Error:	ERROR_string_expected
Severity:	SEVERITY_ERROR
Meaning:	A non-string Instance was provided for a string attribute
Format:	%s - attribute name
Error:	ERROR_too_many_attributes
Severity:	SEVERITY_WARNING
Meaning:	Too many attribute values were provided for a particular entity instantiation
Format:	%s - entity instance identifier
Error:	ERROR_undefined_reference
Severity:	SEVERITY_ERROR
Meaning:	A reference was made to an unknown entity instance identifier
Format:	%s - entity instance identifier
Error:	ERROR_unknown_entity
Severity:	SEVERITY_ERROR
Meaning:	A reference was made to an unknown entity class (type)
Format:	%s - entity class name

Error:	ERROR_index_out_of_range
Severity: Meaning:	An attempt was made to index an aggregate instance outside of the legal bounds
Format:	%d - index value
Error:	ERROR_insufficient_attributes
Severity:	SEVERITY_WARNING
Format.	%s - entity instance identifier
1 01 11 101	
Error:	ERROR_integer_expected
Severity:	SEVERITY_ERROR
Meaning:	A non-integer value was provided for an integer attribute
Format:	%s - attribute name
Error:	ERROR internal expected
Severity:	SEVERITY_WARNING
Meaning:	An non-embedded (external) entity was provided for an attribute with "internal" reference class
Format:	%s - attribute name
Freque	EPPOP list expected
Severity:	SEVERITY ERROR
Meaning:	An aggregate of a specific non-list class was provided for a list attribute
Format:	%s - attribute name
-	
Error:	ERROR_logical_expected
Meaning:	A non-logical value was provided for a logical attribute
Format:	%s - attribute name
Error:	ERROR_number_expected
Severity:	SEVERITY_ERROR
Format	A non-numeric value was provided for a numeric auribute %s - attribute name
1 01 11 101	
Error:	ERROR_set_duplicate_entry
Severity:	SEVERITY_ERROR
Meaning:	A duplicate entry was added to a set
Format:	none
Error:	ERROR_set_expected
Severity:	SEVERITY_ERROR
Meaning:	An aggregate of a specific non-set class was provided for a set attribute
Format:	%s - attribute name
Error:	ERROR set full
Severity:	SEVERITY_WARNING
Meaning:	An item was inserted into an already full set
Format:	none

6 STEP Working Form Error Codes

The Error module, which is used to manipulate these error codes, is described in [Clark90d]. All STEP Working Form error codes are defined in the Instance module.

Error:	ERROR_aggregate_expected
Severity:	SEVERITY_ERROR
Meaning:	A non-aggregate value was provided for an aggregate attribute
Format:	%s - attribute name
Error:	ERROR_array_expected
Severity:	SEVERITY_ERROR
Meaning:	An aggregate of a specific non-array class was provided for an array attribute
Format:	%s - attribute name
Error:	ERROR_bag_expected
Severity:	SEVERITY_ERROR
Meaning:	An aggregate of a specific non-bag class was provided for a bag attribute
Format:	%s - attribute name
Error:	ERROR_bag_full
Severity:	SEVERITY_WARNING
Meaning:	An item was inserted into an already full bag
Format:	none
Error:	ERROR_cannot_instantiate
Severity:	SEVERITY_ERROR
Meaning:	An attempt was made to instantiate an uninstantiable type
Format:	%s - type name
Error:	ERROR_entity_expected
Severity:	SEVERITY_ERROR
Meaning:	A non-entity Instance was provided for an attribute having an entity type
Format:	%s - attribute name
Error:	ERROR_external_expected
Severity:	SEVERITY_WARNING
Meaning:	An embedded (internal) entity was provided for an attribute with "external" reference class
Format:	%s - attribute name
Error:	ERROR_inappropriate_entity
Severity:	SEVERITY_ERROR
Meaning:	An entity of the wrong type was provided for an attribute having an entity type
Format:	%s - attribute name
Error:	ERROR_incompatible_types
Severity:	SEVERITY_ERROR
Meaning:	Some other type problem was encountered in specifying an attribute of some instance.
Format:	%s - attribute name

5.3 Product

Procedure:	PRODadd_instance
Parameters:	Product product - product to modify
	Instance instance - entity instance to add
Returns:	void
Requires:	TYPEget_class(INSTget_type(instance)) == TYPE_ENTITY
Description:	Adds an entity instance to a product model. The instance is assumed already to have been added to the instance list of its class, since INSTcreate_entity() does this.
Errors:	none
Procedure:	PRODcreate
Parameters:	String name - name for new product
i urumeters.	Express model - conceptual schema in which to create product
Returns	Product - a new empty product
Description:	Creates an empty product within a particular conceptual schema
Errors	none
EITOIS.	none
Procedure:	PRODget_conceptual_schema
Parameters:	Product product - product to examine
Returns:	Express - conceptual schema in which the product exists
Errors:	none
Procedure:	PRODget_contents
Parameters:	Product product - product to examine
Returns:	Linked List - entity instances which make up the product
Description:	Retrieves a list of the instances in a product model, in the order in which they were
•	created.
Errors:	none
Procedure:	PRODget_name
Parameters:	Product product - product to examine
Returns:	String - the name of the product
Errors:	none
Procedure:	PRODget_named_instance
Parameters:	Product product - product to examine
-	String name - name of instance to retrieve
Returns:	Instance - the named instance
LDescription:	Retrieves a named instance from a STEP product model, if it is defined.
Errors:	none
Procedure	PRODintialize
Parameters.	none
Returns [.]	void
Description.	Initializes the Product module This is called by STEPinitialize()
Errors:	none

Troccuure.	INSTset_remove_all
Parameters:	Instance set - set to remove from
	Instance remove - set of items to remove
	Error* errc - buffer for error code
Returns:	void
Description:	Removes all items in a set from some other set. This is set subtraction. This operation is destructive: the first set holds the result on return.
Errors:	none
Procedure:	INSTset_subset
Parameters:	Instance set - set to test as superset
	Instance subset - set to test as subset
	Error* errc - buffer for error code
Returns:	Boolean - does the first set contain the second as a subset?
Errors:	none
Procedure:	INSTset unite
Parameters:	Instance set - set to unite onto
	Instance unitee - set to unite with
	Error* errc - buffer for error code
Returns:	void
Description:	Forms the union of two sets. This operation is destructive: the first set holds the
F	resulting union on return.
Errors:	none
Procedure:	INST type cast
Parameters:	Instance instance - instance to be cast
	Type type - type to cast to
	Type type - type to cast to Error* errc - buffer for error code
Returns:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type
Returns: Description:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc ==
Returns: Description:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR none), the original instance should no longer be used. It is guaranteed to be
Returns: Description:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is
Returns: Description:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc,
Returns: Description:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none.
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String)context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_array_expected - value given for an array was not an array
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_array_expected - value given for an array was not an array ERROR_bag_expected - value given for a bag was not a bag
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_harray_expected - value given for an array was not an array ERROR_bag_expected - value given for a bag was not a bag ERROR_entity_expected - value given for an entity was not an entity
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_bag_expected - value given for an array was not an array ERROR_bag_expected - value given for an entity was not an entity ERROR_inappropriate_entity - the entity given as a value was not of an
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_bag_expected - value given for an array was not an array ERROR_hadg_expected - value given for an entity was not an entity ERROR_inappropriate_entity - the entity given as a value was not of an expected class
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_bag_expected - value given for an array was not an array ERROR_bag_expected - value given for an entity was not an entity ERROR_inappropriate_entity - the entity given as a value was not of an expected class ERROR_list_expected - value given for an integer was not an integer ERROR_list_expected - value given for a list was not a list ERROR_logical_expected - value given for a logical was not a logical ERROR_number_expected - value given for a number was not a number
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_bag_expected - value given for an array was not an array ERROR_bag_expected - value given for an entity was not an entity ERROR_inappropriate_entity - the entity given as a value was not of an expected class ERROR_list_expected - value given for an integer was not an integer ERROR_list_expected - value given for a list was not a list ERROR_logical_expected - value given for a logical was not a logical ERROR_number_expected - value given for a number was not a number ERROR_number_expected - value given for a number was not a number
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_bag_expected - value given for an array was not an array ERROR_bag_expected - value given for an entity was not an entity ERROR_inappropriate_entity - the entity given as a value was not of an expected class ERROR_list_expected - value given for an integer was not an integer ERROR_list_expected - value given for a list was not a list ERROR_logical_expected - value given for a logical was not a logical ERROR_number_expected - value given for a number was not a number ERROR_set_expected - value given for a set was not a set ERROR_string expected - value given for a set was not a set ERROR_string expected - value given for a string was not a string
Returns: Description: Errors:	Type type - type to cast to Error* errc - buffer for error code Instance - the instance, cast to the requested type Converts an instance to a new type, if possible. If the cast is successful (*errc == ERROR_none), the original instance should no longer be used. It is guaranteed to be valid only when an error is reported. This call does not report errors to stderr; it is the callers responsibility to check *errc and to call ERRORreport (*errc, (String) context) if it is not ERROR_none. ERROR_aggregate_expected - value given for an aggregate was not an aggregate ERROR_bag_expected - value given for an array was not an array ERROR_bag_expected - value given for an entity was not an entity ERROR_inappropriate_entity - the entity given as a value was not of an expected class ERROR_list_expected - value given for a list was not an integer ERROR_logical_expected - value given for a logical was not a logical ERROR_number_expected - value given for a number was not a number ERROR_set_expected - value given for a set was not a string ERROR_string_expected - value given for a string was not a string ERROR_incompatible types - the value given is not of the expected type. in

Procedure:	INSTput_value
Parameters:	Instance instance - instance to modify
	Generic value - value for instance
	Error* errc - buffer for error code
Returns:	void
Description:	Sets the value of a single-valued instance. The value given should be a char* for a string object. For an integer, real, or logical object, it should be an int*, double*, and Boolean*, respectively. For an enumeration object, the value given should be of type Constant. See INSTaggr_at_put(), INSTarray_at_put(), INSTbag_add(), INSTlist_add_first(), INSTlist_add_last(), and INSTset_add() to store into an aggregate. See INSTput_attribute() to store into an entity instance.
Procedure	INSTset add
Parameters	Instance set - set to modify
i urumeters.	Instance item - item to add
	Error* errc - buffer for error code
Returns:	void
Description:	Inserts an instance into a set, if it is not already present.
Errors:	ERROR set full - there is no more room in the set
Procedure:	INSTset includes
Parameters:	Instance set - set to test
	Instance item - item to test for
	Error* errc - buffer for error code
Returns:	Boolean - does this set contain this item?
Errors:	none
Procedure:	INSTset intersect
Parameters:	Instance set - set to intersect into
	Instance with - set to intersect with
	Error* errc - buffer for error code
Returns:	void
Description:	Intersects two sets. This operation is destructive: the first set holds the resulting
	intersection on return.
Errors:	none
Procedure:	INSTset_remove
Parameters:	Instance set - set to remove from
	Instance item - item to remove
	Error* errc - buffer for error code
Returns:	void
Description:	Remove an item from a set, if it appears.
Errors:	none

Procedure:	INSTput_attribute
Parameters:	Instance instance - instance to modify
	String attributeName - name of attribute to store into
	Instance value - value to store into attribute
	Error* errc - buffer for error code
Returns:	void
Requires:	TYPEget_class(INSTget_type(instance)) == TYPE_ENTITY
Description:	Stores a value into a named attribute of an entity instance. This call is the slower method for storing into an attribute. If the actual attribute record is available, for example from traversing the Entity's attribute list, use INSTfast_put_attribute() instead.
Errors:	ERROR_aggregate_expected - value given for an aggregate was not an aggregate
	ERROR_array_expected - value given for an array was not an array
	ERROR_bag_expected - value given for a bag was not a bag
	ERROR_entity_expected - value given for an entity was not an entity
	ERROR_external_expected - an external attribute was given an internal (embedded) entity as a value
	ERROR_inappropriate_entity - the entity given as a value was not of an expected class
	ERROR_integer_expected - value given for an integer was not an integer
	ERROR_internal_expected - an internal attribute was given an external entity reference as a value
	ERROR_list_expected - value given for a list was not a list
	ERROR_logical_expected - value given for a logical was not a logical
	ERROR_number_expected - value given for a number was not a number
	ERROR_set_expected - value given for a set was not a set
	ERROR_string_expected - value given for a string was not a string
	ERROR_incompatible_types - the value given is not of the expected type, in some way not covered by any of the above messages
Procedure:	INSTput_name
Parameters:	Instance instance - instance to modify
	String name - name for instance
Returns:	void
Description:	Sets the name (identifier) of an instance; normally, only entity instances which are not embedded are named.
Errors:	none
Procedure	INSTrut user data
Parameters:	Instance instance - instance to modify
	Generic value - user data value for instance
	Error* errc - buffer for error code
Returns:	Generic - old value of user data field for this instance
Description:	Stores a value into an instance's user data field
Errors:	none

Procedure:	INSTinitialize
Parameters:	Error* errc - buffer for error code
Returns:	void
Description:	Initialize the Instance module. This is called by STEPinitialize().
Errors:	none
Procedure:	INSTis_external
Parameters:	Instance instance - instance to examine
Returns:	Boolean - is this an external instance (non-embedded entity)?
Errors:	none
Procedure:	INSTis internal
Parameters:	Instance - instance to examine
Returns:	Boolean - is this an internal instance (embedded entity)?
Errors:	none
Procedure	INSTlist add first
Parameters.	Instance list - list to modify
i urumeters.	Instance item - item to insert
	Error* errc - buffer for error code
Returns•	void
Description:	Adds an item to the beginning of a list. This function is not yet implemented
Errors:	none
Duccodyna	NETList add last
Procedure:	INSTITS_add_tast
Parameters:	Instance list - list to modify
	Instance tiem - item to insert
Dotuma	Error* errc - buller for error code
Returns:	VOIU Adds on item to the and of a list. This function is not yet implemented
Errors:	none
Procedure:	INSTlist_concat
Parameters:	Instance list - list to concatenate onto
	Instance tail - list to concatenate
	Error* errc - buffer for error code
Returns:	void
Description:	Concatenate a list onto the end of another. This operation is destructive: the first list is modified so that it includes a copy of the second. Changes to the second will not appear in the first. This function is not yet implemented.
Errors:	none

Procedure:	INSTfast_put_attribute
Parameters:	Instance instance - instance to modify
	Variable attribute - attribute to store into
	Instance value - value to store into attribute
	Error* errc - buffer for error code
Returns:	void
Requires:	TYPEget class(INSTget type(instance)) == TYPE ENTITY
Description:	Store a value into an attribute of an entity instance. This call is faster than INSTput_attribute() when the caller already has the actual attribute record for the desired attribute, rather than simply having its name (as expected by INSTput_attribute()).
Errors:	Same as for INSTput_attribute().
Procedure:	INSTget attribute
Parameters:	Instance instance - instance to examine
	String attributeName - name of attribute to retrieve
	Error* error - buffer for error code
Returns:	Instance - value of the named attribute
Description:	Retrieves the value of a named attribute from an entity instance. This call is the slower method for retrieving an attribute value. If the actual attribute recored is already available, use INSTfast_get_attribute() instead.
Errors:	none
Procedure:	INSTget_name
Parameters:	Instance instance - instance to examine
Returns:	String - the instance's name
Description:	Retrieves the name of an instance. Unnamed instances, which would normally be embedded entities and non-entities, yield STRING_NULL.
Errors:	none
Procedure:	INSTget_type
Parameters:	Instance instance - instance to examine
Returns:	Type - the type of the instance
Errors:	none
Procedure:	INSTget user data
Parameters:	Instance instance to examine
	Error* errc - buffer for error code
Returns:	Generic - value of user data field for this instance
Errors:	none
Dracadura	INST got value
Doromotors:	Instance instance instance to exemine
i ai ainetei s.	Error* arra buffar for arrar code
Doturne	Generic the instance's value
Description:	Patriaves the value of a single valued instance. The value returned will be a gharet
Description.	for a string object, a Constant for an enumeration object, and a pointer to an int, double, or Boolean for an integer, real, or logical object, respectively. See INSTarray_at(), INSTbag_includes(), INSTlist_at(), and INSTset_at() to read from an aggregate. See INSTget_attribute() to read
-	from an entity instance.
Errors:	none

Procedure:	INSTbag_subset
Parameters:	Instance bag - bag to test as superset
	Instance subset - bag to test as subset
	Error* errc - buffer for error code
Returns:	Boolean - does the first bag contain the second as a subset?
Description:	This implementation is not completely correct. In particular, the following returns true: INSTbag, subset $\{a, b, c\}$, $\{a, a\}$
Errors:	none
Procedure:	INSTbag unite
Parameters:	Instance bag - bag to unite onto
	Instance unitee - bag to unite with
	Error* errc - buffer for error code
Returns:	void
Description:	Adds the contents of a bag to another bag. This operation is destructive: the first bag holds the resulting union on return. It is not safe to unite a bag with itself.
Errors:	none
Procedure:	INSTcreate
Parameters:	Type type - type to instantiate
	Error* errc - buffer for error code
Returns:	Instance - a new, empty instance of the given type
Errors:	ERROR_cannot_instantiate - the type given cannot be instantiated (e.g., Generic)
Procedure:	INSTcreate_entity
Parameters:	Entity entity - entity class to instantiate
	Linked_List attributes - list of attribute values
	int line - source line number of the instance to be created
	Error* errc - buffer for error code
Returns:	Instance - a new entity instance, as described
Description:	A new instance of the specified entity type is created. There should be a one-to-one correspondence between the values on the attribute value list and the list of attributes for the entity being instantiated.
Errors:	ERROR_insufficient_attributes - not enough attribute values in the list provided
	ERROR_too_many_attributes - too many attribute values in the list provided
Procedure:	INSTcreate_ud_entity
Description:	Create a user-defined entity. This procedure is not yet implemented.
Procedure:	INSTfast_get_attribute
Parameters:	Instance instance - instance to examine
	Variable attribute - attribute to retrieve
	Error* errc - buffer for error code
Returns:	Instance - value of attribute
Description:	Retrieves the value of an attribute from an entity instance. This call is faster than INSTget_attribute() when the caller already has the actual attribute record for the desired attribute, rather than simply having its name (as expected by INSTget attribute()).
Errors:	none

I I Occuui Ci	INSTarray_at_put
Parameters:	Instance array - array to modify
	int index - index at which to put element
	Instance value - value to insert
	Error* erro - buffer for error code
Returns	void
Decovintion.	Store o volue into on ormov instance
Description:	Store a value into an array instance.
Errors:	ERROR_index_out_of_range - the index is outside of the bounds of the
	aggregate
Procedure:	INSTbag_add
Parameters:	Instance bag - bag to modify
	Instance item - item to add
	Error* errc - buffer for error code
Returns:	void
Description:	Inserts an instance into a bag
Errors.	ERROR bag full - there is no more room in the bag
Lifting:	hator_bag_rarr more is no more room in the bag
D 1	
Procedure:	INS I bag_includes
Parameters:	Instance bag - bag to test
	Instance item - item to test for
	Error* errc - buffer for error code
Returns:	Boolean - does this bag contain this item?
Errors:	none
Duo oo duuuo o	NICThes intersect
Procedure	INNTAR INTERSECT
Procedure:	Instance bag has to intersect into
Procedure: Parameters:	Instance bag - bag to intersect into
Procedure: Parameters:	Instance bag - bag to intersect into Instance unitee - bag to intersect with
Parameters:	Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code
Parameters: Returns:	Invs roag_intersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void
Procedure: Parameters: Returns: Description:	Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting
Procedure: Parameters: Returns: Description:	Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return.
Procedure: Parameters: Returns: Description: Errors:	Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none
Procedure: Parameters: Returns: Description: Errors:	Invs roag_intersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none
Procedure: Parameters: Returns: Description: Errors: Procedure:	Invs roag_intersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INSTbag_remove
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters:	Invs rbag_mersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INSTbag_remove Instance bag - bag to remove from
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters:	Invs roag_intersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INSTbag_remove Instance bag - bag to remove from Instance item - item to remove
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters:	Invs roag_intersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INSTbag_remove Instance bag - bag to remove from Instance item - item to remove Error* errc - buffer for error code
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters: Returns:	Invs roag_intersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INSTbag_remove Instance bag - bag to remove from Instance item - item to remove Error* errc - buffer for error code void
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters: Returns: Description:	INST bag_mersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INST bag_remove Instance bag - bag to remove from Instance item - item to remove Error* errc - buffer for error code void Remove a single occurence of some item from a bag, if it appears
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters: Returns: Description: Errors:	INST bag_mersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INST bag_remove Instance bag - bag to remove from Instance item - item to remove Error* errc - buffer for error code void Remove a single occurence of some item from a bag, if it appears.
Procedure: Parameters: Returns: Description: Errors: Procedure: Parameters: Returns: Description: Errors:	INST bag_mersect Instance bag - bag to intersect into Instance unitee - bag to intersect with Error* errc - buffer for error code void Intersects two bags. This operation is destructive: the first bag holds the resulting intersection on return. none INST bag_remove Instance bag - bag to remove from Instance item - item to remove Error* errc - buffer for error code void Remove a single occurence of some item from a bag, if it appears. none

This is bag subtraction. This operation is destructive: the first bag holds the result on return.

5.2 Instance

Procedure:	INSTaggr_at
Parameters:	Instance instance - instance to examine
	int index - index of requested element
	Error* errc - buffer for error code
Returns:	Instance - value at requested position
Description:	Retrieves the value at some position in an aggregate. Note that the calls which are specific to a particular aggregate class are <u>much</u> to be preferred.
Errors:	ERROR_index_out_of_range - the index is outside of the bounds of the aggregate
Procedure:	INSTaggr_at_put
Parameters:	Instance instance - instance to modify
	int index - index at which to put element
	Instance value - value to insert
	Error* errc - buffer for error code
Returns:	void
Description:	Store a value into an aggregate instance. Note that the calls which are specific to a particular aggregate class are <u>much</u> to be preferred.
Errors:	ERROR_index_out_of_range - the index is outside of the bounds of the aggregate
Procedure:	INSTaggr_lower_bound
Parameters:	Instance instance - instance to examine
	Error* errc - buffer for error code
Returns:	int - the lower bound of the instance
Description:	Retrieves the lower bound of an aggregate instance. For an array, this is the index of the first element of the array. For other aggregates, it is 1.
Errors:	none
Procedure:	INSTaggr_upper_bound
Parameters:	Instance instance - instance to examine
	Error* errc - buffer for error code
Returns:	int - the upper bound of the instance
Description:	Retrieves the upper bound of an aggregate instance. For an aggregate with a constrained size, this is the value of the upper limit or index. For an aggregate with an infinite upper bound, the value returned is guaranteed to be larger than the highest index of a filled slot in the aggregate.
Errors:	none
Procedure:	INSTarray_at
Parameters:	Instance array - array to examine
	int index - index of requested element
	Error* errc - buffer for error code
Returns:	Instance - value at requested position
Description:	Retrieves the value at some position in an array.
Errors:	ERROR_index_out_of_range - the index is outside of the bounds of the aggregate

Since step_static.o and step_dynamic.o both define the function STEPreport(), only one is linked into any given executable. This selection is what determines whether a STEPparse translator links in output modules statically or dynamically. By default, the linkage mechanism will be step_static.o, which actually appears in the Working Form library. This choice can be overridden by placing step_dynamic.o before libstep.a in the link command. Note that a suitable output module (.o file) must appear *after* step_static.o in the linker's argument list when a statically linked translator is being built. For more information on how to build a report generator into a STEPparse translator, see [Clark90d].

5 Working Form Routines

The remainder of this manual consists of specifications and brief descriptions of the access routines and associated error codes for the STEP Working Form. The error codes are manipulated by the Error module [Clark90d]. Each subsection below corresponds to a module in the Working Form library. The Working Form Manager module is listed first, followed by the remaining data abstractions in alphabetical order.

5.1 Working Form Manager

Procedure: Parameters: Returns: Description:	STEPinitialize Error* errc - buffer for error code void Initialize the STEP Working From package. In a typical STEP translator, this is called by the default main() provided in the Working Form library. Other applications
Errors:	should call this function at initialization time.
Ducaduna	STEDnarco
Procedure:	STEPpaise
rarameters:	Summing memanie - the name of the first to be parsed
Dotuma	Express data_inodel - conceptual schema (as produced by EXPRESSpass_2())
Returns:	Product - the product model parsed
Description:	Parse a STEP physical me into the working Form
Procedure:	STEPreport
Parameters:	Product product - the product to output
Returns:	void
Description:	Invoke one or more report generators for a STEP Working Form model.
Description:	Invoke one (or more) report generator(s), according to the selected linkage mechanism.

```
void
entry point(void* product, void* file)
{
     extern void print file();
     print file(product, file);
}
#include "step.h"
... actual output routines . ..
void
print file(void* product, void* file)
{
     print file header((Product)product,
           (FILE*)file);
     STEPprint(product, file);
     print file trailer((Product)product,
           (FILE*)file);
```

The print_file() function will probably always be quite similar to the one shown, although in many cases, the file header and/or trailer may well be empty, eliminating the need for these calls. In this case, STEPprint() and print_file() will probably become interchangeable.

Having said all of the above about templates, code layout, and so forth, we add the following note: In the final analysis, the output module really is a free-form piece of C code. There is one and only one rule which must be followed: The entry point (according to the a.out format) to the .o file which is produced when the report generator is compiled must be appropriate to be called with a Product and a FILE*. The simplest (and safest) way of doing this is to adhere strictly to the layout given, and write an entry_point() routine which jumps to the real (conceptual) entry point. But any other convention which guarantees this property may be used.

4.2 Output Module Linkage Mechanisms

One of the powers of STEPparse is the flexibility which it gives a user with regard to generating output. An important component of this flexibility on BSD Unix systems is the dynamic loading of output modules. Both static and dynamic binding of output modules are supported by STEPparse. This is implemented by providing two distinct versions of the Working Form manager. Code common to both versions (including initialization code and the STEPparse parser itself) is found in step.c, which is included by each of the distinct manager modules. The static linking version of the output pass, without any output module, is in step_static.c, and the corresponding step_static.o is included in libstep.a, making it the default; the dynamic loading version is in step_dynamic.c.

stances were added to the Product, and so is appropriate for applications, such as writing a STEP physical file, which require that there be no forward references to asyet-undefined Instances. Each external Instance is also added to a dictionary which the Product maintains, to allow retrieval by name. And when an entity instance is first created, it is added to the instance list of its class.

4 Writing An Output Module

We now turn to the topic of actually writing a report generator. The end result of this process will be an object module (under Unix, a .o file) which can be loaded into STEPparse. This module contains a single entry point which traverses a given Product and writes its output to a particular file. The conceptual entry point is conventionally called print_file(), while the physical entry point, which simply dispatches to print_file(), is called entry_point().

In most cases, there will be a one-to-one correspondence between Instances in the instantiated Working Form and records to be written on the output. When this is the case, the meat of the report generator can be made fairly simple. Since a list of all of the Instances in the Working Form is available, it is easy to iterate over this list and output each Instance in sequence:

```
STEPprint(Product product, FILE* file)
{
    Linked_List list;
    list = PRODget_contents(product);
    LISTdo(list, inst, Instance)
        INSTprint(inst, file);
    LISTod;
}
```

The only remaining problem is to write a function INSTprint() which emits the output record for a single Instance. Given the variety of types of Instances, this function will probably be controlled by a large switch statement, selecting on the Instance's type class (numbers, strings, and aggregates all have to be printed differently). Code to deal with multi-dimensional arrays an internal/external entity references can get tricky, and should be written carefully. An example of a fairly simple report generator is that used by STEPparse-QDES. The source code for this module is in ~pdes/src/stepparse gdes/step output smalltalk.c.

4.1 Layout of the C Source

The layout of the C source file for a report generator which will be dynamically loaded is of critical importance, due to the primitive level at which the load is carried out. The very first piece of C source in the file must be the entry_point() function, or the loader may find the wrong entry point to the file, resulting in mayhem. Only comments may precede this function; even an #include directive may throw off the loader. An output module is normally layed out as shown: no specified upper bound, however, high may vary with the number of elements actually in the aggregate. The expression (from Express) giving the absolute upper bound on an aggregate is cached in aggregate->max. high is never allowed to be greater than the value of this expression.

The two calls INSTaggr_at() and INSTaggr_at_put() can be used with any kind of aggregate, although they are intended to be used primarily for building general aggregates which will later be INSTtype_cast() into specific types of aggregates. This is how STEPparse builds aggregates, since it is considerably easier than figuring out at parse time what type of aggregate should be built. The various class-specific manipulations (list concatenation, set intersection, etc.) are provided by calls requiring aggregates of a particular class: INSTlist_concat(), INSTset_intersect(), etc. It should be noted that the calls for combning aggregates are destructive: each modifies its first argument to hold its computed result. In general, the two arguments may safely be set equal. Exceptions are noted in the individual function specifications.

Finally, a word about type conversion (also known as casting, as in C). Type conversions of existing Instances are handled by INSTtype_cast(Instance, Type, Error*). Only certain conversions are allowed; other attempted casts leave the Instance unchanged and return an error code. Clearly, any Instance can trivially be cast into its own type. The different numeric types can be cast about at will. A general aggregate can be cast into any specific aggregate class; otherwise, an aggregate can only be cast into another aggregate type of the same class: an array cannot be cast into a set, etc. Each element of the aggregate being cast must, of course, be recursively cast into the appropriate base type; each of these conversions is subject to the same rules as any other cast. Finally, an entity Instance can be converted into an instance of a supertype of its class, or into an instance of a SELECT type containing some type to which it can be cast. These casts of entity instances in fact do not modify the Instance being cast.

3.6 Product

A product in STEP contains a large number of interrelated entity instances, and is represented by the Product abstraction. Each Product is named, and includes a pointer to the Express model which provides the scope in which its component Instances are defined. These component instances can be retrieved from the Product in several ways: a specific (external) entity instance can be retrieved by name; a Linked_List of all of the (external) entity instances in the Product can be requested; or a particular entity class in the Product's conceptual schema can be queried for all of its instances (note that this last method retrieves both internal and external entity instances). Internal (embedded) entity instances and non-entity Instances must appear as attribute values or aggregate elements somewhere in the Product, and are only accessible via ENTITYget_instances() and component retrieval from the containing In-stances.

The above three access methods are supported by storing three references to each Instance in a Product. When an Instance is added to a Product, it is added to the end of the list of external instances. This list preserves the order in which the InThe first two fields are pretty straightforward. Note that user_data is a generic pointer field. In strict ANSI C, only a pointer can be safely stored into this field and later retrieved; it is safest to only store pointers in this field. In particular, the age-old trick of casting pointers and integers back and forth, never completely portable, is now officially frowned upon.

The value union is where things get tricky. This field contains the actual value of the object represented. Unstructured types (numbers, logicals, and strings) are represented directly; e.g., instance.value.integer contains an integer, and instance.value.string, a character pointer. The value of an enumeration instance is represented as a Constant, which will be an element of the appropriate enumeration. The integer representation of this enumeration element can be retrieved by calling (int)CSTget_value(instance.value.enumeration).

An entity instance's value field, value.entity, is a pointer to the base of an array of instances. Each element of this array corresponds to an attribute of the entity; attributes appear in the same order as in a PDES/STEP physical file, with empty attributes explicitly represented by INSTANCE_NULL. The offset to a particular attribute value is retrieved from the Express data dictionary by calling

ENTITYget_attribute_offset(entity, attribute), where entity is the entity class of the instance in question and attribute is the Variable representing the attribute to be located.

The most convoluted instance value representation is that for aggregates. An aggregate value is represented as a pointer to a struct Aggregate, defined as

struct Aggregate	{
int	low;
int	high;
Expression	max;
Instance*	contents
};	

The last field, contents, holds the actual contents of the aggregate, as an array of Instances. The low field provides a lower bound on allowable indices into this array, and doubles as a logical offset to the first element of the array. This value is 1 for any non-array aggregate. Thus, when low is 1, some aggregate [1] is found at contents [0]. Similarly, in an array whose low is 10, the some array [12] is found at contents [12-10 = 2]. low remains constant in any particular aggregate instance. The high field gives an upper bound on the indices of currently filled slots in an aggregate instance. Every index into the aggregate beyond high which is in bounds is guaranteed to return INSTANCE NULL. The end result is that a loop of the form for (i = low; i <= high; ++i) <use contents[i-low]> will always hit all of the elements of an aggregate. This function of offsetting by the lower bound is bundled into the various aggregate indexing functions of the working form (INSTaggr at (), INSTList insert (), etc.), so that the indices which a user sees will be the ones which would be expected based on the Express model. In the current implementation, high in an aggregate whose type (from Express) gives a finite upper bound always remains constant at this bound. In the case of an aggregate with

functions may be implemented as macros; these macros are not distinguished typographically from other functions, and are guaranteed not to have unpleasant side effects like evaluating arguments more than once. These macros are thus virtually indistinguishable from functions. Functions which are intended for internal use only are named FOO_function(), and are usually static as well, unless this is not possible. Global variables are often named FOO_variable; most enumeration identifiers and constants are named FOO_CONSTANT (although these latter two rules are by no means universal). For example, every abstraction defines a constant FOO_NULL, which represents an empty or missing value of the type.

3.4 Memory Management and Garbage Collection

In reading various portions of the STEP Working Form documentation, one may get the impression that the Working Form does some reasonably intelligent memory management. This is not entirely true. The NIST PDES Toolkit is primarily a research tool. This is especially true of the Express and STEP Working Forms. The Working forms allocate huge chunks of memory without batting an eye, and this memory often is not released until an application exits. Hooks for doing memory management do exist (e.g., OBJfree () and reference counts), and some attempt is made to observe them, but this is not given high priority in the current implementation.

3.5 Instance

The Instance abstraction is the basic building block of the STEP Working Form. An Instance is created for each unit of value in a PDES/STEP product model: each entity instance, aggregate, integer, string, etc. On the surface, this would seem to be a reasonably straightforward module to implement: each Instance has an optional name, a Type, and a value. The value may be simple or structured; in either case, it basically comes down to a pointer - either to an array of Instances, or to an integer, real, string, etc.

The definition of an instance is encapsulated in a private struct Instance, which is defined thus:

```
struct Instance {
     Type
                type;
     Generic
                user data;
     union {
           Constant
                     enumeration;
           Integer
                     integer;
           Logical
                     logical;
           Real
                     real;
           String
                     string;
           Instance* entity;
           Aggregate aggregate;
    }
                value;
};
```

called. The code of this module consists of calls to STEP Working Form access functions and to standard output routines. Chapter 4 provides a detailed description of the creation of a new output module.

3 Working Form Implementation

As in the Express Working Form [Clark90e], the Instance abstraction is implemented as an Object header block which ultimately points to a private struct Instance. This C structure contains the real definition of the abstraction, but is never manipulated directly outside of the Instance module. Product is implemented as a pointer to a private structure, struct Product.

Most stylistic and other conventions from the Express Working Form are equally valid for STEP; they are reiterated here for emphasis.

3.1 Primitive Types

The STEP Working Form makes use of several modules from the Toolkit general libraries, including the Error and Linked_List modules. These are described in [Clark90d].

3.2 STEP Working Form Manager Module

In addition to the abstractions discussed in [Clark90c], libstep.acontains one more (conceptual) module, the package manager. Defined in step.c and step.h, this module includes calls to intialize the entire STEP (and Express) Working Form package, and to run each of the passes of a STEPparse translator.

3.3 Code Organization and Conventions

Each abstraction is implemented as a separate module. Modules share only their interface specifications with other modules. A module Foo is composed of two C source files, foo.c and foo.h. The former contains the body of the module, including all non-inlined functions. The latter contains function prototypes for the module, as well as all type and macro definitions. In addition, global variables are defined here, using a mechanism which allows the same declarations to be used both for extern declarations in other modules and the actual storage definition in the declaring module. These globals can also be given constant initializers. Finally, foo.h contains inline function definitions. In a compiler which supports inline functions, these are declared static inline in every module which includes foo.h, including foo.c itself. In other compilers, they are undefined except when included in foo.c, when they are compiled as ordinary functions. foo.c resides in ~pdes/src/step/; foo.h in ~pdes/include/.

The type defined by module Foo is named Foo, and its private structure is struct Foo. Access functions are named as FOOfunction(); this function prefix is abbreviated for longer abstraction names, so that access functions for type Foolhardy_Bartender might be of the form FOO_BARfunction(). Some

2 STEPparse Control Flow

A STEPparse translator consists of two separate passes: parsing and output generation. The first pass builds an instantiated Product representing the product model specified in the STEP input file. This Product can then be traversed by an output module in the second pass, producing whatever report is desired. It is anticipated that users will need output formats other than those provided with the NIST Toolkit. The process of writing a report generator for a new output format is discussed in detail in section 4.

2.1 First Pass: Parsing

The first pass of a STEPparse translator is a very simple parser. The STEPparse grammar itself is independent of any conceptual schema. The lexical analyzer recognizes any entity class name simply as an identifier; the actions associated with rules in the grammar then interpret this name as referring to a particular Express entity, and construct appropriate objects. As each construct is parsed, it is added to the Working Form. Because the STEP physical file format does not allow forward references to as-yet-undefined entity instances, all symbol references can be (and are) resolved during this parsing pass, so that no symbol resolution pass is required.

The STEPparse parser is written using the standard Unix[™] parser generation languages, Yacc and Lex. The grammar is processed by Bison, the Free Software Foundation's¹ implementation of Yacc. The lexical analyzer is produced by Flex², a fast, Public Domain implementation of Lex.

2.2 Second Pass: Output Generation

The report or output generation pass manages the production of the various output files. In the dynamically linked version of STEPparse, this pass loads successive output modules dynamically, calling each to traverse the Working Form. The dynamic linking mechanism is discussed briefly in [Clark90d]. It is also possible to build a statically linked translator, with a particular output module loaded in at build time; this is, in fact, the only mechanism available in an environment which is not derived from BSD 4.2 Unix.

A report generator is an object module, most likely written in C, which has been compiled as a component module for a larger program (i.e., with the -c option to a Unix C compiler). In the dynamically linked version, the object module is linked into the running parser, and its entry point (by convention a function called print file()) is

^{1.} The Free Software Foundation (FSF) of Cambridge, Massachusetts is responsible for the GNU Project, whose ultimate goal is to provide a free implementation of the Unix operating system and environment. These tools are not in the Public Domain: FSF retains ownership and copyright priviledges, but grants free distribution rights under certain terms. At this writing, further information is available by electronic mail on the Internet from gnu@prep.ai.mit.edu.

^{2.} Vern Paxson's Fast Lex is usually distributed with GNU software, although, being in the Public Domain, it is not an FSF product and does not come under the FSF licensing restrictions.

NIST STEP Working Form Programmer's Reference

Stephen Nowland Clark

1 Introduction

The NIST STEP physical file parser [Clark90c], and its associated STEP parser, STEPparse, are Public Domain tools for manipulating product models stored in the STEP physical file format [Altemueller88]. These tools are a part of the NIST PDES Toolkit [Clark90a], and are geared particularly toward building STEP translators. This reference manual discusses the internals of the STEP Working Form, including STEPparse. The reader is assumed to be familiar with the design of the Toolkit ([Clark90a], [Clark90b], [Clark90c]). In some cases, technical knowledge of the Express Working Form [Clark90e] is also required.

The STEP Working Form relies on the NIST Express Working Form [Clark90b] as an in-core data dictionary, which provides a context in which STEP models can be interpreted. The tight dependency of the STEP Working Form abstractions on those of the Express Working Form is due to the schema-independent nature of the former. The STEP Working Form, and, in particular, STEPparse, contain no knowledge of any particular information model. Applications built on these tools can thus manipulate STEP product models in the context of any number of Express information models without requiring recompilation.

1.1 Context

The PDES (Product Data Exchange using STEP) activity is the United States' effort in support of the Standard for the Exchange of Product Model Data (STEP), an emerging international standard for the interchange of product data between various vendors' CAD/CAM systems and other manufacturing-related software [Smith88]. A National PDES Testbed has been established at the National Institute of Standards and Technology to provide testing and validation facilities for the emerging standard. The Testbed is funded by the CALS (Computer-aided Acquisition and Logistic Support) program of the Office of the Secretary of Defense. As part of the testing effort, NIST is charged with providing a software toolkit for manipulating PDES data. This NIST PDES Tool-kit is an evolving, research-oriented set of software tools. This document is one of a set of reports which describe various aspects of the Toolkit. An overview of the Toolkit is provided in [Clark90a], along with references to the other documents in the set.

For further information on the STEP Working Form or other components of the Toolkit, or to obtain a copy of the software, use the attached order form.
