

INVASIVE SPECIES OF MEALYBUGS (HEMIPTERA: PSEUDOCOCCIDAE) AND THEIR THREAT TO U.S. AGRICULTURE

DOUGLASS R. MILLER, GARY L. MILLER, AND GILLIAN W. WATSON

(DRM, GLM) Systematic Entomology Laboratory, Plant Science Institute, Agricultural Research Service, U.S. Department of Agriculture, Beltsville, MD 20705 U.S.A. (DRM e-mail: dmiller@sel.barc.usda.gov; GLM e-mail: gmiller@sel.barc.usda.gov); (GWW) Entomology Department, The Natural History Museum, Cromwell Road, London, SW7 5BD, U.K. (GWW e-mail: g.watson@nhm.ac.uk)

Abstract.—We provide a compilation of 158 species of mealybugs that are either a pest or threat to United States agriculture. Included for each species, where applicable, is reference to: the United States origin and date of introduction; whether it is established in the United States; its pest or threat status in the United States along with a validation citation; its principle hosts; and its biogeographical region of origin.

Key Words: Pseudococcidae, mealybugs, invasive species, biological control, agriculture

Mealybugs (Pseudococcidae) are major agricultural pests and pose serious problems when introduced into new areas of the world without natural enemies. In recent years, it has become increasingly obvious that introduced species have a major economic and esthetic impact on plants. Public concern stimulated Congress to develop a report on the subject (Office of Technology Assessment 1993) and a Presidential initiative (Executive Order 13112) to seek a solution to this problem is currently underway. Scale insects are notorious invaders because they are small, often live in concealed habitats, and frequently are transported on commodities that are common in international commerce. Mealybugs are a group of scale insects that are of special interest because of the recent introduction of four pest species in the United States. They are: the pink hibiscus mealybug, *Macrolenisoccus hirsutus* (Green) (California 1999), the papaya mealybug, *Paracoccus marginatus* Williams and Granara de Wil-

link (Florida 1998), the vine mealybug *Planococcus ficus* (Signoret) (California 1994), and the banana mealybug *Pseudococcus elisae* Borchsenius (Florida 1995). The origin of recent California infestations of *P. ficus* is not clear. This species was collected in several localities in the southeastern United States beginning in 1924, but was always found on fig trees (*Ficus carica* L.). It has not been recollected since 1959 and was never collected east of Texas. The infestation in California is only on grapes and has not been found on figs. It is likely that the California infestation is from an overseas source and not from the eastern United States.

Since invasive species are a major issue in U.S. agriculture, and with several recent introductions of pest mealybug species, we decided to investigate several parameters concerning invasive mealybug species. Our objectives were: 1) to develop a preliminary list of the pest mealybug species of the world; 2) to provide a list of introduced and

pest mealybugs of the United States; 3) to ascertain which of the species in the previous two objectives are introduced or native to the United States; 4) to examine data provided by the United States Department of Agriculture, Animal and Plant Health Inspection Service—Plant Protection and Quarantine (USDA, APHIS-PPQ) concerning the most commonly intercepted mealybug species at the United States ports-of-entry; and 5) using this information, to try to understand which mealybugs are most likely to invade the United States in the future.

MATERIALS AND METHODS

Executive Order 13112 established the National Invasive Species Council and provided a definition of an invasive species as: "... a species that is 1) non-native (or alien) to the ecosystem under consideration and 2) whose introduction causes or is likely to cause economic or environmental harm or harm to human health." This definition not only includes alien species to the United States but also encompasses native species. The definition also has an economic or potential economic component. Using this definition, the grape mealybug, *Pseudococcus maritimus* (Ehrhorn) would be an example of an invasive species in the United States even though it likely is native. The definition that we use is a bit more simplistic. We consider invasive species to be those that are not native to the United States (alien or adventive) regardless of economic harm.

To make a table of pest mealybugs of the world, we have used a broad definition of the term "pest." Essentially, if a species is described in the literature as a pest, or as causing damage, or being controlled, or of economic importance, we have included it in the list. Our perspective for this paper has focused on the impact or potential impact of a pest mealybug in the United States. For example, *Antonina pretiosa* Ferris is known only from bamboo, and therefore, is considered to have relatively minor

pest potential in the United States; it may be far more important in areas of the world where bamboo is a predominant component of the natural or ornamental vegetation. Conversely, *Pseudococcus cryptus* Hempel occurs on an array of agricultural crops that are important to the United States economy and is considered a major threat. The term "threat" is used for species that are considered pests but do not occur in the United States. For adventive species, we have approximated the United States date of introduction by searching the literature for the earliest collection record or have examined specimens in the National Entomological Collection of the National Museum of Natural History, in Beltsville, Maryland for the earliest record. Obviously, these dates are only estimates of when the species first invaded the United States. It is difficult to determine the zoogeographic area of origin for some species. It is clear that they are from the old or new world, but it is not always evident from which area. In some cases, we have simply made an educated guess based on the current distribution of the species, the distribution of what appears to be its closest relatives, and the natural distribution of its primary host plants. We have used the same criteria to determine if a particular species is native to the United States. In several instances, it is not clear, e.g., *Phenacoccus gossypii* Townsend and Cockerell or *P. dearnesii* King.

RESULTS

Table 1 provides information on 158 mealybug species. Since the table includes six species that have been introduced into the United States but are not considered pests, we estimate that there are 152 mealybugs that represent either a pest or threat to the United States agriculture. In the United States, there are 66 pest mealybug species, 19 are considered to be native. Therefore, 47 mealybug pests in the country are invasive species. Based on information presented in ScaleNet on the Pseudococcidae by Ben-Dov and German (2001), there are

Table 1. Pest or threat mealybug species to United States agriculture. Abbreviation for origin are: Afrotropical Region (AF); Australasian Region (AU); Nearctic (NE); Neotropical Region (NT); Oriental Region (OR); Palearctic Region (PA).

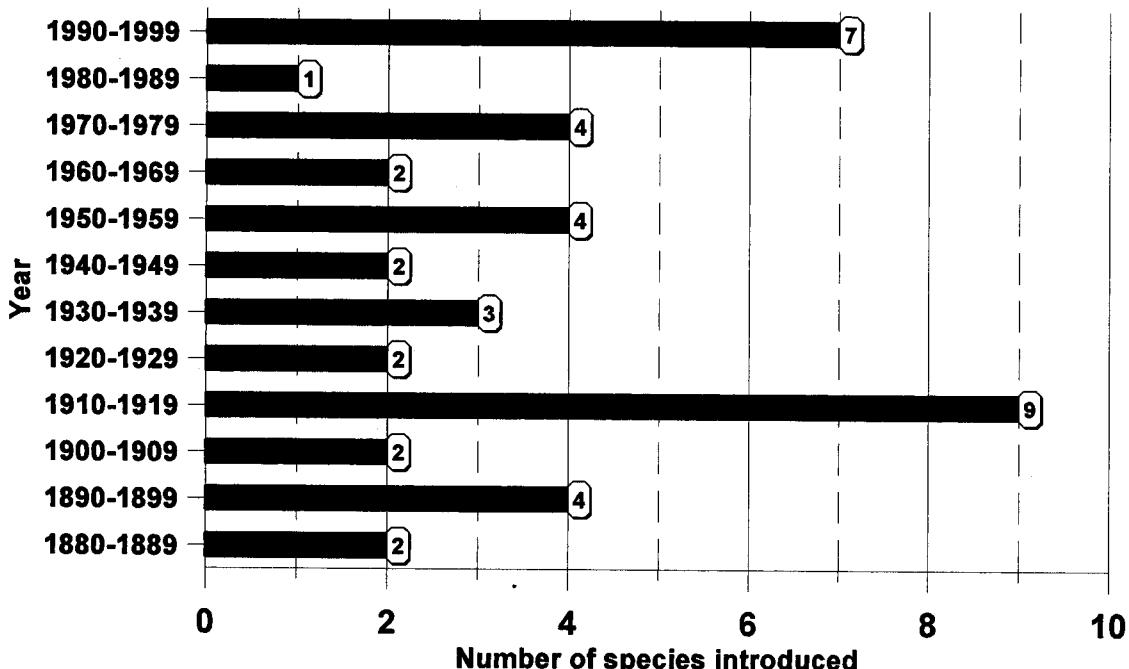

Fig. 1. Introduction of mealybug pests into the United States from 1880–1999.

350 species of mealybugs in the United States; thus, the adventive component of the mealybug fauna in the United States is approximately 13%. With the exception of the 1980's, every decade since the 1880's has seen the introduction of at least 2 species of mealybug pests (Fig. 1). Two periods, the 1910's and the 1990's, witnessed the greatest number of introduced mealybug pests (9 and 7 species, respectively).

A summary of the area of origin of all invasive species in the United States is as follows: Palearctic Region—17 U.S. invaders, 4 of which are considered non-pest adventives; Neotropical Region—12 U.S. invaders, none are considered non-pest adventives; Oriental Region—7 U.S. invaders, one is considered a non-pest adventive; Australasian Region—4 U.S. invaders, one is considered a non-pest adventive; Afrotropical Region—3 U.S. invaders, none are considered non-pest adventives; and Nearctic Region outside of the U.S.—4 U.S. invaders, none are considered non-pest adventives.

Examination of the origin of pest mealy-

bugs worldwide provides the following totals: from the Palearctic Region, 46; Nearctic Region, 27; Neotropical Region, 25; Oriental Region 23; Afrotropical Region, 19; and from the Australasian Region, 18. Host characteristics of these pests include: 22% polyphagous; 20% on grasses; 16% on citrus/tropical fruits; 6% on coffee; and the remainder are not polyphagous and occur on various other hosts. Based on the characteristics of the highest pest mealybug distributions and greatest frequency of host plants, a list of 10 species most likely to invade the United States has been determined. These species include: *Cataenococcus hispidus* (Morrison), *Dysmicoccus neobrevipes* Beardsley, *Helicoccuss bohemicus* Šulc, *Nipaecoccus viridis* (Newstead), *Phenacoccus avenae* Borchsenius, *Phenacoccus azaleae* Kuwana, *Planococcus lila-cinus* (Cockerell), *Planococcus minor* (Maskell), *Pseudococcus cryptus* Hempel, and *Rastrococcus iceryoides* (Green).

Interception records from the past five years from the USDA, APHIS-PPQ also were searched. A list of the 10 species in-

tercepted most frequently at U.S. ports-of-entry are: *Cataenococcus hispidus* (Morrison); *Dysmicoccus bispinosus* Beardsley; *Dysmicoccus mackenziei* Beardsley; *Dysmicoccus neobrevipes* Beardsley; *Maconellicoccus hirsutus* (Green); *Palmicultor palmarum* (Ehrhorn); *Paracoccus marginatus* Williams and Granara de Willink; *Planococcus kraunhiae* (Kuwana); *Planococcus lilacinus* (Cockerell); and *Planococcus minor* (Maskell). Comparison of the two lists reveals four species that are common to both. They are: *Cataenococcus hispidus*; *Dysmicoccus neobrevipes*; *Planococcus lilacinus*; and *Planococcus minor*. We suggest that these species are most likely to be the next invasive mealybugs into the United States.

DISCUSSION

Our data indicate that the decades starting in 1910 and 1990 had the largest number of mealybug introductions. We speculate that the first peak occurred because of implementation of the Plant Quarantine Act in 1912. At this time, new inspection procedures were started causing the detection of many insect contaminants in import commodities at U.S. ports-of-entry. Increased detection caused the development of strategies to reduce the risk of introduction of the potential invasive species. We suspect that the recent increase in world trade and the difficulty of inspecting large volumes of containerized imports may explain the larger number of mealybug establishments in the 1990's.

Our findings provide predictions about the most likely mealybug species to be introduced into the United States in the future and give procedures that may help others make predictions about the next invasive mealybug in other countries. Another criterion for predicting invasive species problems that was not considered here might include examination of all polyphagous species that have several agricultural hosts. A final observation: although invasive species are not always economic before they invade

a new area, examination of the list of U.S. invaders reveals that most were considered to be at least minor pests before they were invasive in the U.S.

ACKNOWLEDGMENTS

We thank Paris Lambdin (The University of Tennessee, Knoxville, USA), Douglas J. Williams (Department of Entomology, The Natural History Museum, London, UK), William F. Gimpel, Jr. (Maryland Department of Agriculture, Annapolis, MD, USA), Steven W. Lingafelter (Systematic Entomology Laboratory, USDA, Washington, DC, USA), and Ronald Ochoa (Systematic Entomology Laboratory, USDA, Beltsville, MD, USA) for their comments and reviews of the manuscript. We are also grateful to Joe Cavey (APHIS-PPQ, Riverdale, MD) for providing mealybug interception data at U.S. ports-of-entry and Penny Gullan (University of California, Davis, CA, USA) for her help in determining the earliest collection date of *Ferrisia malvastria* in the U.S. Thanks is also due to Ray Gill (California Dept. of Food and Agriculture, Sacramento, CA, USA) for allowing us to cite his *in press* work concerning information about *Vryburgia trionymoides*.
