

Motivation (Behind Both Annexes)

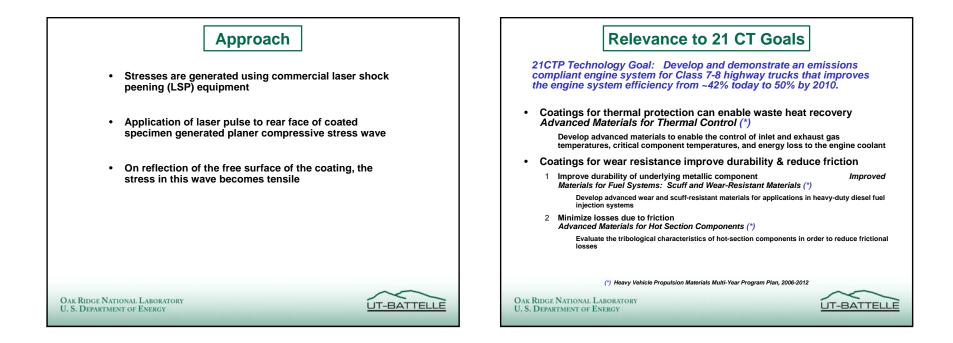

- Considerable effort has been directed towards increasing fuel efficiency and lowering emissions in diesel engines because of rising fuel prices and their environmental impact (NOx and particulates).
- New materials technologies (e.g, alloys, coatings, ceramics) for fuel systems, exhaust after-treatment, valve train, air handling, structural and insulating materials are required to meet these objectives.
- However, the integration of new technologies into the diesel engine community first requires:
 - Research that validates the applicability of these technologies to improve performance (i.e., surface durability and functionality) while lowering or maintaining acceptable life-cycle costs.
 - Commercialization of new materials technologies that have undergone thorough interrogation, test standardization, and component design.

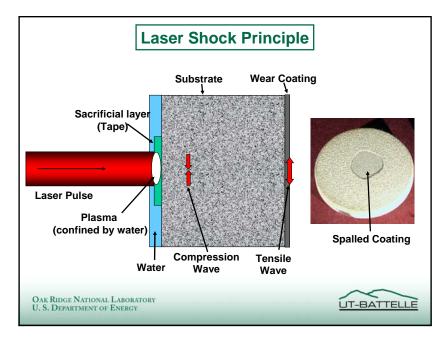

21CTP Technical Gool: Develop and demonstrate an emissions compliant engine system for Class 7-8 highway trucks that improves the engine system efficiency from -42% today to 50% by 2010. Project Objectives Promote commercialization of new materials technologies by developing standard testing and characterization methods in conjunction with national and international standards communities. Were filtering for wara 42% today to 50% by 2010. Completed preliminary investigation of characterization techniques for assessment of contact damage and quantitative adherence measurements for certain of contact damage and quantitative adherence measurements for certain for wara and thermal management. Objectives

- Enable greater use of next generation (i.e., longer lasting, more durable, lower losses due to friction) ceramic and coated metal roller elements for diesel engines
- Correlate rolling contact fatigue (RCF) test methods used internationally

Approach

- Vary the machining of Si₃N₄ ceramic balls to study its ultimate effect on RCF performance
- Develop a test coupon that can readily exploit the evaluation of RCF-limiting flaws in ceramic balls
- Collaborate with international partners and correlate RCF test methods
- Work with domestic suppliers of Si₃N₄ ball compositions to ultimately improve RCF performance

OAK RIDGE NATIONAL LABORATORY U. S. DEPARTMENT OF ENERGY

Relevance to 21 CT Goals

21CTP Technology Goal: Develop and demonstrate an emissions compliant engine system for Class 7-8 highway trucks that improves the engine system efficiency from ~42% today to 50% by 2010.

The substituted use of ceramic roller elements in diesel engines enables

- Higher thermal efficiency
- Longer characteristic life
- Reduction in parasitic losses
- Reduced weight

Accomplishments

· RCF test facility established at ORNL

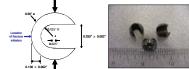

- Testing plan and new test specimen conceived and testing initiated to study subsurface damage effects on RCF performance (satisfied FY05 milestone)
- Method developed to evaluate and discriminate the elastic properties of ball bearings in-situ using resonance ultrasound spectroscopy (RUS)
- Summary report completed on RCF test methods and result interpretations used in Germany, Japan, UK, and USA

Technology Transfer

- C-Sphere test specimen has potential to enable materials
 developers to readily and inexpensive assess RCF performance.
- RUS can both quantify elastic properties and discriminate variability in ceramic balls
- Domestic Si₃N₄ ball manufacturers (Saint-Gobain & Ceradyne) have expressed interest in both of the above. The RUS method has the potential to be easily automated.

Future Work

- Continue to correlate RCF performance with identified flaw population & subsurface damage in Si₃N₄ balls
- Assess if RUS can non-destructively identify RCF-limiting flaws
- Participate in international RCF round robin study with Germany, Japan, and the UK
- Begin RCF interrogation of tribologically-coated metal specimens
