Tempered-states #1

Tempered-states #2

Tempered-states #3

HEP details

- Multi-terabyte data catalogs (2MASS, SDSS, GOODS, etc.)
- In-principle solution to the inference problem: MCMC
  - ◆ Incorporate data from multiple catalogs
  - ◆ Can merge data sources with different attributes
- Current packages—*Bayespack*, *BUGS*, *S-Plus*, *R*
  - ◆ Not production oriented
  - ◆ Although good for proof of concept

Tempered-states #1

Tempered-states #2

Tempered-states #3

HEP details

1. Perform inference & hypothesis testing on large-volume survey data
2. Apply advanced computational techniques to optimize Bayesian methodology
  - Exploit the intrinsic parallelism in MCMC
  - Embed structures optimized for mapped data
  - Multiple data sets incorporated by general data stream architecture (consumer-producer chains)
  - Library, with front-end parser (like Octave)
3. Platform for future development and statistical research

- Tempered-states #1
- Tempered-states #2
- Tempered-states #3
- HEP details

- Multilevel hierarchical prior:
  - ◆ Eliminates high-dim volume at low resolution
  - ◆ Degrades the influence of prior on convergence
  - ◆ Improves MCMC convergence
  - ◆ Rigorously conserves probability
- Multiple temperatures, “Loosened constraints” (with M. Lavine)
  - ◆ Accelerates convergence and mixing
  - ◆ Prevents getting “stuck” in local minima

- Tempered-states #1
- Tempered-states #2
- Tempered-states #3
- HEP details

- Begin with state  $x = X_i$
- Select new state with transition probability:  $q(x, x')$
- Accept  $X_{i+1} = x'$ ; otherwise reject  $x'$  and set  $X_{i+1} = x$ .
- This is a Markov chain with transition probabilities given by:

$$P(x, x') = q(x, x')\alpha(x, x')$$

if  $x \neq x'$ , or

$$P(x, x') = 1 - \sum_{x \neq x'} q(x, x')\alpha(x, x')$$

otherwise.

- HEP details

- If we now set:

$$\alpha(x, x') = \min \left[ 1, \frac{\pi(x')q(x, x')}{\pi(x)q(x', x)} \right]$$

if  $\pi(x)q(x', x) > 0$  and  $\alpha(x, x') = 1$  otherwise.

- It is now easy to check that  $\pi(x)p(x, x') = \pi(x')p(x', x)$ .

# Metropolis-Hastings: details [2]

- HEP details

- If we now set:

$$\alpha(x, x') = \min \left[ 1, \frac{\pi(x')q(x, x')}{\pi(x)q(x', x)} \right]$$

if  $\pi(x)q(x', x) > 0$  and  $\alpha(x, x') = 1$  otherwise.

- It is now easy to check that  $\pi(x)p(x, x') = \pi(x')p(x', x)$ .

Theorem:

One can then show that  $\pi(x)$  is the equilibrium distribution of the Markov chain if  $q(x, x')$  is aperiodic and irreducible (Hastings 1970).

*Want:* sample from a distribution,  $p_0(x)$ , which may have many isolated modes

*Strategy:*

- Define a series of  $n$  other distributions,  $p_1(x), \dots, p_n(x)$
- $p_i$  being easier to sample from than  $p_{i-1}$
- For each  $i$ , define a pair of base transitions,  $\hat{T}_i$  and  $\check{T}_i$
- Each  $p_i$  as an invariant distribution
- Satisfy the following mutual reversibility condition for all  $x$  and  $x'$ :

$$p_i(x)\hat{T}_i(x, x') = \check{T}_i(x', x)p_i(x')$$

- Detailed balance if  $\hat{T}_i = \check{T}_i$
- Find candidate state by transitions in the sequence  $\hat{T}_1 \cdots \hat{T}_n \check{T}_n \cdots \check{T}_1$

- Accepted or rejected based on ratios of probabilities involving intermediate states. Choose levels to be successively broader, *higher temperature*.
- Begin in state  $\hat{x}_0$ , generate candidate state,  $\check{x}_0$ , as follows:
  - Generate  $\hat{x}_1$  from  $\hat{x}_0$  using  $\hat{T}_1$ .
  - Generate  $\hat{x}_1$  from  $\hat{x}_1$  using  $\hat{T}_2$ .
  - ⋮
  - Generate  $\bar{x}_n$  from  $\hat{x}_{n-1}$  using  $\hat{T}_n$ .
  - Generate  $\check{x}_{n-1}$  from  $\bar{x}_0$  using  $\check{T}_n$ .
  - ⋮
  - Generate  $\check{x}_1$  from  $\check{x}_2$  using  $\check{T}_2$ .
  - Generate  $\check{x}_0$  from  $\check{x}_1$  using  $\check{T}_1$ .

- The candidate state is then accepted with probability

$$\alpha = \min \left[ 1, \frac{p_1(\hat{x}_0)}{p_0(\hat{x}_0)} \cdots \frac{p_n(\hat{x}_{n-1})}{p_{n-1}(\hat{x}_{n-1})} \cdot \frac{p_{n-1}(\check{x}_{n-1})}{p_n(\check{x}_{n-1})} \cdots \frac{p_0(\check{x}_0)}{p_1(\check{x}_0)} \right]$$

- Each  $p_i$  occurs an equal number of times in the numerator and denominator of the above product of ratios  $\Rightarrow$  Don't need normalization for  $p_i$
- Need fine spacing of levels to have high acceptance probability
