 contains additional documentation.

### 9.6.10 Get_Version_Distributed_Vector Procedure

The Get_Version_Distributed_Vector procedure returns the version number for the Distributed Vector.

**Calling syntax:**

```
Integer = Version(DV)
```

**Input variables:**

`DV` The Distributed_Vector object to be queried.

**Output variable:**

`Version` The version number of the Distributed_Vector object.

The Get_Version_Distributed_Vector code listing in § D.6.10 on page 389 contains additional documentation.

### 9.6.11 Output_Distributed_Vector Procedure

The Output_Distributed_Vector procedure writes out a section of a Distributed Vector to the specified unit.

**Calling syntax:**

```
call Output (DV, First, Last, Unit, Indent)
```

**Input variables:**

| | |
|---|---|
| `DV` | The Distributed_Vector object to be queried. |
| `First` | The first location to be output. [Optional] |
| `Last` | The last location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Indent` | Number of indentation characters. [Optional] |

The Output_Distributed_Vector code listing in § D.6.11 on page 390 contains additional documentation.

### 9.6.12 Set_Values_Distributed_Vector Procedure

The Set_Values_Distributed_Vector procedure sets the values for the Distributed Vector.

**Calling syntax:**

```
DV = Values                    or
call Set_Values (DV, Values)
```

**Input variable:**

`Values` The bare naked vector of values for the Distributed_Vector object, defined differently on each PE.

**Input/Output variable:**

`DV` The Distributed_Vector object to be set.

**Internal variable:**

`Version_Increment` The amount that the version number is incremented, which is a global class variable.

The Set_Values_Distributed_Vector code listing in § D.6.12 on page 394 contains additional documentation.

### 9.6.13 Set_Version_Distributed_Vector Procedure

The Set_Version_Distributed_Vector procedure sets the version number for the Distributed Vector.

**Calling syntax:**

```
DV = Version                      or
call Set_Version (DV, Version)
```

**Input variable:**

`Version` The version number for the Distributed_Vector object.

**Input/Output variable:**

`DV` The Distributed_Vector object to be set.

The Set_Version_Distributed_Vector code listing in § D.6.13 on page 395 contains additional documentation.

## 9.7 Overlapped_Vector Class

The Overlapped_Vector Class is used to describe an overlapped vector (existing across all the processors) in the CÆSAR Code Package. An Overlapped_Vector is part of the overall data structure strategy in CÆSAR, which is made up of the following classes: Base_Structure, Data_Index, Assembled_Vector, Distributed_Vector, Overlapped_Vector, and Collected_Array. A description of the overall data structure strategy can be found in the Data_Structures Module (described in chapter 9 on page 63).

The form of a collected Overlapped_Vector object is given by:

```
Array ( [dim1, [dim2, [dim3,]]] One_Axis [, Many_Axis] )
```

or

```
Array ( dim_ragged_right, One_Axis [, Many_Axis] )
--> not implemented
```

where One_Axis refers to the axis which is spread across the processors.

**Overlapped_Vector public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes an Overlapped_Vector object. |
| `Finalize` | Finalizes an Overlapped_Vector object. |
| `Valid_State` | Returns false iff an Overlapped_Vector object is in an invalid state. |
| `Initialized` | Returns true iff an Overlapped_Vector object has been initialized. |
| **Operations** | |
| `Collect_and_Access` | Another name for Get_Values. |
| `Collect_and_Combine` | Collects the values from an Overlapped Vector, and then combines them to form a Distributed Vector, according to the internal Many_of_One_Index object. The resultant Distributed Vector is distributed according to the One Structure of the Overlapped Vector. A combination operator, to be put in the place of "Combine", must be specified. Allowed values for "Combine" are: `Average`, `MAX`, `MIN`, or `SUM`. Collect_and_SUM also has an assignment interface. |

| | |
|---|---|
| `Gather` | Does the communication necessary to set an Overlapped Vector from a Distributed Vector (also has an assignment interface). |
| `Get_Values` | Collects and accesses the values from an Overlapped_Vector object and returns them in a bare naked array (also has an assignment interface). |
| `Many_Locus` | Returns the Many Structure locus of the Overlapped_Vector object. |
| `Name` | Returns the name of the Overlapped_Vector object. |
| `One_Locus` | Returns the One Structure locus of the Overlapped_Vector object. |
| `Output` | Writes out the Overlapped_Vector object. |
| `Set_Version` | Sets the version number of the Overlapped_Vector object (also has an assignment interface). |
| `Version` | Returns the version number of the Overlapped_Vector object. |

**Overlapped_Vector public defined type:**

**Overlapped_Vector type**

| | |
|---|---|
| `Dimensionality` | The number of dimensions that the "vector" has, including the dimension that is spread over the processors. "Ragged_Right" indices are signified by a Dimensionality of -1. (Ragged_Right is not yet implemented.) |
| `Dimensions` | The extents of the dimensions that the "vector" has, including the dimension that is spread over the processors, which is last. |
| `DV` | A pointer to the Distributed Vector that this Overlapped Vector is based on. |
| `DV_Internal` | An internal Distributed Vector that is constructed if the Overlapped Vector is not based on an external Distributed Vector. |
| `Initialized` | Initialization status. |
| `Many_of_One_Index` | The Index that is used to modify the Distributed Vector. |
| `Many_Structure` | Basic data structure which corresponds to the structure of the Distributed Vector that this Overlapped Vector is based on. |
| `Name` | The name for this variable (especially useful in a vector of Overlapped Vectors). |
| `One_Structure` | Basic data structure which corresponds to the way that this Overlapped Vector has been formed. If this Overlapped Vector were to be combined, it would result in a Distributed Vector with a One_Structure basis. |
| `Overlap_Index` | The index for the distributed axis of the off-PE values. |
| `Overlap_Trace` | The trace for the distributed axis of the off-PE values. |
| `Overlap_Values`$\{n\}$ | Off-PE values in the vector, that are stored locally, with a different length on each PE. Values may have either 1, 2, 3, or 4 dimensions (n = 1, 2, 3, or 4), or be a ragged right array (n = RR). The last dimension is always the dimension to be spread across the processors. Only one of the variables will be allocated for a given object. Ragged right arrays have not been implemented yet. |
| `Version` | Version number which is incremented every time the vector is modified, or is synced with the version number of a data structure that it depends on when it is updated. |

The Overlapped_Vector Class code listing in § D.7 on page 398 contains additional documentation. The Overlapped_Vector Class also contains a Unit Test Program which is listed in § D.7.13 on page 428.

## 9.7.1 Initialize_Overlapped_Vector Procedure

The Initialize_Overlapped_Vector procedure allocates and initializes a Overlapped_Vector object. There are two ways to initialize an Overlapped_Vector object, depending on whether or not the underlying Distributed_-Vector object is internally created.

**Calling syntax:**

```
call Initialize (OV, DV, Many_of_One_Index, Name, status)                        or
call Initialize (OV, Many_of_One_Index, Dimensionality, Name, status, dim1, dim2, dim3)
```

**Input variables:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be initialized. |
| `DV` | The Distributed_Vector object which the Overlapped_Vector is to be based on. |
| `Many_of_One_Index` | An index giving the relationship of the "Many" and "One" axes to each other for this Overlapped_Vector. |
| `Dimensionality` | The number of dimensions that the "vector" has, including the dimension that is spread over the processors. "Ragged_Right" vectors are signified by a Dimensionality of -1. |
| `Name` | The name for this variable (especially useful in a vector of Overlapped Vectors). [Optional] |
| `dim`$\{n\}$ | The dimensions for this "vector". There must be dimensions specified up to a number one less than the Dimensionality. These are only needed in the second form of the call. [Optional] |

**Output variables:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Overlapped_Vector code listing in § D.7.1 on page 402 contains additional documentation.

### 9.7.2 Finalize_Overlapped_Vector Procedure

The Finalize_Overlapped_Vector procedure deallocates and finalizes an Overlapped_Vector object.

**Calling syntax:**

```
call Finalize (OV, status)
```

**Input variables:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be finalized. |

**Output variables:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Overlapped_Vector code listing in § D.7.2 on page 406 contains additional documentation.

### 9.7.3 Valid_State_Overlapped_Vector Procedure

The Valid_State_Overlapped_Vector procedure returns true iff the Overlapped_Vector is in a valid state – that is, iff the Overlapped_Vector passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(OV)
```

**Input variables:**

`OV` The Overlapped_Vector to be checked.

**Output variable:**

`Valid_State` True iff the Overlapped_Vector is in a valid state.

The Valid_State_Overlapped_Vector code listing in § D.7.3 on page 408 contains additional documentation.

### 9.7.4 Initialized_Overlapped_Vector Procedure

The Initialized_Overlapped_Vector procedure returns true iff the Overlapped_Vector object has been initialized.

**Calling syntax:**

```
Logical = Initialized(OV)
```

**Input variable:**

`OV` The Overlapped_Vector object to be examined.

**Output variable:**

`Initialized` True iff the Overlapped_Vector object has been initialized.

The Initialized_Overlapped_Vector code listing in § D.7.4 on page 409 contains additional documentation.

### 9.7.5 Collect_and_Combine_DV_from_OV Procedure

The Collect_and_Combine_DV_from_OV procedures collect the values from an Overlapped Vector, and then combine them to form a Distributed Vector. Specifically, each procedure does a Collect and Combine on the data in the Overlapped Vector, with the same result that would occur if an intermediate Collected Array had been constructed. (Collect_and_Conserve has not been implemented yet.)

**Calling syntax:**

```
call Collect_and_Average (DV, OV)     ,
call Collect_and_Conserve (DV, OV)    ,
call Collect_and_MAX (DV, OV)         ,
call Collect_and_MIN (DV, OV)         ,
call Collect_and_SUM (DV, OV)         or
DV = OV [Collect_and_SUM]
```

**Input variable:**

`OV` The Overlapped_Vector object to be queried.

**Output variable:**

`DV` The Distributed_Vector object result, distributed with the One_Structure of the Overlapped_Vector object.

The Collect_and_Combine_DV_from_OV code listing in § D.7.5 on page 410 contains additional documentation.

### 9.7.6 Gather_OV_from_DV Procedure

The Gather_OV_from_DV procedure does the communication necessary to set an Overlapped Vector from a Distributed Vector. No communication is done if the Overlapped Vector is already up-to-date with the Distributed Vector.

**Calling syntax:**

```
OV = DV                   or
call Gather (OV, DV)
```

**Input variable:**

`DV` The Distributed_Vector object to be gathered.

**Output variable:**

`OV` The Overlapped_Vector object, updated to correspond with the input Distributed_-Vector object.

The Gather_OV_from_DV code listing in § D.7.6 on page 415 contains additional documentation.

### 9.7.7 Get_Locus_Overlapped_Vector Procedure

The Get_Many_Locus_OV and Get_One_Locus_OV procedures return the loci of the Many and One Structures of the Overlapped Vector respectively.

**Calling syntax:**

```
Character = Many_Locus(OV)    or
Character = One_Locus(OV)
```

**Input variable:**

`OV` The Overlapped_Vector object to be queried.

**Output variable:**

| | |
|---|---|
| `Locus` | The specified locus of the Overlapped_Vector object. |

The Get_Locus_Overlapped_Vector code listing in § D.7.7 on page 417 contains additional documentation.

### 9.7.8 Get_Name_Overlapped_Vector Procedure

The Get_Name_Overlapped_Vector procedure returns the name of the Overlapped Vector.

**Calling syntax:**

```
Character = Name(OV)
```

**Input variable:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be queried. |

**Output variable:**

| | |
|---|---|
| `Name` | The name of the Overlapped_Vector object. |

The Get_Name_Overlapped_Vector code listing in § D.7.8 on page 417 contains additional documentation.

### 9.7.9 Get_Values_Overlapped_Vector Procedure

The Get_Values_Overlapped_Vector procedure gets the values from an Overlapped Vector, in the form of a Bare Naked Array. Specifically, it does a Collect and Access on the data in the Overlapped Vector, with the same result that would occur if an intermediate Collected Array had been constructed.

**Calling syntax:**

```
Values = OV                              ,
call Get_Values (Values, OV)             or
call Collect_and_Access (Values, OV)
```

**Input variable:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be queried. |

**Output variable:**

| | |
|---|---|
| `Values` | The bare naked array of values from the Overlapped_Vector object, defined differently on each PE. |

The Get_Values_Overlapped_Vector code listing in § D.7.9 on page 418 contains additional documentation.

### 9.7.10 Get_Version_Overlapped_Vector Procedure

The Get_Version_Overlapped_Vector procedure returns the version number for the Overlapped Vector.

**Calling syntax:**

```
Integer = Version(OV)
```

**Input variables:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be queried. |

**Output variable:**

| | |
|---|---|
| `Version` | The version number of the Overlapped_Vector object. |

The Get_Version_Overlapped_Vector code listing in § D.7.10 on page 423 contains additional documentation.

### 9.7.11 Output_Overlapped_Vector Procedure

The Output_Overlapped_Vector procedure writes out a section of an Overlapped Vector to the specified unit.

**Calling syntax:**

```
call Output (OV, Many_First, Many_Last, One_First, One_Last, Unit)
```

**Input variables:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be queried. |
| `Many_First` | The first location on the Many Axis to be output. [Optional] |
| `Many_Last` | The last location on the Many Axis to be output. [Optional] |
| `One_First` | The first location on the One Axis to be output. [Optional] |
| `One_Last` | The last location on the One Axis to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Overlapped_Vector code listing in § D.7.11 on page 424 contains additional documentation.

### 9.7.12 Set_Version_Overlapped_Vector Procedure

The Set_Version_Overlapped_Vector procedure sets the version number for the Overlapped Vector.

**Calling syntax:**

```
OV = Version                      or
call Set_Version (OV, Version)
```

**Input variable:**

| | |
|---|---|
| `Version` | The version number for the Overlapped_Vector object. |

**Input/Output variable:**

| | |
|---|---|
| `OV` | The Overlapped_Vector object to be set. |

The Set_Version_Overlapped_Vector code listing in § D.7.12 on page 428 contains additional documentation.

## 9.8 Collected_Array Class

The Collected_Array Class is used to describe a collected array (existing across all the processors) in the CÆSAR Code Package. A Collected_Array is part of the overall data structure strategy in CÆSAR, which is made up of the following classes: Base_Structure, Data_Index, Assembled_Vector, Distributed_Vector, Overlapped_Vector, and Collected_Array. A description of the overall data structure strategy can be found in the Data_Structures Module (described in chapter 9 on page 63).

The form of a Collected_Array object is given by:

```
Array ( [dim1, [dim2, [dim3,]]] One_Axis [, Many_Axis] )
```

or

```
Array ( dim_ragged_right, One_Axis [, Many_Axis] )
--> not implemented
```

where One_Axis refers to the axis which is spread across the processors.

**Collected_Array public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a Collected_Array object. |
| `Finalize` | Finalizes a Collected_Array object. |
| `Valid_State` | Returns false iff a Collected_Array object is in an invalid state. |
| `Initialized` | Returns true iff a Collected_Array object has been initialized. |
| **Operations** | |
| `Collect` | Collects the values from an Overlapped Vector and stores them in a Collected Array. |
| `Combine_with_Op` | Combines the values from a Collected Array, to form a Distributed Vector. The resultant Distributed Vector is distributed according to the One Structure of the Collected Array. A combination operator, to be put in the place of "Op", must be specified. Allowed values for "Op" are: `Average`, `MAX`, `MIN`, or `SUM`. Combine_with_-SUM also has an assignment interface. |
| `Gather` | Does the communication necessary to set a Collected Array from a Distributed Vector (also has an assignment interface). |
| `Gather_and_Collect` | Another name for Gather. |
| `Get_Values` | Accesses the values from a Collected_Array object and returns them in a Bare Naked Array (also has an assignment interface). |
| `Many_Locus` | Returns the Many Structure locus of the Collected_Array object. |
| `Name` | Returns the name of the Collected_Array object. |
| `One_Locus` | Returns the One Structure locus of the Collected_Array object. |
| `Output` | Writes out the Collected_Array object. |
| `Set_Values` | Sets the values of the Collected_Array object to a Bare Naked Array (also has an assignment interface). |
| `Set_Version` | Sets the version number of the Collected_Array object (also has an assignment interface). |
| `Version` | Returns the version number of the Collected_Array object. |

**Collected_Array public defined type:**

| **Collected_Array type** | |
|---|---|
| `A_Dimensionality` | The actual number of dimensions that the "array" has, including the dimension that is spread over the processors (the One_Axis), and also including the Many_-Axis, if it is present. "Ragged_Right" indices are signified by a Dimensionality of -1. (Ragged_Right is not yet implemented.) |

| | |
|---|---|
| `Dimensionality` | The number of dimensions that the "array" has, including the dimension that is spread over the processors (the One_Axis), but not including the Many_Axis, if it is present. "Ragged_Right" indices are signified by a Dimensionality of -1. (Ragged_-Right is not yet implemented.) |
| `Dimensions` | The extents of the dimensions that the "array" has, including the dimensions for the One_Axis and the Many_Axis. |
| `Initialized` | Initialization status. |
| `Many_of_One_Index` | The Index that is used to translate between the Distributed Vectors. |
| `Many_Structure` | Basic data structure which corresponds to the structure of the Distributed Vector that this Collected Array is based on. |
| `Name` | The name for this variable (especially useful in a vector of Collected Arrays). |
| `One_Structure` | Basic data structure which corresponds to the way that this Collected Array has been formed. If this Collected Array were to be combined, it would result in a Distributed Vector with a One_Structure basis. |
| `Values`$\{n\}$ | Values in the array, that are stored locally, with a different length on each PE. Values may have either 1, 2, 3, 4, or 5 dimensions (n = 1, 2, 3, 4, or 5), or be a ragged right array (n = RR). The last dimension is the dimension that is spread across the processors, if the Many_of_One_Index is a vector index. Otherwise, the penultimate axis will be spread across the processors. Only one of the variables will be allocated for a given object. Ragged right arrays have not been implemented yet. |
| `Version` | Version number which is incremented every time the array is modified, or is synced with the version number of a data structure that it depends on when it is updated. |

The Collected_Array Class code listing in § D.8 on page 432 contains additional documentation. The Collected_Array Class also contains a Unit Test Program which is listed in § D.8.15 on page 461.

### 9.8.1 Initialize_Collected_Array Procedure

The Initialize_Collected_Array procedure allocates and initializes a Collected_Array object. There are two ways to initialize an Collected_Array object, depending on whether or not the underlying Distributed_Vector object is internally created.

**Calling syntax:**

```
call Initialize (CA, OV, Name, status)
```

or

```
call Initialize (CA, Many_of_One_Index, Dimensionality, Name, status, dim1, dim2, dim3)
```

**Input variables:**

| | |
|---|---|
| `CA` | The Collected_Array object to be initialized. |
| `OV` | An Overlapped_Vector object which the Collected_Array is to be based on. Note that the Collected_Array will not *contain* the Overlapped_Vector or require the Overlapped_Vector to be used in an assignment statement, but rather the Collected_Array will have a structure that is compatible with the Overlapped_Vector and will be set to the Overlapped_Vector during initialization. |
| `Many_of_One_Index` | An index giving the relationship of the "Many" and "One" axes to each other for this Collected_Array. |
| `Dimensionality` | The number of dimensions that the "array" has, including the dimension that is spread over the processors (the One_Axis), but not including the Many_Axis, if it is present. "Ragged_Right" vectors are signified by a Dimensionality of -1. |
| `Name` | The name for this variable (especially useful in a vector of Collected Arrays). [Optional] |

`dim{n}` The dimensions for this "array". There must be dimensions specified up to a number one less than the Dimensionality. These are only needed in the second form of the call. [Optional]

**Output variables:**

| | |
|---|---|
| `CA` | The Collected_Array object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Collected_Array code listing in § D.8.1 on page 437 contains additional documentation.

### 9.8.2 Finalize_Collected_Array Procedure

The Finalize_Collected_Array procedure deallocates and finalizes an Collected_Array object.

**Calling syntax:**

```
call Finalize (CA, status)
```

**Input variables:**

| | |
|---|---|
| `CA` | The Collected_Array object to be finalized. |

**Output variables:**

| | |
|---|---|
| `CA` | The Collected_Array object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Collected_Array code listing in § D.8.2 on page 442 contains additional documentation.

### 9.8.3 Valid_State_Collected_Array Procedure

The Valid_State_Collected_Array procedure returns true iff the Collected_Array is in a valid state – that is, iff the Collected_Array passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(CA)
```

**Input variables:**

`CA` The Collected_Array to be checked.

**Output variable:**

`Valid_State` True iff the Collected_Array is in a valid state.

The Valid_State_Collected_Array code listing in § D.8.3 on page 443 contains additional documentation.

### 9.8.4 Initialized_Collected_Array Procedure

The Initialized_Collected_Array procedure returns true iff the Collected_Array object has been initialized.

**Calling syntax:**

```
Logical = Initialized(CA)
```

**Input variable:**

`CA` The Collected_Array object to be examined.

**Output variable:**

`Initialized` True iff the Collected_Array object has been initialized.

The Initialized_Collected_Array code listing in § D.8.4 on page 445 contains additional documentation.

### 9.8.5 Collect_CA_from_OV Procedure

The Collect_CA_from_OV procedure collects the values from an Overlapped Vector to form a Collected Array.

**Calling syntax:**

```
call Collect (CA, OV)    or
CA = OV
```

**Input variable:**

`OV` The Overlapped_Vector object to be queried.

**Output variable:**

`CA` The Collected_Array object result.

The Collect_CA_from_OV code listing in § D.8.5 on page 446 contains additional documentation.

### 9.8.6 Combine_DV_from_CA Procedure

The Combine_DV_from_CA procedures combine the values from a Collected Array to form a Distributed Vector. (Conserve has not been implemented yet.)

**Calling syntax:**

```
call Combine_with_Average (DV, CA)    ,
call Combine_with_Conserve (DV, CA)   ,
call Combine_with_MAX (DV, CA)        ,
call Combine_with_MIN (DV, CA)        ,
call Combine_with_SUM (DV, CA)        or
DV = CA [SUM]
```

**Input variable:**

CA The Collected_Array object to be queried.

**Output variable:**

DV The Distributed_Vector object result, distributed with the One_Structure of the Collected_Array object.

The Combine_DV_from_CA code listing in § D.8.6 on page 447 contains additional documentation.

### 9.8.7 Gather_and_Collect_CA_from_DV Procedure

The Gather_and_Collect_CA_from_DV procedure does the communication necessary to set a Collected Array from a Distributed Vector, according to the Many_of_One_Index which is inside the Collected Array. No communication is done if the Collected Array is already up-to-date with the Distributed Vector.

**Calling syntax:**

```
CA = DV                             ,
call Gather (CA, DV)                or
call Gather_and_Collect (CA, DV)
```

**Input variable:**

DV The Distributed_Vector object to be gathered.

**Output variable:**

CA The Collected_Array object, updated to correspond with the input Distributed_-Vector object.

The Gather_and_Collect_CA_from_DV code listing in § D.8.7 on page 449 contains additional documentation.

### 9.8.8 Get_Locus_Collected_Array Procedure

The Get_Many_Locus_CA and Get_One_Locus_CA procedures return the loci of the Many and One Structures of the Collected Array respectively.

**Calling syntax:**

```
Character = Many_Locus(CA)    or
Character = One_Locus(CA)
```

**Input variable:**

CA The Collected_Array object to be queried.

**Output variable:**

Locus The specified locus of the Collected_Array object.

The Get_Locus_Collected_Array code listing in § D.8.8 on page 451 contains additional documentation.

### 9.8.9 Get_Name_Collected_Array Procedure

The Get_Name_Collected_Array procedure returns the name of the Collected Array.

**Calling syntax:**

```
Character = Name(CA)
```

**Input variable:**

CA The Collected_Array object to be queried.

**Output variable:**

Name The name of the Collected_Array object.

The Get_Name_Collected_Array code listing in § D.8.9 on page 452 contains additional documentation.

### 9.8.10 Get_Values_Collected_Array Procedure

The Get_Values_Collected_Array procedure gets the values from an Collected Array, in the form of a Bare Naked Array.

**Calling syntax:**

```
Values = CA                        or
call Get_Values (Values, CA)
```

**Input variable:**

CA The Collected_Array object to be queried.

**Output variable:**

Values The Bare Naked Array of values from the Collected_Array object, defined differently on each PE.

The Get_Values_Collected_Array code listing in § D.8.10 on page 453 contains additional documentation.

### 9.8.11 Get_Version_Collected_Array Procedure

The Get_Version_Collected_Array procedure returns the version number for the Collected Array.

**Calling syntax:**

```
Integer = Version(CA)
```

**Input variables:**

`CA` The Collected_Array object to be queried.

**Output variable:**

`Version` The version number of the Collected_Array object.

The Get_Version_Collected_Array code listing in § D.8.11 on page 454 contains additional documentation.

### 9.8.12 Output_Collected_Array Procedure

The Output_Collected_Array procedure writes out a section of a Collected Array to the specified unit.

**Calling syntax:**

```
call Output (CA, One_First, One_Last, Unit)
```

**Input variables:**

| | |
|---|---|
| `CA` | The Collected_Array object to be queried. |
| `One_First` | The first location on the One Axis to be output. [Optional] |
| `One_Last` | The last location on the One Axis to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Collected_Array code listing in § D.8.12 on page 454 contains additional documentation.

### 9.8.13 Set_Values_Collected_Array Procedure

The Set_Values_Collected_Array procedure sets the values for the Collected Array.

**Calling syntax:**

```
CA = Values                          or
call Set_Values (CA, Values)
```

**Input variable:**

`Values` The Bare Naked Array of values for the Collected_Array object, defined differently on each PE.

**Input/Output variable:**

`CA` The Collected_Array object to be set.

**Internal variable:**

`Version_Increment` The amount that the version number is incremented, which is a global class variable.

The Set_Values_Collected_Array code listing in § D.8.13 on page 459 contains additional documentation.

### 9.8.14 Set_Version_Collected_Array Procedure

The Set_Version_Collected_Array procedure sets the version number for the Collected Array.

**Calling syntax:**

```
CA = Version                          or
call Set_Version (CA, Version)
```

**Input variable:**

`Version` The version number for the Collected_Array object.

**Input/Output variable:**

`CA` The Collected_Array object to be set.

The Set_Version_Collected_Array code listing in § D.8.14 on page 460 contains additional documentation.

# Chapter 10

# Mathematics Module

*To those who do not know mathematics it is difficult to get across a real feeling as to the beauty, the deepest beauty of nature. If you want to learn about nature, to appreciate nature, it is necessary to understand the language that she speaks in. – Richard Feynman (1918-1988)*

*Anyone who cannot cope with mathematics is not fully human. At best he is a tolerable subhuman who has learned to wear boots, bathe, and not make messes in the house. – Robert Heinlein, "Time Enough for Love"*

*. . . beware of mathematicians and all those who make empty prophecies. The danger already exists that mathematicians have made a covenant with the devil to darken the spirit and confine man in the bonds of Hell. – St. Augustine, DeGenesi ad Litteram*

Many mathematical constructions are repeated over and over in a large computer code. In the CÆSAR code package, they are all grouped together to ensure that they are done in a consistent, correct manner which is easily updated.

The Mathematics Module code listing in § E on page 467 contains additional documentation.

## 10.1 Math_Utils Module

The Math_Utils Module provides utility routines to solve mathematical problems for the CÆSAR Code Package.

The Math_Utils methods section in § 15.1 on page 185 describes the methods used in the Math_Utils Class.

**Math_Utils public procedures:**

`Prime_Factors` Returns a vector containing the prime factorization of a number.

The Math_Utils Module code listing in § E.1 on page 467 contains additional documentation. The Math_Utils Module also contains a Unit Test Program which is listed in § E.1.2 on page 471.

### 10.1.1 Prime_Factors_Math_Utils Procedure

The Prime_Factors_Math_Utils procedure returns a vector of the prime factors for a given number. For negative numbers, it returns a vector with "-1" in the first position and then the prime factorization for the corresponding positive number. For zero, it returns a single zero as the prime factorization. The procedure

gives correct answers for all integers in the range [-HUGE(),HUGE()].

**Calling syntax:**

```
call Prime_Factors (Number, NFactors, Factors, Verbose)
```

**Input variables:**

| | |
|---|---|
| `Number` | The number to be factored. |
| `Verbose` | Toggle for output. Default is false. [optional] |

**Output variables:**

| | |
|---|---|
| `NFactors` | The number of prime factors. |
| `Factors(32)` | A vector of the prime factors. |

The Prime_Factors_Math_Utils code listing in § E.1.1 on page 468 contains additional documentation.

## 10.2 Statistics Class

The Statistics Class is used to describe a Statistics object in the CÆSAR Code Package. A Statistics object contains statistical information about a set of values that have been added to it. The statistical information that is available includes means (arithmetic, geometric and harmonic), extrema and the standard deviation. It does not include information that would require the storage of the entire set of values, such as median and mode.

The Statistics methods section in § 15.2 on page 186 describes the methods used in the Statistics Class.

**Statistics public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes a Statistics object. |
| `Finalize` | Finalizes a Statistics object. |
| `Valid_State` | Returns false iff a Statistics object is in an invalid state. |
| `Initialized` | Returns true iff a Statistics object has been initialized. |
| **Operations** | |
| `Add_Value` | Adds a value to the data set of the Statistics object. |
| `Arithmetic_Mean` | Returns the arithmetic mean of the Statistics object. |
| `Average` | Returns the arithmetic mean of the Statistics object. |
| `Count` | Returns the number of values in the Statistics object. |
| `Geometric_Mean` | Returns the geometric mean of the Statistics object. |
| `Harmonic_Mean` | Returns the harmonic mean of the Statistics object. |
| `Maximum` | Returns the maximum value of the Statistics object. |
| `Mean` | Returns the arithmetic mean of the Statistics object. |
| `Minimum` | Returns the minimum value of the Statistics object. |
| `Name` | Returns the name of the Statistics object. |
| `Output` | Writes out the Statistics object. |
| `Standard_Deviation` | Returns the standard deviation of the Statistics object. |
| `Sum` | Returns the sum or total of the Statistics object. |
| `Total` | Returns the sum or total of the Statistics object. |
| `Totally_Positive` | Returns true if all the values in the Statistics object are positive. |
| `Update_Global` | Communicates with all processors to update the global information for the Statistics object. |

**Statistics public defined types:**

| **Statistics type** | |
|---|---|
| `Global_Arithmetic_Mean` | The global arithmetic mean. |
| `Global_Count` | The global number of items in the data set. |
| `Global_Geometric_Mean` | The global geometric mean. |
| `Global_Harmonic_Mean` | The global harmonic mean. |
| `Global_Log_Sum` | The global sum of the log of the values. |
| `Global_Maximum` | The global maximum of the values. |
| `Global_Minimum` | The global minimum of the values. |
| `Global_Reciprocal_Sum` | The global sum of the reciprocal of the values. |
| `Global_Squared_Sum` | The global sum of the squares of the values. |
| `Global_Standard_Deviation` | The global standard deviation. |
| `Global_Sum` | The global sum of values. |
| `Global_Totally_Positive` | True if all items in the data set on all PEs are positive. |
| `Global_Updated` | Global update status. |
| `Initialized` | Initialization status. |
| `Name` | The name for this Statistics object. |
| `PE_Arithmetic_Mean` | The arithmetic mean on this PE. |
| `PE_Count` | The number of items in the data set on this PE. |
| `PE_Geometric_Mean` | The geometric mean on this PE. |
| `PE_Harmonic_Mean` | The harmonic mean on this PE. |
| `PE_Log_Sum` | The sum of the log of the values on this PE. |
| `PE_Maximum` | The maximum of the values on this PE. |
| `PE_Minimum` | The minimum of the values on this PE. |
| `PE_Reciprocal_Sum` | The sum of the reciprocal of the values on this PE. |
| `PE_Squared_Sum` | The sum of the squares of the values on this PE. |
| `PE_Standard_Deviation` | The standard deviation on this PE. |
| `PE_Sum` | The sum of values on this PE. |
| `PE_Totally_Positive` | True if all items in the data set on this PE are positive. |

The Statistics Class code listing in § E.2 on page 472 contains additional documentation. The Statistics Class also contains a Unit Test Program which is listed in § E.2.9 on page 489.

### 10.2.1 Initialize_Statistics Procedure

The Initialize_Statistics procedure allocates and initializes a Statistics object.

**Calling syntax:**

```
call Initialize (Statistics, Name, status)
```

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics object to be initialized. |
| `Name` | The name for the Statistics object. |

**Output variables:**

| | |
|---|---|
| `Statistics` | The Statistics object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Statistics code listing in § E.2.1 on page 474 contains additional documentation.

### 10.2.2 Finalize_Statistics Procedure

The Finalize_Statistics procedure deallocates and finalizes a Statistics object.

**Calling syntax:**

```
call Finalize (Statistics, status)
```

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Statistics` | The Statistics object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Statistics code listing in § E.2.2 on page 477 contains additional documentation.

### 10.2.3 Valid_State_Statistics Procedure

The Valid_State_Statistics procedure returns true iff the Statistics is in a valid state – that is, iff the Statistics passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Statistics)
```

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Statistics is in a valid state. |

**Internal variables:**

| | |
|---|---|
| `Global_Mean_Range` | Global range of the mean. |

| | |
|---|---|
| `Global_Range` | Global range of the distribution. |
| `PE_Mean_Range` | Range of the mean on this PE. |
| `PE_Range` | Range of the distribution on this PE. |

The Valid_State_Statistics code listing in § E.2.3 on page 478 contains additional documentation.

### 10.2.4 Initialized_Statistics Procedure

The Initialized_Statistics procedure returns true iff the Statistics object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Statistics)
```

**Input variable:**

| | |
|---|---|
| `Statistics` | The Statistics object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Statistics object has been initialized. |

The Initialized_Statistics code listing in § E.2.4 on page 481 contains additional documentation.

### 10.2.5 Add_Value_Statistics Procedure

The Add_Value_Statistics procedure adds a new value to the Statistics object.

**Calling syntax:**

```
call Add_Value (Statistics, Value)
```

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics object to be modified. |
| `Value` | Value to be added to Statistics object. |

**Output variables:**

| | |
|---|---|
| `Statistics` | The modified Statistics object. |

**Internal variables:**

| | |
|---|---|
| `N` | Real version of PE_Count. |

The Add_Value_Statistics code listing in § E.2.5 on page 481 contains additional documentation.

### 10.2.6 Get Value Statistics Functions

The Get Value Statistics functions return values from a Statistics object. Local or global values can be returned by specifying the Global logical input variable.

**Calling syntax:**

```
Output = Arithmetic_Mean (Statistics, Global)      ,
Output = Average (Statistics, Global)              ,
Output = Count (Statistics, Global)                ,
Output = Geometric_Mean (Statistics, Global)       ,
Output = Harmonic_Mean (Statistics, Global)        ,
Output = Maximum (Statistics, Global)              ,
Output = Mean (Statistics, Global)                 ,
Output = Minimum (Statistics, Global)              ,
Output = Name (Statistics)                         ,
Output = Standard_Deviation (Statistics, Global)   ,
Output = Sum (Statistics, Global)                  ,
Output = Total (Statistics, Global)                or
Output = Totally_Positive (Statistics, Global)
```

Mean and Average are alternate interface names for the Arithmetic_Mean Procedure, and Total is an alternate interface name for the Sum Procedure.

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics object to be examined. |
| `Global` | If present and true, the function does a global update and then returns the global value. Otherwise, the local PE value is returned. [Optional] |

**Output variable:**

| | |
|---|---|
| `Output` | For Name, returns a character variable containing the name assigned to the object upon initialization. For Count, returns the integer number of values in the Statistics object. For Totally_Positive, returns a logical which is true only if all the values are positive. For all other functions, returns a real variable with the named value for the Statistics object. Note that the values returned by Geometric_Mean and Harmonic_Mean have no significance if Totally_Positive is false. |

The Get Value Statistics code listing in § E.2.6 on page 483 contains additional documentation.

### 10.2.7 Output_Statistics Procedure

The Output_Statistics procedure writes out information from a Statistics object to the specified unit.

**Calling syntax:**

```
call Output (Statistics, Global, Verbose, Unit)
```

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics object to be queried. |
| `Global` | Global flag, defaults to false. If Global is not set to true, no global update is done and whatever value is present on the IO_PE is used. [Optional] |
| `Verbose` | Verbosity flag, defaults to false. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Statistics code listing in § E.2.7 on page 485 contains additional documentation.

### 10.2.8 Update_Global_Statistics Procedure

The Update_Global_Statistics procedure does interprocessor communication to update the global values of a Statistics object.

**Calling syntax:**

```
call Update_Global (Statistics)
```

**Input variables:**

| | |
|---|---|
| `Statistics` | The Statistics object to be globally updated. |

**Output variables:**

| | |
|---|---|
| `Statistics` | The globally updated Statistics object. |

**Internal variables:**

| | |
|---|---|
| `N` | Real version of Global_Count. |

The Update_Global_Statistics code listing in § E.2.8 on page 488 contains additional documentation.

# Chapter 11

# Parallel_Utilities Module

*His narrative style was like parallel parking on a busy street: he proceeded in fits and starts, backed up, edged forward, backed up, while other ideas zoomed past close at hand. – Melissa Fay Greene*

The Parallel Utilities module provides CÆSAR with utilities of a general nature which rely on parallel communication for their operation.

The Parallel_Utilities Module code listing in § F on page 493 contains additional documentation.

## 11.1 Timer Class

The Timer Class is used to keep track of run times in the CÆSAR Code Package. A Timer keeps track of both CPU and Wall Clock times. The time between starting and stopping a Timer is referred to as a split time. A Timer keeps statistics for split and total times, and for each processor in a parallel run.

**Timer public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a Timer object. |
| `Finalize` | Finalizes a Timer object. |
| `Valid_State` | Returns false iff a Timer object is in an invalid state. |
| **Operations** | |
| `Arithmetic_Mean` | Returns the arithmetic mean of the Timer object. |
| `Average` | Returns the arithmetic mean of the Timer object. |
| `Count` | Returns the number of splits in the Timer object. |
| `Geometric_Mean` | Returns the geometric mean of the Timer object. |
| `Get_CPU_Time` | Returns CPU time in seconds. |
| `Get_Wall_Clock_Time` | Returns Wall Clock time in seconds. |
| `Harmonic_Mean` | Returns the harmonic mean of the Timer object. |
| `Initialized` | Returns true iff a Timer object has been initialized. |
| `Maximum` | Returns the maximum value of the Timer object. |
| `Mean` | Returns the arithmetic mean of the Timer object. |
| `Minimum` | Returns the minimum value of the Timer object. |
| `Julian_Day` | Returns the Julian Day number for a given date. |
| `Name` | Returns the name of the Timer object. |
| `Output` | Writes out the Timer object. |
| `Reset` | Resets all the registers in a Timer object, returning it to a freshly initialized state. |

| | |
|---|---|
| `Standard_Deviation` | Returns the standard deviation of the Timer object. |
| `Start` | Instructs a Timer object to begin timing. |
| `Stop` | Instructs a Timer object to discontinue timing. |
| `Sum` | Returns the sum or total of the Timer object. |
| `Total` | Returns the sum or total of the Timer object. |
| `Totally_Positive` | Returns true if all the times in the Timer object are positive. |

**Timer public defined types:**

| | |
|---|---|
| **Timer type** | |
| `CPU_Time` | Time object to track. |
| `Initialized` | Initialization status. |
| `Name` | The name for this Timer object. |
| `Running` | Logical for Timer state. |
| `Wall_Clock_Time` | Time object to track. |
| **Time type** | |
| `Start` | Initial time value. |
| `Statistics` | Statistics for the time splits. |

The Timer Class code listing in § F.1 on page 493 contains additional documentation. The Timer Class also contains a Unit Test Program which is listed in § F.1.13 on page 515.

### 11.1.1 Initialize_Timer Procedure

The Initialize_Timer procedure allocates and initializes a Timer object.

**Calling syntax:**

```
call Initialize (Timer, Name, status)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be initialized. |
| `Name` | The name for the Timer object. |

**Output variables:**

| | |
|---|---|
| `Timer` | The Timer object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Timer code listing in § F.1.1 on page 496 contains additional documentation.

### 11.1.2 Finalize_Timer Procedure

The Finalize_Timer procedure deallocates and finalizes a Timer object.

**Calling syntax:**

```
call Finalize (Timer, status)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Timer` | The Timer object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Timer code listing in § F.1.2 on page 498 contains additional documentation.

### 11.1.3 Valid_State_Timer Procedure

The Valid_State_Timer procedure returns true iff the Timer is in a valid state – that is, iff the Timer passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Timer)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Timer is in a valid state. |

**Internal variables:**

| | |
|---|---|
| `Variable` | Description. [Units] |

The Valid_State_Timer code listing in § F.1.3 on page 499 contains additional documentation.

### 11.1.4 Initialized_Timer Procedure

The Initialized_Timer procedure returns true iff the Timer object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Timer)
```

**Input variable:**

| | |
|---|---|
| `Timer` | The Timer object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Timer object has been initialized. |

The Initialized_Timer code listing in § F.1.4 on page 500 contains additional documentation.

### 11.1.5 Get Value Timer Functions

The Get Value Timer functions return values from a Timer object. Local or global values can be returned by specifying the Global logical input variable. Note that if the Timer object is currently running, data from the current timing is not included. Therefore, it is more meaningful to call these routines after calling Stop_Timer.

**Calling syntax:**

```
Output = Arithmetic_Mean (Timer, Clock, Global, Split)      ,
Output = Average (Timer, Clock, Global, Split)              ,
Output = Count (Timer, Clock, Global, Split)                ,
Output = Geometric_Mean (Timer, Clock, Global, Split)       ,
Output = Harmonic_Mean (Timer, Clock, Global, Split)        ,
Output = Maximum (Timer, Clock, Global, Split)              ,
Output = Mean (Timer, Clock, Global, Split)                 ,
Output = Minimum (Timer, Clock, Global, Split)              ,
Output = Name (Timer)                                       ,
Output = Standard_Deviation (Timer, Clock, Global, Split)   ,
Output = Sum (Timer, Clock, Global, Split)                  ,
Output = Total (Timer, Clock, Global, Split)                or
Output = Totally_Positive (Timer, Clock, Global, Split)
```

Mean and Average are alternate interface names for the Arithmetic_Mean Procedure, and Total is an alternate interface name for the Sum Procedure.

Note that some combinations of options will return values that, while correct, have little useful meaning. For example, the function `Total(Timer, Clock=''Wall_Clock'', Global=.true., Split=.false.)` will return the total wall-clock time summed over all the processors, whereas a more meaningful value would be the maximum wall-clock time over all the processors, given by `Maximum(Timer, Clock=''Wall_Clock'', Global=.true., Split=.false.)` .

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be examined. |
| `Clock` | Should have a value of "CPU" or "Wall_Clock". Default is "CPU". [Optional] |
| `Global` | If present and true, the function does a global update and then returns the global value. Otherwise, the local PE value is returned. [Optional] |

`Split` If present and true, the function returns values based on the individual split times, that is, for all the times that the timer was started and stopped. This can be either local (all the splits on a PE) or global (all the splits on all the PEs). If Split is false or absent, the function returns values based on the total times on each PE. If both Split and Global are false, the function returns values based on the single entry of the total time on the local PE. [Optional]

**Output variables:**

`Output` For Name, returns a character variable containing the name assigned to the object upon initialization. For Count, returns the integer number of values in the Timer object (i.e. the number of splits). For Totally_Positive, returns a logical which is true only if all the values are positive. For all other functions, returns a real variable with the named value for the Timer object. Note that the values returned by Geometric_Mean and Harmonic_Mean have no significance if Totally_Positive is false.

The Get Value Timer code listing in § F.1.5 on page 501 contains additional documentation.

### 11.1.6 Get_CPU_Time Procedure

The Get_CPU_Time procedure returns the current value of the CPU time counter in seconds. It is intended to be used internally to the Timer Class, but is made public in case it is needed elsewhere.

Note: on an old Sun compiler (Sun WorkShop 6 update 2 Fortran 95 6.2 2001/05/15), the CPU_TIME call returns the total time for the parent process, so interpret results carefully. Some runs led me to suspect that CPU_TIME returns Wall Clock Time on Suns – not sure about this.

**Calling syntax:**

```
Real = Get_CPU_Time ()
```

**Output variable:**

`Get_CPU_Time` The current value of the CPU time counter [seconds].

The Get_CPU_Time code listing in § F.1.6 on page 503 contains additional documentation.

### 11.1.7 Get_Wall_Clock_Time Procedure

The Get_Wall_Clock_Time procedure returns the current value of the Wall Clock time counter in seconds. It is intended to be used internally to the Timer Class, but is made public in case it is needed elsewhere.

The returned value is actually the number of seconds, down to the millisecond, since the midnight at the beginning of 4714 BC/11/24 (-4713 CE/11/24). This is the beginning date of the Julian Day counter according to the Gregorian calendar, which is 38 days before the beginning date of the Julian Day counter according to the Julian calendar (4713 BC/01/01 or -4712 CE/01/01).

**Calling syntax:**

```
Real = Get_Wall_Clock_Time ()
```

**Output variable:**

`Get_Wall_Clock_Time` The current value of the Wall Clock time counter [seconds].

The Get_Wall_Clock_Time code listing in § F.1.7 on page 504 contains additional documentation.

### 11.1.8 Julian_Day Procedure

The Julian_Day procedure calculates the Julian Day for a given Year, Month and Day for a specific calendar (Julian or Gregorian).

**Days in a Year**

The Romans originally counted years *ab urbe condita* (a.u.c.), that is, "from the founding of the city (Rome)", posited as April 21, 753 BC. However, common usage numbered years by starting at one every time a new Caesar's reign began. Days were added and subtracted from time to time to keep the calendar on track with the season, which led to problems with planning and abuses for political purposes. (To calculate the equivalent a.u.c. year, add 753 to an AD year or subtract a BC year from 754. This is a rough estimate and may be off by a year.)

To correct problems with this calendar, Julius Caesar instituted a new calendar in 709 a.u.c. (45 BC). This calendar, called the Julian calendar, had years of 365 days and leap years of 366 days every fourth year. Months had a constant number of days, with a new month being added to refer to Julius Caesar himself (July). The year of 45 BC is often called the "year of confusion", as 90 days were added to the year to realign with the seasons.

The Julian calendar was a distinct improvement, but its year length of 365.25 days differed from the true year by about 11 minutes. Two possible values for the true year length are the vernal equinox year, 365.2424 days, and the tropical year, 365.24219 days. The discrepancy in the Julian calendar accumulates to a day roughly every 131 years.

Over the centuries the equinoxes and solstices migrated from their former places in the calendar, which caused problems in the Roman Catholic Church because the determination of the date of Easter was affected. Eventually, Pope Gregory XIII issued a papal bull establishing what is now called the Gregorian calendar. The Gregorian calendar modified the addition of leap days, such that a century year (divisible by 100) was only counted as a leap year if it was also divisible by 400. The Gregorian year length of 365.2425 days is much closer to the true year length, differing by somewhere between 8 and 27 seconds (depending on which true year is used). An entire day of error accumulates in either 3,226 or 10,000 years.

Adoption of the Gregorian calendar required dropping some days to realign the equinoxes and solstices. The first adoption of the Gregorian calendar was by the Catholic countries of Italy, Poland, Portugal, and Spain. They dropped 10 days, following 4 October 1582 immediately with 15 October 1582. Other Catholic countries followed suit, Protestant countries changed over the next two hundred years, and Greek Orthodox countries (Russia, Romania, Bulgaria, Turkey) did not change until the early 1900s. Great Britain and colonies (including American colonies) dropped 11 days when they adopted the Gregorian calendar, following 2 September 1752 with 14 September 1752. (Unix users can see that this fact is incorporated into the cal program by typing "`% cal 9 1752`".)

Extending a calendar before the time when it was adopted is referred to as the "proleptic" version of that calendar.

**Year Numbering Systems**

The designation "A.D." is an abbreviation of "Anni Domini Nostri Jesu Christi", i.e., "in the year of Our Lord Jesus Christ", and "B.C." signifies "Before Christ". There was no year zero in this system – that is, the year 1 BC was followed by 1 AD. A more religiously-neutral system replaces A.D. with C.E. (for Christian Era) and B.C. with B.C.E. (Before Christian Era), and leaves the numbering unchanged.

A third system is called the Common Era calendar, which uses the designation C.E. only. It includes a zero year and negative years, so that 2000 AD = 2000 CE (Christian Era) = 2000 CE (Common Era), and 2 BC = 2 BCE (Before Christian Era) = -1 CE (Common Era).

**Julian Days**

Table 11.18: Chronological Julian Day numbers for some representative dates.

| Date (BC/AD) | Date (CE) | Julian Day (Julian Calendar) | Julian Day (Gregorian Calendar) |
|---|---|---|---|
| 4714 BC/11/24 | -4713 CE/11/24 | -38 | 0 |
| 4713 BC/01/01 | -4712 CE/01/01 | 0 | 38 |
| 753 BC/04/21 | -752 CE/04/21 | 1446501 | 1446509 |
| 2 BC/10/30 | -1 CE/10/30 | 1720995 | 1720997 |
| 1 BC/01/01 | 0 CE/01/01 | 1721058 | 1721060 |
| 1 AD/01/01 | 1 CE/01/01 | 1721424 | 1721426 |
| 200 AD/02/28 | 200 CE/02/28 | 1794166 | 1794167 |
| 200 AD/02/29 | 200 CE/02/29 | 1794167 | 1794168 |
| 200 AD/03/01 | 200 CE/03/01 | 1794168 | 1794168 |
| 300 AD/02/28 | 300 CE/02/28 | 1830691 | 1830691 |
| 300 AD/02/29 | 300 CE/02/29 | 1830692 | 1830692 |
| 300 AD/03/01 | 300 CE/03/01 | 1830693 | 1830692 |
| 1582 AD/10/04 | 1582 CE/10/04 | 2299160 | 2299150 |
| 1582 AD/10/14 | 1582 CE/10/14 | 2299170 | 2299160 |
| 1752 AD/09/02 | 1752 CE/09/02 | 2361221 | 2361210 |
| 1752 AD/09/13 | 1752 CE/09/13 | 2361232 | 2361221 |
| 1858 AD/11/16 | 1858 CE/11/16 | 2400012 | 2400000 |
| 1968 AD/05/23 | 1968 CE/05/23 | 2440013 | 2440000 |
| 1995 AD/10/09 | 1995 CE/10/09 | 2450013 | 2450000 |
| 2000 AD/01/01 | 2000 CE/01/01 | 2451558 | 2451545 |
| 2132 AD/08/31 | 2132 CE/08/31 | 2500014 | 2500000 |

Julian Day numbers had their beginnings in a numbering system that was designed by Joseph Scaliger in 1583. It is sometimes erroneously stated that the system was named to honor his father, Julius Caesar Scaliger, but Scaliger himself wrote "We have termed it Julian because it fits the Julian year ...". His system was based on a 7980-year cycle which started on 1 January 4713 BC in the proleptic Julian calendar.

The astronomer John W. F. Herschel extended this idea to a system which numbered all the days consecutively starting at noon on 1 January -4712 CE (Julian). Noon was used so that the day number would not change in the middle of a night observation. Chronological Julian Day numbers were subsequently defined to start at midnight at the start of 1 January -4712 CE (Julian).

Some representative Julian Day numbers are given in Table 11.1.8.

See `http://www.hermetic.ch/cal_stud/jdn.htm`, `http://www.hermetic.ch/cal_stud/cal_art.htm`, `http://penelope.uchicago.edu/~grout/encyclopaedia_romana/calendar/consuls.html`, `http://en.wikipedia.org/wiki/Ab_urbe_condita`, `http://en.wikipedia.org/wiki/Julian_calendar`, `http://en.wikipedia.org/wiki/Gregorian_calendar`, `http://en.wikipedia.org/wiki/Julian_day`, and `http://astro.nmsu.edu/~lhuber/leaphist.html` for more detailed discussions.

**Calling syntax:**

```
integer = Julian_Day(Year, Month, Day, Calendar, Debug)
```

**Input variables:**

| | |
|---|---|
| `Year` | Year number, with negative numbers for BC and positive numbers for AD. There is no year zero. This procedure will give accurate results (corresponding to the proleptic Julian and Gregorian calendars) from 4713 BC onward. [years] |
| `Month` | Month number. [1–12] |
| `Day` | Day number. [1–31] |
| `Calendar` | Character variable specifying whether to use the Julian or Gregorian calendar (Gregorian is the default). [optional] |

| | |
|---|---|
| `Debug` | Debug toggle, needed to turn off very slow checking during 1000s of repeated calls in the parallel versions of the unit test. (.true. is the default). [optional] |

**Output variables:**

| | |
|---|---|
| `Julian_Day` | The chronological Julian Day number for the input date. [days] |

**Internal variables:**

| | |
|---|---|
| `Julian_Day_Constant` | The number of days between the zero date of the Julian Day numbering system (1 January -4712 CE) and the zero date of this Julian Day calculation (30 October -1 CE). [days] |
| `Julian_Month` | A month number which has been adjusted for ease of calculation. Ranges between 4 and 15. |
| `Julian_Year` | The year, with negative values shifted by one so that there is a "zero year" (there was no zero year between 1 BC and 1 AD). This is also known as the Common Era (CE) year. [years] |
| `Shifted_Julian_Year` | The Julian year shifted by 8000 years for ease of calculation of leap days. [years] |

The Julian_Day code listing in § F.1.8 on page 505 contains additional documentation.

### 11.1.9 Output_Timer Procedure

The Output_Timer procedure writes out information from a Timer object to the specified unit.

**Calling syntax:**

```
call Output (Timer, Global, Verbose, Unit)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be queried. |
| `Global` | Global flag, defaults to false. If Global is not set to true, no global update is done and whatever value is present on the IO_PE is used. [Optional] |
| `Verbose` | Verbosity flag, defaults to false. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |

The Output_Timer code listing in § F.1.9 on page 508 contains additional documentation.

### 11.1.10 Reset_Timer Procedure

The Reset_Timer procedure resets the Timer registers. A Timer that has been reset is identical to one that has just been initialized.

**Calling syntax:**

```
call Reset_Timer (Timer)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be reset. |

**Output variables:**

| | |
|---|---|
| `Timer` | The Timer object that has been reset. |

The Reset_Timer code listing in § F.1.10 on page 513 contains additional documentation.

### 11.1.11 Start_Timer Procedure

The Start_Timer procedure starts the Timer running. The Timer registers are not reset to zero.

**Calling syntax:**

```
call Start_Timer (Timer)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be started. |

**Output variables:**

| | |
|---|---|
| `Timer` | The Timer object that is now running. |

The Start_Timer code listing in § F.1.11 on page 513 contains additional documentation.

### 11.1.12 Stop_Timer Procedure

The Stop_Timer procedure stops the Timer. The Timer registers are not reset to zero.

**Calling syntax:**

```
call Stop_Timer (Timer)
```

**Input variables:**

| | |
|---|---|
| `Timer` | The Timer object to be stopped. |

**Output variables:**

| | |
|---|---|
| `Timer` | The Timer object that has been stopped. |

The Stop_Timer code listing in § F.1.12 on page 514 contains additional documentation.

# Chapter 12

# Linear_Algebra Module

*That fondness for science, ... has encouraged me to compose a short work on calculating by al-jabr and al-muqabala, confining it to what is easiest and most useful in arithmetic, such as men constantly require in cases of inheritance, legacies, partition, lawsuits, and trade, and in all their dealings with one another, or where the measuring of lands, the digging of canals, geometrical computations, and other objects of various sorts and kinds are concerned. – from the algebra treatise Hisab al-jabr w'al-muqabala, the most famous work of Abu Ja'far Muhammad ibn Musa Al-Khwarizmi (c. 780 – c. 850) [al-jabr means "restoring", referring to the process of moving a subtracted quantity to the other side of an equation; al-muqabala is "comparing" and refers to subtracting equal quantities from both sides of an equation.]*

The Linear_Algebra Module contains classes to support the manipulation and solution of linear algebra problems for the CÆSAR Code Package. Several matrix classes (with different storage formats) and a Mathematic Vector class are included. A Solver class is used to drive the solution of linear equations using both external packages and solvers included within CÆSAR.

The Linear_Algebra Module code listing in § G on page 527 contains additional documentation.

## 12.1 Mathematic_Vector Class

The Mathematic_Vector Class is used to describe a Mathematic Vector in the CÆSAR Code Package. A Mathematic_Vector differs from a Distributed_Vector in several ways:

- A Mathematic_Vector has operations which allow it to calculate various mathematic functions (norms, averages, etc.).
- A Mathematic_Vector is used with a matrix class to define a matvec operation.
- A Distributed_Vector can interoperate with other CÆSAR parallel data structures (Assembled_Vector, Overlapped_Vector, Collected_Array).

Note that a Mathematic_Vector contains a Distributed_Vector and a vector of Overlapped_Vectors which it uses for matvecs.

The Mathematic_Vector methods section in § 16.1 on page 187 describes the methods used in the Mathematic_Vector Class.

**Mathematic_Vector public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a Mathematic_Vector object. |
| `Finalize` | Finalizes a Mathematic_Vector object. |
| `Valid_State` | Returns false iff a Mathematic_Vector object is in an invalid state. |
| `Initialized` | Returns true iff a Mathematic_Vector object has been initialized. |
| **Operations** | |
| `Average` | Returns the arithmetic mean of the Mathematic_Vector object. |
| `Add_Values` | Increments the values of a Mathematic_Vector object. |
| `DotProduct` | Returns the global dot product of two Mathematic_Vector objects. |
| `Duplicate` | Makes an exact copy of a Mathematic_Vector (except for the internal DV's and OV's, which will be generated if needed). This procedure is also useful when a compatible Mathematic_Vector is needed. |
| `Get_Values` | Returns the values for a Mathematic_Vector object (also has an assignment interface). |
| `Infinity_Norm` | Returns the infinity norm of the Mathematic_Vector object. |
| `Length_PE` | Returns the length on this PE of the Mathematic_Vector object. |
| `Length_Total` | Returns the total length (all PEs) of the Mathematic_Vector object. |
| `Locus` | Returns the locus of the Mathematic_Vector object. |
| `Maximum` | Returns the maximum of the Mathematic_Vector object. |
| `Mean` | Returns the mean value of the Mathematic_Vector object. |
| `Minimum` | Returns the minimum of the Mathematic_Vector object. |
| `Name` | Returns the name of the Mathematic_Vector object. |
| `Norm` | Returns the two norm of the Mathematic_Vector object. |
| `One_Norm` | Returns the one norm of the Mathematic_Vector object. |
| `Orthogonal` | Returns true if the two Mathematic_Vector objects are orthogonal. |
| `Output` | Writes out the Mathematic_Vector object. |
| `P_Norm` | Returns the P-norm of the Mathematic_Vector object. |
| `Two_Norm` | Returns the two norm of the Mathematic_Vector object. |
| `Set_Not_Up_to_Date` | Puts a Mathematic Vector into a "not up-to-date" state. Can be used externally to force recalculation of norms, extrema, etc. |
| `Set_Values` | Sets the values for a Mathematic_Vector object. |
| `Sum` | Returns the sum of the Mathematic_Vector object. |
| `Total` | Returns the sum of the Mathematic_Vector object. |
| `Update_DV` | Updates the Distributed Vector inside of a Mathematic_Vector object. |

**Mathematic_Vector public defined types:**

| **Mathematic_Vector type** | |
|---|---|
| `Average` | Global average of the Mathematic Vector. |
| `Average_is_Updated` | Updated? toggle for Average. |
| `Dimensionality` | Number of dimensions for the Mathematic Vector (always unity). |
| `DV` | Distributed Vector that is used for matvecs. |
| `Infinity_Norm` | Infinity norm of the Mathematic Vector. |
| `Infinity_Norm_is_Updated` | Updated? toggle for Infinity_Norm. |
| `Initialized` | Initialization status. |
| `Maximum` | Global maximum of the Mathematic Vector. |
| `Maximum_is_Updated` | Updated? toggle for Maximum. |
| `Minimum` | Global minimum of the Mathematic Vector. |
| `Minimum_is_Updated` | Updated? toggle for Minimum. |
| `Name` | The name for this variable (especially useful in a vector of Mathematic Vectors). |
| `One_Norm` | One norm of the Mathematic Vector. |
| `One_Norm_is_Updated` | Updated? toggle for One_Norm. |
| `OV` | A vector of Overlapped Vectors that is used for matvecs. |
| `DV_is_Updated` | Updated? toggle for DV. |

| | |
|---|---|
| `P_Norm` | P norm of the Mathematic Vector. |
| `P_Norm_Exponent` | Exponent used in taking the P norm. |
| `P_Norm_is_Updated` | Updated? toggle for P_Norm. |
| `Structure` | Basic data structure for the Mathematic Vector. |
| `Sum` | Global sum of the Mathematic Vector. |
| `Sum_is_Updated` | Updated? toggle for Sum. |
| `Two_Norm` | Two norm of the Mathematic Vector. |
| `Two_Norm_is_Updated` | Updated? toggle for Two_Norm. |
| `Values` | Values for the Mathematic Vector. |

**Mathematic_Vector public variables:**

| | |
|---|---|
| `Number_of_OVs_in_an_MV` | A parameter specifying the number of Overlapped_Vector objects in a Mathematic_Vector object. This number limits the number of different matrices that MatVecs can be done with quickly. For example, if a Mathematic_Vector object is to be multipied by three matrices, all with the same Column_Structure but with different Data_Indices (Columns arrays), then the set up for all three can be stored as long as `Number_of_OVs_in_an_MV` is equal to or greater than three. Otherwise, multiplication can still be done, but set up phases will have to be repeated. |

The Mathematic_Vector Class code listing in § G.1 on page 527 contains additional documentation. The Mathematic_Vector Class also contains a Unit Test Program which is listed in § G.1.15 on page 557.

### 12.1.1 Initialize_Mathematic_Vector Procedure

The Initialize_Mathematic_Vector procedure allocates and initializes a Mathematic_Vector object.

**Calling syntax:**

```
call Initialize (MV, Structure, Name, status)
```

**Input variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be initialized. |
| `Structure` | The Base_Structure giving the distribution for the Mathematic_Vector. |
| `Name` | The name for this variable (especially useful in a vector of Mathematic Vectors). [Optional] |

**Output variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Mathematic_Vector code listing in § G.1.1 on page 532 contains additional documentation.

### 12.1.2 Duplicate_Mathematic_Vector Procedure

The Duplicate_Mathematic_Vector procedure duplicates a Mathematic Vector – that is, it initializes a new Mathematic Vector with the same structure as the old Mathematic Vector, and copies the internals. Note that the internal structures associated with executing MatVecs (i.e. the DV and the OVs) are not duplicated.

**Calling syntax:**

```
call Duplicate (MV_duplicate, MV_source, status)
```

**Input variables:**

| | |
|---|---|
| `MV_source` | The Mathematic_Vector to be duplicated. |

**Output variables:**

| | |
|---|---|
| `MV_duplicate` | The Mathematic_Vector object is now a copy of the MV_source Mathematic Vector. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

The Duplicate_Mathematic_Vector code listing in § G.1.2 on page 534 contains additional documentation.

### 12.1.3 Finalize_Mathematic_Vector Procedure

The Finalize_Mathematic_Vector procedure deallocates and finalizes a Mathematic_Vector object.

**Calling syntax:**

```
call Finalize (MV, status)
```

**Input variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be finalized. |

**Output variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status mathematic_vector. |
| `i` | Loop variable. |

The Finalize_Mathematic_Vector code listing in § G.1.3 on page 535 contains additional documentation.

### 12.1.4 Valid_State_Mathematic_Vector Procedure

The Valid_State_Mathematic_Vector procedure returns true iff the Mathematic_Vector is in a valid state – that is, iff the Mathematic_Vector passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(MV)
```

**Input variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Mathematic_Vector is in a valid state. |

The Valid_State_Mathematic_Vector code listing in § G.1.4 on page 537 contains additional documentation.

### 12.1.5 Initialized_Mathematic_Vector Procedure

The Initialized_Mathematic_Vector procedure returns true iff the Mathematic_Vector object has been initialized.

**Calling syntax:**

```
Logical = Initialized(MV)
```

**Input variable:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Mathematic_Vector object has been initialized. |

The Initialized_Mathematic_Vector code listing in § G.1.5 on page 539 contains additional documentation.

### 12.1.6 Add_Values_Mathematic_Vector Procedure

The Add_Values_Mathematic_Vector procedure increments the values for the Mathematic Vector by the specified vector of value. Note that if the single value form of this procedure is used, then the same number of procedure calls must take place on every processor – this is required by internal verification calls that use global communication. If a different number of values are to be added on each processor, then the vector form should be used.

**Calling syntax:**

```
call Add_Values (MV, Values)                ,
call Add_Values (MV, Values, Rows, Global)   or
call Add_Values (MV, Value, Row, Global)
```

**Input variable:**

| | |
|---|---|
| `Values` | A vector of values to be added to the Mathematic_Vector object. If the Rows variable is not present, Values must be the same size as the Mathematic_Vector. Otherwise, Values must have a size smaller than or equal to the size of the Mathematic_Vector. |
| `Rows` | An integer vector of rows for the Values vector. [optional] |
| `Global` | A toggle between using global or local (on this PE) indices for the Rows variable. Default is true (use global). [optional] |
| `Value` | A single value to be added to the Mathematic_Vector object. The Row variable must be present for this form of the procedure. |
| `Row` | The row index for the Value variable. |

**Input/Output variable:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be incremented. |

The Add_Values_Mathematic_Vector code listing in § G.1.6 on page 540 contains additional documentation.

### 12.1.7 DotProduct_Mathematic_Vector Procedure

The DotProduct procedure calculates the global dot product of two Mathematic Vectors.

Note that I would rather call this routine "Dot_Product", but the F90 standard does not allow underscores in defined operator names (i.e. ".Dot_Product." is not allowed).

**Calling syntax:**

```
Output = MV1 .DotProduct.  MV2    or
Output = DotProduct(MV1, MV2)
```

**Input variables:**

| | |
|---|---|
| `MV1, MV2` | Two Mathematic_Vector objects to be dotted. |

**Output variable:**

| | |
|---|---|
| `DotProduct` | Scalar result of taking the global dot product of the two Mathematic Vectors. |

The DotProduct_Mathematic_Vector code listing in § G.1.7 on page 543 contains additional documentation.

### 12.1.8 Get Value Mathematic_Vector Functions

The Get_Value_MV functions return values from a Mathematic_Vector object. These operations require global communication (except Get_Name_MV, Get_Length_PE and Get_Length_Total), but if called more than once without modifying the object, no global communication is done for the second call.

**Calling syntax:**

```
Output = Average (MV)          ,
Output = Infinity_Norm (MV)    ,
Output = Length_PE (MV)        ,
Output = Length_Total (MV)     ,
Output = Locus (MV)            ,
Output = Maximum (MV)          ,
Output = Mean (MV)             ,
Output = Minimum (MV)          ,
Output = Name (MV)             ,
Output = Norm (MV)             ,
Output = One_Norm (MV)         ,
Output = P_Norm (MV, P)        ,
Output = Sum (MV)              ,
Output = Total (MV)            or
Output = Two_Norm (MV)
```

Mean is an alternate interface name for the Average Procedure, Norm is an alternate interface name for the Two_Norm Procedure, and Total is an alternate interface name for the Sum Procedure.

**Input variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be examined. |
| `P` | P_Norm exponent. This optional argument is only available in P_Norm. |

**Output variable:**

| | |
|---|---|
| `Output` | For Name and Locus, returns a character variable containing the name or locus assigned to the object upon initialization. For Length_PE and Length_Total, returns an integer variable containing the appropriate length of the Mathematic_Vector object. For all other functions, returns a real variable with the named value for the Mathematic_Vector object. |

The Get Value Mathematic_Vector code listing in § G.1.8 on page 544 contains additional documentation.

### 12.1.9 Get_Values_Mathematic_Vector Procedure

The Get_Values_Mathematic_Vector procedure accesses the values from a Mathematic Vector.

**Calling syntax:**

```
Values = MV                        or
call Get_Values (Values, MV)
```

**Input variable:**

| | |
|---|---|
| `Values` | The bare naked vector of values from the Mathematic_Vector object. Values must be the same size as the Mathematic_Vector. |

**Input/Output variable:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be accessed. |

The Get_Values_Mathematic_Vector code listing in § G.1.9 on page 548 contains additional documentation.

### 12.1.10 Orthogonal_Mathematic_Vector Procedure

The Orthogonal procedure calculates whether or not two Mathematic Vectors are orthogonal.

**Calling syntax:**

```
Logical = MV1 .Orthogonal. MV2    or
Logical = Orthogonal(MV1, MV2)
```

**Input variables:**

| | |
|---|---|
| `MV1, MV2` | Two Mathematic_Vector objects to be dotted. |

**Output variable:**

| | |
|---|---|
| `Orthogonal` | Logical which is true when the two Mathematic Vectors are orthogonal. |

The Orthogonal_Mathematic_Vector code listing in § G.1.10 on page 548 contains additional documentation.

### 12.1.11 Output_Mathematic_Vector Procedure

The Output_Mathematic_Vector procedure writes out a section of a Mathematic Vector to the specified unit.

**Calling syntax:**

```
call Output (MV, First, Last, Unit, Indent)
```

**Input variables:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be queried. |
| `First` | The first location to be output. [Optional] |
| `Last` | The last location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Indent` | Number of indentation characters. [Optional] |

The Output_Mathematic_Vector code listing in § G.1.11 on page 549 contains additional documentation.

### 12.1.12 Set_Not_Up_to_Date_Mathematic_Vector Procedure

The Set_Not_Up_to_Date_Mathematic_Vector procedure puts a Mathematic Vector into a "not up-to-date" state. That is, it unsets the values for all of the updated? variables in the Mathematic Vector. It is mainly used internally to the Mathematic Vector class, but could also be used externally to force recalculation of norms, extrema, etc.

**Calling syntax:**

```
call Set_Not_Up_to_Date (MV)
```

**Input/Output variable:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be set. |

The Set_Not_Up_to_Date_Mathematic_Vector code listing in § G.1.12 on page 552 contains additional documentation.

### 12.1.13 Set_Values_Mathematic_Vector Procedure

The Set_Values_Mathematic_Vector procedure sets the values for the Mathematic Vector. Note that if the single value form of this procedure is used, then the same number of procedure calls must take place on every processor – this is required by internal verification calls that use global communication. If a different number of values are to be set on each processor, then the vector form should be used.

**Calling syntax:**

```
MV = Values                                  ,
call Set_Values (MV, Values)                 ,
call Set_Values (MV, Values, Rows, Global)   or
call Set_Values (MV, Value, Row, Global)
```

**Input variable:**

| | |
|---|---|
| `Values` | A vector of values for the Mathematic_Vector object. If the Rows variable is not present, Values must be the same size as the Mathematic_Vector. Otherwise, Values must have a size smaller than or equal to the size of the Mathematic_Vector. |
| `Rows` | An integer vector of rows for the Values vector. [optional] |
| `Global` | A toggle between using global or local (on this PE) indices for the Rows variable. Default is true (use global). [optional] |
| `Value` | A single value for the Mathematic_Vector object. The Row variable must be present for this form of the procedure. |
| `Row` | The row index for the Value variable. |

**Input/Output variable:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be set. |

The Set_Values_Mathematic_Vector code listing in § G.1.13 on page 553 contains additional documentation.

### 12.1.14 Update_DV_Mathematic_Vector Procedure

The Update_DV_Mathematic_Vector procedure updates the Distributed Vector inside of a Mathematic Vector from the Values objects. If the DV is already updated, no work is done.

**Calling syntax:**

```
call Update_DV (MV)
```

**Input/Output variable:**

| | |
|---|---|
| `MV` | The Mathematic_Vector object to be set. |

The Update_DV_Mathematic_Vector code listing in § G.1.14 on page 556 contains additional documentation.

## 12.2 ELL_Matrix Class

The ELL_Matrix Class is used to describe a matrix in the CÆSAR Code Package. The storage format is ELL, a common storage format originally used by the ELLPACK package[1]. In this storage format, two

[1] `\http://www.cs.purdue.edu/ellpack/`

rectangular arrays are used to store the matrix. The arrays have the same number of rows as the original matrix, but only have as many columns as the maximum number of nonzeros on a row of the original matrix. One of the arrays holds the matrix entries, and the other array holds the column numbers from the original matrix.

As an example, this original matrix:

$$\text{Full Matrix} = \begin{bmatrix} 1 & 2 & 3 & 0 & 0 & 0 \\ 0 & 4 & 5 & 0 & 6 & 0 \\ 7 & 0 & 8 & 0 & 9 & 0 \\ 0 & 8 & 0 & 0 & 7 & 6 \\ 0 & 0 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 0 & 3 & 0 \end{bmatrix} \tag{12.1}$$

which has a maximum number of nonzeros per row of 3, would be stored as

$$\text{Values} = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \\ 8 & 7 & 6 \\ 5 & 0 & 0 \\ 4 & 3 & 0 \end{bmatrix}, \quad \text{Columns} = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 5 \\ 1 & 3 & 5 \\ 2 & 5 & 6 \\ 3 & 0 & 0 \\ 3 & 5 & 0 \end{bmatrix} \tag{12.2}$$

This storage format is most efficient when every row in the original matrix has the same number of nonzeros. It is somewhat easier to work with than the compressed sparse row (CSR) format, but it can use more memory if the matrix has an uneven number of nonzeros per row.

In addition to this, the ELL_Matrix Class is a parallel data structure. The row dimension in the `Values` and `Columns` arrays is distributed across the processors.

The ELL_Matrix methods section in § 16.2 on page 188 describes the methods used in the ELL_Matrix Class.

**ELL_Matrix public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes an ELL_Matrix object. |
| `Finalize` | Finalizes an ELL_Matrix object. |
| `Valid_State` | Returns false iff an ELL_Matrix object is in an invalid state. |
| `Initialized` | Returns true iff an ELL_Matrix object has been initialized. |
| **Operations** | |
| `Add_Values` | Increments the values of an ELL_Matrix object. |
| `Average` | Returns the arithmetic mean of the ELL_Matrix object. |
| `Frobenius_Norm` | Returns the Frobenius norm of the ELL_Matrix object. |
| `Get_Columns` | Returns the column locations for an ELL_Matrix object (also has an assignment interface). |
| `Get_Values` | Returns the values for an ELL_Matrix object (also has an assignment interface). |
| `Infinity_Norm` | Returns the infinity norm of the ELL_Matrix object. |
| `MatVec` | Returns the global matrix-vector product of an ELL_Matrix object and a Mathematic_Vector object. |
| `Max_Nonzeros` | Returns the maximum number of nonzeros of the ELL_Matrix object (the array storage dimension for the columns). |
| `Maximum` | Returns the maximum of the ELL_Matrix object. |
| `Mean` | Returns the mean value of the ELL_Matrix object. |
| `Minimum` | Returns the minimum of the ELL_Matrix object. |
| `Name` | Returns the name of the ELL_Matrix object. |
| `Norm` | Returns the Frobenius norm of the ELL_Matrix object. |
| `NColumns` | Returns the number of columns of the ELL_Matrix object. |

| | |
|---|---|
| `NRows_PE` | Returns the number of rows on this PE of the ELL_Matrix object. |
| `NRows_Total` | Returns the total number of rows of the ELL_Matrix object. |
| `One_Norm` | Returns the one norm of the ELL_Matrix object. |
| `Output` | Writes out the ELL_Matrix object. |
| `Read` | Reads in an ELL_Matrix object from a Harwell-Boeing formatted file. Also reads in Mathematic_Vector objects from the file. |
| `Read_Harwell_Boeing` | Reads in an ELL_Matrix object from a Harwell-Boeing formatted file. Also reads in Mathematic_Vector objects from the file. |
| `Residual` | Calculates the residual vector ($r = Ax - b$) for a linear system. |
| `Set_Not_Up_to_Date` | Puts an ELL Matrix into a "not up-to-date" state. Can be used externally to force recalculation of norms, extrema, etc. |
| `Set_Values` | Sets the values for an ELL_Matrix object. |
| `Sum` | Returns the sum of the ELL_Matrix object. |
| `Total` | Returns the sum of the ELL_Matrix object. |
| `Two_Norm_Estimate` | Returns an estimate of the two norm of the ELL_Matrix object. |
| `Two_Norm_Range` | Returns the range of possible values for the two norm of the ELL_Matrix object. |

**ELL_Matrix public defined types:**

| **ELL_Matrix type** | |
|---|---|
| `Average` | Global average of the ELL Matrix. |
| `Average_is_Updated` | Updated? toggle for Average. |
| `Column_Structure` | Column base structure for the ELL Matrix. |
| `Columns` | Array of column numbers for the ELL Matrix. |
| `Dimensionality` | Number of dimensions for the ELL Matrix (always unity). |
| `Index` | Data Index that is used for matvecs. |
| `Index_is_Updated` | Updated? toggle for Index. |
| `Index_Match_Number` | Index Match Number that is used for matvecs. |
| `Frobenius_Norm` | Frobenius norm of the ELL Matrix. |
| `Frobenius_Norm_is_Updated` | Updated? toggle for Frobenius_Norm. |
| `Infinity_Norm` | Infinity norm of the ELL Matrix. |
| `Infinity_Norm_is_Updated` | Updated? toggle for Infinity_Norm. |
| `Initialized` | Initialization status. |
| `Max_Nonzeros` | Maximum number of nonzero columns on a row in the matrix. |
| `Maximum` | Global maximum of the ELL Matrix. |
| `Maximum_is_Updated` | Updated? toggle for Maximum. |
| `Minimum` | Global minimum of the ELL Matrix. |
| `Minimum_is_Updated` | Updated? toggle for Minimum. |
| `Name` | The name for this variable (especially useful in a vector of ELL Matrices). |
| `One_Norm` | One norm of the ELL Matrix. |
| `One_Norm_is_Updated` | Updated? toggle for One_Norm. |
| `OV` | A vector of Overlapped Vectors that is used for matvecs. |
| `Row_Structure` | Row base structure for the ELL Matrix. |
| `Sum` | Global sum of the ELL Matrix. |
| `Sum_is_Updated` | Updated? toggle for Sum. |
| `Two_Norm_Estimate` | An estimate of the two norm of the ELL Matrix, taken to be the midpoint of the range. |
| `Two_Norm_is_Updated` | Updated? toggle for Two_Norm. |
| `Two_Norm_Range` | The possible range of the two norm of the ELL Matrix. |
| `Values` | Values for the ELL Matrix. |

The ELL_Matrix Class code listing in § G.2 on page 560 contains additional documentation. The ELL_Matrix Class also contains a Unit Test Program which is listed in § G.2.15 on page 599.

### 12.2.1 Initialize_ELL_Matrix Procedure

The Initialize_ELL_Matrix procedure allocates and initializes an ELL_Matrix object.

**Calling syntax:**

```
call Initialize (ELLM, Max_Nonzeros, Row_Structure, Column_Structure, Name, status)
```

**Input variables:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be initialized. |
| `Max_Nonzeros` | The maximum number of nonzero elements per row. |
| `Row_Structure` | The Base_Structure giving the row distribution for the ELL_Matrix. |
| `Column_Structure` | The Base_Structure giving the column distribution for the ELL_Matrix. |
| `Name` | The name for this variable. [Optional] |

**Output variables:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_ELL_Matrix code listing in § G.2.1 on page 564 contains additional documentation.

### 12.2.2 Finalize_ELL_Matrix Procedure

The Finalize_ELL_Matrix procedure deallocates and finalizes an ELL_Matrix object.

**Calling syntax:**

```
call Finalize (ELLM, status)
```

**Input variables:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be finalized. |

**Output variables:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status ell_matrix. |
| `i` | Loop variable. |

The Finalize_ELL_Matrix code listing in § G.2.2 on page 566 contains additional documentation.

### 12.2.3 Valid_State_ELL_Matrix Procedure

The Valid_State_ELL_Matrix procedure returns true iff the ELL_Matrix is in a valid state – that is, iff the ELL_Matrix passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(ELLM)
```

**Input variables:**

`ELLM` The ELL_Matrix to be checked.

**Output variable:**

`Valid_State` True iff the ELL_Matrix is in a valid state.

The Valid_State_ELL_Matrix code listing in § G.2.3 on page 568 contains additional documentation.

### 12.2.4 Initialized_ELL_Matrix Procedure

The Initialized_ELL_Matrix procedure returns true iff the ELL_Matrix object has been initialized.

**Calling syntax:**

```
Logical = Initialized(ELLM)
```

**Input variable:**

`ELLM` The ELL_Matrix object to be examined.

**Output variable:**

`Initialized` True iff the ELL_Matrix object has been initialized.

The Initialized_ELL_Matrix code listing in § G.2.4 on page 570 contains additional documentation.

### 12.2.5 Add_Values_ELL_Matrix Procedure

The Add_Values_ELL_Matrix procedure increments the values for an ELL Matrix by the specified array of values. It may be called two different ways.

The single value form adds to a single matrix entry. If this form is used, then the same number of procedure calls must take place on every processor – this is required by internal verification calls that use global communication. If a different number of values are to be add on each processor, then one of the other calling forms should be used.

The array form, with the plural nomenclature, can be used to add to selected values in the ELL Matrix. Only the rows and columns listed in the Rows and Columns vectors are modified.

**Calling syntax:**

```
call Add_Values (ELLM, Values, Rows, Columns, Global)    or
call Add_Values (ELLM, Value, Row, Column, Global)
```

**Input variable:**

| | |
|---|---|
| `Values` | An array of values to be added to the ELL_Matrix object. Values must have a size smaller than or equal to the size of the ELL_Matrix. |
| `Rows` | An integer vector of rows to be incremented. This vector may be sized smaller than the row size of the ELL_Matrix object. |
| `Columns` | An array of columns for the ELL_Matrix object. Columns must have a size smaller than or equal to the size of the ELL_Matrix. |
| `Global` | A toggle between using global or local (on this PE) indices for the Rows variables. Default is true (use global). Note that the Columns variables are always global. [optional] |
| `Value` | A single value to be added to the ELL_Matrix object. The Row and Column variables must be present for this form of the procedure. |
| `Row` | The row index for the Value variable. |
| `Column` | The column index for the Value variable. |

**Input/Output variable:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be incremented. |

The Add_Values_ELL_Matrix code listing in § G.2.5 on page 571 contains additional documentation.

### 12.2.6 Get Value ELL_Matrix Functions

The Get_Value_ELLM functions return values from an ELL_Matrix object. These operations require global communication (except Get_Max_Nonzeros, Get_Name_ELLM, Get_NColumns, Get_NRows_PE and Get_-NRows_Total), but if called more than once without modifying the object, no global communication is done for the second call.

**Calling syntax:**

```
Output = Average (ELLM)              ,
Output = Frobenius_Norm (ELLM)       ,
Output = Infinity_Norm (ELLM)        ,
Output = Max_Nonzeros (ELLM)         ,
Output = Maximum (ELLM)              ,
Output = Mean (ELLM)                 ,
Output = Minimum (ELLM)              ,
Output = Name (ELLM)                 ,
Output = Norm (ELLM)                 ,
Output = NColumns (ELLM)             ,
Output = NRows_PE (ELLM)             ,
Output = NRows_Total (ELLM)          ,
Output = One_Norm (ELLM)             ,
Output = Sum (ELLM)                  ,
Output = Total (ELLM)                ,
Output = Two_Norm_Estimate (ELLM)    or
Output = Two_Norm_Range (ELLM)
```

Mean is an alternate interface name for the Average Procedure, Norm is an alternate interface name for the Frobenius_Norm Procedure, and Total is an alternate interface name for the Sum Procedure.

The Two Norm is problematic and is not calculated exactly by CÆSAR currently. However, the Two_Norm_-Range function returns limits on the possible values of the Two Norm, and the Two_Norm_Estimate function returns the midpoint of this range.

**Input variables:**

`ELLM` The ELL_Matrix object to be examined.

**Output variable:**

`Output` For Name, returns a character variable containing the name assigned to the object upon initialization. For Max_Nonzeros, NColumns, NRows_PE and NRows_Total, returns an integer variable with the requested number. For all other functions, returns a real variable with the named value for the ELL_Matrix object.

The Get Value ELL_Matrix code listing in § G.2.6 on page 574 contains additional documentation.

### 12.2.7 Get_Columns_ELL_Matrix Procedure

The Get_Columns_ELL_Matrix procedure accesses the column locations from an ELL Matrix.

**Calling syntax:**

```
Columns = ELLM                          or
call Get_Columns (Columns, ELLM)
```

**Input variable:**

`Columns` The bare naked array of columns from the ELL_Matrix object. Columns must be the same size as the ELL_Matrix.

**Input/Output variable:**

`ELLM` The ELL_Matrix object to be accessed.

The Get_Columns_ELL_Matrix code listing in § G.2.7 on page 578 contains additional documentation.

### 12.2.8 Get_Values_ELL_Matrix Procedure

The Get_Values_ELL_Matrix procedure accesses the values from an ELL Matrix.

**Calling syntax:**

```
Values = ELLM                          or
call Get_Values (Values, ELLM)
```

**Input variable:**

`Values` The bare naked array of values from the ELL_Matrix object. Values must be the same size as the ELL_Matrix.

**Input/Output variable:**

`ELLM` The ELL_Matrix object to be accessed.

The Get_Values_ELL_Matrix code listing in § G.2.8 on page 579 contains additional documentation.

### 12.2.9 MatVec_ELL_Matrix Procedure

The MatVec procedure calculates the global matrix-vector product of an ELL Matrix and a Mathematic Vector. It has some "smart" features:

- Overlapped_Vectors are used to store off-processor elements between MatVecs.
- MatVecs between a matrix (that may have changed) and a vector that hasn't changed do not do any global communication.
- The above is true for up to four (current number, could be expanded) different matrices, with different sparsity patterns.

**Calling syntax:**

```
call MatVec (ELLM, MV_in, MV_out)
```

**Input variables:**

| | |
|---|---|
| `ELLM` | An ELL_Matrix object to be multiplied. |
| `MV_in` | A Mathematic_Vector object to be multiplied. The Structure of the Mathematic_Vector must be the same as the Column_Structure of the ELL_Matrix. |
| `MV_out` | Mathematic_Vector object for output, but must have a Valid_State and the same Structure as the Row_Structure of ELLM on input. |

**Output variable:**

| | |
|---|---|
| `MV_out` | Mathematic_Vector object result of multiplying the ELL_Matrix object by the Mathematic_Vector object. The resultant Mathematic_Vector will have the same Structure as the Row_Structure of the ELL_Matrix. |

The MatVec_ELL_Matrix code listing in § G.2.9 on page 579 contains additional documentation.

### 12.2.10 Output_ELL_Matrix Procedure

The Output_ELL_Matrix procedure writes out a section of a ELL Matrix to the specified unit.

**Calling syntax:**

```
call Output (ELLM, Row_First, Row_Last, Unit, Indent)
```

**Input variables:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be queried. |
| `Row_First` | The first row location to be output. [Optional] |
| `Row_Last` | The last row location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Indent` | Number of indentation characters. [Optional] |

The Output_ELL_Matrix code listing in § G.2.10 on page 582 contains additional documentation.

### 12.2.11 Read_Harwell_Boeing_ELL_Matrix Procedure

The Read_Harwell_Boeing_ELL_Matrix procedure reads and initializes an ELL_Matrix object from a Harwell-Boeing formatted file. It will also read in and initialize a Mathematic_Vector object for a right-hand side vector, an initial guess vector and/or an exact solution vector.

**Calling syntax:**

```
call Read_Harwell_Boeing (ELLM, RHS_MV, Solution_MV, Guess_MV, Row_Structure, Column_Structure, Uni
```

**Input variables:**

| | |
|---|---|
| `Unit` | The logical unit for input, which defaults to 5. [Optional] |

**Output variables:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be read in and initialized. |
| `RHS_MV` | The right-hand side Mathematic_Vector object to be read in. [Optional] |
| `Solution_MV` | The exact solution Mathematic_Vector object to be read in. [Optional] |
| `Guess_MV` | The initial guess Mathematic_Vector object to be read in. [Optional] |
| `Row_Structure` | The Base_Structure giving the row distribution for the ELL_Matrix. |
| `Column_Structure` | The Base_Structure giving the column distribution for the ELL_Matrix. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Read_Harwell_Boeing_ELL_Matrix code listing in § G.2.11 on page 586 contains additional documentation.

### 12.2.12 Residual_ELL_Matrix Procedure

The Residual procedure calculates the global residual vector of a linear system represented by an ELL Matrix and a two Mathematic Vectors.

**Calling syntax:**

```
call Residual (Residual_MV, A_ELLM, X_MV, B_MV)
```

**Input variables:**

| | |
|---|---|
| `A_ELLM` | An ELL_Matrix object to be multiplied. |
| `X_MV` | A Mathematic_Vector object to be multiplied. The Structure of the Mathematic_-Vector must be the same as the Column_Structure of the ELL_Matrix. |
| `B_MV` | Mathematic_Vector object to be subtracted from the MatVec. The Structure of the Mathematic_Vector must be the same as the Row_Structure of A_ELLM. |

**Output variable:**

| | |
|---|---|
| `Residual_MV` | Mathematic_Vector object result of multiplying A_ELLM by X_MV and subtracting B_MV. The resultant Mathematic_Vector will have the same Structure as the Row_-Structure of the ELL_Matrix. |

The Residual_ELL_Matrix code listing in § G.2.12 on page 593 contains additional documentation.

### 12.2.13 Set_Not_Up_to_Date_ELL_Matrix Procedure

The Set_Not_Up_to_Date_ELL_Matrix procedure puts an ELL Matrix into a "not up-to-date" state. That is, it unsets the values for all of the updated? variables in the ELL Matrix. It is mainly used internally to the ELL Matrix class, but could also be used externally to force recalculation of norms, extrema, etc.

**Calling syntax:**

```
call Set_Not_Up_to_Date (ELLM)
```

**Input/Output variable:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be set. |

The Set_Not_Up_to_Date_ELL_Matrix code listing in § G.2.13 on page 594 contains additional documentation.

### 12.2.14 Set_Values_ELL_Matrix Procedure

The Set_Values_ELL_Matrix procedure sets the values for the ELL Matrix. It may be called three different ways.

The single value form replaces a single matrix entry. If this form is used, then the same number of procedure calls must take place on every processor – this is required by internal verification calls that use global communication. If a different number of values are to be set on each processor, then one of the other calling forms should be used.

The array form, without the Rows variable, can be used to replace the entire contents of the ELL Matrix. The Values and Columns variables must be exactly the same size as the ELL Matrix variables with the same name.

The array form, with the Rows variable, can be used to replace selected values in the ELL Matrix. Only the rows listed in the Rows vector are modified.

**Calling syntax:**

```
call Set_Values (ELLM, Values, Columns)                ,
call Set_Values (ELLM, Values, Rows, Columns, Global)   or
call Set_Values (ELLM, Value, Row, Column, Global)
```

**Input variable:**

| | |
|---|---|
| `Values` | An array of values for the ELL_Matrix object. If the Rows variable is not present, Values must be the same size as the ELL_Matrix. Otherwise, Values must have a size smaller than or equal to the size of the ELL_Matrix. |
| `Rows` | An integer vector of rows to be replaced. This vector may be sized smaller than the row size of the ELL_Matrix object. [optional] |
| `Columns` | An array of columns for the ELL_Matrix object. If the Rows variable is not present, Columns must be the same size as the ELL_Matrix. Otherwise, Columns must have a size smaller than or equal to the size of the ELL_Matrix. |

| | |
|---|---|
| `Global` | A toggle between using global or local (on this PE) indices for the Rows variables. Default is true (use global). Note that the Columns variables are always global. [optional] |
| `Value` | A single value for the ELL_Matrix object. The Row and Column variables must be present for this form of the procedure. |
| `Row` | The row index for the Value variable. |
| `Column` | The column index for the Value variable. |

**Input/Output variable:**

| | |
|---|---|
| `ELLM` | The ELL_Matrix object to be set. |

The Set_Values_ELL_Matrix code listing in § G.2.14 on page 594 contains additional documentation.

## 12.3 Solver Class

The Solver Class is used to describe a Solver in the CÆSAR Code Package. A Solver interacts with the other Solver class by blah blah blah.

The Solver methods section in § 16.3 on page 189 describes the methods used in the Solver Class.

**Solver public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes a Solver object. |
| `Finalize` | Finalizes a Solver object. |
| `Valid_State` | Returns false iff a Solver object is in an invalid state. |
| `Initialized` | Returns true iff a Solver object has been initialized. |
| **Operations** | |
| `Procedure` | Description. |
| `Name` | Returns the name of the Solver object. |
| `Output` | Writes out the Solver object. |

**Solver public defined types:**

| | |
|---|---|
| **solver type** | |
| `Variable` | Description. [Units] |

| | |
|---|---|
| **solver type** | |
| `Variable` | Description. [Units] |
| `Initialized` | Initialization status. |

**Solver public variables:**

| | |
|---|---|
| **variable type** | |
| `Variable` | Description. [Units] |

| | |
|---|---|
| **variable type** | |
| `Variable` | Description. [Units] |

The Solver Class code listing in § G.3 on page 605 contains additional documentation. The Solver Class also

contains a Unit Test Program which is listed in § G.3.8 on page 618.

### 12.3.1 Initialize_Solver Procedure

The Initialize_Solver procedure allocates and initializes a Solver object.

**Calling syntax:**

```
call Initialize (Solver, Package, status)
```

**Input variables:**

| | |
|---|---|
| `Solver` | The Solver object to be initialized. |
| `Package` | The linear algebra package to call. |

**Output variables:**

| | |
|---|---|
| `Solver` | The Solver object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Solver code listing in § G.3.1 on page 607 contains additional documentation.

### 12.3.2 Finalize_Solver Procedure

The Finalize_Solver procedure deallocates and finalizes a Solver object.

**Calling syntax:**

```
call Finalize (Solver, status)
```

**Input variables:**

| | |
|---|---|
| `Solver` | The Solver object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Solver` | The Solver object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Solver code listing in § G.3.2 on page 608 contains additional documentation.

### 12.3.3 Valid_State_Solver Procedure

The Valid_State_Solver procedure returns true iff the Solver is in a valid state – that is, iff the Solver passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Solver)
```

**Input variables:**

| | |
|---|---|
| `Solver` | The Solver to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Solver is in a valid state. |

The Valid_State_Solver code listing in § G.3.3 on page 610 contains additional documentation.

### 12.3.4 Initialized_Solver Procedure

The Initialized_Solver procedure returns true iff the Solver object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Solver)
```

**Input variable:**

| | |
|---|---|
| `Solver` | The Solver object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Solver object has been initialized. |

The Initialized_Solver code listing in § G.3.4 on page 611 contains additional documentation.

### 12.3.5 Set_Solver_Variable Procedure

The Set_Solver_Variable procedure sets a Solver internal variable.

**Calling syntax:**

```
call Set (Solver, Variable, Value)
```

**Input variables:**

| | |
|---|---|
| `Solver` | The Solver object to be set. |

`Variable` The variable within the Solver object to be set. Valid variables, their types and descriptions are:

| | | |
|---|---|---|
| Epsilon | real | Solver solution tolerance. |
| Maximum_Iterations | integer | For iterative solvers, the maximum number of iterations allowed. |
| Stopping_Test | character | The stopping test. Currently the only stopping test available is '——r——/——b—— ¡ Eps'. |
| LAMG_levout | integer | The output level variable for the LAMG package. |

`Value` The value to set the variable to, which is required to be the proper type (real, integer, character, logical) for a given variable.

**Output variables:**

`Solver` Modified Solver object.

The Set_Solver_Variable code listing in § G.3.5 on page 611 contains additional documentation.

### 12.3.6 Convert_ELL_to_LAMG Procedure

The Convert_ELL_to_LAMG procedure converts an ELL Matrix object to the LAMG matrix storage format. While converting to the LAMG CSR (compressed storage row) format, the zero entries in the ELL Matrix are removed, which will result in faster operation. This function is only available if CÆSAR has been compiled with LAMG.

**Calling syntax:**

```
call Convert (LAMG_Matrix, ELLM, LAMG_Communicator, LAMG_Options, status)
```

**Input variables:**

`ELLM` The ELL_Matrix object to be converted.
`LAMG_Communicator` The Communicator object for the LAMG package.
`LAMG_Options` The Options object for the LAMG package.

**Output variables:**

`LAMG_Matrix` The matrix in LAMG format.
`status` If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough.

**Internal variables:**

**Status variables**
`allocate_status` Allocation Status.
`consolidated_status` Consolidated Status.
`LAMG_Status` LAMG status.
**Matrix variables**
`NNonzeros_PE` Number of nonzeros on this PE.
`Columns_BNA` Matrix columns bare naked array.
`Values_BNA` Matrix values bare naked array.
`LAMG_BR_Matrix` LAMG block-row format matrix.

**Counter variables**

| | |
|---|---|
| `BR_Location` | Location in the block-row matrix. |
| `ELL_Location` | Location in the ELL matrix. |
| `row` | Row loop counter. |

The Convert_ELL_to_LAMG code listing in § G.3.6 on page 612 contains additional documentation.

### 12.3.7 Solve Procedure

The Solve procedure sets a Solver internal variable.

**Calling syntax:**

```
call Set (Solver, Variable, Value)
```

**Input variables:**

**Subtype variables**
`Variable` Description. [Units]

**Subtype variables**
`Variable` Description. [Units]

**Output variables:**

`Variable` Description. [Units]

**Internal variables:**

`Variable` Description. [Units]

The Solve code listing in § G.3.7 on page 615 contains additional documentation.

# Chapter 13

# Equation Module

## 13.1 Monomial Class

The Monomial Class is used to describe a Monomial in the CÆSAR Code Package. A Monomial interacts with the other Monomial class by blah blah blah.

The Monomial methods section in § ?? on page ?? describes the methods used in the Monomial Class.

**Monomial public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes a Monomial object. |
| `Finalize` | Finalizes a Monomial object. |
| `Valid_State` | Returns false iff a Monomial object is in an invalid state. |
| `Initialized` | Returns true iff a Monomial object has been initialized. |
| **Operations** | |
| `Add_to_Matrix_Equation_Monomial` | Description. |
| `Name` | Returns the name of the Monomial object. |
| `Output` | Writes out the Monomial object. |

**Monomial public defined types:**

**monomial type**

| | |
|---|---|
| `Variable` | Description. [Units] |

**monomial type**

| | |
|---|---|
| `Variable` | Description. [Units] |
| `Initialized` | Initialization status. |

**Monomial public variables:**

**variable type**

| | |
|---|---|
| `Variable` | Description. [Units] |

**variable type**

| | |
|---|---|
| `Variable` | Description. [Units] |

The Monomial Class code listing in § H.1 on page 621 contains additional documentation. The Monomial Class also contains a Unit Test Program which is listed in § H.1.8 on page 633.

### 13.1.1 Initialize_Monomial Procedure

The Initialize_Monomial procedure allocates and initializes a Monomial object.

**Calling syntax:**

```
call Initialize (Monomial, Coefficient, Exponent, Phi_MV, Locus, Mesh, Name, status)
```

**Input variables:**

**Subtype variables**

| | |
|---|---|
| `Monomial` | The Monomial object to be initialized. |
| `Coefficient` | A vector of coefficents for the monomial. |
| `Exponent` | The degree (exponent) of the monomial. |
| `Phi_MV` | An Mathematic Vector of the independent variable that this monomial is based on (past time step or iterate value). |
| `Locus` | The location for the monomial (e.g. Cells, Nodes or Faces) |
| `Mesh` | The Mesh object that this monomial is based on. |
| `Name` | The name for this variable. [Optional] |

**Output variables:**

| | |
|---|---|
| `Monomial` | The Monomial object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Monomial code listing in § H.1.1 on page 623 contains additional documentation.

### 13.1.2 Finalize_Monomial Procedure

The Finalize_Monomial procedure deallocates and finalizes a Monomial object.

**Calling syntax:**

```
call Finalize (Monomial, status)
```

**Input variables:**

| | |
|---|---|
| `Monomial` | The Monomial object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Monomial` | The Monomial object has been finalized and is no longer valid. |

| | |
|---|---|
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `Variable` | Description. [Units] |
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Monomial code listing in § H.1.2 on page 625 contains additional documentation.

### 13.1.3 Valid_State_Monomial Procedure

The Valid_State_Monomial procedure returns true iff the Monomial is in a valid state – that is, iff the Monomial passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Monomial)
```

**Input variables:**

| | |
|---|---|
| `Monomial` | The Monomial to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Monomial is in a valid state. |

**Internal variables:**

| | |
|---|---|
| `Variable` | Description. [Units] |

The Valid_State_Monomial code listing in § H.1.3 on page 626 contains additional documentation.

### 13.1.4 Initialized_Monomial Procedure

The Initialized_Monomial procedure returns true iff the Monomial object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Monomial)
```

**Input variable:**

| | |
|---|---|
| `Monomial` | The Monomial object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Monomial object has been initialized. |

The Initialized_Monomial code listing in § H.1.4 on page 627 contains additional documentation.

### 13.1.5 Add_to_Matrix_Equation_Monomial Procedure

The Add_to_Matrix_Equation_Monomial procedure adds the linearized version of the Monomial Term to the specified matrix equation. It currently assumes that there is a one-to-one correspondence between the Monomial locus (e.g. Cells) and the equation and variable numbering, and furthermore assumes that the locus is Cells.

**Calling syntax:**

```
call Add_to_Matrix_Equation (Monomial, ELLM, RHS_MV)
```

**Input variables:**

| | |
|---|---|
| `Monomial` | The Monomial Term to be added. |
| `ELLM` | The ELL Matrix to be incremented. |
| `RHS_MV` | The right-hand side Mathematic Vector to be incremented. |

**Output variables:**

| | |
|---|---|
| `ELLM` | The ELL Matrix that has been incremented. |
| `RHS_MV` | The right-hand side Mathematic Vector that has been incremented. |

**Internal variables:**

| | |
|---|---|
| `Matrix_Columns` | Columns for the added matrix values. |
| `Matrix_Rows` | Rows for the added matrix values. |
| `Matrix_Values` | Calculated values to be added to the matrix or vector. |

The Add_to_Matrix_Equation_Monomial code listing in § H.1.5 on page 628 contains additional documentation.

### 13.1.6 Get Value Monomial Functions

The Get_Value_Monomial functions return values from a Monomial object.

**Calling syntax:**

```
Output = Locus (Monomial)    or
Output = Name (Monomial)
```

**Input variables:**

| | |
|---|---|
| `Monomial` | The Monomial object to be examined. |

**Output variable:**

| | |
|---|---|
| `Output` | Returns a character variable containing the name or locus assigned to the object upon initialization. |

The Get Value Monomial code listing in § H.1.6 on page 630 contains additional documentation.

### 13.1.7 Output_Monomial Procedure

The Output_Monomial procedure writes out a section of a Mathematic Vector to the specified unit.

**Calling syntax:**

```
call Output (Monomial, First, Last, Unit, Indent, status)
```

**Input variables:**

| | |
|---|---|
| `Monomial` | The Monomial object to be queried. |
| `First` | The first location to be output. [Optional] |
| `Last` | The last location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Indent` | Number of indentation characters. [Optional] |

**Output variables:**

| | |
|---|---|
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `Coefficient_MV` | Temporary Mathematic Vector for the Coefficient. |
| `Phi_MV` | Temporary Mathematic Vector for Phi. |
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Output_Monomial code listing in § H.1.7 on page 631 contains additional documentation.

## 13.2 Ortho_Diffusion Class

The Ortho_Diffusion Class is used to describe an Orthogonal Diffusion equation term in the CÆSAR Code Package.

The Ortho_Diffusion methods section in § ?? on page ?? describes the methods used in the Ortho_Diffusion Class.

**Ortho_Diffusion public procedures:**

| | |
|---|---|
| **Fundamental procedures** | |
| `Initialize` | Initializes an Ortho_Diffusion object. |
| `Finalize` | Finalizes an Ortho_Diffusion object. |
| `Valid_State` | Returns false iff an Ortho_Diffusion object is in an invalid state. |
| `Initialized` | Returns true iff an Ortho_Diffusion object has been initialized. |
| **Operations** | |
| `Add_to_Matrix_Equation` | Adds the linearized version of the Ortho_Diffusion Term to the specified matrix equation. |
| `Evaluate_Gradient_Cells` | Evaluates the gradient of Phi at the cell centers using the linearization of the Ortho_Diffusion Term. |
| `Locus` | Returns the locus of the Ortho_Diffusion object. |
| `Name` | Returns the name of the Ortho_Diffusion object. |
| `Output` | Writes out the Ortho_Diffusion object. |

**Ortho_Diffusion public defined types:**

| **Ortho_Diffusion type** | |
|---|---|
| `Boundary_Condition` | The boundary condition flag for each face of each cell. |
| `Coefficient` | The diffusion coefficient, defined on the cells for now. |
| `Initialized` | Initialization status. |
| `Locus` | Evaluation locus. |
| `Mesh` | Mesh that this Ortho_Diffusion object is defined on. |
| `Name` | The name for this variable. |
| `Phi` | The independent variable at the linearization value (past time step or iterate). |
| `Phi_BC` | The boundary condition constant for each face of each cell. |
| `Structure` | Locus Base_Structure. |

**Ortho_Diffusion private procedures:**

| | |
|---|---|
| `Get_Harmonic_Diffusion_Coef` | Returns the harmonic diffusion coefficients for each face of each cell. |

The Ortho_Diffusion Class code listing in § H.2 on page 635 contains additional documentation. The Ortho_-Diffusion Class also contains a Unit Test Program which is listed in § H.2.10 on page 658.

### 13.2.1 Initialize_Ortho_Diffusion Procedure

The Initialize_Ortho_Diffusion procedure allocates and initializes an Ortho_Diffusion Term object.

**Calling syntax:**

```
call Initialize (Diff_Term, Coefficient, Phi_MV, Locus, Mesh, Name, Extrapolation, status)
```

**Input variables:**

| **Subtype variables** | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion object to be initialized. |
| `Coefficient` | A vector of diffusion coefficents. |
| `Phi_MV` | An Mathematic Vector of the independent variable that this Ortho_Diffusion object is based on (past time step or iterate value). |
| `Locus` | The location for the Ortho_Diffusion Term (e.g. Cells, Nodes or Faces) |
| `Mesh` | The Mesh object that this Ortho_Diffusion Term is based on. |
| `Name` | The name for this variable. [Optional] |
| `Extrapolation` | A factor used in the source and vacuum boundary conditions, which effectively sets the extrapolation distance to Coefficient/Extrapolation. [Optional, default is 1/2] |

**Output variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Ortho_Diffusion code listing in § H.2.1 on page 638 contains additional documentation.

### 13.2.2 Finalize_Ortho_Diffusion Procedure

The Finalize_Ortho_Diffusion procedure deallocates and finalizes an Ortho_Diffusion object.

**Calling syntax:**

```
call Finalize (Diff_Term, status)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| `Variable` | Description. [Units] |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Ortho_Diffusion code listing in § H.2.2 on page 641 contains additional documentation.

### 13.2.3 Valid_State_Ortho_Diffusion Procedure

The Valid_State_Ortho_Diffusion procedure returns true iff the Ortho_Diffusion Term is in a valid state – that is, iff the Ortho_Diffusion Term passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Diff_Term)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Ortho_Diffusion Term is in a valid state. |

The Valid_State_Ortho_Diffusion code listing in § H.2.3 on page 642 contains additional documentation.

### 13.2.4 Initialized_Ortho_Diffusion Procedure

The Initialized_Ortho_Diffusion procedure returns true iff the Ortho_Diffusion Term object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Diff_Term)
```

**Input variable:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Ortho_Diffusion Term object has been initialized. |

The Initialized_Ortho_Diffusion code listing in § H.2.4 on page 643 contains additional documentation.

### 13.2.5 Add_to_Matrix_Equation_Ortho_Diffusion Procedure

The Add_to_Matrix_Equation_Ortho_Diffusion procedure adds the linearized version of the Ortho_Diffusion Term to the specified matrix equation. It currently assumes that there is a one-to-one correspondence between the Ortho_Diffusion locus (e.g. Cells) and the equation and variable numbering, and furthermore assumes that the locus is Cells.

**Calling syntax:**

```
call Add_to_Matrix_Equation (Diff_Term, ELLM, RHS_MV)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term to be added. |
| `ELLM` | The ELL Matrix to be incremented. |
| `RHS_MV` | The right-hand side Mathematic Vector to be incremented. |

**Output variables:**

| | |
|---|---|
| `ELLM` | The ELL Matrix that has been incremented. |
| `RHS_MV` | The right-hand side Mathematic Vector that has been incremented. |

**Internal variables:**

| | |
|---|---|
| `Matrix_Columns` | Columns for the added matrix values. |
| `Matrix_Rows` | Rows for the added matrix values. |
| `Matrix_Values` | Calculated values to be added to the matrix or vector. |

The Add_to_Matrix_Equation_Ortho_Diffusion code listing in § H.2.5 on page 643 contains additional documentation.

### 13.2.6 Evaluate_Gradient_Cells_Ortho_Diffusion Procedure

The Evaluate_Gradient_Cells_Ortho_Diffusion procedure evaluates the gradient of Phi at the cell centers using the specified Ortho_Diffusion Term.

**Calling syntax:**

```
call Evaluate_Gradient_Cells (Diff_Term, Phi_MV, Grad_Cells)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term to be evaluated. |
| `Phi_MV` | The Phi Mathematic Vector to use in the evaluation. |

**Output variables:**

| | |
|---|---|
| `Grad_Cells` | The gradient of Phi vector evaluated at the cell centers. |

**Internal variable:**

| | |
|---|---|
| `Grad_dot_N_Faces_of_Cells` | The gradient of Phi dotted with the unit normal at each face of each cell. |

The Evaluate_Gradient_Cells_Ortho_Diffusion code listing in § H.2.6 on page 648 contains additional documentation.

### 13.2.7 Get_Harmonic_Diffusion_Coef_Ortho_Diffusion Procedure

The Get_Harmonic_Diffusion_Coef_Ortho_Diffusion procedure calculates the harmonic average of the diffusion coefficient at each face of each cell.

**Calling syntax:**

```
call Get_Harmonic_Diffusion_Coef ( Harmonic_Diffusion_Coef_F_of_C, Diff_Term)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term to be queried. |

**Output variables:**

| | |
|---|---|
| `Harmonic_Diffusion_Coef_F_of_C` | The harmonic average diffusion coefficient evaluated at each face of each cell on this PE. |

The Get_Harmonic_Diffusion_Coef_Ortho_Diffusion code listing in § H.2.7 on page 652 contains additional documentation.

### 13.2.8 Get Value Ortho_Diffusion Functions

The Get_Value_Ortho_Diffusion functions return values from an Ortho_Diffusion Term object.

**Calling syntax:**

```
Output = Locus (Diff_Term)    or
Output = Name (Diff_Term)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion Term object to be examined. |

**Output variable:**

| | |
|---|---|
| `Output` | Returns a character variable containing the name or locus assigned to the object upon initialization. |

The Get Value Ortho_Diffusion code listing in § H.2.8 on page 654 contains additional documentation.

### 13.2.9 Output_Ortho_Diffusion Procedure

The Output_Ortho_Diffusion procedure writes out a section of a Ortho_Diffusion object to the specified unit.

**Calling syntax:**

```
call Output (Diff_Term, First, Last, Unit, Indent, status)
```

**Input variables:**

| | |
|---|---|
| `Diff_Term` | The Ortho_Diffusion object to be queried. |
| `First` | The first location to be output. [Optional] |
| `Last` | The last location to be output. [Optional] |
| `Unit` | The logical unit for output, which defaults to 6. [Optional] |
| `Indent` | Number of indentation characters. [Optional] |

**Output variables:**

| | |
|---|---|
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `Coefficient_MV` | Temporary Mathematic Vector for the Coefficient. |
| `Phi_MV` | Temporary Mathematic Vector for Phi. |
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Output_Ortho_Diffusion code listing in § H.2.9 on page 655 contains additional documentation.

# Chapter 14

# Mesh Module

## 14.1 Multi_Mesh Class

The Multi_Mesh Class is used to describe a mesh in the CÆSAR Code Package.

The following is incomplete documentation – or rather documentation in the middle of being written.

| Dims | Uniformity | Orthogonality | Structure | AMR | Cell-Shape | Geometry |
|---|---|---|---|---|---|---|
| 1 | Uniform | Orthogonal | Structured | no | Segmented | x-Cartesian |
| 1 | Uniform | Orthogonal | Structured | no | Segmented | r-Cylindrical |
| 1 | Uniform | Orthogonal | Structured | no | Segmented | r-Spherical |
| 1 | Nonuniform | Orthogonal | Structured | no | Segmented | x-Cartesian |
| 1 | Nonuniform | Orthogonal | Structured | no | Segmented | r-Cylindrical |
| 1 | Nonuniform | Orthogonal | Structured | no | Segmented | r-Spherical |
| 1 | Nonuniform | Orthogonal | Unstructured | no | Segmented | x-Cartesian |
| 1 | Nonuniform | Orthogonal | Unstructured | no | Segmented | r-Cylindrical |
| 1 | Nonuniform | Orthogonal | Unstructured | no | Segmented | r-Spherical |
| 2 | Uniform | Orthogonal | Structured | no | Quadrilateral | xy-Cartesian |
| 2 | Uniform | Orthogonal | Structured | no | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Orthogonal | Structured | no | Quadrilateral | xy-Cartesian |
| 2 | Nonuniform | Orthogonal | Structured | no | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Nonorthogonal | Structured | no | Quadrilateral | xy-Cartesian |
| 2 | Nonuniform | Nonorthogonal | Structured | no | Quadrilateral | rz-Cylindrical |
| 2 | Uniform | Orthogonal | Structured | yes | Quadrilateral | xy-Cartesian |
| 2 | Uniform | Orthogonal | Structured | yes | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Orthogonal | Structured | yes | Quadrilateral | xy-Cartesian |
| 2 | Nonuniform | Orthogonal | Structured | yes | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Nonorthogonal | Structured | yes | Quadrilateral | xy-Cartesian |
| 2 | Nonuniform | Nonorthogonal | Structured | yes | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Nonorthogonal | Unstructured | no | Quadrilateral | xy-Cartesian |
| 2 | Nonuniform | Nonorthogonal | Unstructured | no | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Nonorthogonal | Unstructured | yes | Quadrilateral | xy-Cartesian |
| 2 | Nonuniform | Nonorthogonal | Unstructured | yes | Quadrilateral | rz-Cylindrical |
| 2 | Nonuniform | Nonorthogonal | Unstructured | no | Triangular | xy-Cartesian |
| 2 | Nonuniform | Nonorthogonal | Unstructured | no | Triangular | rz-Cylindrical |
| 2 | Nonuniform | Nonorthogonal | Unstructured | no | Polygonal | xy-Cartesian |
| 2 | Nonuniform | Nonorthogonal | Unstructured | no | Polygonal | rz-Cylindrical |
| 3 | Uniform | Orthogonal | Structured | no | Hexahedral | xyz-Cartesian |

```
3   Nonuniform  Orthogonal     Structured    no  Hexahedral    xyz-Cartesian
3   Nonuniform  Nonorthogonal  Structured    no  Hexahedral    xyz-Cartesian
3   Uniform     Orthogonal     Structured    yes Hexahedral    xyz-Cartesian
3   Nonuniform  Orthogonal     Structured    yes Hexahedral    xyz-Cartesian
3   Nonuniform  Nonorthogonal  Structured    yes Hexahedral    xyz-Cartesian
3   Nonuniform  Nonorthogonal  Unstructured  no  Hexahedral    xyz-Cartesian
3   Nonuniform  Nonorthogonal  Unstructured  yes Hexahedral    xyz-Cartesian
3   Nonuniform  Nonorthogonal  Unstructured  no  Tetrahedral   xyz-Cartesian
3   Nonuniform  Nonorthogonal  Unstructured  no  Polyhedral    xyz-Cartesian

In general, treat the mesh as:

*   Nonuniform  Nonorthogonal  Unstructured  *   *             if-check

where *-values are mostly handled inside the parallel data structures.

Implications:

 Uniform meshes must be structured.
 1-D meshes must be orthogonal.
 2-D means "not spherical".
```

Mesh Nomenclature

A mesh consists of a collection of spatial locations or points, called *nodes*, that are connected in various ways to define distinct spatial volumes, called *cells*, and to define surface areas, called *faces*, between the cells and on the boundaries of the mesh.

In a three-dimensional mesh, nodes are zero-dimensional, faces are two-dimensional[1], and cells are three-dimensional.

In a two-dimensional mesh, nodes are zero-dimensional, faces are one-dimensional (with a suppressed second dimension), and cells are two-dimensional (with a suppressed third dimension).

In a one-dimensional mesh, nodes are zero-dimensional, faces are zero-dimensional (with two suppressed dimensions), and cells are one-dimensional (with two additional suppressed dimensions).

The *connectivity* of a mesh refers to the way that nodes are connected to form cells, and the way that cells are connected to each other. The connectivity of a mesh may be specified in several ways, but a common form gives the node numbers surrounding each cell in an array.

The *cell-shape* of a mesh is determined by the maximum allowed number of faces for a cell in the mesh. In some meshes, degenerate cells are allowed which have fewer than the maximum number of faces. For one-dimensional meshes, the only possible cell-shape is *segmented*, which refers to a line segment or bar as the representation of a cell. For two-dimensional meshes, the possible cell-shapes are *triangular*, *quadrilateral*, or *polygonal*. For three-dimensional meshes, the possible cell-shapes are *tetrahedral*, *hexahedral*, or *polyhedral*.

The *geometry* of a mesh refers to both the coordinate system used by the mesh and the common names for the coordinate axes that are not suppressed. With a Cartesian coordinate system, using the common names of $x$, $y$, and $z$ for the axes, the possible geometries are $x$-Cartesian, $xy$-Cartesian, and $xyz$-Cartesian. With a cylindrical coordinate system, using the common names of $r$, $\theta$, and $z$ for the axes, the possible unique geometries are $r$-Cylindrical, $\theta$-Cylindrical, $r\theta$-Cylindrical, $rz$-Cylindrical, and $r\theta z$-Cylindrical. With a spherical coordinate system, using the common names of $r$, $\theta$ (azimuth, range of 0-$2\pi$), and $\phi$ (zenith, range of 0-$\pi$) for the axes, the possible unique geometries are $r$-Spherical, $\theta$-Spherical, $\phi$-Spherical, $r\theta$-Spherical, $r\phi$-Spherical, $\theta\phi$-Spherical, and $r\theta\phi$-Spherical. In CÆSAR only the major geometries are included, namely $x$-Cartesian, $r$-Cylindrical, $r$-Spherical, $xy$-Cartesian, $rz$-Cylindrical, and $xyz$-Cartesian.

[1] Even though faces are two-dimensional surfaces, they may be warped in such a way that they are not flat, in the same way that the surface of a sphere is not flat even though it is two-dimensional

Mesh Type Descriptions:

In the mesh descriptions that follow, distinctions are made for the connectivity of the mesh

**Unstructured Polyhedral or Polygonal Mesh**

**A mesh is said to be *structured*, or *logically rectangular*,** if its nodes and cells can be numbered with an index for each dimension. For example, in three dimensions every cell in a structured mesh can be referred to by an $(i, j, k)$ triplet. In a structured mesh the connectivity is known a priori – mesh cell $(i, j, k)$ shares a face with cells $(i+1, j, k), (i-1, j, k), (i, j+1, k), (i, j-1, k), (i, j, k+1),$ and $(i, j, k-1)$ and is defined by nodes $(i, j, k), (i+1, j, k), (i, j+1, k), (i+1, j+1, k), (i, j, k+1), (i, j, k+1), (i+1, j, k+1), (i, j+$ and $(i+1, j+1, k+1)$. Structured meshes must be formed from quadrilateral meshes in 2-D and hexahedral meshes in 3-D.

**A mesh is said to be *orthogonal*** if all of the mesh faces are aligned with the coordinate axes. Thus, one can speak of a minus $x$-face or a plus $y$-face of a cell with no ambiguity. All angles between faces are either zero or 90°. Orthogonal meshes are composed of rectangles in 2-D and right rectangular prisms (also known as rectangular parallelepipeds) in 3-D. In addition, each face is planar in 3-D.

**A *uniform* mesh** has cells that all have the same shape and size. All cells have the same volume and face areas. Stating a cell-width and the number of cells in each direction completely specifies a uniform mesh. Uniform meshes are composed of rectangles in 2-D and right rectangular prisms (also known as rectangular parallelepipeds) in 3-D.

**AMR (Adaptive Mesh Refinement) meshes** can be thought of as a halfway point between quadrilateral/hexahedral cell-shapes and polygonal/polyhedral cell-shapes.

Initialize (Mesh, "Uniform", Geometry, NDimensions, dx, dy, dz

**Multi_Mesh public procedures:**

| **Fundamental procedures** | |
|---|---|
| `Initialize` | Initializes a Multi_Mesh object. |
| `Finalize` | Finalizes a Multi_Mesh object. |
| `Valid_State` | Returns false iff a Multi_Mesh object is in an invalid state. |
| `Initialized` | Returns true iff a Multi_Mesh object has been initialized. |
| **Operations** | |
| `Name` | Returns the name of the Multi_Mesh object. |
| `Output` | Writes out the Multi_Mesh object. |
| `Set_Version` | Sets the version number of the Multi_Mesh object (also has an assignment interface). |
| `Version` | Returns the version number of the Multi_Mesh object. |

**Multi_Mesh public defined type:**

| **Multi_Mesh type** | |
|---|---|
| `Initialized` | Initialization status. |
| `Name` | The name for this mesh. |
| `Version` | Version number which is incremented every time the array is modified, or is synced with the version number of a data structure that it depends on when it is updated. |

The Multi_Mesh Class code listing in § I.1 on page 681 contains additional documentation. The Multi_Mesh Class also contains a Unit Test Program which is listed in § I.1.24 on page 746.

### 14.1.1 Initialize_Base_Multi_Mesh Procedure

The Initialize_Base_Multi_Mesh procedure allocates and initializes the fundamental parts of a Multi_Mesh object that are common to all mesh types. It sets the following mesh data:

- mesh type information (NDimensions, Geometry, Uniformity, Orthogonality, Structure, AMR, Shape),
- mesh scalar information (NCells_total, NCells_PE, Last_Cell_PE, First_Cell_PE, Range_Cells_PE, NNodes_total, NNodes_PE, Last_Node_PE, First_Node_PE, Range_Nodes_PE, NFaces_total, NFaces_PE, Last_Face_PE, First_Face_PE, Range_Faces_PE, Nodes_per_Cell, Nodes_per_Face, Faces_per_Cell),
- mesh base structures (Node_Structure, Cell_Structure, Face_Structure),
- mesh coordinates (Coordinates_Nodes), and
- mesh node-cell connectivity (Nodes_of_Cells_Index).

The Initialize_Base_Multi_Mesh procedure is most often used in specific mesh initialization procedures.

**Calling syntax:**

```
call Initialize (Mesh, NDimensions, Geometry, Uniformity, Orthogonality, Structure, AMR, Shape, NNo
```

**Input variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be initialized. |
| `NDimensions` | The number of spatial dimensions. [1,2,3] |
| `Geometry` | The geometry type. [Cartesian, Cylindrical, or Spherical] |
| `Uniformity` | The uniformity of the mesh. [Uniform, Nonuniform] |
| `Orthogonality` | The orthogonality of the mesh. [Orthogonal, Nonorthogonal] |
| `Structure` | The mesh structure. [Structured, Unstructured] |
| `AMR` | Logical which is true for Adaptive Mesh Refinement (AMR, H-type |
| `Shape` | The shape of cells in the mesh. [Segmented, Triangular, Quadrilate Tetrahedral, Hexahedral, Polyhedral] |
| `NNodes_Vector` | A vector containing the number of mesh nodes on each PE. |
| `NCells_Vector` | A vector containing the number of mesh cells on each PE. |
| `NFaces_Vector` | A vector containing the number of mesh faces on each PE. |
| `Coordinates_Nodes_PE(NDimensions,Nodes_PE)` | The coordinates of the nodes on this PE. |
| `Nodes_of_Cells_PE(Cells_PE,Nodes_per_Cell)` | The node numbers for each cell on this PE. |
| `dim`$\{n\}$ | The dimensions for this "array". There must be dimensions specified one less than the Dimensionality. These are only needed in the seco call. [Optional] |
| `Mesh_Name` | The name for this mesh. [Optional] |

**Output variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Base_Multi_Mesh code listing in § I.1.1 on page 688 contains additional documentation.

### 14.1.2 Initialize_Uniform_Multi_Mesh Procedure

The Initialize_Uniform_Multi_Mesh procedure allocates and initializes a uniform Multi_Mesh object. A uniform mesh is a structured, orthogonal, cartesian[2] mesh where every cell is exactly the same size and shape. There is a single $\Delta x$, $\Delta y$ and $\Delta z$ for the entire mesh, which has a block-shaped domain (i.e. a right rectangular prism in 3D). In parallel, each PE also contains a block-shaped domain, but each PE may have a different-sized block. An optimum partitioning of the mesh, given these constraints, is generated by the Gen_StructureMesh_Connectivity procedure.

In addition to the mesh data set by the Initialize_Base_Multi_Mesh procedure, this procedure also sets the following uniform-specific mesh data:

- mesh cell-cell connectivity (Cells_of_Cells_Index),
- mesh face flags to indicate left (-x), right (+x), front (-y), back (+y), bottom (-z), top (+z) and interior faces (Flag_Faces_of_Cells),
- physical dimensions of the entire domain (Lengths),
- the volume of every cell (Volume_All_Cells), and
- the area for all faces (Area_All_Faces).

**Calling syntax:**

```
call Initialize (Mesh, NDimensions, Lengths, NCells_X_total, NCells_Y_total, NCells_Z_total, Mesh_N
```

**Input variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be initialized. |
| `NDimensions` | The number of dimensions for the mesh. |
| `Lengths` | A vector of the physical lengths for the mesh. |
| `NCells_X_total` | Total number of cells in the X-direction, defined on every PE. |
| `NCells_Y_total` | Total number of cells in the Y-direction, defined on every PE. [Optional] |
| `NCells_Z_total` | Total number of cells in the Z-direction, defined on every PE. [Optional] |
| `Mesh_Name` | The name for this mesh. [Optional] |

**Output variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Uniform_Multi_Mesh code listing in § I.1.2 on page 692 contains additional documentation.

[2]capability for non-cartesian uniform meshes could be added, but each cell would no longer have the same volume and face areas, so those procedures would need to be modified also

### 14.1.3 Initialize_Orthogonal_Multi_Mesh Procedure

The Initialize_Orthogonal_Multi_Mesh procedure allocates and initializes an orthogonal Multi_Mesh object. An orthogonal mesh is a structured, cartesian[3] mesh with block-shaped cells. Each cell may have a different $\Delta x$, $\Delta y$ and $\Delta z$, but the entire mesh can be described by vectors of coordinates along the three axes. The mesh has a block-shaped domain (i.e. a right rectangular prism in 3D). In parallel, each PE also contains a block-shaped domain, but each PE may have a different-sized block. An optimum partitioning of the mesh, given these constraints, is generated by the Gen_StructureMesh_Connectivity procedure.

In addition to the mesh data set by the Initialize_Base_Multi_Mesh procedure, this procedure also sets the following orthogonal-specific mesh data:

- mesh cell-cell connectivity (Cells_of_Cells_Index),
- mesh face flags to indicate left (-x), right (+x), front (-y), back (+y), bottom (-z), top (+z) and interior faces (Flag_Faces_of_Cells), and
- physical dimensions of the entire domain (Lengths).

**Calling syntax:**

```
call Initialize (Mesh, NDimensions, Coordinates_Nodes_X, Coordinates_Nodes_Y, Coordinates_Nodes_Z,
```

**Input variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be initialized. |
| `NDimensions` | The number of dimensions for the mesh. |
| `Coordinates_Nodes_X` | The X-coordinates for all of the nodes, defined on every PE. |
| `Coordinates_Nodes_Y` | The Y-coordinates for all of the nodes, defined on every PE. [Optional] |
| `Coordinates_Nodes_Z` | The Z-coordinates for all of the nodes, defined on every PE. [Optional] |
| `Mesh_Name` | The name for this mesh. [Optional] |

**Output variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object has been allocated and initialized. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `allocate_status` | Allocation Status. |
| `consolidated_status` | Consolidated Status. |

The Initialize_Orthogonal_Multi_Mesh code listing in § I.1.3 on page 696 contains additional documentation.

### 14.1.4 Finalize_Multi_Mesh Procedure

The Finalize_Multi_Mesh procedure deallocates and finalizes a Multi_Mesh object.

**Calling syntax:**

[3] capability for non-cartesian orthogonal meshes could be added, if the volume and face area procedures were modified accordingly

```
call Finalize (Mesh, status)
```

**Input variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be finalized. |

**Output variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object has been finalized and is no longer valid. |
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

**Internal variables:**

| | |
|---|---|
| `consolidated_status` | Consolidated Status. |
| `deallocate_status` | Deallocation Status vector. |

The Finalize_Multi_Mesh code listing in § I.1.4 on page 712 contains additional documentation.

### 14.1.5 Valid_State_Multi_Mesh Procedure

The Valid_State_Multi_Mesh procedure returns true iff the Multi_Mesh is in a valid state – that is, iff the Multi_Mesh passes all of the valid state tests.

**Calling syntax:**

```
Logical = Valid_State(Mesh)
```

**Input variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh to be checked. |

**Output variable:**

| | |
|---|---|
| `Valid_State` | True iff the Multi_Mesh is in a valid state. |

The Valid_State_Multi_Mesh code listing in § I.1.5 on page 714 contains additional documentation.

### 14.1.6 Initialized_Multi_Mesh Procedure

The Initialized_Multi_Mesh procedure returns true iff the Multi_Mesh object has been initialized.

**Calling syntax:**

```
Logical = Initialized(Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be examined. |

**Output variable:**

| | |
|---|---|
| `Initialized` | True iff the Multi_Mesh object has been initialized. |

The Initialized_Multi_Mesh code listing in § I.1.6 on page 715 contains additional documentation.

### 14.1.7 Dump_CGNS_Multi_Mesh Procedure

NOTE: This procedure has not been fully implemented and tested.

The Dump_CGNS_Multi_Mesh procedure writes a CGNS output file for a mesh to the specified filename.

**Calling syntax:**

```
call Dump_CGNS (Mesh, Filename, status)
```

**Input variables:**

| | |
|---|---|
| `Filename` | The filename for CGNS dump output. |
| `Mesh` | The Multi_Mesh object to be queried. |

The Dump_CGNS_Multi_Mesh code listing in § I.1.7 on page 716 contains additional documentation.

### 14.1.8 Dump_GMV_Multi_Mesh Procedure

The Dump_GMV_Multi_Mesh procedure writes a GMV plotting file for a mesh and any listed variables to the specified filename.

**Calling syntax:**

```
call Dump_GMV (Filename, Mesh, Variable1_MV, ..., VariableN_MV, Variable1_DV, ..., VariableN_DV, st
```

**Input variables:**

| | |
|---|---|
| `Filename` | The filename for GMV dump output. |
| `Mesh` | The Multi_Mesh object to be output to the GMV dump file. |
| `Variable#_MV` | Mathematical vectors to be output along with the mesh. The pound sign may be replaced with a number from 1 to `REP_NUMBER`. [Optional] |
| `Variable#_DV` | Distributed vectors to be output along with the mesh. The pound sign may be replaced with a number from 1 to `REP_NUMBER`. [Optional] |

**Output variable:**

| | |
|---|---|
| `status` | If present, the status variable is set to either `'File Error'`, `'Memory Error'`, `'Multiple Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

The Dump_GMV_Multi_Mesh code listing in § I.1.8 on page 720 contains additional documentation.

### 14.1.9 Dump_GMV DV and MV Vector Procedures

The Dump_GMV_Distributed_Vector and Dump_GMV_Mathematic_Vector procedures are used internally to output a variable to the middle of a GMV plotting file.

**Calling syntax:**

```
call Dump_GMV_Distributed_Vector (Variable, Mesh, unit, status)   or
call Dump_GMV_Mathematic_Vector (Variable, Mesh, unit, status)
```

**Input variables:**

| | |
|---|---|
| `Variable` | Mathematical or Distributed Vector to be output. |
| `Mesh` | The Multi_Mesh object for this GMV dump. |
| `unit` | The unit for GMV dump output. |

**Output variable:**

| | |
|---|---|
| `status` | If present, the status variable is set to either `'Memory Error'` or `'Success'` depending on program execution. If not present, the procedure aborts if unsuccessful when the `DEBUG_LEVEL` is set high enough. |

The Dump_GMV DV and MV Vector code listing in § I.1.9 on page 724 contains additional documentation.

### 14.1.10 Get_Area_Faces_of_Cells_Multi_Mesh Procedure

The Get_Area_Faces_of_Cells_Multi_Mesh procedure returns the vector areas for each face of each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_Area_Faces_of_Cells (Area_Faces_of_Cells, Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object. |

**Output variable:**

| | |
|---|---|
| `Area_Faces_of_Cells` | An array of the vector areas for each face of the cells on this PE. |

The Get_Area_Faces_of_Cells_Multi_Mesh code listing in § I.1.10 on page 727 contains additional documentation.

### 14.1.11 Get_Coordinates_Cells_Multi_Mesh Procedure

The Get_Coordinates_Cells_Multi_Mesh procedure returns the cell center coordinates for each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_Coordinates_Cells (Coordinates_Cells, Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object. |

**Output variable:**

| | |
|---|---|
| `Coordinates_Cells` | The cell-center coordinates for each cell on this PE. |

The Get_Coordinates_Cells_Multi_Mesh code listing in § I.1.11 on page 729 contains additional documentation.

### 14.1.12 Get_Coordinates_Cells_of_Cells_Multi_Mesh Procedure

The Get_Coordinates_Cells_of_Cells_Multi_Mesh procedure returns the coordinates for the cell on the other side of each face of each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_Coordinates_Cells_of_Cells (Coordinates_Cells_of_Cells, Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object. |

**Output variable:**

| | |
|---|---|
| `Coordinates_Cells_of_Cells` | An array of the coordinates for the cells on the other side of each face of the cells on this PE. |

The Get_Coordinates_Cells_of_Cells_Multi_Mesh code listing in § I.1.12 on page 730 contains additional documentation.

### 14.1.13 Get_Coordinates_Faces_of_Cells_Multi_Mesh Procedure

The Get_Coordinates_Faces_of_Cells_Multi_Mesh procedure returns the coordinates for each face of each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_Coordinates_Faces_of_Cells (Coordinates_Faces_of_Cells, Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object. |

**Output variable:**

| | |
|---|---|
| `Coordinates_Faces_of_Cells` | An array of the coordinates for each face of the cells on this PE. |

The Get_Coordinates_Faces_of_Cells_Multi_Mesh code listing in § I.1.13 on page 732 contains additional documentation.

### 14.1.14 Get_Coordinates_Nodes_of_Cells_Multi_Mesh Procedure

The Get_Coordinates_Nodes_of_Cells_Multi_Mesh procedure returns the node coordinates for each node of each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_Coordinates_Nodes_of_Cells (Coordinates_Nodes_of_Cells, Mesh)
```

**Input variable:**

`Mesh` The Multi_Mesh object.

**Output variable:**

`Coordinates_Nodes_of_Cells` The coordinates of the nodes for each cell on this PE.

The Get_Coordinates_Nodes_of_Cells_Multi_Mesh code listing in § I.1.14 on page 734 contains additional documentation.

### 14.1.15 Get_DeltaR21_Cells_of_Cells_Multi_Mesh Procedure

The Get_DeltaR21_Cells_of_Cells_Multi_Mesh procedure returns the absolute distance between the cell center and the cell center across each face (the "other" cell) for each face of each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_DeltaR21_Cells_of_Cells (DeltaR21_Cells_of_Cells, Mesh)
```

**Input variable:**

`Mesh` The Multi_Mesh object.

**Output variable:**

`DeltaR21_Cells_of_Cells` The absolute distance between the cell center and the other_cell center (across the face) for each cell on this PE.

The Get_DeltaR21_Cells_of_Cells_Multi_Mesh code listing in § I.1.15 on page 735 contains additional documentation.

### 14.1.16 Get_DeltaR1f_Cells_of_Cells_Multi_Mesh Procedure

The Get_DeltaR1f_Cells_of_Cells_Multi_Mesh procedure returns the absolute distance between the cell center and each face center for each cell of a Multi_Mesh object. Although the locus could be thought of as Faces_of_Cells, it is called Cells_of_Cells to correspond with other variables across the face (e.g. DeltaR2f_-Cells_of_Cells).

**Calling syntax:**

```
call Get_DeltaR1f_Cells_of_Cells (DeltaR1f_Cells_of_Cells, Mesh)
```

**Input variable:**

`Mesh` The Multi_Mesh object.

**Output variable:**

`DeltaR1f_Cells_of_Cells` The absolute distance between the cell center and each face center for each cell on this PE.

The Get_DeltaR1f_Cells_of_Cells_Multi_Mesh code listing in § I.1.16 on page 737 contains additional documentation.

### 14.1.17 Get_DeltaR2f_Cells_of_Cells_Multi_Mesh Procedure

The Get_DeltaR2f_Cells_of_Cells_Multi_Mesh procedure returns the absolute distance between the cell center across the face (the "other" cell) and the face itself for each face of each cell of a Multi_Mesh object.

**Calling syntax:**

```
call Get_DeltaR2f_Cells_of_Cells (DeltaR2f_Cells_of_Cells, Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object. |

**Output variable:**

| | |
|---|---|
| `DeltaR2f_Cells_of_Cells` | The absolute distance between the other cell center and each face center for each cell on this PE. |

The Get_DeltaR2f_Cells_of_Cells_Multi_Mesh code listing in § I.1.17 on page 738 contains additional documentation.

### 14.1.18 Get_Flag_Faces_of_Cells_Multi_Mesh Procedure

The Get_Flag_Faces_of_Cells_Multi_Mesh procedure returns the Flag for each face of each cell of a Multi_Mesh object. These flags are set to:

| | |
|---|---|
| 0 | internal faces |
| 1 | left faces (-x) |
| 2 | right faces (+x) |
| 3 | front faces (-y) |
| 4 | back faces (+y) |
| 5 | bottom faces (-z) |
| 6 | top faces (+z) |

**Calling syntax:**

```
call Get_Flag_Faces_of_Cells (Flag_Faces_of_Cells, Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object. |

**Output variable:**

| | |
|---|---|
| `Flag_Faces_of_Cells` | The flags for each face of the cells on this PE. |

The Get_Flag_Faces_of_Cells_Multi_Mesh code listing in § I.1.18 on page 739 contains additional documentation.

### 14.1.19 Get Value Multi_Mesh Functions

The Get_Value_Multi_Mesh functions return values from a Multi_Mesh object.

**Calling syntax:**

```
Pointer = Cell_Structure(Mesh)       ,
Pointer = Face_Structure(Mesh)       ,
Output = First_Cell_PE(Mesh)         ,
Output = First_Face_PE(Mesh)         ,
Output = First_Node_PE(Mesh)         ,
Output = Get_Faces_per_Cell(Mesh)    ,
Output = Get_NDimensions(Mesh)       ,
Output = Last_Cell_PE(Mesh)          ,
Output = Last_Face_PE(Mesh)          ,
Output = Last_Node_PE(Mesh)          ,
Output = Name(Mesh)                  ,
Output = NCells_PE(Mesh)             ,
Output = NCells_Total(Mesh)          ,
Output = NFaces_PE(Mesh)             ,
Output = NFaces_Total(Mesh)          ,
Output = NNodes_PE(Mesh)             ,
Output = NNodes_Total(Mesh)          ,
Pointer = Node_Structure(Mesh)       ,
Range = Range_Cells_PE(Mesh)         ,
Range = Range_Faces_PE(Mesh)         or
Range = Range_Nodes_PE(Mesh)
```

**Input variable:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be queried. |

**Output variables:**

| | |
|---|---|
| `Pointer` | A pointer to a Base Structure within the Mesh object. |
| `Output` | For Name, returns a character variable containing the name assigned to the Mesh upon initialization. Otherwise, an integer with the named value from the Mesh object is returned. |
| `Range` | A dimension(2) integer with the specified range from the Mesh object. |

The Get Value Multi_Mesh code listing in § I.1.19 on page 740 contains additional documentation.

### 14.1.20 Get_Version_Multi_Mesh Procedure

The Get_Version_Multi_Mesh procedure returns the version number for a Multi_Mesh Object.

**Calling syntax:**

```
Integer = Version(Mesh)
```

**Input variables:**

| | |
|---|---|
| `Mesh` | The Multi_Mesh object to be queried. |

**Output variable:**

| | |
|---|---|
| `Version` | The version number of the Multi_Mesh object. |

The Get_Version_Multi_Mesh code listing in § I.1.20 on page 742 contains additional documentation.

### 14.1.21 Get_Volume_Cells_Multi_Mesh Procedure

The Get_Volume_Cells_Multi_Mesh procedure returns the cell volumes from a Multi_Mesh object.

**Calling syntax:**

```
call Get_Volume_Cells (Volume_Cells, Mesh)
```

**Input variable:**

`Mesh` The Multi_Mesh object.

**Output variable:**

`Volume_Cells` An array of the cell volumes on this PE.

The Get_Volume_Cells_Multi_Mesh code listing in § I.1.21 on page 743 contains additional documentation.

### 14.1.22 Set_Coordinates_Multi_Mesh Procedure

Note: This procedure is not finished and does not currently work.

The Set_Coordinates_Multi_Mesh procedure sets the coordinates for the Multi_Mesh object.

**Calling syntax:**

```
Mesh = Coordinates                          or
call Set_Coordinates (Mesh, Coordinates)
```

**Input variable:**

`Coordinates` The Bare Naked Array of coordinates for the Multi_Mesh object, defined differently on each PE.

**Input/Output variable:**

`Mesh` The Multi_Mesh object to be set.

**Internal variable:**

`Version_Increment` The amount that the version number is incremented, which is a global class variable.

The Set_Coordinates_Multi_Mesh code listing in § I.1.22 on page 745 contains additional documentation.

### 14.1.23 Set_Version_Multi_Mesh Procedure

The Set_Version_Multi_Mesh procedure sets the version number for the Multi_Mesh object.

**Calling syntax:**

```
Mesh = Version                    or
call Set_Version (Mesh, Version)
```

**Input variable:**

`Version` The version number for the Multi_Mesh object.

**Input/Output variable:**

`Mesh` The Multi_Mesh object to be set.

The Set_Version_Multi_Mesh code listing in § I.1.23 on page 746 contains additional documentation.

# Part III

# Cæsar Package Methods Discussion

# Chapter 15

# Mathematics Methods

This chapter describes the general mathematical methods used in CÆSAR. Each section uses its own unique nomenclature.

## 15.1 Math_Utils Methods

The CÆSAR Math_Utils Module contains the following procedures:

**Math_Utils public procedures:**

| | |
|---|---|
| `Prime_Factors` | Returns a vector containing the prime factorization of a number. |

### 15.1.1 Prime_Factors Procedure

The Prime_Factors procedure uses an optimized direct search procedure to calculate the prime factorization of a number $N$:

- Factors of $N$ are found by systematically performing trial divisions using a sequence of increasing numbers.

- Note that a direct search to discover the prime factors does not need to go further than $\sqrt{N}$, since all integers greater than $\sqrt{N}$ have already had their cofactors tested.

- Recognize that if, for example, all factors of 2 are factored out of a number (to yield $N' = N/2^p$), then the problem has been reduced to finding the prime factorization of the smaller number $N'$, using integers between 3 and $\sqrt{N'}$.

- Also, a procedure is used to eliminate multiples of small primes from the testing procedure. Once the first two primes have been factored out of the number (to yield $N'' = N/\left(2^p 3^q\right)$), then the remaining primes are included within the set $\{6i-1, 6i+1\}$. This is true because the entire set of integers can be represented as $\{6i, 6i+1, 6i+2, 6i+3, 6i+4, 6i+5\}$; all but $\{6i+1, 6i+5\}$ are divisible by 2 and/or 3; and $\{6i+1, 6i+5\}$ is equivalent to $\{6i-1, 6i+1\}$. Therefore, only integers of the forms $6i-1$ and $6i+1$ need be checked.

## 15.2 Statistics Methods

The CÆSAR Statistics Class is used to keep track of the statistics associated with a sample population or distribution. Currently, the class stores only conglomerate information about the population and does not store the entire distribution. Therefore, certain types of statistical information, such as the median and the mode, are not available. The following values are calculated by the class.

Given a set of $N$ variables denoted by $\{x_i\}$, the arithmetic mean, or average, of the distribution is given by

$$\langle x \rangle = \frac{1}{N} \sum_{i=1}^{N} x_i \; . \tag{15.1}$$

The geometric mean of the distribution (calculated only if all $x_i$ are positive) is given by

$$\langle x \rangle_G = \sqrt[N]{\prod_{i=1}^{N} x_i} \; , \tag{15.2}$$

or equivalently by

$$\langle x \rangle_G = \exp\left( \frac{1}{N} \sum_{i=1}^{N} \ln x_i \right) \; . \tag{15.3}$$

The harmonic mean of the distribution is given by:

$$\langle x \rangle_H = \left[ \frac{1}{N} \sum_{i=1}^{N} \frac{1}{x_i} \right]^{-1} \; . \tag{15.4}$$

The standard deviation of the distribution is given by

$$s = \sqrt{\frac{1}{N-1} \sum_{i=1}^{N} \left( x_i - \langle x \rangle \right)^2} \; , \tag{15.5}$$

or equivalently by

$$s = \sqrt{\frac{1}{N-1} \left[ \sum_{i=1}^{N} \left( x_i^2 \right) - N \langle x \rangle^2 \right]} \; . \tag{15.6}$$

Note that the factor $N - 1$, rather than $N$, is required in the denominator to account for the fact that the parameter $\langle x \rangle$ has been determined from the distribution and not independently. This formula for the standard deviation is sometimes called the sample standard deviation. The limits of the sample mean and the sample standard deviation give the true values:

$$\mu = \lim_{N \to \infty} \langle x \rangle \; , \tag{15.7}$$

$$\sigma = \lim_{N \to \infty} s \; . \tag{15.8}$$

$$\tag{15.9}$$

The Statistics Class also calculates minimum and maximum values for the distribution. The Valid_State procedure verifies that all of the means lie within the extremum bounds, and that the following mathematical relationship holds:

$$\langle x \rangle_H \le \langle x \rangle_G \le \langle x \rangle \; . \tag{15.10}$$

# Chapter 16

# Linear Algebra Methods

This chapter describes the general linear algebra methods used in CÆSAR. Each section uses its own unique nomenclature.

## 16.1 Mathematic_Vector Methods

The CÆSAR Code Package uses the Mathematic_Vector class to contain and manipulate algebraic vectors. The following discussion assumes that $x$ and $y$ are vectors of length $N$.

The CÆSAR Code Package contains procedures to calculate norms and dot products of vectors. In parallel, these operations require global communication. Dot products are defined by

$$x^T y = x \cdot y = (x, y) = \sum_{i=1,N} x_i \, y_i \; . \tag{16.1}$$

A vector norm is any scalar-valued function on a vector, denoted by the double bar notation $||x||$, that satisfies these properties:

$$\begin{array}{ll} ||x|| \geq 0 & (||x|| = 0 \text{ iff } x = 0) \; , \\ ||x + y|| \leq ||x|| + ||y|| \; , & \\ ||sx|| = |s| \, ||x|| \; , & \text{where } s \text{ is a scalar} \; . \end{array} \tag{16.2}$$

The general class of vector norms known as the $p$-norms are defined by

$$||x||_p = \sqrt[p]{\sum_{i=1,N} |x_i|^p} \qquad , p \geq 1 \; . \tag{16.3}$$

In particular, the 1, 2, and $\infty$ norms are the most important:

$$||x||_1 = \sum_{i=1,N} |x_i| \; , \tag{16.4}$$

$$||x||_2 = \sqrt{\sum_{i=1,N} |x_i|^2} = x^T x \; , \qquad \text{and} \tag{16.5}$$

$$||x||_\infty = \max_{1 \leq i \leq N} |x_i| \; . \tag{16.6}$$

The following vector norm relationships are verified by the Mathematic_Vector Valid_State procedure:

$$\begin{array}{ccccc} ||x||_2 & \leq & ||x||_1 & \leq & \sqrt{N} \, ||x||_2 \; , \\ ||x||_\infty & \leq & ||x||_2 & \leq & \sqrt{N} \, ||x||_\infty \; , \\ ||x||_\infty & \leq & ||x||_1 & \leq & N \, ||x||_\infty \; . \end{array} \tag{16.7}$$

The Cauchy-Schwartz inequality is verified by the Mathematic_Vector DotProduct procedure:

$$\left|x^T y\right| \leq \|x\|_2 \, \|y\|_2 \ . \tag{16.8}$$

For a similar but more complete discussion of vector operations see Golub and Van Loan (1989).

## 16.2 ELL_Matrix Methods

The CÆSAR Code Package uses the ELL_Matrix class to contain and manipulate algebraic matrices. The following discussion assumes that $A$ and $B$ are matrices of dimension $M \times N$, $a_{i,j}$ is an element of $A$, $x$ is a vector of length $N$, and $y$ is a vector of length $M$.

The CÆSAR Code Package contains procedures to calculate matrix norms and matrix-vector products. In parallel, these operations require global communication. Matrix-vector products (MatVecs) are defined by

$$Ax = y = \sum_{j=1,N} a_{i,j}\, x_j \ . \tag{16.9}$$

A matrix norm is any scalar-valued function on a matrix, denoted by the double bar notation $\|A\|$, that satisfies these properties:

$$\begin{array}{ll} \|A\| \geq 0 & (\|A\| = 0 \text{ iff } A = 0)\ , \\ \|A+B\| \leq \|A\| + \|B\|\ , & \\ \|sA\| = |s|\,\|A\|\ , & \text{where } s \text{ is a scalar}\ . \end{array} \tag{16.10}$$

A frequently used matrix norm is the Frobenius norm:

$$\|A\|_F = \sqrt{\sum_{i=1,M}\sum_{j=1,N} |a_{i,j}|^2}\ . \tag{16.11}$$

The general class of matrix norms known as the $p$-norms are defined in terms of vector norms by:

$$\|A\|_p = \sup_{x\neq 0} \frac{\|Ax\|_p}{\|x\|_p} = \max_{x:\|x\|_p=1} \|Ax\|_p \qquad , p \geq 1\ . \tag{16.12}$$

In particular, the 1 and $\infty$ norms are the most easily calculated:

$$\|A\|_1 = \max_{1\leq j\leq N} \sum_{i=1,M} |a_{i,j}| \qquad \text{(maximum absolute column sum)}, \tag{16.13}$$

$$\|A\|_\infty = \max_{1\leq i\leq M} \sum_{j=1,N} |a_{i,j}| \qquad \text{(maximum absolute row sum)}. \tag{16.14}$$

In general, $p$-norms are difficult to calculate. The 2-norm can be shown to be:

$$\|A\|_2 = \sqrt{\text{maximum eigenvalue of } A^H A}\ , \tag{16.15}$$

$$= \sqrt{\text{maximum eigenvalue of } A^T A}\ , \qquad \text{if } A \text{ is real}\ , \tag{16.16}$$

where $A^H$ is the Hermitian (or complex conjugate transpose, or adjoint) of $A$. Calculating the 2-norm of a matrix requires an iterative procedure, and is not currently done in CÆSAR (only Frobenius, $p = 1$ and $p = \infty$ norms are calculated). However, CÆSAR calculates an estimate of the 2-norm as a range (or the middle of the range) using the following relationships:

$$\begin{array}{rcccl} \frac{1}{\sqrt{N}}\|A\|_F & \leq & \|A\|_2 & \leq & \|A\|_F\ , \\ \max_{i,j}|a_{i,j}| & \leq & \|A\|_2 & \leq & \sqrt{MN}\max_{i,j}|a_{i,j}|\ , \\ \frac{1}{\sqrt{N}}\|A\|_\infty & \leq & \|A\|_2 & \leq & \sqrt{M}\,\|A\|_\infty\ , \\ \frac{1}{\sqrt{M}}\|A\|_1 & \leq & \|A\|_2 & \leq & \sqrt{N}\,\|A\|_1\ , \\ & & \|A\|_2 & \leq & \sqrt{\|A\|_1\,\|A\|_\infty}\ . \end{array} \tag{16.17}$$

For a similar but more complete discussion of matrix operations see Golub and Van Loan (1989).

## 16.3 Solver Methods

The CÆSAR Code Package uses the blorp method to calculate Solvers.

## A.1 Settings m4 Macros

The main documentation of the Settings m4 Macros in section 6.1 contains additional explanation of this code listing.

```
dnl
dnl Author: Michael L. Hall
dnl         P.O. Box 1663, MS-D409, LANL
dnl         Los Alamos, NM 87545
dnl         ph: 505-665-4312
dnl         email: hall@lanl.gov
dnl
dnl Created on: 02/26/98
dnl Date:       03/21/00, 17:15:20
dnl Version:    6.8

dnl Change the quotation characters to avoid F90 conflicts.

m4_changequote([,])

dnl Change the comment characters to eliminate m4 macro
dnl expansion in F90 comments.

m4_changecom([!])

dnl Redefine the "dnl" command to be unprefixed. Note that the "dnl"
dnl command is nonfunctional before this definition is made, but that
dnl unwanted output from the processing of this file is avoided by
dnl diverting the entire output (up until now) to nowhere. (Notice the
dnl m4_divert(-1) command in the initialization.)

m4_define([dnl],m4_defn([m4_dnl]))
m4_divert
```

```
dnl Define unprefixed versions of m4 builtin macros that are
dnl commonly used. All other m4 builtin macros must be prefixed
dnl by "m4_".

m4_define([define],m4_defn([m4_define]))
m4_define([ifdef],m4_defn([m4_ifdef]))
m4_define([ifelse],m4_defn([m4_ifelse]))
m4_define([include],m4_defn([m4_include]))
m4_define([popdef],m4_defn([m4_popdef]))
m4_define([pushdef],m4_defn([m4_pushdef]))
m4_define([undefine],m4_defn([m4_undefine]))

dnl The m4_chop macro (based on perl's chop command) returns the
dnl input string minus its final character. m4_chop is useful for
dnl removing "\n" from m4_esyscmd strings.

define([m4_chop], [m4_substr($1, 0, m4_decr(m4_len($1)))])

dnl Define cpp-style predefined macros for date and time information.
dnl These names correspond to those described in "The C Programming
dnl Language", B. W. Kernighan and D. M. Ritchie (1988), page 233.
dnl The __file__ and __line__ predefined macros are already defined
dnl in Gnu m4, but are redefined here to remove the "m4_" prefix.

define([__date__], [m4_chop(m4_esyscmd(date +%D))])
define([__time__], [m4_chop(m4_esyscmd(date +%T))])
define([__file__], m4_defn([m4___file__]))
define([__line__], m4_defn([m4___line__]))

dnl The m4_die macro (based on perl's die command) prints an error
dnl message and then terminates.

define([m4_die],[m4_errprint([m4:]__FILE__:__LINE__: [$1]) m4_m4exit(1)])

dnl The expand macro is used to force macro expansion in a word
dnl containing underscores, since underscores are not a word-delimiter
dnl in standard m4.

define([expand], [m4_translit(m4_translit([$1], [_], [*]), [*], [_])])

dnl The forloop macro, which iterates a section of text numerically,
dnl letting the loop variable take on successive numerical values when
dnl expressing the section of text. This version is better than the
dnl version in the Gnu m4 manual because it checks for the case of
dnl starting loop value greater than final loop value, and produces
dnl no output when this occurs.
dnl
dnl The arguments for the forloop macro are:
```

```
dnl
dnl   $1 - The name of the iteration variable.
dnl   $2 - The starting value.
dnl   $3 - The final value.
dnl   $4 - The text to be expanded for each iteration.

define([forloop],
[ifelse(
  m4_eval($2 > $3),  1,
    [],
  m4_eval($2 <= $3), 1,
    [pushdef([$1], [$2])$4[]popdef([$1])])[]dnl
ifelse(
  m4_eval($2 < $3), 1,
    [forloop([$1], m4_incr($2), [$3], [$4])])])

dnl The firstword and tailwords macros operate on a space-delimited list
dnl of words. The firstword macro returns the first word in the list, and
dnl the tailwords macro returns a space-delimited list of words derived
dnl by eliminating the first word.

define([firstword],
[ifelse(
  m4_index([$1], [ ]), [-1],
    [$1],
    [m4_substr([$1],0,m4_index([$1], [ ]))])[]dnl
])

define([tailwords],
[ifelse(
  m4_index([$1], [ ]), [-1],
    [],
    [m4_substr([$1],m4_incr(m4_index([$1], [ ])))])[]dnl
])

dnl The fortext macro is similar to the forloop macro, except that the
dnl loop variable takes on successive textual values instead of numerical
dnl values. The arguments for the fortext macro are:
dnl
dnl   $1 - The name of the iteration variable.
dnl   $2 - A string of values for the iteration variable, separated by
dnl        spaces.
dnl   $3 - The text to be expanded for each iteration.

define([fortext],
[ifelse(
  firstword($2), [],
    [],
    [pushdef([$1],[firstword($2)])$3[]fortext(
      [$1], tailwords($2), [$3])])popdef([$1])[]dnl
])
```

## A.2 Type m4 Macros

The main documentation of the Type m4 Macros in section 6.2 contains additional explanation of this code listing.

```
dnl
dnl Author: Michael L. Hall
dnl         P.O. Box 1663, MS-D409, LANL
dnl         Los Alamos, NM 87545
dnl         ph: 505-665-4312
dnl         email: hall@lanl.gov
dnl
dnl Created on: 11/12/98
dnl Date:       03/21/00, 17:16:07
dnl Version:    4.0

dnl Define a real$kind private macro based on the desired precision.

ifdef([SINGLE],[
  define([real$kind],[1.0e0])
],[
  ifdef([UNICOS],[
    define([real$kind],[1.0e0])
  ],[
    define([real$kind],[1.0d0])
  ])
])

dnl Define a private macro to expand to the pointer and dimensioning
dnl info.

define([pnt$dim],
       [ifelse(
         [$1], [],
           [],
         [$1], [0],
           [],
         [ifelse([$2], [], [, pointer]), dimension(:forloop([i],2,$1,[,:]))])])

dnl Define a type macro which interprets real, integer, logical
dnl and character types correctly and leaves other types unchanged.
dnl
dnl Arguments to the type macro:
dnl   $1 - The main type: real, integer, logical or character. If the
dnl        type is character, the next argument is the character
dnl        length (and all the remaining argument numbers are
dnl        incremented). If another word appears as argument 1 ($1),
dnl        then no action is taken, which is correct for a derived
```

```
dnl        type.
dnl   $2 - The rank of the variable, between zero and seven (default =
dnl        zero).
dnl   $3 - If anything appears here, then the variable is *not* declared
dnl        to be a pointer, but otherwise it is. An exception is that
dnl        scalars are never declared to be pointers.

define([type],
       [ifelse(
         [$1], [real],
           [real (kind=KIND(m4_indir(real$kind)))m4_indir(pnt$dim,$2,$3)],
         [$1], [integer],
           [integer (kind=KIND(1))m4_indir(pnt$dim,$2,$3)],
         [$1], [logical],
           [logical (kind=KIND(.true.))m4_indir(pnt$dim,$2,$3)],
         [$1], [character],
           [character (len=$2)m4_indir(pnt$dim,$3,$4)],
         [$1], [],
           [[type]],
         [[type]($*)])])

dnl Define a changetype macro which interprets real and integer type
dnl conversions correctly and emits an error message if incorrectly
dnl called.

define([changetype],
       [ifelse(
         [$1], [real],
           [REAL($2, KIND(m4_indir(real$kind)))],
         [$1], [integer],
           [INT($2, KIND(1))],
         [m4_die([Error in changetype command.])])])
```

## A.3 Verify m4 Macros

The main documentation of the Verify m4 Macros in section 6.3 contains additional explanation of this code listing.

```
dnl
dnl Author: Michael L. Hall
dnl         P.O. Box 1663, MS-D409, LANL
dnl         Los Alamos, NM 87545
dnl         ph: 505-665-4312
dnl         email: hall@lanl.gov
dnl
dnl Created on: 02/19/98
dnl Date:       09/18/00, 20:45:35
dnl Version:    6.0

dnl Initialize the DEBUG_LEVEL and WARNING_LEVEL to zero if they
```

```
dnl are not already defined.

ifdef([DEBUG_LEVEL], [
],[
  define([DEBUG_LEVEL], 0)
])

ifdef([WARNING_LEVEL], [
],[
  define([WARNING_LEVEL], 0)
])

dnl Set the default communication style.

define([VERIFY_COMMUNICATION],[Global])

dnl Define the VERIFY macro.

define([VERIFY], [
  ifelse(m4_eval(DEBUG_LEVEL >= $2), 1, [
    define([HIDE], [])
  ],m4_eval(DEBUG_LEVEL == -1), 1, [
    define([HIDE], [[!]])
  ],[
    define([HIDE], [[!]])
  ])
  define([COMMAND_TEXT],m4_changequote(["],["])$1[]m4_changequote("[","]"))
  ifelse(VERIFY_COMMUNICATION, Global, [
    HIDE if (.not. Global_ALL($1)) then
    HIDE   if (this_is_IO_PE) then
    HIDE     write (6,*) "Verification failed: ", &
    HIDE                 "COMMAND_TEXT, ", &
    HIDE                 "file __file__, ", &
    HIDE                 "line __line__."
    HIDE   end if
    HIDE   call Abort
    HIDE end if
  ],[
    HIDE if (.not. ($1)) then
    HIDE   write (6,*) "Verification failed: ", &
    HIDE               "COMMAND_TEXT, ", &
    HIDE               "file __file__, ", &
    HIDE               "line __line__."
    HIDE   stop
    HIDE end if
  ])
  undefine([COMMAND_TEXT])
  undefine([HIDE])
])

dnl Define the WARN_IF macro.
```

```
define([WARN_IF], [
  ifelse(m4_eval(WARNING_LEVEL >= $2), 1, [
    define([HIDE], [])
  ],m4_eval(WARNING_LEVEL == -1), 1, [
    define([HIDE], [[!]])
  ],[
    define([HIDE], [[!]])
  ])
  define([COMMAND_TEXT],m4_changequote(["],["])$1[]m4_changequote("[","]"))
  ifelse(VERIFY_COMMUNICATION, Global, [
    HIDE if (Global_ANY($1)) then
    HIDE   if (this_is_IO_PE) then
    HIDE     write (6,*) "Warning - test failed: ", &
    HIDE                 "COMMAND_TEXT, ", &
    HIDE                 "file __file__, ", &
    HIDE                 "line __line__."
    HIDE   end if
    HIDE end if
  ],[
    HIDE if ($1) then
    HIDE   write (6,*) "Warning - test failed: ", &
    HIDE               "COMMAND_TEXT, ", &
    HIDE               "file __file__, ", &
    HIDE               "line __line__."
    HIDE end if
  ])
  undefine([COMMAND_TEXT])
  undefine([HIDE])
])
```

## A.4 Replicate m4 Macros

The main documentation of the Replicate m4 Macros in section 6.4 contains additional explanation of this code listing.

```
dnl
dnl Author: Michael L. Hall
dnl         P.O. Box 1663, MS-D409, LANL
dnl         Los Alamos, NM 87545
dnl         ph: 505-665-4312
dnl         email: hall@lanl.gov
dnl
dnl Created on: 12/04/98
dnl Date:       03/21/00, 17:18:38
dnl Version:    4.9

dnl Define the REPLICATE macro.

define([REPLICATE],[
```

```
  forloop([i], 0, 7, [define([REP_NUMBER],[i]) REPLICATE_ROUTINE(i)])
])

dnl Define the REPLICATE_ARRAYS macro.

define([REPLICATE_ARRAYS],[
  forloop([i], 1, 7, [define([REP_NUMBER],[i]) REPLICATE_ROUTINE(i)])
])

dnl Define the ARRAY_ONLY macro.

define([ARRAY_ONLY],
[ifelse(
  [0], REP_NUMBER,
    [!],
  [])])

dnl Define the SCALAR_ONLY macro.

define([SCALAR_ONLY],
[ifelse(
  [0], REP_NUMBER,
    [],
  [!])])

dnl Define the REP_EXPAND command, which expands text with a glorified do-loop.
dnl The arguments are:
dnl
dnl   REP_NUMBER - The number of iterations.
dnl   $1 - Beginning text that is present if the iteration count is non-zero.
dnl   $2 - The text to be repeated in each iteration. The iteration variable,
dnl        i, may be used in this text.
dnl   $3 - Separator text to be put between iterations.
dnl   $4 - Final text that is present if the iteration count is non-zero.
dnl
dnl So, an iteration count of "0" yields no output, and an iteration count
dnl of "4" yields:
dnl
dnl   $1$2$3$2$3$2$3$2$4
dnl
dnl Note that the separator text ($3) appears only 3 times.

define([REP_EXPAND],
[ifelse([0], REP_NUMBER,
  [],
  [$1[]forloop([i], 1, 1, [$2])])dnl
ifelse(m4_eval(REP_NUMBER >= 2), 1,
  [forloop([i], 2, REP_NUMBER, [$3][$2])])dnl
ifelse([0], REP_NUMBER,
  [],
```

```
  [$4])])

dnl Define the REPLICATE_INTERFACE macro.

define([REPLICATE_INTERFACE],[
  interface $1
forloop([i], 0, 7, [    module procedure $2_[]i
])dnl
  end interface
])

dnl Define some useful macros based on the REP_EXPAND macro.

dnl REP_DECLARE:    form -->  real :: var1, var2, var3
dnl
dnl  $1 - Declaration type (everything up to the double colon).
dnl  $2 - Variable name to replicate, which should contain an "i"
dnl       for the iteration number.

define([REP_DECLARE],
  [REP_EXPAND([$1 :: ], [$2], [, ], [])])

dnl REP_ALLOCATE:   form -->  ALLOCATE(R(var1, var2, var3))
dnl
dnl  $1 - Variable to allocate.
dnl  $2 - Dimensioning variable name to replicate, which should
dnl       contain an "i" for the iteration number.
dnl  $3 - Name for the status variable.

define([REP_ALLOCATE],
  [REP_EXPAND([ALLOCATE($1(], [$2], [, ], [), stat=$3)])])

dnl REP_ARGS:     form -->  , var1, var2, var3
dnl
dnl  $1 - Variable name to replicate, which should contain an "i"
dnl       for the iteration number.

define([REP_ARGS],
  [REP_EXPAND([, ], [$1], [, ], [])])

dnl Input text used to generate documentation:

dnl module test_replicate
dnl   REPLICATE_INTERFACE([Generic_Routine], [Specific_Routine])
dnl contains
dnl
dnl define([REPLICATE_ROUTINE],[
dnl   function Specific_Routine_$1 (R[]REP_ARGS([var[]i]))
dnl     type(real,$1) :: R
dnl     REP_DECLARE([type(integer)], [var[]i])
dnl     REP_ALLOCATE(R, [var[]i], [status])
```

```
dnl     ARRAY_ONLY DEALLOCATE(R)
dnl     SCALAR_ONLY R = 999.
dnl     <other routine contents>
dnl   end function Specific_Routine_$1
dnl
dnl ])
dnl REPLICATE
dnl end module test_replicate
```

## A.5 Superclass m4 Macros

The main documentation of the Superclass m4 Macros in section 6.5 contains additional explanation of this code listing.

```
dnl
dnl Author: Michael L. Hall
dnl         P.O. Box 1663, MS-D409, LANL
dnl         Los Alamos, NM 87545
dnl         ph: 505-665-4312
dnl         email: hall@lanl.gov
dnl
dnl Created on: 1/20/99
dnl Date:       03/21/00, 17:19:14
dnl Version:    4.6

dnl The MAKE_INTERFACES macro expands into standard interface
dnl specifications using the arguments:
dnl
dnl  $1 - Specific Class Suffix
dnl  $2 - Generic Interface Names (separated by spaces)

define([MAKE_INTERFACES],[
  public :: m4_patsubst(m4_shift($@), [ ], [, ])

fortext([BASENAME], m4_shift($@), [
  interface BASENAME
    module procedure BASENAME[]_[]$1
  end interface
]) ])
dnl MAKE_INTERFACES([One], [Initialize Verify_State Finalize])

dnl The SUPERCLASS_USE_ASSOCIATIONS macro outputs the needed "use
dnl association" statements based on the definition of SUBCLASSES,
dnl which should be a space-delimited list of the subclasses.

define([SUPERCLASS_USE_ASSOCIATIONS],[
fortext([subclass], SUBCLASSES, [
  use subclass[]_Class
]) ])
```

```
dnl The SUPERCLASS_TYPE macro outputs a standard superclass type
dnl definition. It requires the following definitions:
dnl
dnl   - SUPERCLASS should already be defined to be the name of the
dnl     superclass.
dnl
dnl   - SUBCLASSES should already be defined to be a space-delimited
dnl     list of the subclasses.

define([SUPERCLASS_TYPE],[
  type SUPERCLASS[]_type
    type(character,80) :: Subclass
fortext([subclass], SUBCLASSES, [
    type(subclass[]_type) :: subclass
])
  end type SUPERCLASS[]_type
])

dnl Define the SUPERCLASS_DECLARATIONS macro, which is used internally
dnl by the SUPERCLASS_ROUTINE and SUPERCLASS_FUNCTION macros. This macro
dnl takes each group of three arguments, expands them in a declaration
dnl form like so:
dnl
dnl   $1 :: $2 ! $3
dnl
dnl and shifts them off the stack. It then continues with the next
dnl group of three arguments until there are no more arguments.

define([SUPERCLASS_DECLARATIONS],[
    ifelse($#, 0, ,
           $#, 1, [$1],
           $#, 2, [$1 :: $2],
           $#, 3, [$1 :: $2 [!] $3],
           [$1 :: $2 [!] $3 SUPERCLASS_DECLARATIONS(m4_shift(m4_shift(m4_shift($@))))]
    )])

dnl Define the SUPERCLASS_ARGUMENTS macro, which is used internally
dnl by the SUPERCLASS_ROUTINE and SUPERCLASS_FUNCTION macros. This macro
dnl takes each group of three arguments (in the same form as the
dnl SUPERCLASS_DECLARATIONS argument list) and pulls out the second
dnl argument (the actual variable) only, like so:
dnl
dnl   , $2
dnl
dnl and shifts the original three arguments off the stack. It then
dnl continues with the next group of three arguments until there are
dnl no more arguments. At the end of this operation, a variable list
dnl has been extracted in this form:
dnl
dnl   , var1, var2, var3, var4
```

```
define([SUPERCLASS_ARGUMENTS],
   [ifelse($#, 0, ,
           $#, 1, ,
           $#, 2, [, $2],
           $#, 3, [, $2],
           [, $2[]SUPERCLASS_ARGUMENTS(m4_shift(m4_shift(m4_shift($@))))])])

dnl Define the SUPERCLASS_ROUTINE macro, which expands into a complete
dnl subroutine for the superclass. This subroutine dynamically
dnl dispatches calls to the superclass to the correct subclass routine.
dnl There are some restrictions that must be true for this macro to
dnl behave correctly:
dnl
dnl   - SUPERCLASS should already be defined to be the name of the
dnl     superclass.
dnl
dnl   - SUBCLASSES should already be defined to be a space-delimited
dnl     list of the subclasses.
dnl
dnl   - The argument list for the superclass subroutine call must be the
dnl     same as the argument list for all of the subclass subroutine calls,
dnl     with the exception that the subclass calls are passed a component
dnl     of the superclass derived type corresponding to that subclass
dnl     instead of the entire superclass derived type.
dnl
dnl   - The superclass type must correspond to the type generated by the
dnl     the SUPERCLASS_TYPE macro.
dnl
dnl The arguments for the SUPERCLASS_ROUTINE macro are:
dnl
dnl   $1 - Generic Routine (and Interface) Name.
dnl   $(2 + n*3) - Type declaration for an additional variable to be added
dnl                to the argument list.
dnl   $(3 + n*3) - Variable name for an additional variable to be added
dnl                to the argument list.
dnl   $(4 + n*3) - Comment for an additional variable to be added to the
dnl                argument list.
dnl
dnl where n may be 0, 1, 2, etc., and the only required macro argument is
dnl the first one.

define([SUPERCLASS_ROUTINE],[
  pushdef([ROUT_NAME], [$1_[]SUPERCLASS])
  pushdef([VARLIST], [m4_shift($@)])
  pushdef([ARGS], [SUPERCLASS_ARGUMENTS(VARLIST)])

  subroutine ROUT_NAME (SUPERCLASS[]ARGS)

    type(SUPERCLASS[]_type) SUPERCLASS
    SUPERCLASS_DECLARATIONS(VARLIST)

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
```

```
    select case (SUPERCLASS%Subclass)

  fortext([subclass], SUBCLASSES, [
    case ("subclass")

      call $1 (SUPERCLASS%subclass[]ARGS)
  ])
    case default

      write (6,*) 'Error: no ', SUPERCLASS%Subclass, ' in SUPERCLASS[]_Class.'

    end select

  end subroutine ROUT_NAME

  popdef([ROUT_NAME])
  popdef([VARLIST])
  popdef([ARGS])
])

dnl Define the SUPERCLASS_FUNCTION macro, which expands into a complete
dnl function for the superclass. This subroutine dynamically
dnl dispatches calls to the superclass to the correct subclass function.
dnl There are some restrictions that must be true for this macro to
dnl behave correctly:
dnl
dnl   - SUPERCLASS should already be defined to be the name of the
dnl     superclass.
dnl
dnl   - SUBCLASSES should already be defined to be a space-delimited
dnl     list of the subclasses.
dnl
dnl   - The argument list for the superclass function call must be the
dnl     same as the argument list for all of the subclass function calls,
dnl     with the exception that the subclass calls are passed a component
dnl     of the superclass derived type corresponding to that subclass
dnl     instead of the entire superclass derived type.
dnl
dnl   - The superclass type must correspond to the type generated by the
dnl     the SUPERCLASS_TYPE macro.
dnl
dnl The arguments for the SUPERCLASS_FUNCTION macro are:
dnl
dnl   $1 - Generic Function (and Interface) Name.
dnl   $2 - Type declaration for the function.
dnl   $(3 + n*3) - Type declaration for an additional variable to be added
dnl                to the argument list.
dnl   $(4 + n*3) - Variable name for an additional variable to be added
dnl                to the argument list.
dnl   $(5 + n*3) - Comment for an additional variable to be added to the
dnl                argument list.
dnl
```

```
dnl where n may be 0, 1, 2, etc., and the only required macro arguments are
dnl the first two.

end module Caesar_Status_Class

### B.1.1 Initialize_Status Procedure

The main documentation of the Initialize_Status Procedure in § 7.1.1 on page 36 contains additional explanation of this code listing.

```
subroutine Initialize_Status (S)

  ! Output variable.

  type(Status_type), intent(out) :: S  ! Status to be initialized.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements - none.

  ! Initializations.

  S = 'Unset'

  ! Verify guarantees.

  VERIFY(Valid_State(S),1)  ! S is now valid.

  return
end subroutine Initialize_Status
```

### B.1.2 Initialize_Status_Vector Procedure

The main documentation of the Initialize_Status_Vector Procedure in § 7.1.2 on page 36 contains additional explanation of this code listing.

```
subroutine Initialize_Status_Vector (S)

  ! Output variable.

  ! Status vector to be initialized:
  type(Status_type), dimension(:), intent(out) :: S

  ! Internal variable.

  type(integer) :: i  ! Loop counter.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements - none.

  ! Initializations.

  do i = 1, SIZE(S)
    call Initialize (S(i))
  end do

  ! Verify guarantees.

  VERIFY(Valid_State(S),1)  ! S is now valid.

  return
end subroutine Initialize_Status_Vector
```

### B.1.3 Finalize_Status Procedure

The main documentation of the Finalize_Status Procedure in § 7.1.3 on page 37 contains additional explanation of this code listing.

```
subroutine Finalize_Status (S)

  ! Input/Output variable.

  type(Status_type), intent(inout) :: S  ! Status to be finalized.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements.

  VERIFY(Valid_State(S),1)         ! S is valid.

  ! Finalizations.

  S%status = 0

  ! Verify guarantees.
```

```
    VERIFY(.not.(Valid_State(S)),1)  ! S is no longer valid.

    return
  end subroutine Finalize_Status
```

### B.1.4 Finalize_Status_Vector Procedure

The main documentation of the Finalize_Status_Vector Procedure in § 7.1.4 on page 37 contains additional explanation of this code listing.

```
  subroutine Finalize_Status_Vector (S)

    ! Input/Output variable.

    ! Status vector to be finalized:
    type(Status_type), dimension(:), intent(inout) :: S

    ! Internal variable.

    type(integer) :: i  ! Loop counter.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(S),1)         ! S is valid.

    ! Finalizations.

    do i = 1, SIZE(S)
      call Finalize (S(i))
    end do

    ! Verify guarantees.

    VERIFY(.not.(Valid_State(S)),1)  ! S is no longer valid.

    return
  end subroutine Finalize_Status_Vector
```

### B.1.5 Valid_State_Status Procedure

The main documentation of the Valid_State_Status Procedure in § 7.1.5 on page 37 contains additional explanation of this code listing.

```
  function Valid_State_Status (S) result(Valid)

    ! Input variable.
```

```
    type(Status_type), intent(in) :: S  ! Status to be checked.

    ! Output variable.

    type(logical) :: Valid              ! Logical state.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Start out true.

    Valid = .true.

    ! Make sure the status variable is in range.

    Valid = Valid .and. S%status <= NFlags
    Valid = Valid .and. S%status >= 1

    return
  end function Valid_State_Status
```

### B.1.6 Valid_State_Status_Vector Procedure

The main documentation of the Valid_State_Status_Vector Procedure in § 7.1.6 on page 37 contains additional explanation of this code listing.

```
  function Valid_State_Status_Vector (S) result(Valid)

    ! Input variable.

    type(Status_type), dimension(:), intent(in) :: S  ! Status to be checked.

    ! Output variable.

    type(logical) :: Valid   ! Logical state.

    ! Internal variable.

    type(integer) :: i       ! Loop counter.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Start out true.

    Valid = .true.

    ! Check each element.

    do i = 1, SIZE(S)
      Valid = Valid .and. Valid_State(S(i))
    end do

    return
```

```
end function Valid_State_Status_Vector
```

### B.1.7 Character_Equal_Status Procedure

The main documentation of the Character_Equal_Status Procedure in § 7.1.7 on page 38 contains additional explanation of this code listing.

```
function Character_Equal_Status (C, SS) result(Equal)

  ! Input variables.

  type(Status_type), intent(in) :: SS  ! Status variable to be compared.
  type(character,*), intent(in) :: C   ! Selector flag string to be compared.

  ! Output variable.

  type(logical) :: Equal               ! Equality boolean.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements.

  VERIFY(Valid_State(SS),1)   ! SS is valid.

  ! Check equality.

  Equal = status_flag(SS%status)%selector == C

  ! Verify guarantees.

  ! Equal should be what it was set to.
  VERIFY(Equal .eqv. (status_flag(SS%status)%selector == C),2)

  return
end function Character_Equal_Status
```

### B.1.8 Character_Not_Equal_Status Procedure

The main documentation of the Character_Not_Equal_Status Procedure in § 7.1.8 on page 38 contains additional explanation of this code listing.

```
function Character_Not_Equal_Status (C, SS) result(Not_Equal)

  ! Input variable.

  type(Status_type), intent(in) :: SS  ! Status variable to be compared.
  type(character,*), intent(in) :: C   ! Selector flag string to be compared.

  ! Output variable.
```

```
    type(logical) :: Not_Equal               ! Nonequality boolean.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(SS),1)   ! SS is valid.

    ! Check nonequality.

    Not_Equal = status_flag(SS%status)%selector /= C

    ! Verify guarantees.

    ! Not_Equal should be what it was set to.
    VERIFY(Not_Equal .eqv. (status_flag(SS%status)%selector /= C),2)

    return
  end function Character_Not_Equal_Status
```

### B.1.9 Consolidate_Status Procedure

The main documentation of the Consolidate_Status Procedure in § 7.1.9 on page 39 contains additional explanation of this code listing.

```
  subroutine Consolidate_Status (Consolidated_S, Multiple_S)

    ! Input variable.

    ! Vector of status variables to be consolidated:
    type(Status_type), intent(in), dimension(:) :: Multiple_S

    ! Output variable.

    type(Status_type), intent(out) :: Consolidated_S  ! Consolidated status.

    ! Internal variable.

    type(integer) :: i  ! Loop counter.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(Multiple_S),1)   ! Multiple_S is valid.

    ! The following table shows the value of Consolidated_S after it has been
    ! combined with a single value from the vector Multiple_S, based on the
    ! previous value of Consolidated_S:
    !
    !                                           Multiple_S(i)
```

```
!
!                             Unset    Success  ME  MW  Error  Warning
!                           +-------------------------------------------+

### B.1.10 Error_Status Procedure

The main documentation of the Error_Status Procedure in § 7.1.10 on page 39 contains additional explanation of this code listing.

```
function Error_Status (S) result(Error)

  ! Input variable.

  type(Status_type), intent(in) :: S  ! Status to be checked.

  ! Output variable.

  type(logical) :: Error              ! Error condition boolean.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements.

  VERIFY(Valid_State(S),1)   ! S is valid.

  ! Set error boolean.

  Error = status_flag(S%status)%severity == 'Error'

  ! Verify guarantees.

  ! Error should be what it was set to.
  VERIFY(Error .eqv. (status_flag(S%status)%severity == 'Error'),2)
```

```
    return
  end function Error_Status
```

### B.1.11 Get_Status_Output Procedure

The main documentation of the Get_Status_Output Procedure in § 7.1.11 on page 40 contains additional explanation of this code listing.

```
  subroutine Get_Status_Output (Status_String, S)

    ! Input variable.

    type(Status_type), intent(in) :: S  ! Status.

    ! Output variable.

    ! Output string for this Status.
    type(character,*), intent(out) :: Status_String

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(S),1)   ! S is valid.

    ! Determine which output string is to be set.

    Status_String = status_flag(S%status)%output_string

    ! Verify guarantees.

    ! Status_String should be what it was set to.
    VERIFY(Status_String == status_flag(S%status)%output_string,2)

    return
  end subroutine Get_Status_Output
```

### B.1.12 Normal_Status Procedure

The main documentation of the Normal_Status Procedure in § 7.1.12 on page 40 contains additional explanation of this code listing.

```
  function Normal_Status (S) result(Normal)

    ! Input variable.

    type(Status_type), intent(in) :: S  ! Status to be checked.
```

```
    ! Output variable.

    type(logical) :: Normal             ! Normal condition boolean.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(S),1)   ! S is valid.

    ! Set normal boolean.

    Normal = status_flag(S%status)%severity == 'Normal'

    ! Verify guarantees.

    ! Normal should be what it was set to.
    VERIFY(Normal .eqv. (status_flag(S%status)%severity == 'Normal'),2)

    return
  end function Normal_Status
```

### B.1.13 Set_Status Procedure

The main documentation of the Set_Status Procedure in § 7.1.13 on page 40 contains additional explanation of this code listing.

```
  subroutine Set_Status (S, Selector_Flag)

    ! Input variable.

    ! String to select status value.
    type(character,*), intent(in) :: Selector_Flag

    ! Output variable.

    type(Status_type), intent(out) :: S  ! Status to be set.

    ! Internal variable.

    type(integer) :: i  ! Loop counter.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    ! Selector_Flag must be one of the possible flags.
    VERIFY(ANY(Selector_Flag == status_flag%selector),1)

    ! Determine which flag is to be set.

    do i = 1, NFlags
```

```
      if (Selector_Flag == status_flag(i)%selector) S%status = i
    end do

    ! Verify guarantees.

    VERIFY(Valid_State(S),1)   ! S is now valid.

    return
  end subroutine Set_Status
```

### B.1.14 Status_Equal_Character Procedure

The main documentation of the Status_Equal_Character Procedure in § 7.1.14 on page 41 contains additional explanation of this code listing.

```
  function Status_Equal_Character (S, C) result(Equal)

    ! Input variables.

    type(Status_type), intent(in) :: S  ! Status variable to be compared.
    type(character,*), intent(in) :: C   ! Selector flag string to be compared.

    ! Output variable.

    type(logical) :: Equal               ! Equality boolean.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(S),1)   ! S is valid.

    ! Check equality.

    Equal = status_flag(S%status)%selector == C

    ! Verify guarantees.

    ! Equal should be what it was set to.
    VERIFY(Equal .eqv. (status_flag(S%status)%selector == C),2)

    return
  end function Status_Equal_Character
```

### B.1.15 Status_Equal_Status Procedure

The main documentation of the Status_Equal_Status Procedure in § 7.1.15 on page 41 contains additional explanation of this code listing.

```
function Status_Equal_Status (S1, S2) result(Equal)

  ! Input variables.

  type(Status_type), intent(in) :: S1, S2  ! Status variables to be compared.

  ! Output variable.

  type(logical) :: Equal                   ! Equality boolean.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements.

  VERIFY(Valid_State(S1),1)   ! S1 is valid.
  VERIFY(Valid_State(S2),1)   ! S2 is valid.

  ! Check equality.

  Equal = S1%status == S2%status

  ! Verify guarantees.

  ! Equal should be what it was set to.
  VERIFY(Equal .eqv. (S1%status == S2%status),2)

  return
end function Status_Equal_Status
```

### B.1.16 Status_Not_Equal_Character Procedure

The main documentation of the Status_Not_Equal_Character Procedure in § 7.1.16 on page 42 contains additional explanation of this code listing.

```
function Status_Not_Equal_Character (S, C) result(Not_Equal)

  ! Input variables.

  type(Status_type), intent(in) :: S  ! Status variable to be compared.
  type(character,*), intent(in) :: C  ! Selector flag string to be compared.

  ! Output variable.

  type(logical) :: Not_Equal          ! Nonequality boolean.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements.

  VERIFY(Valid_State(S),1)   ! S is valid.

  ! Check nonequality.
```

```
    Not_Equal = status_flag(S%status)%selector /= C

    ! Verify guarantees.

    ! Not_Equal should be what it was set to.
    VERIFY(Not_Equal .eqv. (status_flag(S%status)%selector /= C),2)

    return
  end function Status_Not_Equal_Character
```

### B.1.17 Status_Not_Equal_Status Procedure

The main documentation of the Status_Not_Equal_Status Procedure in § 7.1.17 on page 42 contains additional explanation of this code listing.

```
  function Status_Not_Equal_Status (S1, S2) result(Not_Equal)

    ! Input variables.

    type(Status_type), intent(in) :: S1, S2  ! Status variables to be compared.

    ! Output variable.

    type(logical) :: Not_Equal               ! Nonequality boolean.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(S1),1)   ! S1 is valid.
    VERIFY(Valid_State(S2),1)   ! S2 is valid.

    ! Check nonequality.

    Not_Equal = S1%status /= S2%status

    ! Verify guarantees.

    ! Not_Equal should be what it was set to.
    VERIFY(Not_Equal .eqv. (S1%status /= S2%status),2)

    return
  end function Status_Not_Equal_Status
```

### B.1.18 Warning_Status Procedure

The main documentation of the Warning_Status Procedure in § 7.1.18 on page 42 contains additional explanation of this code listing.

```
  function Warning_Status (S) result(Warning)

    ! Input variable.

    type(Status_type), intent(in) :: S  ! Status to be checked.

    ! Output variable.

    type(logical) :: Warning            ! Warning condition boolean.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(S),1)   ! S is valid.

    ! Set warning boolean.

    Warning = status_flag(S%status)%severity == 'Warning'

    ! Verify guarantees.

    ! Warning should be what it was set to.
    VERIFY(Warning .eqv. (status_flag(S%status)%severity == 'Warning'),2)

    return
  end function Warning_Status
```

### B.1.19 Status Class Unit Test Program

This lightly commented program performs a unit test on the Status Class, which is described in § 7.1 on page 35.

```
program Unit_Test

  use Caesar_Status_Class
  implicit none

  type(integer), parameter :: NStats=12
  type(Status_type), dimension(NStats) :: Status
  type(Status_type) :: Final_Status
  type(character,36) :: status_string
  type(integer) :: i, j

  ! Initialize status.

  call Initialize (Status)
  call Initialize (Final_Status)

  ! Check state of status.
```

```
VERIFY(Valid_State(Status),0)
VERIFY(Valid_State(Final_Status),0)

! Testing statements.

Status(6)  = 'Unset'
Status(7)  = 'Success'
Status(8)  = 'Memory Warning'
Status(9)  = 'Multiple Warning'
Status(10) = 'Success'
Status(11) = 'Multiple Error'
Status(12) = 'Multiple Warning'

write (6,101) 'Assignment tests:'

do i = 1, NStats
  if (Error(Status(i))) write (6,100,advance='no') 'Error: '
  if (Warning(Status(i))) write (6,100,advance='no') 'Warning: '
  if (Normal(Status(i))) write (6,100,advance='no') 'Normal: '
  status_string = Status(i)
  write (6,*) status_string
end do

write (6,101) 'Consolidation tests:'

do i = 1, NStats
  do j = i, NStats
    Final_Status = Status(i:j)
    if (Error(Final_Status)) write (6,100,advance='no') 'Error: '
    if (Warning(Final_Status)) write (6,100,advance='no') 'Warning: '
    if (Normal(Final_Status)) write (6,100,advance='no') 'Normal: '
    status_string = Final_Status
    write (6,*) status_string
  end do
  write (6,*)
end do

! Format statement.

100 format (a)
101 format (/,a,/)

! Check state of status.

VERIFY(Valid_State(Status),0)
VERIFY(Valid_State(Final_Status),0)

! Finalize status.

call Finalize (Status)
```

```
  call Finalize (Final_Status)

end
```

## B.2 Real Class Code Listing

The main documentation of the Real Class in § 7.2 on page 43 contains additional explanation of this code listing.

**SUM_Real_Scalar (§ B.2.6, page 241)**

**VeryClose_Real (§ B.2.7, page 241)**

end module Caesar_Real_Class

### B.2.1 Initialize_Real Procedure

The main documentation of the Initialize_Real Procedure in § 7.2.1 on page 43 contains additional explanation of this code listing.

```
  subroutine Initialize_Real_0 (R, status)

    ! Use association information.

    use Caesar_Flags_Module, only: initialize_real_flag

    ! Output variables.

    type(real), intent(out) :: R        ! Variable to be initialized.
    type(Status_type), intent(out), optional :: status ! Exit status.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements - none.
```

```
  ! Initialize to flag value.

  R = initialize_real_flag

  ! No errors for initialization possible for scalars.

  if (PRESENT(status)) status = 'Success'

  ! Verify guarantees - none.

  return
end subroutine Initialize_Real_0

define([REPLICATE_ROUTINE],[
  subroutine Initialize_Real_$1 (R REP_ARGS([dim[]i]), status)

    ! Use association information.

    use Caesar_Flags_Module, only: initialize_real_flag

    ! Input variables.

    REP_DECLARE([type(integer), intent(in)], [dim[]i])  ! Array dimensions.

    ! Input/Output variable.

    type(real,$1) :: R                 ! Variable to be initialized.

    ! Output variable.

    type(Status_type), intent(out), optional :: status  ! Exit status.

    ! Internal variable.

    type(integer) :: allocate_status   ! Allocation Status.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    ! The association status of a unallocated pointer is officially
    ! undefined according to the Fortran standard. With most compilers,
    ! the status is unassociated.
    ifelse(COMPILER, NAGWare,
      [], [
      VERIFY(.not.ASSOCIATED(R), 0)   ! R starts out unassociated.
    ])

    ! Allocation (for arrays only).

    REP_ALLOCATE([R], [dim[]i], [allocate_status])

    ! Initialize to flag value.
```

```
    R = initialize_real_flag

    ! Verify guarantees and/or set status flag.

    if (PRESENT(status)) then

type(real) :: one, ten, zero  ! Numbers are not parameterized
                              ! to fool smart compilers.

!~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

! Set numbers carefully (so that the compiler
! doesn't know that zero=0).

ten = 1.d1
one = 1.d0
zero = one - one

! Start out true.

Valid = .true.

! First, make sure that the variable has been allocated.

POINTER_ONLY ARRAY_ONLY Valid = Valid .and. ASSOCIATED(R)
POINTER_ONLY ARRAY_ONLY if (.not.Valid) return

! Make sure the variable has not been finalized.

SCALAR_ONLY Valid = Valid .and. R /= finalize_real_flag

! Check for Infs. This check determines whether R(1-e) = R, where e
! is a small number. This should only be true if R = 0 or if R is
! not a valid number.
!
! Pass Table:
!             Intel  Intel   Intel    Intel  Apple   Sun   SGI   IBM
!             Lahey  Absoft  NAGWare  PGI    Absoft
!   Infinity  Fail   Fail    Fail     Fail   Fail    Fail  Fail  Fail
!  -Infinity  Fail   Fail    Fail     Fail   Fail    Fail  Fail  Fail
!   NaN       Pass   Pass    Pass     Pass   Pass    Pass  Pass  Pass

Valid = Valid .and. ALL(R == zero .or. R*(one - ten*EPSILON(one)) /= R)
TESTWRITE (6,100) 'Test 1, R(1-e) = R     ==>', &
  IF_UNIT_TEST ALL(R == zero .or. R*(one - ten*EPSILON(one)) /= R)

! For IEEE-conforming reals, the following is (supposedly) a check
! for NaNs.
!
! Pass Table (test 2):
!             Intel  Intel   Intel    Intel  Apple   Sun   SGI   IBM
!             Lahey  Absoft  NAGWare  PGI    Absoft
```

```
!   Infinity  Pass   Pass    Pass     Pass   Pass    Pass  Pass  Pass
!  -Infinity  Pass   Pass    Pass     Pass   Pass    Pass  Pass  Pass
!   NaN       Pass   Fail    Fail     Pass   Fail    Fail  Pass  Fail
!
! NaN behavior details:
!
! Intel/Lahey (pre-L6.20c), Intel/Absoft, Intel/NAGWare
! (with -ieee=full), Apple/Absoft and Sun (with -ftrap=%none):
!   Fail on tests 2 and 2a, but pass on 2b, for scalars.
!   Fail on test 2, but pass on 2a and 2b, for arrays.
! Intel/Lahey:
!   With the L6.20c compiler, the behavior is:
!   Fail on test2a, but pass on 2 and 2b, for scalars.
!   Passes on tests 2, 2a and 2b, for arrays.
!   In other words, since test 2 passes for both scalars and arrays,
!   this is not a good test for the Lahey compiler.
! Sun:
!   Changed behavior after the 107356-02 patch; the new behavior
!   is reflected here. So, with the Sun 5.0 compiler with 107377-02
!   and 107356-02 patches, and the -ftrap=%none flag set to disable
!   exception trapping, this now works as a check for NaNs.
! IBM:
!   Fails on tests 2 and 2a, but passes on 2b. (Recheck behavior with
!   arrays to see if it is the same as some other compilers above if
!   IBM access is regained.)

### B.2.4 MaxVal_Real_Scalar Procedure

The main documentation of the MaxVal_Real_Scalar Procedure in § 7.2.4 on page 45 contains additional explanation of this code listing.

```
function MaxVal_Real_Scalar (R)

  ! Input variable.

  type(real), intent(in) :: R

  ! Output variable.

  type(real) :: MaxVal_Real_Scalar

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! MaxVal_Real_Scalar is equal to R.

  MaxVal_Real_Scalar = R

  return
end function MaxVal_Real_Scalar
```

### B.2.5 MinVal_Real_Scalar Procedure

The main documentation of the MinVal_Real_Scalar Procedure in § 7.2.5 on page 45 contains additional explanation of this code listing.

```
function MinVal_Real_Scalar (R)

  ! Input variable.

  type(real), intent(in) :: R

  ! Output variable.

  type(real) :: MinVal_Real_Scalar

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
```

```
    ! MinVal_Real_Scalar is equal to R.

    MinVal_Real_Scalar = R

    return
  end function MinVal_Real_Scalar
```

### B.2.6 SUM_Real_Scalar Procedure

The main documentation of the SUM_Real_Scalar Procedure in § 7.2.6 on page 45 contains additional explanation of this code listing.

```
  function SUM_Real_Scalar (R)

    ! Input variable.

    type(real), intent(in) :: R

    ! Output variable.

    type(real) :: SUM_Real_Scalar

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! SUM_Real_Scalar is equal to R.

    SUM_Real_Scalar = R

    return
  end function SUM_Real_Scalar
```

### B.2.7 VeryClose_Real Procedure

The main documentation of the VeryClose_Real Procedure in § 7.2.7 on page 46 contains additional explanation of this code listing.

```
  define([VERY_CLOSE_ROUTINE],[
    pushdef([DIM], [$1])
    pushdef([VeryClose_Real_DIM], expand(VeryClose_Real_DIM))

    function VeryClose_Real_DIM (X, Y) result(VeryClose)

      ! Use association for numbers.

      use Caesar_Numbers_Module, only: two, ten

      ! Input variables.

      type(real,DIM,np), intent(in) :: X, Y         ! Variables to be checked.
```

```
      ! Output variable.

      type(logical) :: VeryClose                    ! Result of check.

      !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

### B.3.4 MaxVal_Integer_Scalar Procedure

The main documentation of the MaxVal_Integer_Scalar Procedure in § 7.3.4 on page 48 contains additional explanation of this code listing.

```
function MaxVal_Integer_Scalar (I)

  ! Input variable.

  type(integer), intent(in) :: I

  ! Output variable.
```

```
    type(integer) :: MaxVal_Integer_Scalar

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! MaxVal_Integer_Scalar is equal to I.

    MaxVal_Integer_Scalar = I

    return
  end function MaxVal_Integer_Scalar
```

### B.3.5 MinVal_Integer_Scalar Procedure

The main documentation of the MinVal_Integer_Scalar Procedure in § 7.3.5 on page 48 contains additional explanation of this code listing.

```
  function MinVal_Integer_Scalar (I)

    ! Input variable.

    type(integer), intent(in) :: I

    ! Output variable.

    type(integer) :: MinVal_Integer_Scalar

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! MinVal_Integer_Scalar is equal to I.

    MinVal_Integer_Scalar = I

    return
  end function MinVal_Integer_Scalar
```

### B.3.6 SUM_Integer_Scalar Procedure

The main documentation of the SUM_Integer_Scalar Procedure in § 7.3.6 on page 49 contains additional explanation of this code listing.

```
  function SUM_Integer_Scalar (I)

    ! Input variable.

    type(integer), intent(in) :: I

    ! Output variable.
```

```
    type(integer) :: SUM_Integer_Scalar

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! SUM_Integer_Scalar is equal to I.

    SUM_Integer_Scalar = I

    return
  end function SUM_Integer_Scalar
```

### B.3.7 Integer Class Unit Test Program

This lightly commented program performs a unit test on the Integer Class, which is described in § 7.3 on page 46.

```
module Unit_Test_Module
  use Caesar_Integer_Class
  implicit none

contains

  subroutine testint (I)
    type(integer) :: I
    type(logical) :: vs
    write (6,100) 'I = ', I
    vs = Valid_State(I)
    write (6,101) 'Valid_State(I)         ==> ', vs
    100 format (/, a, i14)
    101 format (2x, a, l1)
    return
  end subroutine testint

  subroutine testint3 (I3)
    type(integer), pointer, dimension(:,:,:) :: I3
    type(logical) :: vs
    write (6,100) 'I3(1,1,1) = ', I3(1,1,1)
    vs = Valid_State(I3)
    write (6,101) 'Valid_State(I3)        ==> ', vs
    100 format (/, a, i14)
    101 format (2x, a, l1)
    return
  end subroutine testint3

end module Unit_Test_Module

program Unit_Test
  use Unit_Test_Module
  use Caesar_Integer_Class
  implicit none

  type(integer) :: I
```

```
type(integer,3) :: I3

! Initializations.

call Initialize (I)
call Initialize (I3, 3, 4, 5)

! Integer tests.

I = 0
call testint (I)
I = HUGE(I)
call testint (I)
I = -HUGE(I)
call testint (I)

I3(1,1,1) = 0
call testint3 (I3)
I3(1,1,1) = HUGE(I3)
call testint3 (I3)
I3(1,1,1) = -HUGE(I3)
call testint3 (I3)

! Note that the compiler figures out the error unless it is given in
! two steps, as follows. Also, note that adding 1 to HUGE wraps to
! a low negative number, as does subtracting 2 from -HUGE.

I = HUGE(I)
I = I+1
call testint (I)
I = -HUGE(I)
I = I-2
call testint (I)

I3(1,1,1) = HUGE(I3)
I3(1,1,1) = I3(1,1,1)+1
call testint3 (I3)
I3(1,1,1) = -HUGE(I3)
I3(1,1,1) = I3(1,1,1)-2
call testint3 (I3)

! The bottom line is that there are really no invalid integers. The
! Valid_State_Integer routine is primarily added for completeness.

! Integer scalar function tests.

I = 123456789
write (6,*) 'MaxVal(I) = ', MaxVal(I)
write (6,*) 'MinVal(I) = ', MinVal(I)
write (6,*) 'SUM(I)    = ', SUM(I)

! Finalizations.

call Finalize (I)
```

```
  call Finalize (I3)

end
```

## B.4 Logical Class Code Listing

The main documentation of the Logical Class in § 7.4 on page 49 contains additional explanation of this code listing.

### B.4.11 Logical Class Unit Test Program

This lightly commented program performs a unit test on the Logical Class, which is described in § 7.4 on page 49.

```
program Unit_Test
  use Caesar_Logical_Class
  implicit none

  type(logical) :: L
  type(logical,3) :: L3

  ! Initialize logicals.

  call Initialize (L)
  call Initialize (L3, 3, 4, 5)

  ! Logical Valid_State tests.

  L = .false.
  write (6,*) 'Valid_State L =', Valid_State(L)
  L = .true.
  write (6,*) 'Valid_State L =', Valid_State(L)
  L3 = .false.
  write (6,*) 'Valid_State L3 =', Valid_State(L3)
  L3 = .true.
  write (6,*) 'Valid_State L3 =', Valid_State(L3)

  ! Logical scalar function tests.

  L = .false.
  write (6,*) 'COUNT(L) =', COUNT(L)
  write (6,*) 'ALL(L) =', ALL(L)
  write (6,*) 'ANY(L) =', ANY(L)
  L = .true.
  write (6,*) 'COUNT(L) =', COUNT(L)
  write (6,*) 'ALL(L) =', ALL(L)
  write (6,*) 'ANY(L) =', ANY(L)
```

```
  ! Logical interval tests.

  write (6,*) 'Following intervals should use brackets, '
  write (6,*) 'but they are not available in F90.'
  write (6,*) 'Is 1 in (1,99)?:', 1 .InInterval. (/1, 99/)
  write (6,*) 'Is 5 in (3,7)?:', 5 .InInterval. (/3, 7/)
  write (6,*) 'Is (6,3,4) in (3,7)?:', &
              (/6, 3, 4/) .InInterval. (/3, 7/)
  write (6,*) 'Is (6,3,4,8) in (3,7)?:', &
              (/6, 3, 4, 8/) .InInterval. (/3, 7/)
  write (6,*) 'Is 1.0 in (1.0,99.0)?:', 1.d0 .InInterval. (/1.d0, 99.d0/)
  write (6,*) 'Is 3.14159 in (2.3,10.4)?:', &
              3.14159d0 .InInterval. (/2.3d0, 10.4d0/)
  write (6,*) 'Is (3.14159,4.2,5.8) in (2.3,10.4)?:', &

contains
```

The Character_Class contains the following routines which are listed in separate sections:

**Initialize_Character (§ B.5.1, page 268)**

**Finalize_Character (§ B.5.2, page 270)**

**Valid_State_Character (§ B.5.3, page 272)**

end module Caesar_Character_Class

## B.5.1 Initialize_Character Procedure

The main documentation of the Initialize_Character Procedure in § 7.5.1 on page 54 contains additional explanation of this code listing.

```
  subroutine Initialize_Character_0 (C, status)

    ! Use association information.

    use Caesar_Flags_Module, only: initialize_character_flag

    ! Output variables.

    type(character,*), intent(out) :: C  ! Variable to be initialized.
    type(Status_type), intent(out), optional :: status  ! Exit status.
```

```
  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements - none.

  ! Initialize to flag value.

  C = initialize_character_flag

  ! No errors for initialization possible for scalars.

  if (PRESENT(status)) status = 'Success'

  ! Verify guarantees - none.

  return
end subroutine Initialize_Character_0

define([REPLICATE_ROUTINE],[
  subroutine Initialize_Character_$1 (C REP_ARGS([dim[]i]), status)

    ! Use association information.

    use Caesar_Flags_Module, only: initialize_character_flag

    ! Input variable.

    REP_DECLARE([type(integer), intent(in)], [dim[]i]) ! Array dimensions.

    ! Input/Output variable.

    type(character,*,$1) :: C            ! Variable to be initialized.

    ! Output variable.

    type(Status_type), intent(out), optional :: status  ! Exit status.

    ! Internal variable.

    type(integer) :: allocate_status     ! Allocation Status.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    ! The association status of a unallocated pointer is officially
    ! undefined according to the Fortran standard. With most compilers,
    ! the status is unassociated.
    ifelse(COMPILER, NAGWare,
      [], [
      VERIFY(.not.ASSOCIATED(C), 0)   ! C starts out unassociated.
    ])

    ! Allocation (for arrays only).
```

```
    REP_ALLOCATE([C], [dim[]i], [allocate_status])

    ! Initialize to flag value.

    C = initialize_character_flag

    ! Verify guarantees and/or set status flag.

### C.3.1 Capitalize_Text_Utils Procedure

The main documentation of the Capitalize_Text_Utils Procedure in § 8.3.1 on page 60 contains additional explanation of this code listing.

```
  function Capitalize_Text_Utils (String) result(Capitalize)

    ! Input variables.

    type(character,*), intent(in) :: String         ! String to be capitalized.

    ! Output variables.

    type(character,255) :: Capitalize   ! The capitalize version of the string.

    ! Internal variables.

    type(integer) :: letter     ! Loop counter.
    type(logical) :: new_word   ! True if the next character starts a new word.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(String),5)          ! String is valid.

    ! Loop through letters, setting capitalized version.

    Capitalize = ' '
    new_word = .true.
    do letter = 1, LEN_TRIM(String)
      if (new_word) then
        Capitalize(letter:letter) = Uppercase(String(letter:letter))
      else
        Capitalize(letter:letter) = Lowercase(String(letter:letter))
      end if
      new_word = &
```

```
      (ICHAR(String(letter:letter)) .NotInInterval. Majuscules) .AND. &
      (ICHAR(String(letter:letter)) .NotInInterval. Minuscules)
  end do

  ! Verify guarantees.

  VERIFY(Valid_State(Capitalize),5)  ! Capitalize is valid.

  return
end function Capitalize_Text_Utils
```

### C.3.2 Lowercase_Text_Utils Procedure

The main documentation of the Lowercase_Text_Utils Procedure in § 8.3.2 on page 60 contains additional explanation of this code listing.

```
function Lowercase_Text_Utils (String) result(Lowercase)

  ! Input variables.

  type(character,*), intent(in) :: String         ! String to be lowercased.

  ! Output variables.

  type(character,255) :: Lowercase    ! The lowercase version of the string.

  ! Internal variable.

  type(integer) :: letter             ! Loop counter.

  !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

  ! Verify requirements.

  VERIFY(Valid_State(String),5)          ! String is valid.

  ! Loop through letters, setting lowercase version.

  Lowercase = ' '
  do letter = 1, LEN_TRIM(String)
    if (ICHAR(String(letter:letter)) .InInterval. Majuscules) then
      Lowercase(letter:letter) = &
        CHAR(ICHAR(String(letter:letter)) - Capitalization)
    else
      Lowercase(letter:letter) = String(letter:letter)
    end if
  end do

  ! Verify guarantees.

  VERIFY(Valid_State(Lowercase),5)  ! Lowercase is valid.
```

```
    return
  end function Lowercase_Text_Utils
```

### C.3.3 Uppercase_Text_Utils Procedure

The main documentation of the Uppercase_Text_Utils Procedure in § 8.3.3 on page 61 contains additional explanation of this code listing.

```
  function Uppercase_Text_Utils (String) result(Uppercase)

    ! Input variables.

    type(character,*), intent(in) :: String         ! String to be uppercased.

    ! Output variables.

    type(character,255) :: Uppercase    ! The uppercase version of the string.

    ! Internal variable.

    type(integer) :: letter             ! Loop counter.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Verify requirements.

    VERIFY(Valid_State(String),5)          ! String is valid.

    ! Loop through letters, setting uppercase version.

    Uppercase = ' '
    do letter = 1, LEN_TRIM(String)
      if (ICHAR(String(letter:letter)) .InInterval. Minuscules) then
        Uppercase(letter:letter) = &
          CHAR(ICHAR(String(letter:letter)) + Capitalization)
      else
        Uppercase(letter:letter) = String(letter:letter)
      end if
    end do

    ! Verify guarantees.

    VERIFY(Valid_State(Uppercase),5)  ! Uppercase is valid.

    return
  end function Uppercase_Text_Utils
```

### C.3.4 Text_Utils Module Unit Test Program

This lightly commented program performs a unit test on the Text_Utils Module, which is described in § 8.3 on page 60.

```
program Unit_Test

  use Caesar_Intrinsics_Module
  use Caesar_Text_Utils_Module
  implicit none

  type(character,80) :: String

  ! Testing statements.

  String = 'one two three four five six'
  write (6,*) ' '
  write (6,*) 'String =           ', TRIM(String)
  write (6,*) 'Lowercase =        ', TRIM(Lowercase(String))
  write (6,*) 'Capitalized =      ', TRIM(Capitalize(String))
  write (6,*) 'Uppercase =        ', TRIM(Uppercase(String))

**Generate_Shell_Partition (§ D.4.5, page 346)**

**Get_Values_Data_Index (§ D.4.6, page 348)**

**Initialize_Shell_Partition (§ D.4.7, page 350)**

**Output_Data_Index (§ D.4.8, page 352)**

end module Caesar_Data_Index_Class

### D.4.1 Initialize_Data_Index Procedure

The main documentation of the Initialize_Data_Index Procedure in § 9.4.1 on page 84 contains additional explanation of this code listing.

```
  subroutine Initialize_Data_Index (Index, Many_Structure, One_Structure, &
                                    Many_of_One_Vector, Many_of_One_Array, &
                                    ! Many_of_One_Ragged, &
                                    status)

    ! Use associations.

    use Caesar_Flags_Module, only: initialized_flag

    ! Input variables.

    type(Base_Structure_type), target :: Many_Structure ! Column base structure.
    type(Base_Structure_type), target :: One_Structure  ! Row base structure.
    type(integer,1), optional :: Many_of_One_Vector     ! Vector indices.
    type(integer,2), optional :: Many_of_One_Array      ! Array indices.
    !type(Ragged_Integer_type), optional :: Many_of_One_Ragged ! Ragged indices.

    ! Output variables.

    ! Data_Index to be initialized.
    type(Data_Index_type), intent(out) :: Index
    type(Status_type), intent(out), optional :: status  ! Exit status.

    ! Internal variables.
```

```
type(Status_type), dimension(6) :: allocate_status ! Allocation Status.
type(Status_type) :: consolidated_status         ! Consolidated Status.
type(integer,1) :: Off_PE_Index_Temp             ! Off_PE_Index temporary.
type(integer) :: entry, i, j                     ! Loop indices.

!~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

! Verify requirements.

VERIFY(Valid_State(Many_Structure),5) ! Many_Structure is valid.
VERIFY(Valid_State(One_Structure),5)  ! One_Structure is valid.

! Set allocation status.

call Initialize (allocate_status)
call Initialize (consolidated_status)

! Set up trace.

if (PRESENT(Many_of_One_Vector)) then
  call Initialize (Index%Trace, Many_of_One_Vector, &
                   Length_PE(Many_Structure), allocate_status(1))
else if (PRESENT(Many_of_One_Array)) then
  call Initialize (Index%Trace, Many_of_One_Array, &
                   Length_PE(Many_Structure), allocate_status(1))
end if

! Initialize temporary to store off-PE indices.
!
! Note that the size that this variable needs to be is unknown. Assuming
! that the number of off-PE indices is less than the number of on-PE
! indices gives a size of Length_PE(One_Structure). This assumption
! means that the number of "boundary" values needed is less than
! the number of on-processor values, which will often be a reasonable
! assumption. However, one can imagine an almost worst-case scenario (not
! counting an extremely bad poly-connected structure, like a polyhedral
! mesh) consisting of a contiguous line of items connected like a
! 3-D structured hex mesh. Each item would connect to 8 off-PE items
! perpindicularly, and some others that are overlapped. The "end-caps"
! would not overlap, so would have an additional 9 items each. This
! gives rise to the following formula for the maximum:
!
!   Max size = 8 * Length_PE(One_Structure) + 18
!
! This size is used for a temporary -- the actual variable is then sized
! to be exactly the needed size.

call Initialize (Off_PE_Index_Temp, 8*Length_PE(One_Structure) + 18, &
                 allocate_status(2))

! Set up structure pointers.

Index%Many_Structure => Many_Structure

  ! Public type definitions.

  public :: Assembled_Vector_type

  type Assembled_Vector_type

    ! Initialization flag.

    type(integer) :: Initialized

    ! The name for this variable (especially useful in a vector of Assembled
    ! Vectors).

    type(character,name_length) :: Name

    ! Version number which is incremented every time the vector is modified,
    ! or is synced with the version number of a data structure that it
    ! depends on when it is updated.

    type(integer) :: Version

    ! Basic data structure for the axis that is spread over the processors.

    type(Base_Structure_type), pointer :: Structure

    ! The number of dimensions that the "vector" has, including the dimension
    ! that is spread over the processors. "Ragged_Right" vectors are signified
    ! by a Dimensionality of -1.
```

```
    type(integer) :: Dimensionality

    ! The extents of the dimensions that the "vector" has, including
    ! the dimension that is spread over the processors, which is last.

    type(integer,1) :: Dimensions

    ! Total number of values in this vector.

    type(integer) :: NValues_Total

    ! Values in the vector, only defined on IO_PE. Values may have either 1,
    ! 2, 3, or 4 dimensions, or be a ragged right array. The last dimension
    ! is always the dimension to be spread across the processors. Only one
    ! of the following variables will be allocated for a given object.

    type(real,1) :: Values1
    type(real,2) :: Values2
    type(real,3) :: Values3
    type(real,4) :: Values4
    ! Needed for Adaptive Angular Refinement.
    ! type(Ragged_Right_Real_type) :: ValuesRR

  end type Assembled_Vector_type

  ! Global class variables.

  type(integer), parameter :: Version_Increment = 1

contains

! Public type definitions.

public :: Overlapped_Vector_type

type Overlapped_Vector_type

  ! Initialization status.

  type(integer) :: Initialized

  ! The name for this variable (especially useful in a vector of Overlapped
  ! Vectors).

  type(character,name_length) :: Name

  ! Version number which is incremented every time the vector is modified,
  ! or is synced with the version number of a data structure that it
  ! depends on when it is updated.

  type(integer) :: Version

  ! Basic data structures. The Many_Structure corresponds to the structure
  ! of the Distributed Vector that this Overlapped Vector is based on. The
  ! One_Structure corresponds to the way that this Overlapped Vector
  ! has been formed. If this Overlapped Vector were to be combined, it
  ! would result in a Distributed Vector with a One_Structure basis. This
  ! Overlapped Vector can be thought of as a "Many of One" relationship
  ! (e.g. Many Faces of Each Cell, or Faces_of_Cells).
```

```
    type(Base_Structure_type), pointer :: Many_Structure
    type(Base_Structure_type), pointer :: One_Structure

    ! The number of dimensions that the "vector" has, including the dimension
    ! that is spread over the processors. "Ragged_Right" vectors are signified
    ! by a Dimensionality of -1.

    type(integer) :: Dimensionality

    ! The extents of the dimensions that the "vector" has, including
    ! the dimension that is spread over the processors, which is last.

    type(integer,1) :: Dimensions

    ! The Distributed Vector that this Overlapped Vector is based on. If
    ! this Overlapped Vector is not based on an external Distributed
    ! Vector, an internal Distributed Vector will be constructed and the
    ! Distributed_Vector variable will point to that one instead.

    type(Distributed_Vector_type), pointer :: DV
    type(Distributed_Vector_type) :: DV_Internal

    ! The Index that is used to modify the Distributed Vector.

    type(Data_Index_type), pointer :: Many_of_One_Index

    ! Off-PE values in the vector, that are stored locally, with a different
    ! length on each PE. Values may have either 1, 2, 3, or 4 dimensions,
    ! or be a ragged right array. The last dimension is always the dimension
    ! that is spread across the processors. Only one of the following
    ! variables will be allocated for a given object.

    type(real,1) :: Overlap_Values1
    type(real,2) :: Overlap_Values2
    type(real,3) :: Overlap_Values3
    type(real,4) :: Overlap_Values4
    ! Needed for Adaptive Angular Refinement.
    ! type(Ragged_Right_Real_type) :: Overlapped_ValuesRR

    ! The index and trace for the distributed axis of the off-PE values.

    type(integer,1) :: Overlap_Index
    type(Trace_type), pointer :: Overlap_Trace

  end type Overlapped_Vector_type

  ! Global class variables.

  type(integer), parameter :: Version_Increment = 16

contains
```

! Public type definitions.

public :: Collected_Array_type

type Collected_Array_type

  ! Initialization flag.

  type(integer) :: Initialized

  ! The name for this variable (especially useful in a vector of Collected
  ! Arrays).

  type(character,name_length) :: Name

  ! Version number which is incremented every time the array is modified,
  ! or is synced with the version number of a data structure that it
  ! depends on when it is updated.

  type(integer) :: Version

  ! Basic data structures. The Many_Structure corresponds to the structure
  ! of the Distributed Vector that this Collected Array is based on. The
  ! One_Structure corresponds to the way that this Collected Array
  ! has been formed. If this Collected Array were to be combined, it
  ! would result in a Distributed Vector with a One_Structure basis. This
  ! Collected Array can be thought of as a "Many of One" relationship
  ! (e.g. Many Faces of Each Cell, or Faces_of_Cells).

  type(Base_Structure_type), pointer :: Many_Structure
  type(Base_Structure_type), pointer :: One_Structure

  ! The number of dimensions that the "array" has, including the dimension
  ! that is spread over the processors (the One_Axis), but not including
  ! the Many_Axis, if it is present. "Ragged_Right" vectors are signified
  ! by a Dimensionality of -1. Note that the Collected Array will have the
  ! same Dimensionality as the Distributed Vector it is based on and the
  ! Distributed Vector it can be combined to form, even though in reality
  ! it may have an extra dimension. The "Actual Dimensionality", which
  ! potentially includes the Many_Axis, is given by A_Dimensionality.

  type(integer) :: Dimensionality
  type(integer) :: A_Dimensionality

  ! The extents of the dimensions that the "array" has, including
  ! the dimensions for the One_Axis and the Many_Axis (if present).

  type(integer,1) :: Dimensions

  ! The Index that is used to translate between the Distributed Vectors.
```

```
    type(Data_Index_type), pointer :: Many_of_One_Index

    ! Values in the array, that are stored locally, with a different
    ! length on each PE. Values may have either 1, 2, 3, 4, or 5 dimensions,
    ! or be a ragged right array. The last dimension is the dimension
    ! that is spread across the processors, if the Many_of_One_Index is a
    ! vector index. Otherwise, the penultimate axis will be spread across the
    ! processors. The form of the Values array is:
    !
    !   Values( [dim1, [dim2, [dim3,]]] One_Axis [, Many_Axis] )
    !
    ! Only one of the following variables will be allocated for a given object.

    type(real,1) :: Values1
    type(real,2) :: Values2
    type(real,3) :: Values3
    type(real,4) :: Values4
    type(real,5) :: Values5
    ! Needed for Adaptive Angular Refinement.
    ! type(Ragged_Right_Real_type) :: ValuesRR

  end type Collected_Array_type

  ! Global class variables.

  type(integer), parameter :: Version_Increment = 64

contains

```

The Math_Utils Module contains the following routines which are listed in separate sections:

**Prime_Factors_Math_Utils (§ E.1.1, page 468)**

end module Caesar_Math_Utils_Module

### E.1.1 Prime_Factors_Math_Utils Procedure

The main documentation of the Prime_Factors_Math_Utils Procedure in § 10.1.1 on page 115 contains additional explanation of this code listing.

```
  subroutine Prime_Factors_Math_Utils (Number, NFactors, Factors, Verbose)

    ! Input variables.

    type(integer), intent(in) :: Number             ! The number to be factored.
    type(logical), intent(in), optional :: Verbose ! Verbosity.

    ! Output variables.
```

```
! The number of prime factors found.
type(integer), intent(out) :: NFactors
! The vector of prime factors.
type(integer), dimension(32), intent(out) :: Factors

! Internal variables.

type(logical) :: A_Verbose         ! Actual verbosity.
type(integer) :: i                 ! Loop counter.
type(integer) :: Remaining_Factor ! The current number to be factored.

!~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

! Verify requirements.

VERIFY(Valid_State(Number),5)              ! Number is valid.

! Set verbosity toggle.

if (PRESENT(Verbose)) then
  A_Verbose = Verbose
else
  A_Verbose = .false.
end if

! Initializations.

Factors = 0
NFactors = 0

! Set Remaining_Factor based on sign of Number, pull out -1
! factor if negative, treat special cases of 0 and 1.

select case (Number)
case (:-1)
  Remaining_Factor = -Number
  NFactors = 1
  Factors(1) = -1
case (2:)
  Remaining_Factor = Number
case (1)
  NFactors = 1
  Factors(1) = 1
  go to 1  ! Output if requested and return.
case (0)
  NFactors = 1
  Factors(1) = 0
  go to 1  ! Output if requested and return.
end select

! Pull out all factors of 2 and 3. Note that the problem size
! is reduced with every factor that is found.
```

```
    call Extract_Factor (Remaining_Factor, Factors, NFactors, 2)
    call Extract_Factor (Remaining_Factor, Factors, NFactors, 3)

    ! Next, notice that the set of integers may be written:
    !
    !   <Integers> = {6i, 6i+1, 6i+2, 6i+3, 6i+4, 6i+5}
    !
    ! Since all factors of 2 and 3 have already been removed from
    ! Remaining_Factor, we only need to check numbers that are
    ! not divisible by 2 and 3. This rules out 6i, 6i+2, 6i+3, and
    ! 6i+4. Therefore, we only need to check numbers in the set {6i+1,
    ! 6i+5}, or equivalently, the set {6i-1, 6i+1}. The next prime
    ! number to check after 3 is 5, so we start with i=1.
    !
    ! The problem size is again reduced every time a factor is found.
    ! When the current i value becomes greater than the square root of
    ! the current problem size, we are finished. Note that the upper
    ! limit on this do-loop is unimportant -- the exit statements are
    ! always executed first.

    do i = 6, ABS(Number), 6
      call Extract_Factor (Remaining_Factor, Factors, NFactors, i-1)
      if (i - 1 > INT(sqrt(REAL(Remaining_Factor)))) exit
      call Extract_Factor (Remaining_Factor, Factors, NFactors, i+1)
      if (i + 1 > INT(sqrt(REAL(Remaining_Factor)))) exit
    end do

    ! Include the Remaining_Factor if necessary.

    if (Remaining_Factor /= 1) then
      NFactors = NFactors + 1
      Factors(NFactors) = Remaining_Factor
    end if

    ! Output.

1   if (A_Verbose) then
      write (6,*)
      write (6,100) 'Number:        ', Number
      write (6,100) 'Prime Factors: ', Factors(1:NFactors)
100   format (a,6i11,/,(15x,6i11))
    end if

    ! Verify guarantees.

    VERIFY(NFactors<=32,5)         ! Factors array is big enough.
    ! Product of factors is correct.
    VERIFY(Number==PRODUCT(Factors(1:NFactors)),5)

    return
  end subroutine Prime_Factors_Math_Utils

  ! Auxiliary procedure for Prime_Factors_Math_Utils.
```

```
  subroutine Extract_Factor_Math_Utils (Remaining_Factor, Factors, NFactors, &
                                        Divisor)

    implicit none

    ! Variables described in Prime_Factors_Math_Utils.

    integer, intent(inout) :: Factors(32), NFactors, Remaining_Factor

    ! Internal variables.

    integer, intent(in) :: Divisor  ! Divisor to be checked.
    integer :: Remainder   ! The remainder when Remaining_Factor is
                           ! divided by Divisor.

    !~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

    ! Pull out all multiples of Divisor.

    do
      Remainder = Remaining_Factor - Divisor*(Remaining_Factor/Divisor)
      if (Remainder == 0) then
        NFactors = NFactors + 1
        Factors(NFactors) = Divisor
        Remaining_Factor = Remaining_Factor/Divisor
        cycle
      end if
      exit
    end do
    return

  end subroutine Extract_Factor_Math_Utils
```

### E.1.2 Math_Utils Module Unit Test Program

This lightly commented program performs a unit test on the Math_Utils Module, which is described in § 10.1 on page 115.

```
program Unit_Test

  use Caesar_Math_Utils_Module
  implicit none
  integer :: Factors(32), NFactors

  ! Testing statements.

  call Prime_Factors (         -1, NFactors, Factors, Verbose=.true.)
  call Prime_Factors (          0, NFactors, Factors, Verbose=.true.)
  call Prime_Factors (          1, NFactors, Factors, Verbose=.true.)
  call Prime_Factors (       1024, NFactors, Factors, Verbose=.true.)
  call Prime_Factors ( 1095059400, NFactors, Factors, Verbose=.true.)
  call Prime_Factors ( 1234567890, NFactors, Factors, Verbose=.true.)
```

```
  call Prime_Factors (-1073741824, NFactors, Factors, Verbose=.true.)
  call Prime_Factors (    HUGE(1), NFactors, Factors, Verbose=.true.)
  call Prime_Factors (   -HUGE(1), NFactors, Factors, Verbose=.true.)

end
```

## E.2 Statistics Class Code Listing

  !
  ! Comment: After scrutiny, I determined that the Absoft compiler is
  ! optimizing out the work on the PEs that don't need to communicate
  ! back! This is with no optimization on! Full output shows that,
  ! for example, the 32-PE CPU time is 1.46 on the IO_PE and an
  ! average of 0.08 on the other 31 PEs, resulting in an overall average
  ! of 0.13.

! Set mesh type info for a Structured Mesh.

AMR = .false.
Structure = 'Structured'

! Determine parallel distributions: the number of PEs in each
! direction. The method used is to divide the problem between PEs so
! that the PE blocks look like a structured mesh with dimensions
! NPEs_X x NPEs_Y x NPEs_Z. Each block will have roughly the same number
! of cells, so load-balancing will be good (in 3D, each block will have
! roughly NCells_PE = (NCells_X_total/NPEs_X) * (NCells_Y_total/NPEs_Y) *
! (NCells_Z_total/NPEs_Z) ).
!
! To balance potential communication costs, the number of PEs in each
! direction are chosen to keep the physical dimensions of the blocks as
! equal as possible. The algorithm chosen is to prime factorize the
! total NPEs, then to iteratively add the largest remaining factor to the
! direction with the largest value of Length/NPEs until all the factors
! are used. This should make the blocks more equal (cubical), but it may
! not be the absolute optimal method. An additional requirement is that
! the NPEs in any direction must remain less than or equal to the number
! of cells in that direction.
!
! Better partitioning could be done if the overlying physics were known,
! however the mesh has no knowledge of the physics, and could indeed be
```

```
! used with different physics at different times.
