Preface

Without a doubt, all of humanity is alarmed by the HIV/AIDS pandemic, due to its negative effects on both population and socio-economic development. These effects already touch day-to-day life of ordinary Mozambicans. In the future, the impacts of the epidemic may even worsen unless we all take precautions to prevent the infection and its spread. Providing the most accurate possible knowledge about the size and geographic distribution of HIV/AIDS in our country will contribute greatly to decision-making and more comprehensive and integrated policy formulation to combat the epidemic.

The present publication emerges from this context. It attempts to provide updated information about HIV/AIDS prevalence and its demographic impact. It is worth mentioning that the information contained therein should be treated and interpreted with care from both the longitudinal and cross-sectional point of view, since it was obtained from different sources. As has been described previously, the calculations for HIV/AIDS prevalence rates are based on information gathered from sentinel sites whose geographic coverage has increased during the past few years. While only four sentinel sites existed at the time of the 1998 epidemiological surveillance round, the number increased to 20 in 2000.

In addition to these efforts to obtain more accurate data, we are pleased to recognize the incorporation of new institutions in the Technical Group, which produced the information presented in this publication. Indeed, the integration of technical experts from the Ministry of Education, the Medical Faculty of Eduardo Mondlane University, and the National AIDS Council will certainly bring in new dynamics, multi-disciplinary vision and ever more comprehensive perspectives.

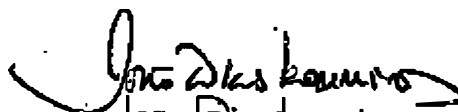

To this end, we would like to praise the Technical Group and encourage them to continue with similar initiatives, which are particularly important for disseminating information about HIV/AIDS in Mozambique in a clear and accessible manner.

We would also like to thank the CDC/USAID/POLICY Project for technical assistance and UNICEF for financial assistance, without which it would not have been possible to produce this publication.

Maputo, 5 February 2000.

Francisco Songane
Ministry of Health

João Dias Loureiro
President of INE

Introduction

Following the consensus on provincial, regional, and national HIV prevalence rates reached at the meeting of 6 September 2001, the Technical Group proceeded to update projections of the Demographic Impact of HIV/AIDS in Mozambique that were originally based on the 1998 epidemiological surveillance round.

The objective of the present document is to disseminate the updated results of the Demographic Impact of HIV/AIDS in Mozambique, based on the HIV rates from the 2000 epidemiological surveillance round.

The document is divided in three chapters:

- Historical background of HIV/AIDS research
- Overview of the epidemiological surveillance in 2000
- Selected updated projections of demographic and health impacts of the HIV/AIDS epidemic in Mozambique based on new epidemiological data.

Historical background

The growing HIV/AIDS epidemic in Mozambique and the need for redefinition of strategies to improve the national response made it necessary to estimate the impact of HIV/AIDS on demography and health. In this context the Technical Group carried out the first intensive study of demographic and HIV/AIDS epidemiological data. At that time, the Technical Group consisted of the National Institute of Statistics, Ministry of Health, Ministry of Planning and Finance, and Center for Population Studies (Eduardo Mondlane University). It was later strengthened by the addition of the National AIDS Council, Ministry of Education and Medical Faculty (Eduardo Mondlane University).

Initially, the HIV surveillance system consisted of only four sentinel sites, one in the Southern Region and three in the Center. Data from the Northern Region were based on a single rapid assessment carried out in Nampula City and Monapo District with an urban population sample. The 1997 population census and analysis of the socio-economic and demographic situation in the country during the war and post-war periods provided important baseline information for developing the first projections of the Demographic Impact of HIV/AIDS published in 1999-2000.

In that publication it was assumed that during the 1990's the HIV prevalence in the Central Region was twice as high as in the South, and that HIV prevalence in the Northern Region was 25% higher than in the South. It was also thought that, due to its earlier outset in the Central Region, the epidemic there would decline to a level 50% higher than the South, while prevalence levels in the North and South would become equal. If these tendencies persisted, the national prevalence rate would continue to grow beyond 2003.

Given the limited availability of data at the time the Technical Group also issued the following caveats:

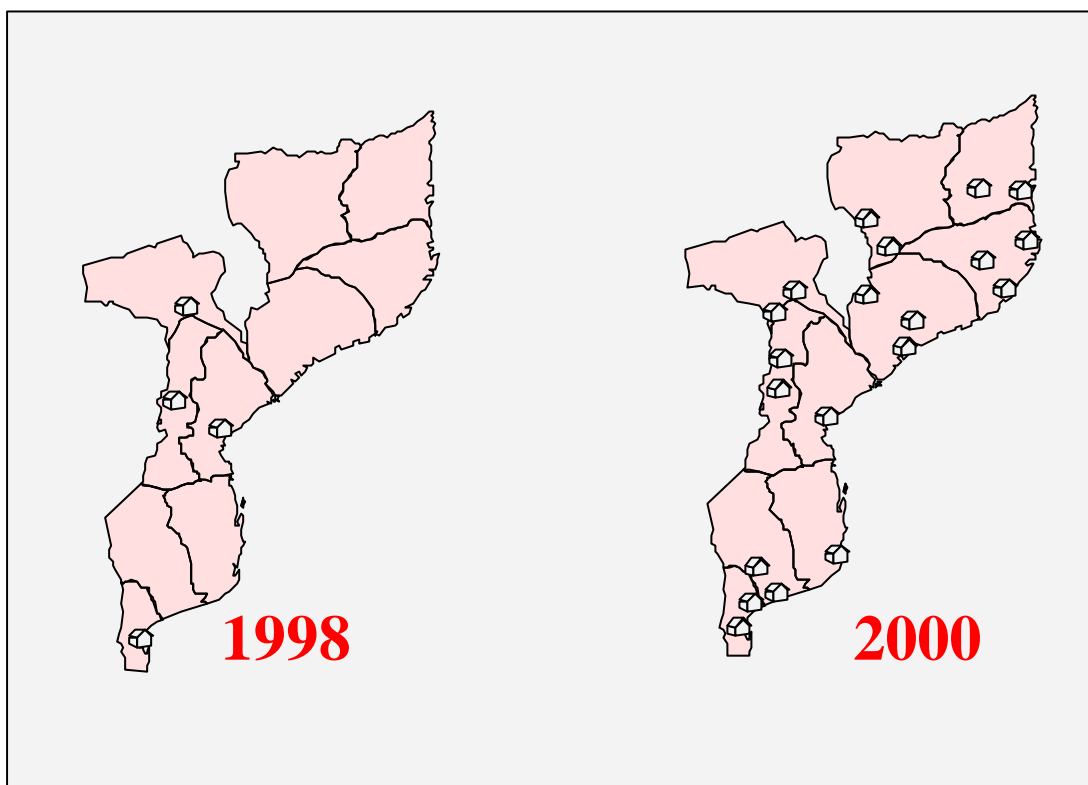

- That the published estimates should be not considered definitive, but rather as indicative to guide the process of improving the national response.

- That measurement of HIV prevalence in the Northern Region should be improved.
- That the number of sentinel sites should be expanded to cover both rural and urban areas to better reflect the national profile.

Geographic Location of Sentinel Sites

HIV prevalence rates for the year 2000 were estimated from information taken from pregnant women examined at 20 sentinel sites, of which 11 were in urban and nine in rural areas. The Northern Region, which previously had no sentinel sites, was covered with seven sites whilst the Center and South were covered by eight and five sites respectively.

In addition to the expansion of the network of sentinel sites to obtain more nationally- representative data, for the first time the 2000 sentinel round applied quality control measures to ensure the reliability of the results here presented.

HIV Prevalence rates among pregnant women (15-49 years) by Sentinel Sites. Mozambique 1988-2000

H. C. - Health Center

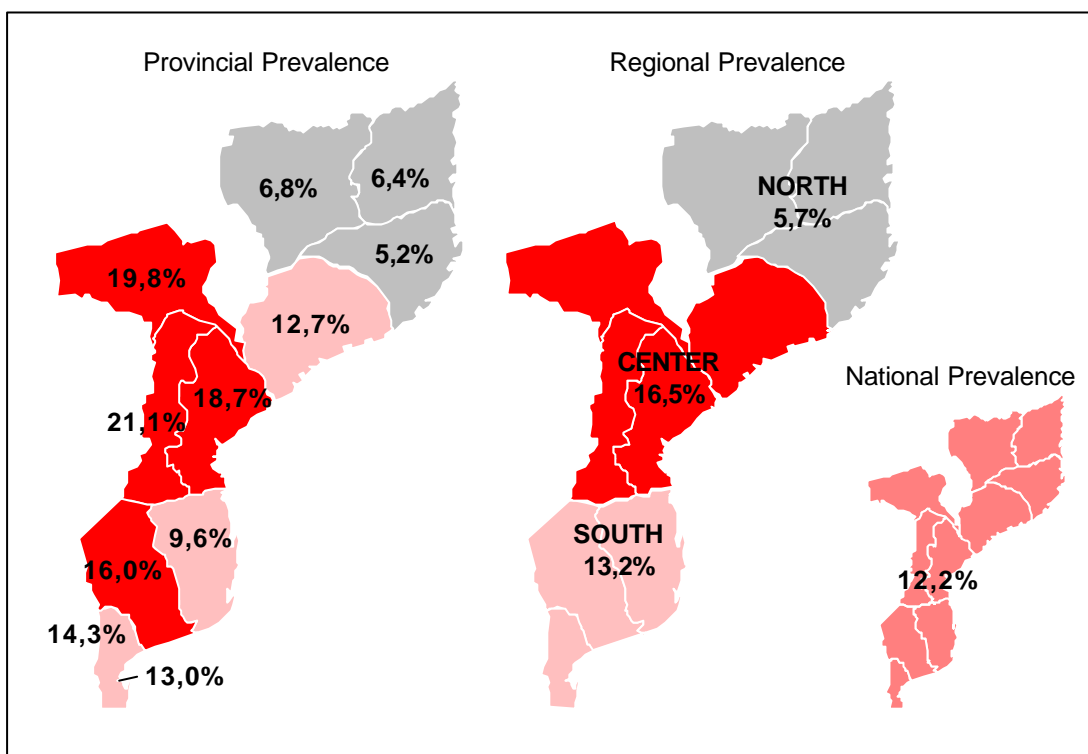

R.H. - Rural Hospital

C.H. - Central Hospital

The 2000 HIV surveillance round was carried out in 20 of the country's 144 districts. In order to estimate prevalence rates for the remaining districts, the Technical Group identified common characteristics that could allow comparisons across districts; these included population mobility, road access, health services, presence of population groups at high risk for HIV infection, culture and tradition, economic situation and educational level. Based on these criteria districts with similar characteristics were assigned to districts with sentinel posts and given the same HIV prevalence rates. District-level prevalence rates were then weighted by population size to estimate provincial, regional and national prevalence rates.

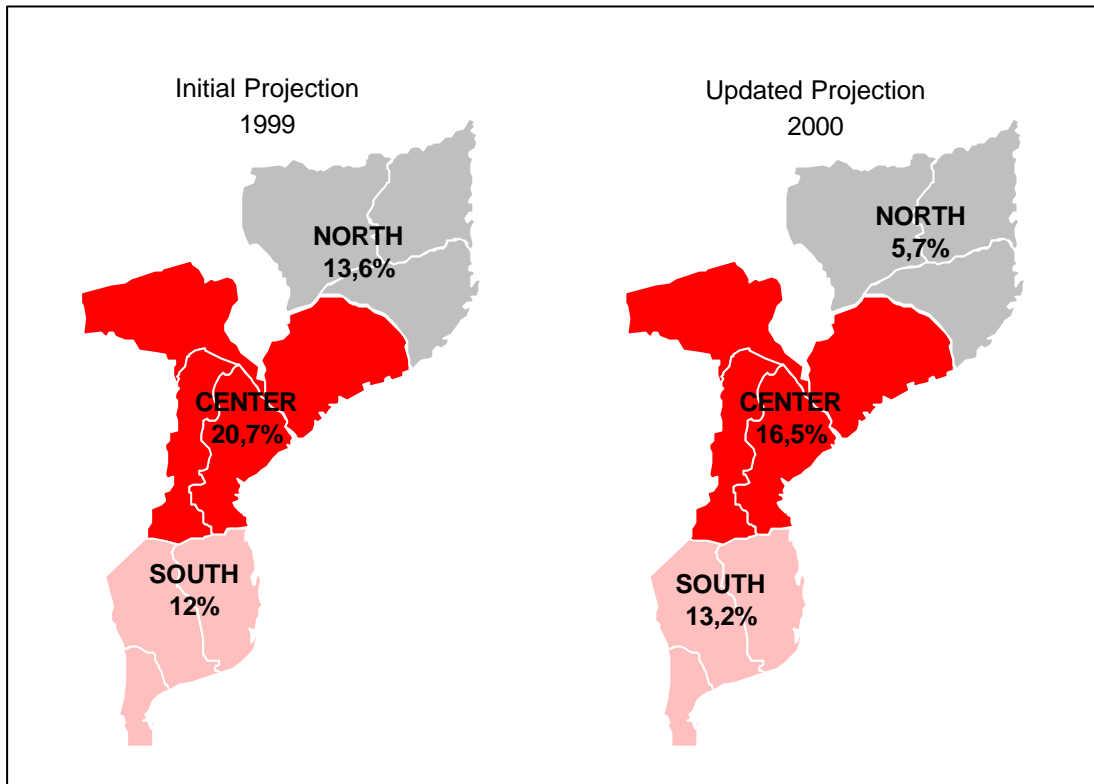

HIV Prevalence Rates among Adults (15-49 years) at Provincial, Regional and National levels. Mozambique 2000

Compared to the rest of the country, the three northern provinces show the lowest HIV prevalence rates. These estimates are consistent with the prevalence rates obtained during the rapid assessment in 1999 in Nampula City (5%) and Monapo District (6.1%). Apart from Zambézia, the central provinces are fairly homogeneous and show the highest prevalence rates in the country. The Southern Region shows intermediate prevalence. The prevalence rates in the southern provinces show wider heterogeneity than the other regions, with Gaza Province presenting the highest prevalence rate.

HIV Prevalence Rate among Adults (15-49 years) by Region. Mozambique 2000

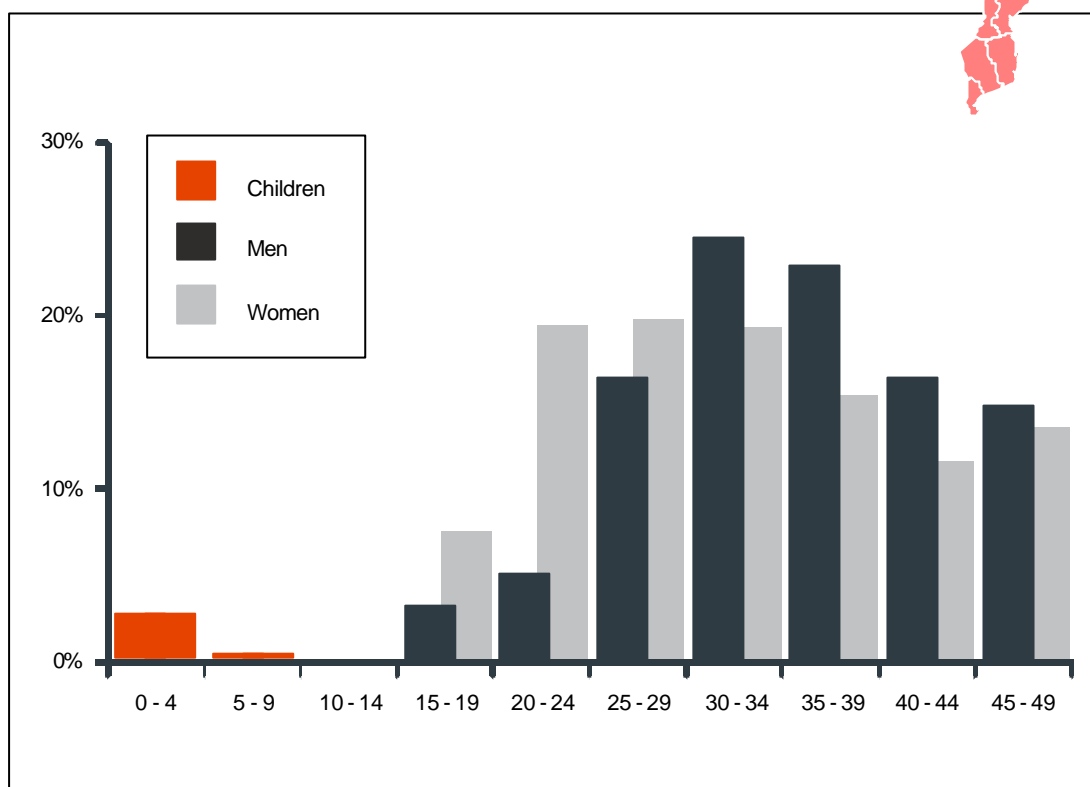

The HIV prevalence rate in the Southern Region was estimated at 13.2% which is consistent with the projection made in 1999 (12%).

Excluding Zambézia Province, the prevalence in the Central Region (20%) is consistent with the projection made in 1999 (20.7%). The regional prevalence rate, at 16.5%, is lower due to the lower prevalence rate in Zambézia, a province with a relatively large population.

One of the challenges presented by the Technical Group was to learn more about the Northern Region where there were no sentinel sites at the time of the first publication. With seven operational sentinel sites in 2000, the prevalence in the Northern Region was estimated at 6%, which is comparable to the prevalence rate in Maputo City during the mid 1990's.

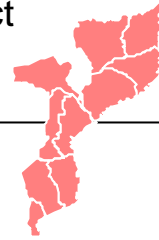

HIV Prevalence by Age and Sex. Mozambique 2000

The graph above presents the distribution of HIV prevalence by age and sex; the estimates were derived from application of the AIDS IMPACT MODEL (AIM). We see three distinct prevalence segments: the first among children under 10 years of age, with an estimated prevalence rate of 3%; most of these HIV-infected children are in fact under five years old. The second segment includes the 10-14 year age group; this group has been called the “window of opportunity”, as prevalence is close to 0%. The third segment refers to people 15 years and older. Women between 15-29 years present higher prevalence rates than men; and HIV prevalence among women between 20-24 years is estimated to be four times higher than men of the same age.

Projections of Demographic and Health Impact

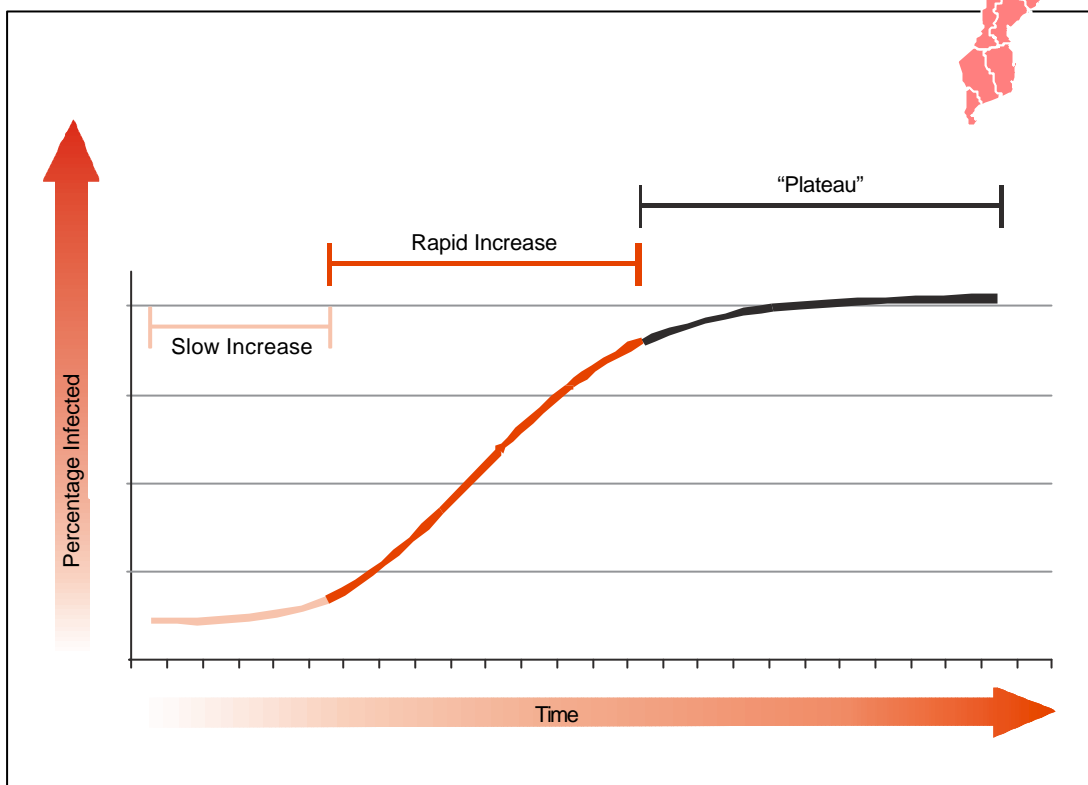

- Projected HIV Prevalence among Adults
- Projected Demographic Impact of HIV/AIDS

Next, we will present some additional projections, starting with HIV prevalence among adults, followed by the demographic impact of the epidemic.

Projected HIV Prevalence among Adults (15-49 years) at the National Level

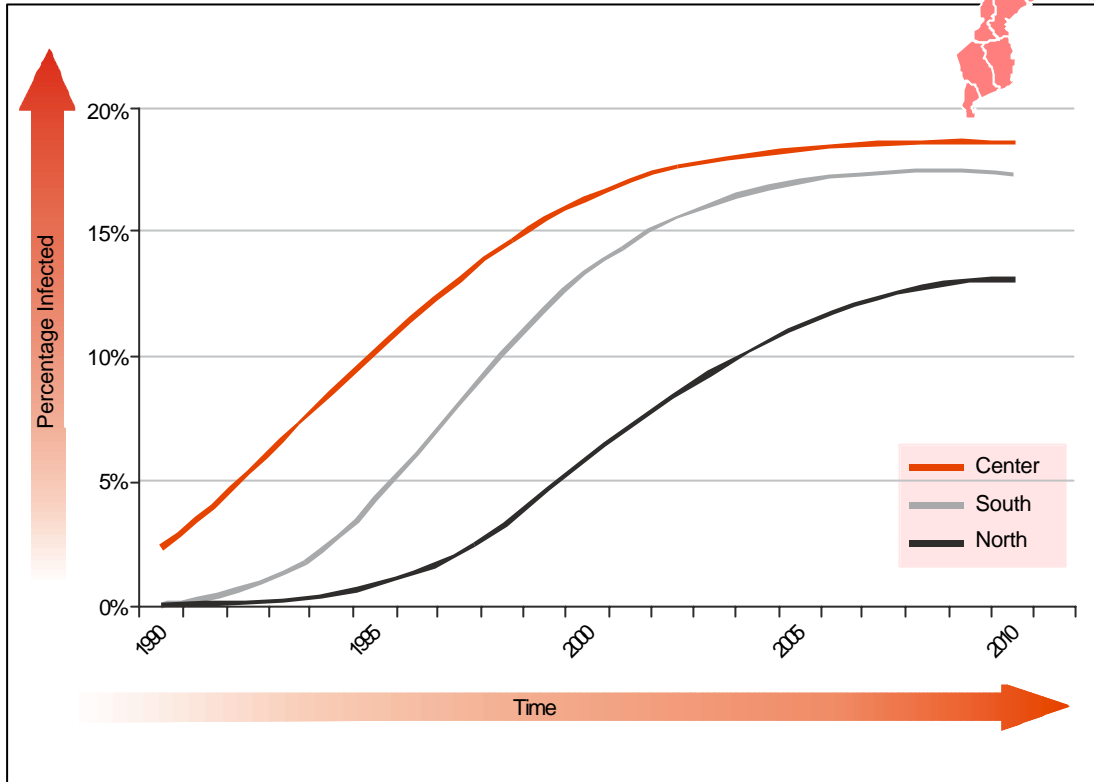

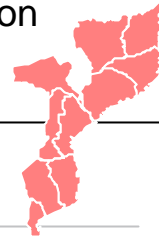

The graph above presents a natural evolution process of an epidemic in which no preventive interventions are applied. This natural evolution follows three different phases: starting with a period of slow increase followed by a phase of rapid increase and finally a plateau phase.

The growth of HIV prevalence among the adult population (15-49 years) at regional and national levels was projected by applying the AIDSproj mathematical model to the 2000 HIV epidemiological surveillance round and historical data.

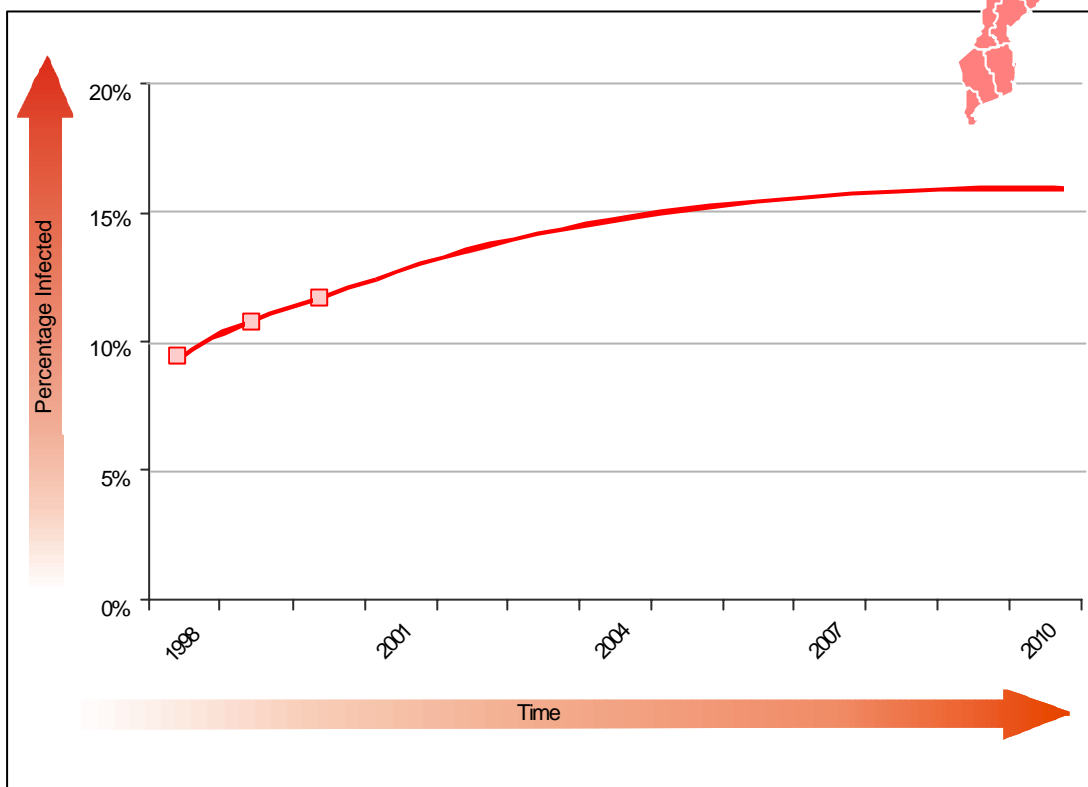

HIV Prevalence among Adults (15-49 years) by Region

As shown in graph above, the Central region presents the highest prevalence rate with an estimated 16.5% in 2000. It is predicted that without immediate, intensive, and effective preventive measures, the Central Region will reach its plateau around the year 2005. The Southern Region is at an intermediate position with an estimated prevalence rate at 13.2% in the year 2000. It is expected that in this Region the epidemic will continue increasing until attaining its plateau round 2005/6. The Northern Region, with 5.7% prevalence in 2000, presents the lowest prevalence rate. If current patterns of growth continue, it is anticipated that the epidemic in this Region will continue increasing until approximately 2010 when it should arrive at its plateau.

HIV Prevalence among Adults (15-49 years). Mozambique 2000

This graph presents the national HIV prevalence rate among adults 15-49 years of age. In 2000 the national prevalence rate was estimated at 12 %, and it is anticipated that without effective prevention, it will reach approximately 16% before it stabilizing around the year 2008.

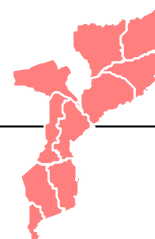

Projections of Demographic Impact of HIV/AIDS.
Mozambique 2000

The application of the AIM Model produced various projections of demographic impact of HIV/AIDS, presented here below.

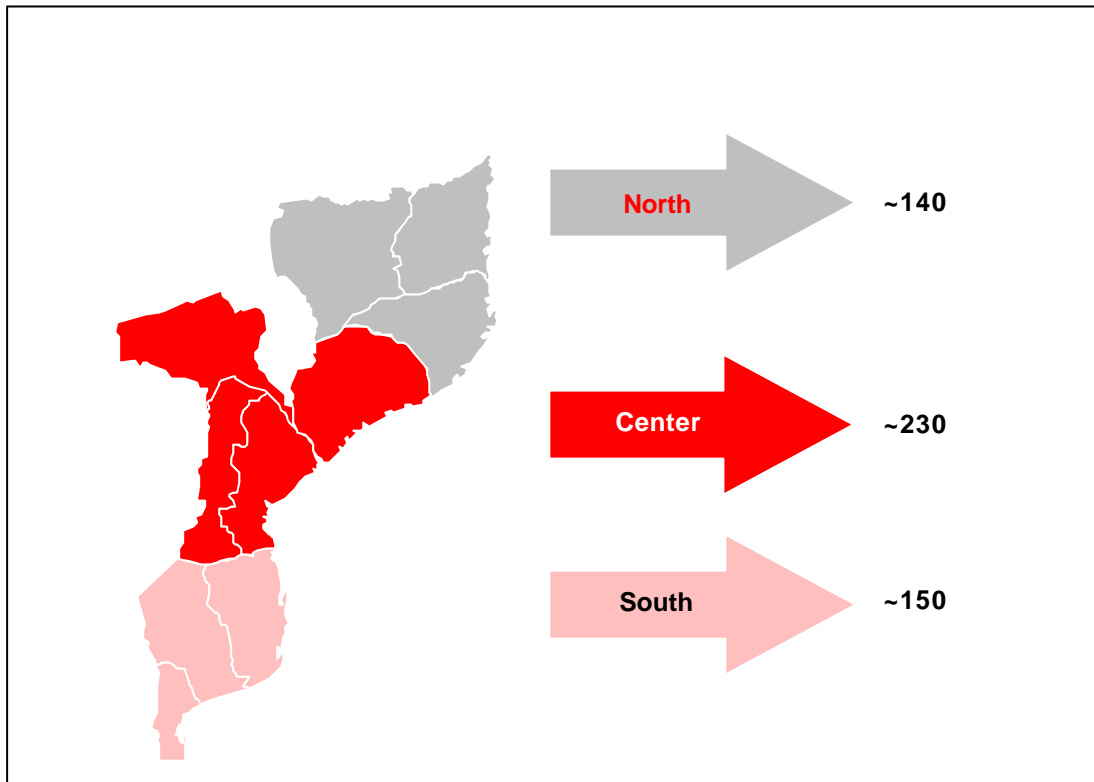

In 2000, it was estimated that 1.1 million people were infected by HIV/AIDS in the country including:

- **68,000 Children**
- **443,000 Men**
- **597,000 Women**

In 2000, it was estimated that more than 1 million Mozambicans already were infected. Approximately 10% are children infected through vertical transmission from mother to child. The principal mode of transmission among adults is unprotected sexual relations where women are the most vulnerable.

Daily new infections of HIV

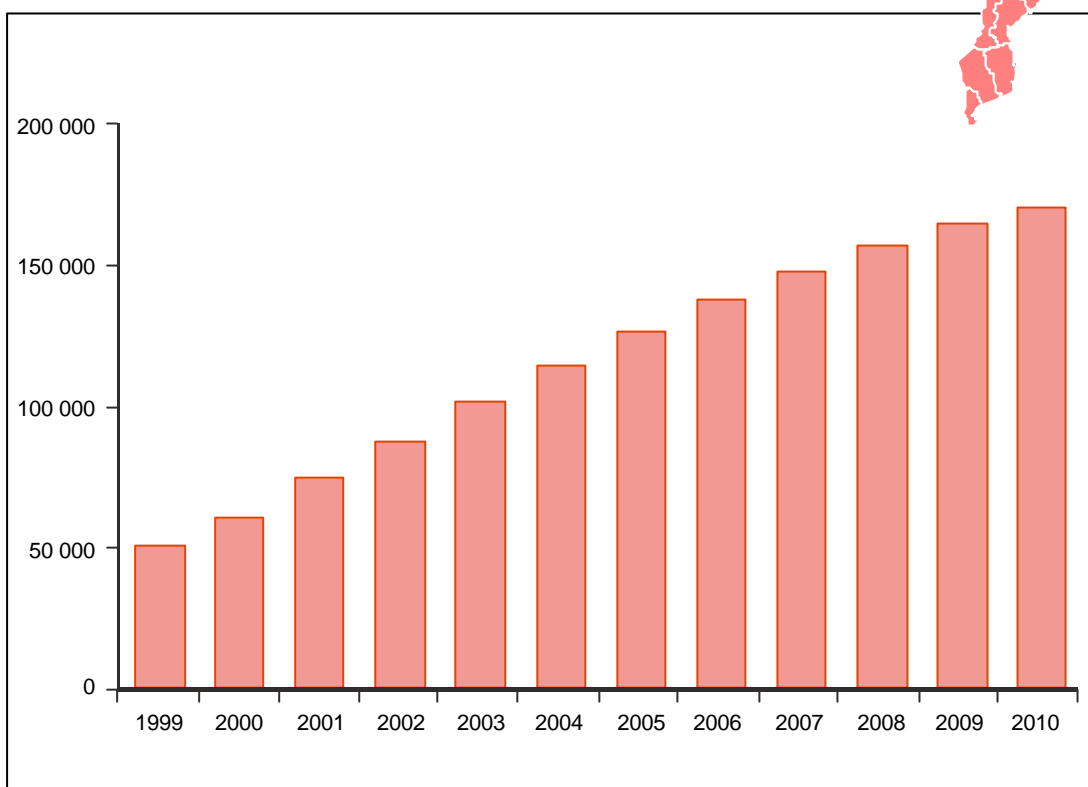

The projections indicate that more than 500 people became infected with HIV each day in Mozambique throughout 2001. Approximately 45% of these new infections occurred in the Central region, due to its large population size and higher HIV prevalence.

Compared to previous years, the number of new infections is decreasing. This is not to say, by any means, that we are winning the war against AIDS. It is simply a new phase in the evolution of the epidemic. Furthermore, as the epidemic is still expanding in South and North, these two regions will account for higher proportions of the national total of new infections.

New AIDS cases 1999-2010

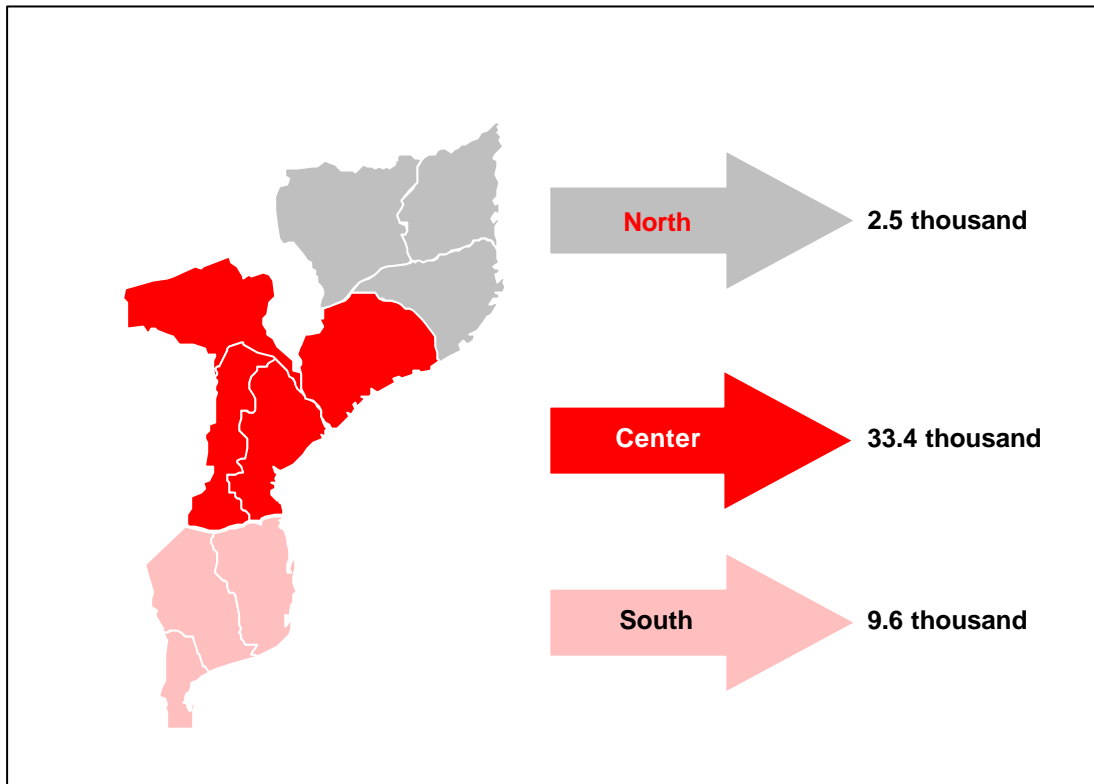

The incubation period from HIV infection to AIDS varies according to age. Normally, this period is shorter in children than in adults with medians of one and eight years respectively.

In 2001, it was estimated that there were approximately 74,000 new AIDS cases in Mozambique. This number should increase every year; two years later the number of new cases will reach 100,000. The majority of new AIDS cases will occur among those already HIV positive. According to the projections, the number of new AIDS cases may increase to 170,000 by the year 2010 without immediate and effective interventions.

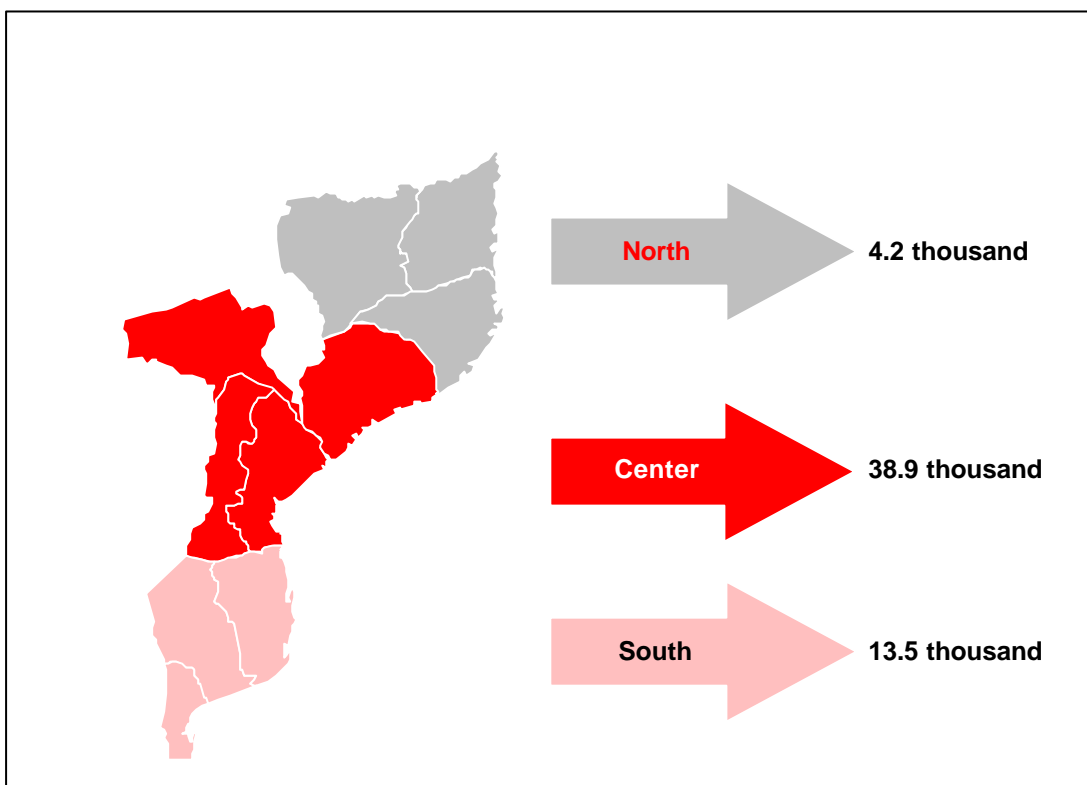

AIDS related Deaths among people ages 15 years and older in 2000

In the year 2000 in Mozambique, 45,000 people died from AIDS. It is important to note that the AIDS related mortality is differentiated by region. Approximately 74% of the deaths occurred in the Central Region. The higher mortality in this Region is due to its large population and an earlier onset of the epidemic.

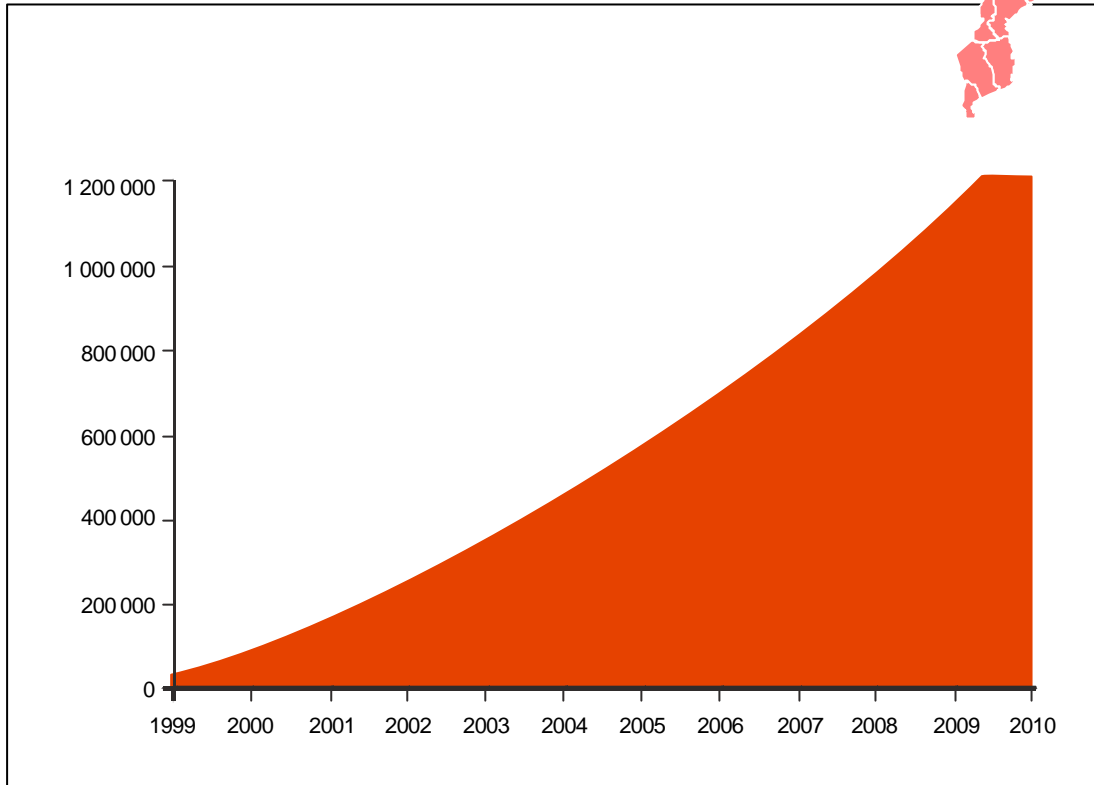

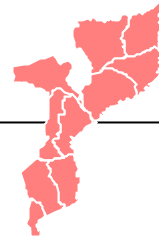

AIDS related Deaths among people ages 15 years and older in 2001

In 2001, it was estimated that 57,000 people died from AIDS in Mozambique. Again, approximately 68% of these deaths occurred in the Central Region.

Cumulative AIDS related Deaths 1999-2010

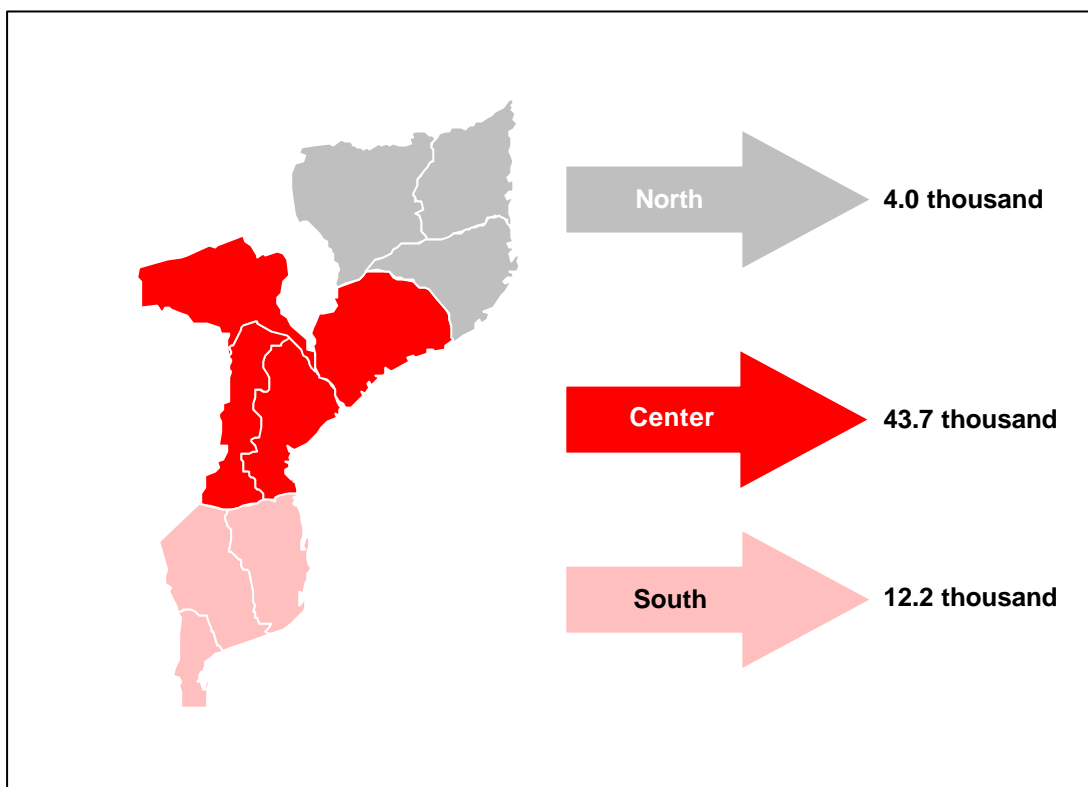

The projection of AIDS related deaths increases rapidly.

Since 1999, more than 150,000 people have died from AIDS. By the end of 2008 – **in just ten years** – it is anticipated that almost 1 million people will die.

New maternal orphans due to AIDS in 2000

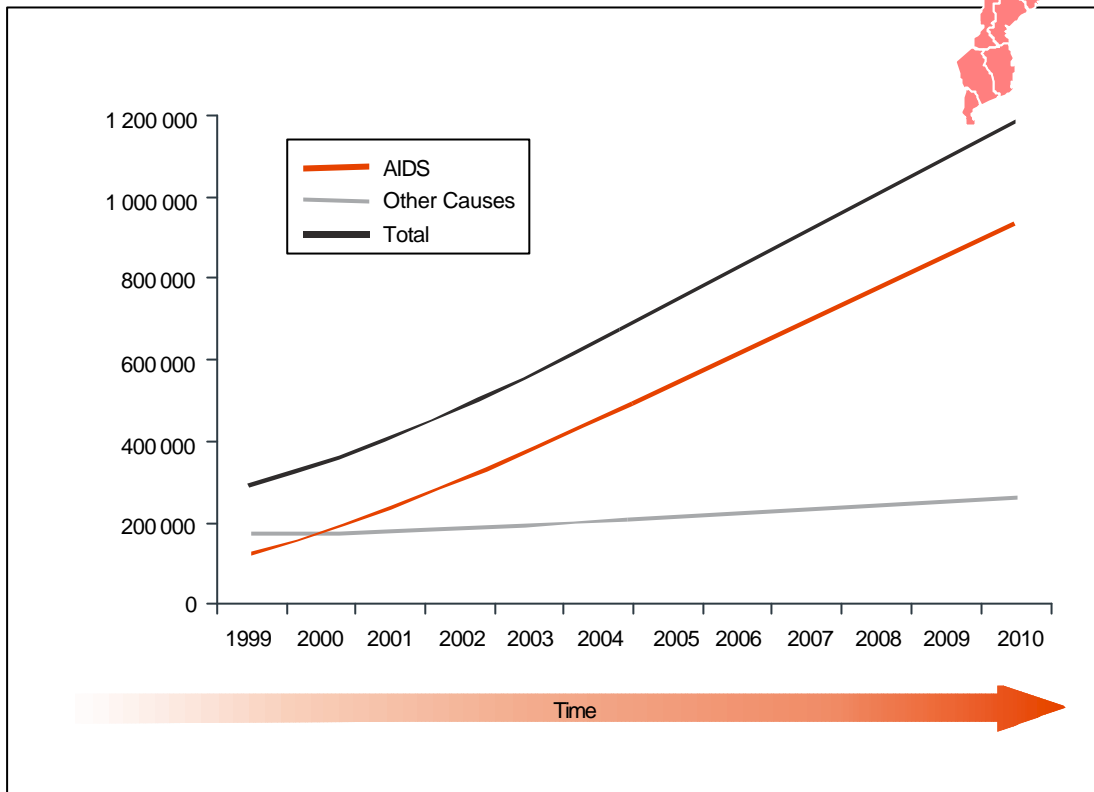

In the year 2000, more than 25,000 women died due to AIDS in Mozambique, leaving behind approximately 60,000 orphans younger than 15 years. Of these orphans, 65% are from the Central Region. Prevailing high fertility and higher HIV prevalence led to this regional difference.

It is important to point out that having lost the mother to AIDS does not mean that these orphans are HIV positive. The majority of these children are HIV negative and in need of support from society (especially for health and education).

Maternal Orphans 1999-2010

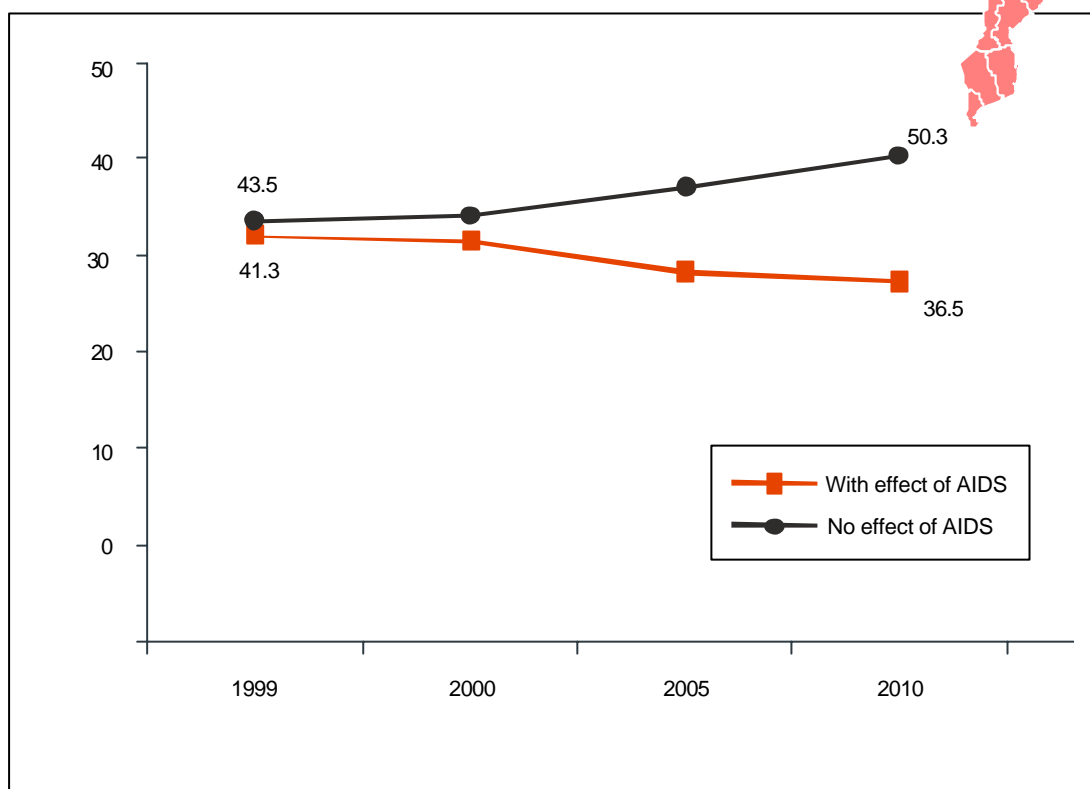

We can compare the number of orphans whose mothers died of AIDS and orphans whose mothers died of other causes. Beginning this year, the majority of maternal orphans in Mozambique will occur as a result of AIDS. By the end of 2001, it was estimated that there were 233,000 maternal orphans (around 57% of all the maternal orphans in the country) due to AIDS.

With time, the proportion of orphans due to AIDS will tend to increase. It is anticipated that in the year 2010, there will be more than 900,000 maternal orphans due to AIDS unless immediate and effective intervention is applied.

Life Expectancy 1999-2010

Another consequence of AIDS is the reduction of life expectancy of the population. The graph above shows the changes in life expectancy at birth in Mozambique, i.e. the average number of years a person born in a given year can expect to live.

In a scenario without AIDS, it was estimated that the life expectancy at birth would increase from approximately 44 years in 1999 to roughly 50 years in 2010.

In contrast, the HIV/AIDS epidemic should shorten future life expectancy of Mozambicans. As a consequence of AIDS, it is estimated that the shortfall in the life expectancy at birth is currently around 3.5 years. By the year 2010, it is expected that this shortfall will increase to more than 14 years **if no immediate and effective interventions are implemented.**

Conclusions

- 
- A graphic of a tree with a white speech bubble as its canopy. The trunk is split into two colors: orange on the left and grey on the right. The speech bubble contains three bullet points.
- **AIDS is not a problem of “others”**
 - **It is a problem for all of us**
 - **Active participation of all of society is an obligation and a right.**
