# The Big Payoff: Educational Attainment and Synthetic Estimates of Work-Life Earnings 

Special Studies

Does going to school pay off? Most people think so. Currently, almost 90 percent of young adults graduate from high school and about 60 percent of high school seniors continue on to college the following year. People decide to go to college for many reasons. One of the most compelling is the expectation of future economic success based on educational attainment.

This report illustrates the economic value of an education, that is, the added value of a high school diploma or college degree. It explores the relationship between educational attainment and earnings and demonstrates how the relationship has changed over the last 25 years. Additionally, it provides, by level of education, synthetic estimates of the average total earnings adults are likely to accumulate over the course of their working lives.

These synthetic estimates of work-life earnings, which are based on data from the Current Population Survey (CPS), are illustrative and do not predict actual future earnings. The synthetic work-life earnings are "expected average amounts" based on cross-sectional earnings data for the preceding calendar year by age, sex, full- or part-time work experience, race, Hispanic origin, and educational attainment groupings, as collected in the March 1998, 1999, and 2000 Current Population Surveys (CPS). ${ }^{1}$ The synthetic work-life

[^0]
#### Abstract

"Synthetic" estimates of work-life earnings are created by using the working population's 1 -year annual earnings and summing their age-specific average earnings for people ages 25 to 64 years. The resulting totals represent what individuals with the same educational level could expect to earn, on average, in today's dollars, during a hypothetical 40 -year working life. A typical worklife is defined as the period from age 25 through age 64. While many people stop working at an age other than 65 , or start before age 25 , this range of 40 years provides a practical benchmark for many people.

estimates are thus based on 1997-1999 earnings data and are shown in terms of "present value" (constant 1999 dollars). ${ }^{2}$ These synthetic estimates are shown in detail in three tables at the end of this report.

## EDUCATION AND EARNINGS

We are more educated than ever. In 2000, 84 percent of American adults ages 25 and over had at least completed

[^1]Current Population Reports

By
Jennifer Cheeseman Day and
Eric C. Newburger
high school; 26 percent had a bachelor's degree or higher. ${ }^{3}$ Both figures were all-time highs. In 1975, 63 percent of adults had a high school diploma, and 14 percent had obtained a bachelor's degree. ${ }^{4}$ Much of the increase in educational attainment levels of the adult population is due to a more educated younger population replacing an older, less educated population. As more and more people continue their schooling, this more highlyeducated population pursues opportunities to enter into occupations yielding higher returns in earnings.

## Earnings increase with educational level.

Adults ages 25 to 64 who worked at any time during the study period ${ }^{5}$ earned an average of $\$ 34,700$ per year. ${ }^{6}$ Average earnings ranged from $\$ 18,900$ for high school dropouts to $\$ 25,900$ for high school graduates, $\$ 45,400$ for college graduates, and \$99,300 for workers with professional degrees (M.D., J.D., D.D.S., or D.V.M.). As shown in Figure 1, with the exception of
${ }^{3}$ For a further explanation about educational attainment, see Eric Newburger and Andrea Curry, Educational Attainment in the United States: March 1999, Current Population Reports, P20-528, U.S. Census Bureau, Washington, DC, 2000.
${ }^{4}$ Prior to 1992, educational attainment was measured using a two-part question referring to years of schooling "What is the highest grade or year of regular school ever attended?" and "Did you complete the grade?" Since 1992, a new question asks specific degree completion levels beyond high school. For a more detailed discussion of the question changes, see Robert Kominski and Andrea Adams, Educational Attainment in the United States: March 1993 and 1992, U.S. Bureau of the Census, Current Population Reports, P20-476, U.S. Government Printing Office, Washington, DC, 1994.
${ }^{5}$ The study period covers 3 years - 1997, 1998, and 1999. Earnings are represented in 1999 dollars.
${ }^{6}$ Though medians provide a measure of central tendency less sensitive to outliers, and so are often used in describing earnings data, means present fewer computational difficulties, both in modeling the synthetic work-life estimates and in creating statistical procedures to test these estimates.

Figure 1.

## Work Experience and Average Annual Earnings of Workers 25 to 64 Years Old by Educational Attainment: 1997-1999

Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.
workers with professional degrees who have the highest average earnings, each successively higher education level is associated with an increase in earnings.

Work experience also influences earnings. Average earnings for people who worked full-time, yearround were somewhat higher than average earnings for all workers (which include people who work part-time or for part of the year). Most workers worked full-time and year-round (74 percent). However, the commitment to work full-time, year-round varies with demographic factors, such as educational attainment, sex, and age. For instance, high school dropouts (65 percent) are less likely than people with bachelor's degrees (77 percent) to
work full-time and year-round. Historically, women's attachment to the labor force has been more irregular than men's due mostly to competing family responsibilities. ${ }^{7}$ Earnings estimates based on all workers (which includes part-time workers) include some of this variability. Yet, regardless of work experience, the education advantage remains.

Earnings estimates based on fulltime, year-round workers provide a more straight-forward view of potential earnings and remove some biases for demographic group comparisons. The resulting

[^2]Figure 2.

## Average Earnings of Full-Time, Year-Round Workers as a Proportion of the Average Earnings of High School Graduates by Educational Attainment: 1975 to 1999

synthetic work-life estimates assume full employment throughout one's work-life. These estimates cannot account for an individual's past partial employment or unemployment, which may reduce current full-time earnings. ${ }^{8}$ The text of this report discusses earnings for full-time, year-round workers only, though findings for all workers are shown in the tables.

[^3]
## Historically, education has paid off.

Over the past 25 years, earnings differences have grown among workers with different levels of educational attainment. As Figure 2 shows, in 1975, full-time, yearround workers with a bachelor's degree had 1.5 times the annual earnings of workers with only a high school diploma. ${ }^{9}$ By 1999, this ratio had risen to 1.8. Workers with an advanced degree, who earned 1.8 times the earnings of high school graduates in 1975, averaged 2.6 times the earnings of workers with a high school diploma in 1999. During the same period, the relative earnings of the least educated workers fell. While in 1975,

[^4]full-time, year-round workers without a high school diploma earned 0.9 times the earnings of workers with a high school diploma; by 1999, they were earning only 0.7 times the average earnings of high school graduates.

The historical change in relative earnings by educational attainment may be explained by both the supply of labor and the demand for skilled workers. In the 1970s, the premiums paid to college graduates dropped because of an increase in their numbers, which kept the relative earnings range among the educational attainment levels rather narrow. Recently, however, technological changes favoring more skilled (and educated) workers have tended to increase earnings among working adults with higher educational attainment, while, simultaneously, the decline of labor unions and a decline in the minimum wage in constant dollars have contributed to a relative drop in the wages of less educated workers. ${ }^{10}$

## SYNTHETIC EARNINGS

## Earnings differences by educational attainment compound over one's lifetime.

Synthetic estimates of work-life earnings dramatically illustrate the differences that develop between workers of different educational levels over the course of their working lives.

As shown in Figure 3, for full-time, year-round workers, the 40-year synthetic earnings estimates are about $\$ 1.0$ million (in 1999 dollars) for high school dropouts, while completing high school would increase earnings by anoth-

[^5]er quarter-million dollars (to $\$ 1.2$ million). People who attended some college (but did not earn a degree) might expect work-life earnings of about $\$ 1.5$ million, and slightly more for people with associates degrees ( $\$ 1.6$ million). Over a work-life, individuals who have a bachelor's degree would earn on average $\$ 2.1$ million - about onethird more than workers who did not finish college, and nearly twice as much as workers with only a high school diploma. A master's degree holder tops a bachelor's degree holder at $\$ 2.5$ million. Doctoral ( $\$ 3.4$ million) and professional degree holders ( $\$ 4.4$ million) do even better.

The large differences in average work-life earnings among the educational levels reflect both differential starting salaries and also disparate earnings trajectories - that is, the path of earnings over one's life. As Figure 4 shows, the earnings paths of people with doctoral and professional degrees look very different from those of workers at other levels of education. At most ages, however, more education equates to higher earnings. ${ }^{11}$ Indeed, the educational payoff is most notable at the highest educational levels.

## SEX, EDUCATION, AND EARNINGS

## The educational gap between men and women is narrowing.

Among people ages 25 and older, the percentage of men and women with a bachelor's degree has increased sharply over the past 25 years, with women markedly

[^6]Figure 3.

# Synthetic Work-Life Earnings Estimates for Full-Time, Year-Round Workers by Educational Attainment Based on 1997-1999 Work Experience 

(In millions of 1999 dollars)

Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.
narrowing the gap. In 1975, 18 percent of men and 11 percent of women had attained a bachelor's degree. By 2000, 28 percent of men and 24 percent of women had a bachelor's degree. In fact, in each year since 1982, more American women than men have received bachelor's degrees. ${ }^{12}$ Additionally, 84 percent of both men and women had completed high school in 2000, up from 63 percent for men and 62 percent for women in 1975.

## Men earn more than women at each education level.

Men had higher average earnings than women with similar educational attainment. Among fulltime, year-round workers ages 25 to 64, the female-to-male earnings ratio was 0.67 during the study

[^7]period. ${ }^{13}$ This wage gap occurred with very little variation at every level of educational attainment.

Across the ages, however, the female-to-male earnings ratio was higher among younger full-time, year-round workers ( 0.84 ) than among older workers (0.56). Clearly, younger women begin their work-life with earnings much closer to those realized by men. ${ }^{14}$ This pattern of male and female younger workers starting with closer earnings than those of older

[^8]Figure 4.
Earnings Trajectories for Full-Time, Year-Round Workers by
Educational Attainment Based on 1997-1999 Work Experience

Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.

Figure 5.
Women's Earnings Relative to Men's by Age and Educational Attainment: 1997-1999

Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.
workers is not new. In 1975, the earnings ratio was 0.69 for younger workers compared with 0.56 for older workers. The age differences remain, although the earnings gap between younger men and women is closing.

Figure 5 illustrates the variation in female-to-male earnings ratios by age and education level for the 1997-1999 study period. At both the high school and bachelor's attainment level, the earnings of younger women and men are relatively close with women earning about four-fifths of men's earnings. However, for workers with a bachelor's attainment, the earnings difference between men and women becomes more pronounced as workers age (from 0.81 for ages 25 to 29 years compared with 0.60 for ages 60 to 64), compared with
a relatively flat earnings difference for workers at the high school level. ${ }^{15}$

Numerous events over one's worklife may account for the expanding wage gap with age, such as continuous participation in the labor force, commitment to career goals, competing events, discrimination, and promotions. These and other factors may lower the earnings of women relative to men, and these differences play out dramatically with total work-life earnings.

## The gap between men's and women's work-life earnings is substantial.

On average, a man with a high school education will earn about $\$ 1.4$ million from ages 25 to 64 years. This compares with about $\$ 2.5$ million for men completing a bachelor's degree and $\$ 4.8$ million for men with a professional degree. In contrast, men with less than a high school education will earn an average of $\$ 1.1$ million (Figure 6).

Women completing high school will earn an average of $\$ 1.0$ million, about 40 percent less than the estimated $\$ 1.6$ million for women completing a bachelor's degree. The work-life payoffs for women with professional ( $\$ 2.9$ million) and doctoral ( $\$ 2.5$ million) degrees, though substantial, lag markedly behind those of men with the same educational attainment.

The cumulated difference between men and women amounts to about $\$ 350,000$ for high school

[^9]Figure 6.
Synthetic Work-Life Earnings Estimates for Full-Time,
Year-Round Workers by Sex and Educational
Attainment Based on 1997-1999 Work Experience

Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.
dropouts. The difference increases to $\$ 450,000$ for high school graduates and to about twice that for bachelor's degree holders. Men with professional degrees may expect to earn almost $\$ 2$ million more than their female counterparts over their work-life.

## RACE AND HISPANIC ORIGIN, EDUCATION, AND EARNINGS

## Educational attainment and work-life earnings vary by race and Hispanic origin.

Educational attainment differs significantly by race and Hispanic origin. Among adults 25 years old and over in 2000, 88 percent of White non-Hispanics, 86 percent of Asians and Pacific Islanders, and 79 percent of Blacks had attained
at least a high school diploma. ${ }^{16}$ Similarly, 28 percent of White nonHispanics, 44 percent of Asians and Pacific Islanders, and 17 percent of Blacks had received a Bachelor's degree. For Hispanics (who may be of any race), only 57 percent had a high school diploma and 11 percent a bachelor's degree. Even accounting for these large differences in

[^10]Figure 7.

## Synthetic Work-Life Earnings Estimates for Full-Time, Year-Round Workers by Educational Attainment, Race, and Hispanic Origin Based on 1997-1999 Work Experience

(In millions of 1999 dollars)<br><br>White non-Hispanic Black<br>Asian and Pacific Islander<br>Hispanic (of any race)

Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.
educational attainment by looking at earnings within each education category, earnings differences persist and can accumulate dramatically over a 40-year work-life. ${ }^{17}$

White non-Hispanics earn more than Blacks or Hispanics at almost

[^11]every level of educational attainment. ${ }^{18}$ For example, among full-time, year-round workers with a high school education, White non-Hispanics will earn an average of $\$ 1.3$ million during their working life, compared with about \$1.1 million earned by Blacks and Hispanics (Figure 7). At the

[^12]bachelor's level, White non-
Hispanics can expect total earnings of about $\$ 2.2$ million, compared with $\$ 1.7$ million for Blacks or Hispanics.

While Asians and Pacific Islanders earn less than White non-Hispanics with similar educational attainment at the high school graduate level and the bachelor's level, Asians and Pacific Islanders with graduate degrees (master's, doctoral, or professional) have earnings similar to those of White non-Hispanics. Among full-time, year-round workers with a high school diploma or bachelor's degree, Asians and Pacific Islanders will earn about $\$ 200,000$ and $\$ 400,000$ less, respectively, than White nonHispanics during their work-life.

Though on average, work-life earnings are lower for Blacks and Hispanics than White non-Hispanics of the same educational attainment level, the educational investment still pays off. Black workers with less than a high school education would earn less than a million dollars during their work-life, increasing to $\$ 1.0$ million for workers with a high school education, $\$ 1.7$ for a bachelor's degree, and $\$ 2.5$ million for an advanced degree. Likewise, Hispanic work-life earnings also reflect this ascending outcome. Thus, regardless of race or ethnicity, higher educational attainment equates to higher earnings.

The economic reward for each succeeding level of educational attainment differs by group. Though the work-life earnings differences between a high school dropout and a high school graduate are fairly uniform for the three race groups and Hispanics, about \$200,000 each, work-life earnings for workers with a bachelor's degree compared
with workers with just a high school diploma increased by about $\$ 1,000,000$ for White non-Hispanics and about \$700,000 for Asians and Pacific Islanders, Blacks, and Hispanics. More dramatic differences appear between the work-life earnings for people with advanced degrees and bachelor's degrees. Continuing college beyond the bachelor's level pays an extra \$800,000 for White non-Hispanics and Blacks compared with $\$ 1.3$ million for Asians and Pacific Islanders. ${ }^{19}$

## METHODOLOGY

## Assumptions and limitations

An individual's work-life earnings are the sum of each year's earnings over that person's work-life. In this report, "synthetic" estimates of work-life earnings were created by using the working population's 1 year annual earnings and summing age-specific average earnings for people ages 25 and 64 years. The resulting totals represent what individuals with the same educational level would expect to earn on average in 1999 dollars, in a hypothetical 40-year working life.

The work-life earnings estimates in this report depend upon several assumptions. First, the estimates assume current cross-sectional earnings are representative of the patterns in future earnings. Second, the average earnings of individuals in each age group have been based on all members within an age group without regard to work history, past performance, or other factors which may affect pay. Third, these estimates do not

[^13]account for any future productivity gains in the economy, and therefore, the estimates may be low. Fourth, this report assumes uninterrupted labor force participation from age 25 to 64. Since earnings are based on currently surviving workers and past research indicates differential mortality by education, the work-life estimates may be inflated differentially by education level.

The limitations in the CPS universe also affect earnings estimates. Selecting only the resident, noninstitutional population with earnings excludes a segment of adults with less education. This results in a higher estimate of the earnings of people with less education, and consequently, may understate the difference in work-life earnings between workers with less education and workers with more.

Many factors which affect earnings are not covered in this report. These include college major, continuity of occupation (or "career path"), or the motivation and effort put in at work by the individual. Information on other characteristics known to affect earnings is available from the Current Population Survey, but the limited sample size of these data preclude their use in this analysis. Occupation, marital status, family responsibilities or income requirements, area of residence, local job availability, and employment rates fall into this category. In addition, non-cash or fringe benefits data are not considered in the average earnings estimates.

## Computational procedure

The following equation describes the estimates,
work-life earnings $=$
$\sum_{x=25}^{x=64}$ average (earnings) age $(x)$
where work-life earnings equals the sum of all the average earnings of workers of each age from 25 to 64 years old.

One of the difficulties in producing reasonable work-life estimates is the reliability of the available data. For many groups, the limited sample size of the Current Population Survey made earnings averages for members of certain sub-population groups unreliable. To account for limited sample size, two steps were taken in developing the estimates.

First, 3 years of sample data from the March 1998, 1999, and 2000 CPS were consolidated into a single data set for analysis. ${ }^{20}$ All earnings data were adjusted to reflect 1999 dollars using the Consumer Price Index. ${ }^{21}$

Second, average earnings were generated on consolidated age groups rather than single years of age. For the total population of workers, and workers grouped by sex, averages were generated for 5-year age groups, summed, and multiplied by 5. For workers grouped by race or ethnic origin, 10-year groups were used to generate averages, which were then summed and multiplied by 10 . Limiting the sample to fulltime, year-round workers had little impact on sample sizes by characteristic and so was not considered when choosing age groups.

For example, earnings of Blacks were calculated using 10-year age

[^14]groups. The estimation model thus took the following form.

Work-life earnings $=10 *$ (Average earnings of Black workers ages 25 to 34 years) +10 *(Average earnings of Black workers ages 35 to 44 years) +10 (Average earnings of Black workers ages 45 to 54 years) +10 *(Average earnings of Black workers ages 55 to 64 years).

## SOURCE OF THE DATA

Most estimates in this report come from data obtained in March 1998, 1999, and 2000 from the Current Population Survey (CPS). Some estimates are based on data obtained from the CPS in earlier years. The U.S. Census Bureau conducts the survey every month, although this report uses only March data for its estimates.

## ACCURACY AND RELIABILITY OF THE DATA

Statistics from sample surveys are subject to sampling and nonsampling error. All comparisons presented in this report have taken sampling error into account and meet the Census Bureau's standards for statistical significance. Nonsampling errors in surveys may
be attributed to a variety of sources, such as how the survey was designed, how respondents interpret questions, how able and willing respondents are to provide correct answers, and how accurately answers are coded and classified. The Census Bureau employs quality control procedures throughout the production process - including the overall design of surveys, testing the wording of questions, review of the work of interviewers and coders, and statistical review of reports.

The CPS employs ratio estimation, whereby sample estimates are adjusted to independent estimates of the national population by age, race, sex, and Hispanic origin. This weighting partially corrects for bias due to undercoverage, but how it affects different variables in the survey is not precisely known. Moreover, biases may also be present when people who are missed in the survey differ from those interviewed in ways other than the categories used in weighting (age, race, sex, and Hispanic origin). All of these considerations affect comparisons across different surveys or data sources. Please contact Brandi York of the Demographic Statistical Methods Division via Internet e-mail
at dsmd_s\&a@census.gov for information on the source of the data, the accuracy of the estimates, the use of standard errors, and the computation of standard errors.

## MORE INFORMATION

The electronic version of this report is available on the Internet at the Census Bureau's World Wide Web site (www.census.gov). Once on the site, click on "E" under the "Subjects A-Z" heading, and then "Educational Attainment."

${ }^{1}$ Advanced degree includes master's, professional, or doctoral degrees.
${ }^{2}$ This figure added to or subtracted from the estimate provides the 90 -percent confidence interval.
Note: Average earnings based on means.
Source: U.S. Census Bureau, Current Population Surveys, March 1998, 1999, and 2000.

[^0]:    'This report refers to "work-life earnings" rather than "life-time earnings." The latter would account for the probability of life events, which might alter the average number of years people work, such as early death or accidents leading to disability.

[^1]:    ${ }^{2}$ See the Methodology section of this report for a detailed explanation of the limitations of these estimates. The estimates in this report are based on responses from a sample of the population. As with all surveys, estimates may vary from the actual values for the entire population because of sampling variation, or other factors. All statements made in this report have undergone statistical testing and meet Census Bureau standards for statistical accuracy.

[^2]:    ${ }^{7}$ See Suzanne M. Bianchi and Daphne Spain. American Women in Transition. Russell Sage Foundation, New York, 1986. pp. 139-168.

[^3]:    ${ }^{8}$ The annual earnings and work-life earnings for a specific individual may differ significantly from the group averages presented in this report. Some factors, which can help explain the differences, include the individual's work history and continuity, occupation, type and quality of education and field of training (college major), motivation, and location. For further discussion on field of training and earnings, see Bauman, Kurt and Camille Ryan, What's It Worth? Field of Training and Economic Status: 1996, Current Population Reports, P70-72, U.S. Census Bureau, Washington DC, 2001.

[^4]:    ${ }^{9}$ Data in Figure 2 are based on full-time, year-round workers 18 years old and over.

[^5]:    ${ }^{10}$ Boesel, David, College for All? Is There Too Much Emphasis on Getting a 4-year College Degree? National Library of Education Department of Education NLE 1999-2024, 1999.

[^6]:    ${ }^{11}$ With the exception of workers with professional degrees who have the highest average earnings. At some ages, average earnings for people with some college and for people with an associates degree are not significantly different.

[^7]:    ${ }^{12}$ See National Center for Education Statistics, Digest of Education Statistics 1999, U.S. Department of Education, NCES2000-031, Table 249.

[^8]:    ${ }^{13}$ Among all workers, including part-time workers, the female-to-male earnings ratio was 0.57. This greater difference reflects a higher proportion of part-time or seasonal workers among women.
    ${ }^{14}$ Some of the persistent, though shrinking, differences in earnings may be related to field of study. Women have historically tended to major in fields with lower economic rewards than have men. While this remains the case, a growing proportion of female college graduates now receive bachelor's degrees in more highly paid fields, such as business or computers (National Center for Education Statistics, " 1999 Digest of Education Statistics," U.S. Department of Education, NCES 2000-031).

[^9]:    ${ }^{15}$ The female-to-male earnings ratio for workers ages 60-64 with a high school diploma does not differ significantly from the ratio for younger workers, ages 25-29.

[^10]:    ${ }^{16}$ Because Hispanics may be of any race, data in this report for Hispanics overlap slightly with data for the Black population and for the Asian and Pacific Islander population. Based on the March 1998, 1999, and 2000 Current Population Survey samples, 3 percent of Black adults 25 to 64 years old and 2 percent of Asian and Pacific Islanders 25 to 64 years old are also of Hispanic origin. Data for the American Indian and Alaska Native population are not shown in this report because of their small sample size in the March 1998, 1999, and 2000 Current Population Surveys.

[^11]:    ${ }^{17}$ The small sample size of workers by race and ethnicity prevents this report from providing some kinds of detailed analysis by race or ethnicity for some education levels. However, summary statistics are possible, and these have been included.

[^12]:    ${ }^{18}$ With the exception of workers with an associates degree where the work-life earnings estimates for Hispanics do not differ significantly than those for White non-Hispanics.

[^13]:    ${ }^{19}$ For Hispanics, the estimated difference of $\$ 900,000$ between the average work-life earnings of workers with bachelor's degrees and workers with advanced degrees is not significantly different from those for White non-Hispanics, Blacks, or Asians and Pacific Islanders.

[^14]:    ${ }^{20}$ The CPS March Supplement asks respondents to report earnings from the previous calendar year. Therefore, March 1998, 1999, and 2000 CPS include data on 1997, 1998, and 1999 earnings. Because a proportion of households are re-sampled and thus appear in 2 years of data, a correlation coefficient which accounts for the resulting covariation is used in the calculation of standard errors, confidence intervals, and statistical tests of significance.
    ${ }^{21}$ "CPI for All Urban Consumers, U.S. City Average for All Items," as published by the U.S. Department of Labor, Bureau of Labor Statistics, series ID\# CUUR0000SA0.

[^15]:    ${ }^{1}$ This figure added to or subtracted from the estimate provides the 90-percent confidence interval.
    Note: Average earnings based on means.
