Language Environment Debugging Guide

GA22-7560-08

Note

Before using this information and the product it supports, be sure to read the general information under “Notices” on page 479.

Ninth Edition, September 2007

This is a major revision of GA22-7560-07.

This edition applies to Language Environment in z/OS Version 1 Release 9 (5694-A01) and to all subsequent releases and modifications until otherwise indicated in new editions.

IBM welcomes your comments. A form for readers' comments may be provided at the back of this document, or you may address your comments to the following address:

International Business Machines Corporation

Summary of Changes xxiii

Part 1. Introduction to debugging in Language Environment 1

Chapter 1. Preparing your routine for debugging 3
Setting compiler options 3
XL C and XL C++ compiler options 3
COBOL compiler options 5
Fortran compiler options 5
PL/I compiler options 6
Enterprise PL/I for z/OS compiler options 7
Using Language Environment run-time options 8
Determining run-time options in effect 9
Using the CLER CICS transaction to display and set run-time options 11
Controlling storage allocation 11
Stack storage statistics 17
Heap storage statistics 18
HeapPools storage statistics 19
Modifying condition handling behavior 20
Language Environment callable services 20
Language Environment run-time options 20
Customizing condition handlers 22
Invoking the assembler user exit 23
Establishing enclave termination behavior for unhandled conditions 24
Using messages in your routine 24
C/C++ 25
COBOL 25
Fortran 25
PL/I 25
Using condition information 25
Using the feedback code parameter 25
Using the symbolic feedback code 27

Chapter 2. Classifying errors 29
Identifying problems in routines 29
Language Environment module names 29
Common errors in routines 29

Interpreting run-time messages 30
Message prefix 31
Message number 31
Severity code 31
Message text 32
Understanding abend codes 32
User abends 32
System abends 32
Using edcmtext to obtain information about errno2 values 33
Format 33
Description 33
Usage notes 33
Message returns 33
Examples 34
Exit Values 34

Chapter 3. Using Language Environment debugging facilities 35
Debug tools 35
Language Environment dump service, CEE3DMP 35
Generating a Language Environment dump with CEE3DMP 35
Generating a Language Environment dump with TERMTHDACT 39
Generating a Language Environment dump with language-specific functions 43
Understanding the Language Environment dump 43
Debugging with specific sections of the Language Environment dump. . . . 62
Using the DLL failure control block 78
Multiple enclave dumps. 78
Generating a system dump 80
Steps for generating a system dump in a batch run-time environment. . . . 81
Steps for generating a system dump in an IMS run-time environment 81
Steps for generating a system dump in a CICS run-time environment 81
Steps for generating a Language Environment U4039 abend 82
Steps for generating a system dump in a z/OS UNIX shell 82
Formatting and analyzing system dumps 83
Preparing to use the Language Environment support for IPCS 84
Language Environment IPCS Verbexit – LEDATA 84
Format 85
Parameters 85
Understanding the Language Environment IPCS Verbexit LEDATA output 87
Understanding the HEAP LEDATA output. 105
Diagnosing heap fragmentation problems 111
Understanding the HEAPPOOLS trace LEDATA output 111
Understanding the C/C++-specific LEDATA output 113
C/C++-specific sections of the LEDATA output 118
Understanding the COBOL-specific LEDATA output 119
COBOL-specific sections of the LEDATA Output 121
Formatting individual control blocks 122
Requesting a Language Environment trace for debugging 124
Locating the trace dump 125
Using the Language Environment trace table format in a dump report . . . 126
Understanding the trace table entry (TTE) 126
Sample dump for the trace table entry 133

Part 2. Debugging language-specific routines 135

Chapter 4. Debugging C/C++ routines 137
Debugging C/C++ programs 137

Using the __amrc and __amrc2 structures to debug input/output 137
Displaying an error message with the perror() function 144
Using __errno2() to diagnose application problems 144
Diagnosing DLL problems 146
Using C/C++ listings 146
Finding variables 147
Generating a Language Environment dump of a C/C++ routine 155
cdump() 155
csnap() 156
ctrace() 156
Sample C routine that calls cdump() 156
Sample C++ routine that generates a Language Environment dump 158
Sample Language Environment dump with C/C++-specific information 160
Finding C/C++ information in a Language Environment dump 166
Sample Language Environment dump with XPLINK-specific information 171
Finding XPLINK information in a Language Environment dump 176
C/C++ contents of the Language Environment trace tables 177
Debugging examples of C/C++ routines 184
Divide-by-zero error 184
Calling a nonexistent non-XPLINK function 188
Calling a nonexistent XPLINK function 191
Handling dumps written to the z/OS UNIX file system 194
Multithreading consideration 196
Understanding C/C++ heap information in storage reports 196
Language Environment storage report with HeapPools statistics 196
C function __uheapreport() storage report 197
MEMCHECK VHM memory leak analysis tool 199
Invoking MEMCHECK VHM 199
MEMCHECK VHM environment variables 200
MEMCHECK VHM report sample scenario 201
MEMCHECK VHM report examples 202

Chapter 5. Debugging COBOL programs 207
Determining the source of error 207
Tracing program logic 207
Finding input/output errors 207
Handling input/output errors 208
Validating data (class test) 208
Assessing switch problems 208
Generating information about procedures 208
Using COBOL listings 211
Generating a Language Environment dump of a COBOL program 211
COBOL program that calls another COBOL program 211
COBOL program that calls the Language Environment CEE3DMP callable service 212
Sample Language Environment dump with COBOL-specific information 213
Finding COBOL information in a dump 215
Debugging example COBOL programs 220
Subscript range error 220
Calling a nonexistent subroutine 223
Divide-by-zero error 226

Chapter 6. Debugging Fortran routines 233
Determining the source of errors in Fortran routines 233
Identifying run-time errors 233
Using Fortran compiler listings 235

Generating a Language Environment dump of a Fortran routine 235
DUMP/PDUMP subroutines 236
CDUMP/CPDUMP subroutines 237
SDUMP subroutine 238
Finding Fortran information in a Language Environment dump 241
Understanding the Language Environment traceback table 242
Examples of debugging Fortran routines 243
Calling a nonexistent routine 243
Divide-by-zero error. 245

Chapter 7. Debugging PL/I for MVS & VM routines 249
Determining the source of errors in PL/I for MVS & VM routines 249
Logic errors in the source routine. 249
Invalid use of PL/I for MVS & VM 249
Unforeseen errors 250
Invalid input data. 250
Compiler or run-time routine malfunction 250
System malfunction. 250
Unidentified routine malfunction 250
Storage overlay problems 251
Using PL/I for MVS & VM compiler listings 252
Generating PL/I for MVS & VM listings and maps. 252
Finding information in PL/I for MVS & VM listings. 253
Generating a Language Environment dump of a PL/I for MVS & VM routine 259
PLIDUMP syntax and options 259
PLIDUMP usage notes 260
Finding PL/I for MVS & VM information in a dump 261
Traceback 261
Control blocks for active routines. 264
Control blocks associated with the thread. 268
PL/I for MVS & VM contents of the Language Environment trace table 270
Debugging example of PL/I for MVS & VM routines 271
Subscript range error 271
Calling a nonexistent subroutine 275
Divide-by-zero error. 277

Chapter 8. Debugging Enterprise PL/I routines 285
Determining the source of errors in Enterprise PL/I routines 285
Logic errors in the source routine. 285
Invalid use of Enterprise PL/I 285
Unforeseen errors 286
Invalid input data. 286
Compiler or run-time routine malfunction 286
System malfunction. 286
Unidentified routine malfunction 286
Storage overlay problems 287
Using Enterprise PL/I compiler listings. 288
Generating Enterprise PL/I listings and maps 288
Finding information in Enterprise PL/I listings 289
Generating a Language Environment dump of an Enterprise PL/I routine 294
PLIDUMP syntax and options 295
PLIDUMP usage notes 296
Finding Enterprise PL/I information in a dump 297
Traceback 297
Control blocks for active routines. 299
Control blocks associated with the thread. 301

Enterprise PL/I contents of the Language Environment trace table 304
Debugging example of Enterprise PL/I routines 304
Subscript range error 304
Calling a nonexistent subroutine 308
Divide-by-zero error. 312

Chapter 9. Debugging under CICS 317
Accessing debugging information. 317
Locating Language Environment run-time messages 317
Locating the Language Environment traceback. 317
Locating the Language Environment dump 318
Using CICS transaction dump 319
Using CICS register and program status word contents 319
Using Language Environment abend and reason codes 319
Using Language Environment return codes to CICS 320
Activating Language Environment feature trace records under CICS 320
Ensuring transaction rollback 323
Finding data when Language Environment returns a nonzero return code 323
Finding data when Language Environment abends internally 323
Finding data when Language Environment abends from an EXEC CICS command 324
Displaying and modifying run-time options with the CLER transaction 324

Part 3. Debugging Language Environment AMODE 64 applications 327

Chapter 10. Preparing your AMODE 64 application for debugging 329
Setting compiler options 329
XL C and XL C++ compiler options for AMODE 64 applications 329
Using Language Environment run-time options. 329
Determining run-time options in effect 330
Controlling storage allocation 331
HeapPools storage statistics 335
Modifying exception handling behavior. 335
Language Environment application program interfaces (API). 335
Language Environment run-time options 335
Customizing exception handlers 336
Using condition information 336
Using the feedback code parameter. 336
Using the symbolic feedback code 338

Chapter 11. Classifying AMODE 64 application errors 339
Identifying problems in routines 339
Language Environment module names 339
Common errors in routines 339
Interpreting run-time messages 340
Message prefix 341
Message number 341
Severity code 341
Message text 341
Understanding abend codes 341
User abends 342
System abends 342

Chapter 12. Using Language Environment AMODE 64 debugging facilities 343
Debugging tools 343
Language Environment dumps 343

Generating a Language Environment dump with TERMTHDACT 343
Generating a Language Environment dump with language-specific functions 345
Understanding the Language Environment dump 345
Generating a system dump 362
Steps for generating a system dump in a batch run-time environment . . . 363
Steps for generating a system dump in a z/OS UNIX shell 364
Formatting and analyzing system dumps 365
Preparing to use the Language Environment support for IPCS 365
Language Environment IPCS Verbexit – LEDATA 365
Format 366
Parameters 366
Understanding the Language Environment IPCS Verbexit LEDATA output 368
Understanding the HEAP LEDATA output 384
Diagnosing heap fragmentation problems 395
Understanding the HEAPPOOLS trace LEDATA output 395
Understanding the C/C++-specific LEDATA output 397
C/C++-specific sections of the LEDATA output 405
Understanding the AUTH LEDATA output 406
Sections of the AUTH LEDATA Verbexit formatted output 411
Formatting individual control blocks 412
Requesting a Language Environment trace for debugging 414
Locating the trace dump 415
Using the Language Environment trace table format in a dump report . . . 416
Understanding the trace table entry (TTE) 416
Sample dump for the trace table entry 422

Chapter 13. Debugging AMODE 64 C/C++ routines 425
Debugging C/C++ programs 425
Using the __amrc and __amrc2 structures to debug input/output 425
Displaying an error message with the perror() function 432
Using __errno2() to diagnose application problems 433
Using C/C++ listings 435
Finding variables 435
Generating a Language Environment dump of a C/C++ routine 438
cdump() 438
csnap() 439
ctrace() 439
Sample C routine that calls cdump() 439
Sample C++ routine that generates a Language Environment dump 441
Sample Language Environment dump with C/C++-specific information 443
C/C++ contents of the Language Environment trace tables 448
Debugging examples of C/C++ routines 450
Divide-by-zero error 450
Calling a nonexistent function 457
Handling dumps written to the z/OS UNIX file system 464
Multithreading consideration 465
Understanding C/C++ heap information in storage reports 465
Language Environment storage report with HeapPools statistics 466
C function __uheapreport() storage report 467

Appendix A. Diagnosing problems with Language Environment 469
Diagnosis checklist 469
Locating the name of the failing routine for a non-XPLINK application . . . 470
Searching the IBM Software Support Database 473
Preparing documentation for an Authorized Program Analysis Report (APAR) 473

Appendix B. Accessibility 477
Using assistive technologies 477
Keyboard navigation of the user interface. 477
z/OS information 477

Notices 479
Programming Interface Information 481
Trademarks. 481

Figures

1. Options report example produced by run-time option RPTOPTS(ON). . . . 10
2. Storage report produced by run-time option RPTSTG(ON) . . . 12
3. Storage report produced by RPTSTG(ON) with XPLINK . . . 14
4. Language Environment condition token . . . 27
5. The C program CELSAMP . . . 44
6. The C DLL CELDLL. . . . 47
7. Example dump using CEE3DMP . . . 48
8. Upward-growing (non-XPLINK) stack frame format . . . 64
9. Downward-growing (XPLINK) stack frame format . . . 65
10. Common anchor area . . . 66
11. Condition information block . . . 75
12. Machine state information block . . . 77
13. Language Environment dump of multiple enclaves . . . 79
14. Example of formatted output from LEDATA Verbexit . . . 88
15. Example of formatted PTBL output from LEDATA Verbexit . . . 104
16. Example formatted detailed heap segment report from LEDATA Verbexit . . . 106
17. Example formatted detailed HEAPPOOLS trace report from LEDATA Verbexit . . . 111
18. Example formatted C/C++ output from LEDATA Verbexit . . . 114
19. Example formatted COBOL output from LEDATA Verbexit . . . 120
20. The CAA formatted by the CBFORMAT IPCS command . . . 123
21. Format of the trace table entry . . . 126
22. Trace table in dump output. . . . 134
23. __amrc structure . . . 138
24. __amrc2 structure . . . 139
25. Example of a routine using perror() . . . 144
26. Example of a routine using __errno2() . . . 145
27. Sample output of a routine using __errno2() . . . 145
28. Example of a routine using _EDC_ADD_ERRNO2 . . . 145
29. Sample output of a routine using _EDC_ADD_ERRNO2 . . . 145
30. Example of a routine using __err2ad() in combination with __errno2() . . . 146
31. Sample output of routine using __err2ad() in combination with __errno2() . . . 146
32. Writable static map produced by prelinker . . . 149
33. Location of RENT static variable in storage. . . . 150
34. Writable static map produced by prelinker . . . 150
35. Location of NORENT static variable in storage . . . 151
36. Example code for parameter variable . . . 152
37. Example code for parameter variable . . . 152
38. Partial storage offset listing . . . 153
39. Example code for structure variable . . . 153
40. Example of aggregate map . . . 154
41. Writable static map produced by prelinker . . . 154
42. Example C routine using cdump() to generate a dump . . . 157
43. Fetched module for C routine. . . . 158
44. Example C++ routine with protection exception generating a dump . . . 159
45. Template file STACK.C . . . 159
46. Header file STACK.H . . . 160
47. Example dump from sample C routine . . . 161
48. Memory file control block . . . 169
49. Registers on entry to CEE3DMP . . . 170
50. Parameters, registers, and variables for active routines . . . 170
51. Condition information for active routines . . . 171
52. Sample XPLINK-compiled program (tranmain) which calls a NOXPLINK-compiled program 172
53. Sample NOXPLINK-compiled program (trandll) which calls an XPLINK-compiled program 173

| 54. Example dump of calling between XPLINK and non-XPLINK programs . . . 174
55. Trace table with C/C++ trace table entry types 1 thru 4 . . . 179
56. Trace table with XPLINK trace table entries 5 and 6. . . . 181
57. Trace table with trace table entry types 7 and 8 . . . 182
58. C routine with a divide-by-zero error . . . 184
| 59. Sections of the dump from example C/C++ routine . . . 185
| 60. Pseudo assembly listing. . . . 186
| 61. C/C++ CAA information in dump. . . . 187
| 62. Writable static map . . . 187
| 63. Enclave storage section of dump . . . 188
64. C/C++ example of calling a nonexistent subroutine . . . 188
| 65. Sections of the dump from example C routine. . . . 189
| 66. Pseudo assembly listing. . . . 190
| 67. Writable static map . . . 190
| 68. Enclave control blocks and storage sections in dump . . . 191
69. C/C++ example of calling a nonexistent subroutine . . . 191
| 70. Sections of the dump from example C routine. . . . 192
71. Pseudo assembly listing. . . . 193
72. Writable static map . . . 194
| 73. Enclave control blocks and storage sections in dump . . . 194
74. IPCS panel for entering data set information . . . 195
75. Storage report generated by __uheapreport() . . . 199
76. Trace report generated by MEMCHECK VHM. . . . 203
77. Heap Leak Report generated by MEMCHECK VHM . . . 205
78. Example of using the WITH DEBUGGING MODE clause . . . 210
79. COBOL program COBDUMP1 calling COBDUMP2 . . . 212
80. COBOL program COBDUMP2 calling the Language Environment dump service CEE3DMP 213
| 81. Sections of the Language Environment dump called from COBDUMP2 . . . 214
| 82. Control block information for active COBOL routines . . . 216
| 83. Storage for active COBOL programs . . . 217
| 84. Enclave-level data for COBOL programs. . . . 219
| 85. Process-level control blocks for COBOL programs . . . 220
86. COBOL example of moving a value outside an array range. . . . 221
| 87. Sections of Language Environment dump for COBOLX . . . 222
| 88. COBOL listing for COBOLX . . . 223
89. COBOL example of calling a nonexistent subroutine . . . 223
90. Sections of Language Environment dump for COBOLY . . . 224
| 91. COBOL Listing for COBOLY . . . 225
| 92. Parameters, registers, and variables for active routines section of dump for COBOLY . . . 226
93. Main COBOL program, COBOL subroutine, and assembler routine . . . 227
| 94. Sections of Language Environment dump for program COBOLZ1 . . . 228
| 95. COBOL listing for COBOLZ2 . . . 229
| 96. Listing for ASSEMZ3 . . . 230
97. Variables section of Language Environment dump for COBOLZ2. . . . 230
| 98. Listing for COBOLZ2 . . . 231
99. Variables section of Language Environment dump for COBOLZ1. . . . 231
100. Example program that calls SDUMP . . . 240
101. Language Environment dump generated using SDUMP . . . 241
102. Sections of the Language Environment dump . . . 242
103. Example of calling a nonexistent routine. . . . 243
104. Sections of the Language Environment dump resulting from a call to a nonexistent routine 244
105. Fortran routine with a divide-by-zero error . . . 245
106. Language Environment dump from divide-by-zero Fortran example . . . 246
107. PL/I for MVS & VM routine compiled with LIST and MAP . . . 253
108. Compiler-generated listings from example PL/I for MVS & VM routine . . . 254
| 109. Traceback section of dump . . . 262

| 110. Task traceback section 263
| 111. Control blocks for active routines section of the dump 265

| 113. Example of moving a value outside an array range 272
| 114. Sections of the Language Environment dump 273
| 115. Example of calling a nonexistent subroutine 275
| 116. Sections of the Language Environment dump 276
| 117. PL/I for MVS & VM routine with a divide-by-zero error 278
118. Variables from routine SAMPLE 278
| 119. Object code listing from example PL/I for MVS & VM routine 279
| 120. Language Environment dump from example PL/I for MVS & VM routine 280
| 121. Enterprise PL/I routine compiled with LIST, MAP, and SOURCE 289
| 122. Compiler-generated listings from example Enterprise PL/I routine 290
| 123. Traceback section of dump 298
| 124. Control blocks for active routines section of the dump 300
| 125. Control blocks associated with the thread section of the dump 302
| 126. Example of moving a value outside an array range 305
| 127. Sections of the Language Environment dump 306
| 128. Example of calling a nonexistent subroutine 309
| 129. Sections of the Language Environment dump 310
| 130. Enterprise PL/I routine with a divide-by-zero error 312
| 131. Variables from routine SAMPLE 312
| 132. Object code listing from example Enterprise PL/I routine 313
| 133. Language Environment dump from example Enterprise PL/I routine. 314
| 134. Language Environment traceback written to the transient data queue 318
135. CICS trace output in the ABBREV format. 321
136. CICS trace output in the FULL format. 322
| 137. 64–bit options report 331
| 138. 64–bit storage report 332
139. Language Environment condition token 337
140. The C program CELQSAMP 347
141. The C DLL CELQDLL 349
| 142. Example dump using CEE3DMP 349
| 143. Example of formatted output from LEDATA Verbexit 369
| 144. Example of formatted PTBL output from LEDATA Verbexit 383
| 145. Example formatted detailed heap segment report from LEDATA Verbexit 385
| 146. Example formatted detailed HEAPPOOLS trace report from LEDATA Verbexit 396
| 147. Example formatted C/C++ output from LEDATA Verbexit 397
| 148. Example of formatted AUTH output from LEDATA Verbexit 407
| 149. The CAA formatted by the CBFORMAT IPCS command 413
150. Format of the trace table entry 416
151. Trace table in dump output. 423
152. __amrc structure 427
153. __amrc2 structure 427
154. Example of a routine using perror() 433
| 155. Example of a routine using __errno2() 433
| 156. Sample output of routine using __errno2() 434
| 157. Example of a routine using _EDC_ADD_ERRNO2 434
| 158. Sample output of a routine using _EDC_ADD_ERRNO2 434
| 159. Example of a routine using __err2ad() in combination with __errno2() 435
| 160. Sample output of routine using __err2ad() in combination with __errno2() 435
161. Example code for structure variables 438
162. Example of aggregate map 438
163. Example C routine using cdump() to generate a dump 440
164. Fetched module for C routine 441
165. Example C++ routine with protection exception generating a dump 442

166. Template file STACK.C 442
167. Header file STACK.H 443
168. Example dump from sample C routine 444
169. Trace table with XPLINK trace table entries 5 and 6. 449
170. C routine with a divide-by-zero error 451
171. Sections of the dump from example C/C++ routine 452
172. Pseudo assembly listing. 454
173. C/C++ CAA information in dump. 456
174. Writable static map 457

About this document

This document supports z/OS (5694–A01).

IBM® z/OS Language Environment (also called Language Environment) provides common services and language-specific routines in a single run-time environment for C, C++, COBOL, Fortran (z/OS only; no support for z/OS UNIX System Services or CICS®), PL/I, and assembler applications. It offers consistent and predictable results for language applications, independent of the language in which they are written.

Language Environment is the prerequisite run-time environment for applications generated with the following IBM compiler products:

- z/OS XL C/C++ (feature of z/OS)
- z/OS C/C++
- OS/390 C/C++
- C/C++ for MVS/ESA™
- C/C++ for z/VM
- AD/Cycle® C/370™
- VisualAge for Java, Enterprise Edition for OS/390
- Enterprise COBOL for z/OS
- Enterprise COBOL for z/OS and OS/390
- COBOL for OS/390 & VM
- COBOL for MVS & VM (formerly COBOL/370)
- Enterprise PL/I for z/OS
- Enterprise PL/I for z/OS and OS/390
- VisualAge PL/I
- PL/I for MVS & VM (formerly PL/I MVS™ & VM)
- VS FORTRAN and FORTRAN IV (in compatibility mode)

Although not all compilers listed are currently supported, Language Environment supports the compiled objects that they created.

Language Environment supports, but is not required for, an interactive debug tool for debugging applications in your native z/OS environment. The IBM interactive Debug Tool is available with the latest releases of the COBOL and PL/I compiler products.

Debug Tool is also available as a standalone product. Debug Tool Utilities and Advanced Functions is also available. For more information, see http://www.ibm.com/software/awdtools/debugtool/.

Language Environment supports, but is not required for, VS FORTRAN Version 2 compiled code (z/OS only).

Language Environment consists of the common execution library (CEL) and the run-time libraries for C/C++, COBOL, Fortran, and PL/I.

For more information on VisualAge for Java, Enterprise Edition for OS/390, program number 5655-JAV, see the product documentation.

Using your documentation

The publications provided with Language Environment are designed to help you:

- Manage the run-time environment for applications generated with a Language Environment-conforming compiler.
- Write applications that use the Language Environment callable services.
- Develop interlanguage communication applications.
- Customize Language Environment.
- Debug problems in applications that run with Language Environment.
- Migrate your high-level language applications to Language Environment.

Language programming information is provided in the supported high-level language programming manuals, which provide language definition, library function syntax and semantics, and programming guidance information.

Each publication helps you perform different tasks, some of which are listed in Table 1. All books are available in printable (PDF) and BookManager softcopy formats. For a complete list of publications that you may need, see "Bibliography" on page 483.

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

Symbols

The following symbols may be displayed in syntax diagrams:

Symbol	Definition
▸▸—	Indicates the beginning of the syntax diagram.
—▸	Indicates that the syntax diagram is continued to the next line.
▸—	Indicates that the syntax is continued from the previous line.
—▸◂	Indicates the end of the syntax diagram.

Syntax items

Syntax diagrams contain many different items. Syntax items include:

- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase, and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.

Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

Item type	Definition
Required	Required items are displayed on the main path of the horizontal line.
Optional	Optional items are displayed below the main path of the horizontal line.
Default	Default items are displayed above the main path of the horizontal line.

Syntax examples

The following table provides syntax examples.

Table 2. Syntax examples

Item	Syntax example
Required item. Required items appear on the main path of the horizontal line. You must specify these items.	
Required choice. A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack.	
Optional item. Optional items appear below the main path of the horizontal line.	
Optional choice. An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack.	
Default. Default items appear above the main path of the horizontal line. The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items.	
Variable. Variables appear in lowercase italics. They represent names or values.	
Repeatable item. An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated. A character within the arrow means you must separate repeated items with that character. An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected, or a single item can be repeated.	 
Fragment. The fragment symbol indicates that a labelled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram.	 **fragment:** 
This debugging guide

z/OS Language Environment Debugging Guide provides assistance with detecting and locating programming errors that occur during run time under Language Environment. It can help you establish a debugging process to analyze data and narrow the scope and location of where an error might have occurred. You can read about how to prepare a routine for debugging, how to classify errors, and how to use the debugging facilities Language Environment provides. Also included are chapters on debugging HLL-specific routines and routines that run under CICS. Debugging for AMODE 64 applications is covered in separate chapters, corresponding to the topics and contents provided above.

This book is for application programmers interested in techniques for debugging run-time programs. To use this book, you should be familiar with:

- Language Environment
- Appropriate languages that use the compilers listed above
- Program storage concepts

Where to find more information

Please see *z/OS Information Roadmap* for an overview of the documentation associated with z/OS, including the documentation available for z/OS Language Environment.

Using LookAt to look up message explanations

LookAt is an online facility that lets you look up explanations for most of the IBM messages you encounter, as well as for some system abends and codes. Using LookAt to find information is faster than a conventional search because in most cases LookAt goes directly to the message explanation.

You can use LookAt from these locations to find IBM message explanations for z/OS® elements and features, z/VM®, VSE/ESA™, and Clusters for AIX® and Linux™:

- The Internet. You can access IBM message explanations directly from the LookAt Web site at www.ibm.com/servers/eserver/zseries/zos/bkserv/lookat/.
- Your z/OS TSO/E host system. You can install code on your z/OS or z/OS.e systems to access IBM message explanations using LookAt from a TSO/E command line (for example: TSO/E prompt, ISPF, or z/OS UNIX® System Services).
- Your Microsoft® Windows® workstation. You can install LookAt directly from the *z/OS Collection* (SK3T-4269) or the *z/OS and Software Products DVD Collection* (SK3T-4271) and use it from the resulting Windows graphical user interface (GUI). The command prompt (also known as the DOS > command line) version can still be used from the directory in which you install the Windows version of LookAt.
- Your wireless handheld device. You can use the LookAt Mobile Edition from www.ibm.com/servers/eserver/zseries/zos/bkserv/lookat/lookatm.html with a handheld device that has wireless access and an Internet browser (for example: Internet Explorer for Pocket PCs, Blazer or Eudora for Palm OS, or Opera for Linux handheld devices).

You can obtain code to install LookAt on your host system or Microsoft Windows workstation from:

- A CD-ROM in the *z/OS Collection* (SK3T-4269).
- The *z/OS and Software Products DVD Collection* (SK3T-4271).

- The LookAt Web site (click **Download** and then select the platform, release, collection, and location that suit your needs). More information is available in the LOOKAT.ME files available during the download process.

Using IBM Health Checker for z/OS

IBM Health Checker for z/OS is a z/OS component that installations can use to gather information about their system environment and system parameters to help identify potential configuration problems before they impact availability or cause outages. Individual products, z/OS components, or ISV software can provide checks that take advantage of the IBM Health Checker for z/OS framework. This book refers to checks or messages associated with this component.

For additional information about checks and about IBM Health Checker for z/OS, see *IBM Health Checker for z/OS: User's Guide*. Starting with z/OS V1R4, z/OS users can obtain the IBM Health Checker for z/OS from the z/OS Downloads page at http://www.ibm.com/servers/eserver/zseries/zos/downloads/.

SDSF also provides functions to simplify the management of checks. See *z/OS SDSF Operation and Customization* for additional information.

Information updates on the web

For the latest information updates that have been provided in PTF cover letters and Documentation APARs for z/OS, see the online document at: http://publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/BOOKS/ZIDOCMST/CCONTENTS

This document is updated weekly and lists documentation changes before they are incorporated into z/OS publications.

Summary of Changes

Summary of Changes
for GA22-7560-08
z/OS Version 1 Release 9

This document contains information previously presented in *z/OS Language Environment Debugging Guide*, GA22-7560-07, which supported z/OS Version 1 Release 8.

The following summarizes the changes to that information.

New Information

- A new chapter, Chapter 8, “Debugging Enterprise PL/I routines,” on page 285, has been added to provide information about debugging Enterprise PL/I routines.
- Language Environment® improves DLL error diagnostics so that you can more easily debug DLL application problems. For more information, see “Diagnosing DLL problems” on page 146 and “Using the DLL failure control block” on page 78.
- A new section, “Using edcmtext to obtain information about errno2 values” on page 33, has been added to provide the edcmtext utility (similar to bpxmtext), which allows faster error resolution when an errno2 is encountered in Language Environment.

Changed Information

- In Chapter 3, Chapter 3, “Using Language Environment debugging facilities,” on page 35, the following sections have been updated:
  - “Debug tools” on page 35
  - “Understanding the Language Environment dump” on page 43
  - “The Common Anchor Area” on page 65
  - “Formatting and analyzing system dumps” on page 83
- In Chapter 4, Chapter 4, “Debugging C/C++ routines,” on page 137, the following sections have been updated:
  - “Using __errno2() to diagnose application problems” on page 144
  - “Sample Language Environment dump with C/C++-specific information” on page 160
  - “Sample Language Environment dump with XPLINK-specific information” on page 171
  - “Debugging examples of C/C++ routines” on page 184
  - “Understanding C/C++ heap information in storage reports” on page 196, example storage reports and the description of the HeapPools storage statistics section of the storage report are updated.
- In Chapter 5, Chapter 5, “Debugging COBOL programs,” on page 207, figures have been updated in the following sections:
  - “Sample Language Environment dump with COBOL-specific information” on page 213
  - “Finding COBOL information in a dump” on page 215
  - “Debugging example COBOL programs” on page 220
- In Chapter 7, Chapter 7, “Debugging PL/I for MVS & VM routines,” on page 249, the following sections have been updated:

  - "Finding PL/I for MVS & VM information in a dump" on page 261
  - "Debugging example of PL/I for MVS & VM routines" on page 271
- In Chapter 9, Chapter 9, "Debugging under CICS," on page 317, Figure 134 on page 318, Figure 134 on page 318 has been updated; enhancements are made in the CICS CLER transaction for displaying and modifying Language Environment run-time options. For more information, see "Displaying and modifying run-time options with the CLER transaction" on page 324.
- In Chapter 10, Chapter 10, "Preparing your AMODE 64 application for debugging," on page 329, Figure 137 on page 331 and Figure 138 on page 332 have been updated.
- In Chapter 12, Chapter 12, "Using Language Environment AMODE 64 debugging facilities," on page 343, the following sections have been updated:
  - "Understanding the Language Environment dump" on page 345
  - "Language Environment IPCS Verbexit – LEDATA" on page 365
  - "Understanding the Language Environment IPCS Verbexit LEDATA output" on page 368
  - "Understanding the HEAP LEDATA output" on page 384
  - "Formatting individual control blocks" on page 412
- In Chapter 13, Chapter 13, "Debugging AMODE 64 C/C++ routines," on page 425, the following sections have been updated:
  - "Using __errno2() to diagnose application problems" on page 433
  - "Calling a nonexistent function" on page 457
  - "Understanding C/C++ heap information in storage reports" on page 465

You may notice changes in the style and structure of some content in this document—for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Summary of Changes
for GA22-7560-07
z/OS Version 1 Release 8

This document contains information previously presented in *z/OS Language Environment Debugging Guide*, GA22-7560-06, which supported z/OS Version 1 Release 7.

The following summarizes the changes to that information.

New Information

- In Chapter 3, "Using Language Environment debugging facilities," on page 35, the Language Environment trace table entry and sample dump are updated for XPLINK transitions support.
- In Chapter 4, "Debugging C/C++ routines," on page 137, the C/C++ contents of the trace tables are updated to include extended VSAM support.

- In Chapter 4, “Debugging C/C++ routines,” on page 137, the C/C++ __armc and __armc2 structures are updated for C run-time support for large data sets (more than 64KB tracks per volume).
- In Chapter 3, “Using Language Environment debugging facilities,” on page 35 and Chapter 12, “Using Language Environment AMODE 64 debugging facilities,” on page 343, the sections titled, ″Generating a system dump,″ have been updated to include steps for capturing an IPCS-readable dump when no SYSMDUMP DD statement is available. For more information, see: “Generating a system dump” on page 80 and “Generating a system dump” on page 362.

Changed Information

- In Chapter 3, “Using Language Environment debugging facilities,” on page 35 and Chapter 12, “Using Language Environment AMODE 64 debugging facilities,” on page 343, the examples of formatted output from the Language Environment IPCS verbexit LEDATA are updated.
- In Chapter 4, “Debugging C/C++ routines,” on page 137, the steps for finding RENT static variables are updated.
- In Chapter 12, “Using Language Environment AMODE 64 debugging facilities,” on page 343, the CEEDUMP dump example using CEE3DMP is updated to show that source statement numbers are displayed in the traceback section for AMODE 64 applications. For more information, see, “Understanding the Language Environment dump” on page 345.

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability.

Summary of Changes
for GA22-7560-06
z/OS Version 1 Release 7

This document contains information previously presented in *z/OS Language Environment Debugging Guide*, GA22-7560-05, which supported z/OS Version 1 Release 6.

The following summarizes the changes to that information.

New Information

- Run-time options parmlib and DD statement
- Updates for debugging AMODE 64 applications

References to OpenEdition have been replaced with z/OS UNIX System Services, or z/OS UNIX.

This document contains terminology, maintenance, and editorial changes, including changes to improve consistency and retrievability.

Part 1. Introduction to debugging in Language Environment

This part provides information about options and features you can use to prepare your routine for debugging. It describes some common errors that occur in routines and provides methods of generating dumps to help you get the information you need to debug your routine.

Chapter 1. Preparing your routine for debugging

This chapter describes options and features that you can use to prepare your routine for debugging. The following topics are covered:

- Compiler options for C, C++, COBOL, Fortran, and PL/I
- Language Environment run-time options
- Use of storage in routines
- Options for modifying condition handling
- Assembler user exits
- Enclave termination behavior
- User-created messages
- Language Environment feedback codes and condition tokens

Setting compiler options

The following sections discuss language-specific compiler options important to debugging routines in Language Environment. These sections cover only the compiler options that are important to debugging. For a complete list of compiler options, see the appropriate HLL publications.

The use of some compiler options (such as TEST) can affect the performance of your routine. You must set these options before you compile. In some cases, you might need to remove the option and recompile your routine before delivering your application.

XL C and XL C++ compiler options

When using XL C, set the TEST(ALL) suboption, which is equivalent to TEST(LINE,BLOCK,PATH,SYM,HOOK). For XL C++, the option TEST is equivalent to TEST(HOOK). Following is a list of TEST suboptions that you can use to simplify run-time debugging.

ALL Sets all of the TEST suboptions.

BLOCK Generates symbol information for nested blocks.

HOOK Generates all possible hooks. For details on this suboption, see *z/OS XL C/C++ User's Guide*.

LINE Generates line number hooks and allows a debugging tool to generate a symbolic dump.

PATH Generates hooks at all path points; for example, hooks are inserted at if-then-else points before a function call and after a function call.

SYM Generates symbol table information and enables Language Environment to generate a dump at run time.

When you specify SYM, you also get the value and type of variables displayed in the Local Variables section of the dump. For example, if in block 4 the variable x is a signed integer of 12, and in block 2 the variable x is a signed integer of 1, the following output appears in the Local Variables section of the dump:

```
%BLOCK4:>x   signed int         12
%BLOCK2:>x   signed int          1
```

If a nonzero optimization level is used, variables do not appear in the dump.

You can use these C/C++ compiler options to make run-time debugging easier:

AGGREGATE (C)	Specifies that a layout for `struct` and `union` type variables appear in the listing.
ATTRIBUTE (C++)	For XL C++ compile, cross reference listing with attribute information. If XREF is specified, the listing also contains reference, definition and modification information.
CHECKOUT (C)	Provides informational messages indicating possible programming errors.
EVENTS	Produces an events file that contains error information and source file statistics.
EXPMAC	Macro expansions with the original source.
FLAG	Specifies the minimum severity level that is tolerated.
GONUMBER	Generates line number tables corresponding to the input source file. This option is turned on when the TEST option is used. This option is needed to show statement numbers in dump output.
INFO (C++)	Indication of possible programming errors.
INLINE	Inline Summary and Detailed Call Structure Reports. (Specify with the REPORT sub-option).
INLRPT	Generates a report on status of functions that were inlined. The OPTIMIZE option must also be specified.
LIST	Listing of the pseudo-assembly listing produced by the compiler.
OFFSET	Displays the offset addresses relative to the entry point of each function.
PHASEID	Causes each compiler module (phase) to issue an informational message which identifies the compiler phase module name, product identifier, and build level.
PPONLY	Completely expanded z/OS XL C, or z/OS XL C++ source code, by activating the preprocessor (PP) only. The output shows, for example, all the ″#include″ and ″#define″ directives.
SERVICE	Places a string in the object module, which is displayed in the traceback if the application fails abnormally.
SHOWINC	All included text in the listing.
SOURCE	Includes source input statements and diagnostic messages in the listing.
TERMINAL	Directs all error messages from the compiler to the terminal. If not specified, this is the default.
TEST	Generates information for debugging interface. This also generates symbol tables needed for symbolic variables in the dump.
XPLINK (BACKCHAIN)	Generates a prolog that saves redundant information in the calling function's stack frame.
XPLINK (STOREARGS)	Generates code to store arguments that are normally passed in registers, into the argument area.
XREF	For XL C compile, cross reference listing with reference, definition, and modification information. For XL C++ compile, cross reference listing with reference, definition, and modification information. If you specify ATTRIBUTE, the listing also contains attribute information.

For a detailed explanation of these options, see *z/OS XL C/C++ User's Guide*.

Refer to the Inter-procedural Analysis chapter in the *z/OS XL C/C++ Programming Guide* for an overview and more details about Inter-procedural Analysis.

COBOL compiler options

When using COBOL, set the SYM suboption of the TEST compiler option. The SYM suboption of TEST causes the compiler to add debugging information into the object program to resolve user names in the routine and to generate a symbolic dump of the DATA DIVISION. With this suboption specified, statement numbers will also be used in the dump output along with offset values.

To simplify debugging, use the NOOPTIMIZE compiler option. Program optimization can change the location of parameters and instructions in the dump output.

You can use the following COBOL compiler options to prepare your program for run-time debugging:

LIST Produces a listing of the assembler expansion of your source code and global tables, literal pools, information about working storage, and size of routine's working storage.

MAP Produces lists of items in data division including a data division map, global tables, literal pools, a nested program structure map, and attributes.

OFFSET Produces a condensed PROCEDURE DIVISION listing containing line numbers, statement references, and location of the first instruction generated for each statement.

OUTDD Specifies the destination of DISPLAY statement messages.

SOURCE Produces a listing of your source program with any statements embedded by PROCESS, COPY, or BASIS statements.

TEST Produces object code that can run with a debugging tool, or adds information to the object program to produce formatted dumps. With or without any suboptions, this option forces the OBJECT option. When specified with any of the hook-location suboption values except NONE, this option forces the NOOPTIMIZE option. SYM suboption includes statement numbers in the Language Environment dump and produces a symbolic dump.

VBREF Produces a cross-reference of all verb types used in the source program and a summary of how many times each verb is used.

XREF Creates a sorted cross-reference listing.

For more detail on these options and functions, see *Enterprise COBOL for z/OS Programming Guide* or *COBOL for OS/390 & VM Programming Guide*

Fortran compiler options

You can use these Fortran compiler options to prepare your program for run-time debugging:

FIPS Specifies whether standard language flagging is to be performed. This is valuable if you want to write a program conforming to Fortran 77.

FLAG Specifies the level of diagnostic messages to be written. **I** (Information), **E** (Error), **W** (Warning), or **S** (Severe). You can also use FLAG to suppress messages that are below a specified level. This is useful if you want to suppress information messages, for example.

GOSTMT Specifies that statement numbers are included in the run-time messages and in the Language Environment dump.

ICA Specifies whether intercompilation analysis is to be performed, specifies the files containing intercompilation analysis information to be used or updated, and controls output from intercompilation analysis. Specify ICA when you have a group of programs and subprograms that you want to process together and you need to know if there are any conflicting external references, mismatched commons, and so on.

LIST	Specifies whether the object module list is to be written. The LIST option lets you see the pseudo-assembly language code that is similar to what is actually generated.
MAP	Specifies whether a table of source program variable names, named constants, and statement labels and their displacements is to be produced.
OPTIMIZE	Specifies the optimizing level to be used during compilation. If you are debugging your program, it is advisable to use NOOPTIMIZE.
SDUMP	Specifies whether dump information is to be generated.
SOURCE	Specifies whether a source listing is to be produced.
SRCFLG	Controls insertion of error messages in the source listing. SRCFLG allows you to view error messages after the initial line of each source statement that caused the error, rather than at the end of the listing.
SXM	Formats SREF or MAP listing output to a 72-character width.
SYM	Invokes the production of SYM cards in the object text file. SYM cards contain location information for variables within a Fortran program.
TERMINAL	Specifies whether error messages and compiler diagnostics are to be written on the SYSTERM data set and whether a summary of messages for all the compilations is to be written at the end of the listing.
TEST	Specifies whether to override any optimization level above OPTIMIZE(0). This option adds run-time overhead.
TRMFLG	Specifies whether to display the initial line of source statements in error and their associated error messages at the terminal.
XREF	Creates a cross-reference listing.
VECTOR	Specifies whether to invoke the vectorization process. A vectorization report provides detailed information about the vectorization process.

For more detail on these options and functions, see *VS FORTRAN Version 2 Programming Guide for CMS and MVS* or *VS FORTRAN Version 2 Language and Library Reference.*

PL/I compiler options

When using PL/I, specify the TEST compiler option to control the level of testing capability that are generated as part of the object code. Suboptions of the TEST option such as SYM, BLOCK, STMT, and PATH control the location of test hooks and specify whether or not a symbol table is generated. For more information about TEST, its suboptions, and the placement of test hooks, see *PL/I for MVS & VM Programming Guide*.

To simplify debugging and decrease compile time, set optimization to NOOPTIMIZE or OPTIMIZE(0). Higher optimization levels can change the location where parameters and instructions appear in the dump output.

You can use these compiler options to prepare PL/I routines for debugging:

AGGREGATE	Specifies that a layout for arrays and major structures appears in the listing.
ESD	Includes the external symbol dictionary in the listing.
GONUMBER / GOSTMT	Tells the compiler to produce additional information specifying that line numbers from the source routine can be included in run-time messages and in the Language Environment dump.
INTERRUPT	Specifies that users can establish an ATTENTION ON-unit that gains control when an attention interrupt occurs.
LIST	Produces a listing of the assembler expansion of source code and global tables, literal pools, information about working storage, and size of routine's working storage.

LMESSAGE	Tells the compiler to produce run-time messages in a long form. If the cause of a run-time malfunction is a programmer's understanding of language semantics, specifying LMESSAGE could better explain warnings or other information generated by the compiler.
MAP	Tells the compiler to produce tables showing how the variables are mapped in the static internal control section and in the stack frames, thus enabling static internal and automatic variables to be found in the Language Environment dump. If LIST is also specified, the MAP option also produces tables showing constants, control blocks, and INITIAL variable values.
OFFSET	Specifies that the compiler prints a table of statement or line numbers for each procedure with their offset addresses relative to the primary entry point of the procedure.
SOURCE	Specifies that the compiler includes a listing of the source routine in the listing.
STORAGE	Includes a table of the main storage requirements for the object module in the listing.
TERMINAL	Specifies what parts of the compiler listing produced during compilation are directed to the terminal.
TEST	Specifies the level of testing capability that is generated as part of the object code. TEST also controls the location of test hooks and whether or not the symbol table is generated. Because the TEST option increases the size of the object code and can affect performance, limit the number and placement of hooks.
XREF and ATTRIBUTES	Creates a sorted cross-reference listing with attributes.

For more detail on PL/I compiler options, see *PL/I for MVS & VM Programming Guide*.

Enterprise PL/I for z/OS compiler options

The following Enterprise PL/I for z/OS compiler options can be specified when preparing your Enterprise PL/I for z/OS routines for debugging:

AGGREGATE	Specifies that a layout for arrays and major structures appears in the listing.
GONUMBER / GOSTMT	Tells the compiler to produce additional information specifying that line numbers from the source routine can be included in run-time messages and in the Language Environment dump.
INTERRUPT	Specifies that users can establish an ATTENTION ON-unit that gains control when an attention interrupt occurs.
LIST	Produces a listing of the assembler expansion of source code and global tables, literal pools, information about working storage, and size of routine's working storage.
OFFSET	Displays the offset addresses relative to the entry point of each function.
SOURCE	Specifies that the compiler includes a listing of the source routine in the listing.
STORAGE	Includes a table of the main storage requirements for the object module in the listing.
TEST	Specifies the level of testing capability that is generated as part of the object code. TEST also controls the location of test hooks and whether or not the symbol table is generated. Because the TEST option increases the size of the object code and can affect performance, limit the number and placement of hooks.
XREF and ATTRIBUTES	Creates a sorted cross-reference listing with attributes.

For further details on the Enterprise PL/I for z/OS compiler options, see *Enterprise PL/I for z/OS Programming Guide*.

Using Language Environment run-time options

There are several run-time options that affect debugging in Language Environment. The TEST run-time option, for example, can be used with a debugging tool to specify the level of control the debugging tool has when the routine being initialized is started. The ABPERC, CHECK, DEPTHCONDLMT, DYNDUMP, ERRCOUNT, HEAPCHK, INTERRUPT, TERMTHDACT, TRACE, TRAP, and USRHDLR options affect condition handling. The ABTERMENC option affects how an application ends (that is, with an abend or with a return code and reason code) when an unhandled condition of severity 2 or greater occurs.

The following Language Environment run-time options affect debugging:

ABPERC Specifies that the indicated abend code bypasses the condition handler.

ABTERMENC Specifies enclave termination behavior for an enclave ending with an unhandled condition of severity 2 or greater.

CEEDUMP Specifies options to control the processing of the Language Environment dump report.

CHECK Determines whether run-time checking is performed.

NODEBUG Controls the COBOL USE FOR DEBUGGING declarative.

DEPTHCONDLMT Specifies the limit for the depth of nested synchronous conditions in user-written condition handlers. (Asynchronous signals do not affect DEPTHCONDLMT.)

DYNDUMP Provides a way to obtain IPCS-readable dumps of user applications that would ordinarily be lost due to the absence of a SYSMDUMP, SYSUDUMP, or SYSABEND DD statement

ERRCOUNT Specifies the number of synchronous conditions of severity 2 or greater tolerated. (Asynchronous signals do not affect ERRCOUNT.)

HEAPCHK Determines whether additional heap check tests are performed.

INFOMSGFILTER Filters user specified informational messages from the MSGFILE. **Note:** Affects only those messages generated by Language Environment and any routine that calls CEEMSG. Other routines that write to the message file, such as CEEMOUT, do not have a filtering option.

INTERRUPT Causes Language Environment to recognize attention interrupts.

MSGFILE Specifies the ddname of the Language Environment message file.

MSGQ Specifies the number of instance specific information (ISI) blocks that are allocated on a per-thread basis for use by an application. Located within the Language Environment condition token is an ISI token. The ISI contains information used by the condition manager to identify and react to a specific occurrence of a condition.

PROFILE Controls the use of an optional profiler tool, which collects performance data for the running application. When this option is in effect, the profiler is loaded and the debugger cannot be loaded. If the TEST option is in effect when PROFILE is specified, the profiler tool will not be loaded.

RPTOPTS Causes a report to be produced which contains the run-time options in effect. See “Determining run-time options in effect” on page 9 below.

RPTSTG Generates a report of the storage used by an enclave. See “Controlling storage allocation” on page 11.

STORAGE	Specifies that Language Environment initializes all heap and stack storage to a user-specified value.
TERMTHDACT	Controls response when an enclave terminates due to an unhandled condition of severity 2 or greater.
TEST	Specifies the conditions under which a debugging tool assumes control.
TRACE	Activates Language Environment run-time library tracing and controls the size of the trace table, the type of trace, and whether the trace table should be dumped unconditionally upon termination of the application.
TRAP	When TRAP is set to ON, Language Environment traps routine interrupts and abends, and optionally prints trace information or invokes a user-written condition handling routine. With TRAP set to OFF, the operating system handles all interrupts and abends. You should generally set TRAP to ON, or your run-time results can be unpredictable.
USRHDLR	Specifies the behavior of two user-written condition handlers. The first handler specified will be registered at stack frame 0. The second handler specified will be registered before any other user-written condition handlers, once the handler is enabled by a condition.
XUFLOW	Specifies whether or not an exponent underflow causes a routine interrupt.

For a more detailed discussion of these run-time options, see *z/OS Language Environment Programming Reference* .

Determining run-time options in effect

The run-time options in effect at the time the routine is run can affect routine behavior. Use RPTOPTS(ON) to generate an options report in the Language Environment message file when your routine terminates. The options report lists run-time options, and indicates where they were set.

Figure 1 on page 10 shows a sample options report.

```
Options Report for Enclave main 12/07/06 6:25:56 PM

Figure 1. Options report example produced by run-time option RPTOPTS(ON)

Using the CLER CICS transaction to display and set run-time options

The CICS transaction (CLER) allows you to display all the current Language Environment run-time options for a region, and to also have the capability to modify a subset of these options.

For more information about the CICS CLER transaction, see “Displaying and modifying run-time options with the CLER transaction” on page 324.

Controlling storage allocation

The following run-time options control storage allocation:

- STACK
- THREADSTACK
- LIBSTACK
- THREADHEAP
- HEAP
- ANYHEAP
- BELOWHEAP
- STORAGE
- HEAPPOOLS

z/OS Language Environment Programming Guide provides useful tips to assist with the tuning process. Appropriate tuning is necessary to avoid performance problems.

To generate a report of the storage a routine (or more specifically, an enclave) used during its run, specify the RPTSTG(ON) run-time option. The storage report, generated during enclave termination provides statistics that can help you understand how space is being consumed as the enclave runs. If storage management tuning is desired, the statistics can help you set the corresponding storage-related run-time options for future runs. The output is written to the Language Environment message file.

Neither the storage report nor the corresponding run-time options include the storage that Language Environment acquires during early initialization, before run-time options processing, and before the start of space management monitoring. In addition, Language Environment does not report alternative Vendor Heap Manager activity.

Figure 2 on page 12 and Figure 3 on page 14 show sample storage reports. The sections that follow these reports describe the contents of the reports.

Figure 3. Storage report produced by RPTSTG(ON) with XPLINK (Part 4 of 4)

The statistics for initial and incremental allocations of storage types that have a corresponding run-time option differ from the run-time option settings when their values have been rounded up by the implementation, or when allocations larger than the amounts specified were required during execution. All of the following are rounded up to an integral number of double-words:

- Initial STACK allocations
- Initial allocations of THREADSTACK
- Initial allocations of all types of heap
- Incremental allocations of all types of stack and heap

The run-time options should be tuned appropriately to avoid performance problems. Refer to *z/OS Language Environment Programming Guide* for tips on tuning.

Stack storage statistics

Language Environment stack storage is managed at the thread level—each thread has its own stack-type resources.

STACK, THREADSTACK, LIBSTACK, and IPT STACK statistics for the upward-growing stack

- Initial size — the actual size of the initial segment assigned to each thread. (If a pthread-attributes-table is provided on the invocation of pthread-create, then the stack size specified in the pthread-attributes-table will take precedence over the STACK run-time option.)
- Increment size — the size of each incremental segment acquired, as determined by the increment portion of the corresponding run-time option.
- Maximum used by all concurrent threads — the maximum amount allocated in total at any one time by all concurrently executing threads.
- Largest used by any thread — the largest amount allocated ever by any single thread.
- Number of segments (or increments) allocated — the number of incremental segments allocated by all threads.
- Number of segments freed — the number of incremental segments freed by all threads.

The number of incremental segments freed could be less than the number allocated if any of the segments were not freed individually during the life of the thread, but rather were freed implicitly in the course of thread termination.

XPLINK statistics — XPLINK STACK and XPLINK THREADSTACK statistics for the downward-growing stack

These sections of the storage report only apply if XPLINK is in effect.

- Initial size — the actual size of the initial segment assigned to each thread.
- Increment size — the size of each incremental segment acquired, as determined by the increment portion of the corresponding run-time option.
- Maximum used by all concurrent threads — the maximum amount allocated in total at any one time by all concurrently executing threads.
- Largest used by any thread — the largest amount allocated ever by any single thread.
- Number of segments allocated — the number of incremental segments allocated by all threads.
- Number of segments freed — the number of incremental segments freed by all threads.

The number of incremental segments freed could be less than the number allocated if any of the segments were not freed individually during the life of the thread, but rather were freed implicitly in the course of thread termination.

Determining the applicable threads

If the application is not a multithreading or PL/I multitasking application, then the STACK statistics are for the one and only thread that executed, and the THREADSTACK statistics are all zero.

If the application is a multithreading or PL/I multitasking application, and THREADSTACK(ON) was specified, then the STACK statistics are for the initial thread (the IPT), and the THREADSTACK statistics are for the other threads. However, if THREADSTACK(OFF) was specified, then the STACK statistics are for all of the threads, initial and other.

Allocating stack storage

Another type of stack, called the reserve stack, is allocated for each thread and used to handle out-of-storage conditions. Its size is controlled by the 4th subparameter of the STORAGE run-time option, but its usage is neither tracked nor reported in the storage report.

In a single-threaded environment, Language Environment allocates the initial segments for STACK, LIBSTACK and reserve stack using GETMAIN. The LIBSTACK initial segment allocation is deferred until first use, except when STACK(,,BELOW,,) is in effect. The reserve stack is allocated with STACK. In a multi-threaded POSIX(ON) environment, allocation of stack storage for the initial processing thread (IPT) is the same as the single-threaded environment. For threads other than the IPT, the initial STACK (or THREADSTACK) segment and reserve stack is allocated from ANYHEAP or BELOWHEAP, according to the STACK (or THREADSTACK) location. The initial LIBSTACK segment allocation is again deferred until first use, except when STACK(,,BELOW,,) or THREADSTACK(ON,,,BELOW,,) is in effect. When a STACK, THREADSTACK, or LIBSTACK overflow occurs on any thread, Language Environment obtains the new segment using GETMAIN. The reserve stack does not tolerate overflow.

Heap storage statistics

Language Environment heap storage, other than what is explicitly defined using THREADHEAP, is managed at the enclave level—each enclave has its own heap-type resources, which are shared by the threads that execute within the enclave. Heap storage defined using THREADHEAP is controlled at the thread level.

THREADHEAP statistics

- Initial size—the default initial allocation, as specified by the corresponding run-time option. Please note that for HEAP24, the initial size is the value of the initsz24 of the HEAP option.
- Increment size—the minimum incremental allocation, as specified by the corresponding run-time option. Please note that for HEAP24, the increment size is the value of the incrsz24 of the HEAP option.
- Maximum used by all concurrent threads—the maximum total amount used by all concurrent threads at any one time.
- Largest used by any thread—the largest amount used by any single thread.
- Successful Get Heap requests—the number of Get Heap requests.
- Successful Free Heap requests—the number of Free Heap requests.
- Number of segments allocated—the number of incremental segments allocated.
- Number of segments freed—the number of incremental segments individually freed.

These statistics, in all cases, specify totals for the whole enclave. For THREADHEAP, they indicate the total across all threads in the enclave.

HEAP, HEAP24, ANYHEAP, and BELOWHEAP statistics

- Initial size—the default initial allocation, as specified by the corresponding run-time option. Please note that for HEAP24, the initial size is the value of the initsz24 of the HEAP option.
- Increment size—the minimum incremental allocation, as specified by the corresponding run-time option. Please note that for HEAP24, the increment size is the value of the incrsz24 of the HEAP option.
- Total heap storage used—the largest total amount used by the enclave at any one time.
- Successful Get Heap requests—the number of Get Heap requests.
- Successful Free Heap requests—the number of Free Heap requests.
- Number of segments allocated—the number of incremental segments allocated.
- Number of segments freed—the number of incremental segments individually freed.

The number of Free Heap requests could be less than the number of Get Heap requests if the pieces of heap storage acquired by individual Get Heap requests were not freed individually, but rather were freed implicitly in the course of enclave termination.

The number of incremental segments individually freed could be less than the number allocated if the segments were not freed individually, but rather were freed implicitly in the course of enclave termination.

These statistics, in all cases, specify totals for the whole enclave. For THREADHEAP, they indicate the total across all threads in the enclave.

Additional heap statistics

Besides the fixed types of heap, additional types of heap can be created, each with its own heap ID. You can create and discard these additional types of heap by using the CEECRHP

- Successful Create Heap requests—the number of successful Create Heap requests.
- Successful Discard Heap requests—the number of successful Discard Heap requests.

  The number of Discard Heap requests could be less than the number of Create Heap requests if the special heaps allocated by individual Create Heap requests were not freed individually, but rather were freed implicitly in the course of enclave termination.
- Total heap storage used—the largest total amount used by the enclave at any one time.
- Successful Get Heap requests—the number of Get Heap requests.
- Successful Free Heap requests—the number of Free Heap requests.
- Number of segments allocated—the number of incremental segments allocated.
- Number of segments freed—the number of incremental segments individually freed.

HeapPools storage statistics

The HEAPPOOLS run-time option (for C/C++ applications only) controls usage of the heap pools storage algorithm at the enclave level. The heap pools algorithm allows for the definition of one to twelve heap pools, each consisting of a number of

storage cells of a specified length. For further details regarding HeapPools storage statistics in the storage report, see “HeapPools storage statistics” on page 196.

Modifying condition handling behavior

Setting the condition handling behavior of your routine affects the response that occurs when the routine encounters an error.

You can modify condition handling behavior in the following ways:
- Callable services
- Run-time options
- User-written condition handlers
- POSIX functions (used to specifically set signal actions and signal masks)

Language Environment callable services

You can use these callable services to modify condition handling:

CEE3ABD Terminates an enclave using an abend.

CEEMRCE Moves the resume cursor to an explicit location where resumption is to occur after a condition has been handled.

CEEMRCR Moves the resume cursor relative to the current position of the handle cursor.

CEE3CIB Returns a pointer to a condition information block (CIB) associated with a given condition token. The CIB contains detailed information about the condition.

CEE3GRO Returns the offset of the location within the most current Language Environment-conforming routine where a condition occurred.

CEE3SPM Specifies the settings of the routine mask. The routine mask controls:
- Fixed overflow
- Decimal overflow
- Exponent underflow
- Significance

You can use CEE3SPM to modify Language Environment hardware conditions. Because such modifications can affect the behavior of your routine, however, you should be careful when doing so.

CEE3SRP Sets a resume point within user application code to resume from a Language Environment user condition handler.

Fortran programs cannot directly call Language Environment callable services. For more information about callable services, see *z/OS Language Environment Programming Reference*.For more information about how to invoke callable services from Fortran, see *Language Environment Fortran Run-Time Migration Guide*.

Language Environment run-time options

These Language Environment run-time options can affect your routine’s condition handling behavior:

ABPERC Specifies a system- or user-specified abend code that percolates without further action while the Language Environment condition handler is enabled. Normal condition handling activities are performed for everything except the specified abend code. System abends are specified as S**hhh**, where **hhh** is a hexadecimal system abend code.

User abends are specified as U`dddd`, where `dddd` is a decimal user abend code. Any other 4-character EBCDIC string, such as NONE, that is not of the form S**hhh** can also be specified as a user-specified abend code. You can specify only one abend code with this option. This option assumes the use of TRAP(ON). ABPERC is not supported in CICS.

Language Environment ignores ABPERC(0Cx). No abend is percolated and Language Environment condition handling semantics are in effect.

CHECK Specifies that checking errors within an application are detected. The Language Environment-conforming languages can define error checking differently.

DEPTHCONDLMT Limits the extent to which synchronous conditions can be nested in a user-written condition handler. (Asynchronous signals do not affect DEPTHCONDLMT.) For example, if you specify 5, the initial condition and four nested conditions are processed. If the limit is exceeded, the application terminates with abend code 4091 and reason code 21 (X'15').

ERRCOUNT Specifies the number of synchronous conditions of severity 2, 3, and 4 that are tolerated before the enclave terminates abnormally. (Asynchronous signals do not affect ERRCOUNT.) If you specify 0 an unlimited number of conditions is tolerated.

INTERRUPT Causes attentions recognized by the host operating system to be passed to and recognized by Language Environment after the environment has been initialized.

TERMTHDACT Sets the level of information that is produced when a condition of severity 2 or greater remains unhandled within the enclave. There are five possible parameter settings for different levels of information:

- QUIET for no information
- MSG for message only
- TRACE for message and a traceback
- DUMP for message, traceback, and Language Environment dump
- UAONLY for message and a system dump of the user address space
- UATRACE for message, Language Environment dump with traceback information only, and a system dump of the user address space
- UADUMP for message, traceback, Language Environment dump, and system dump
- UAIMM for a system dump of the user address space of the original abend or program interrupt prior to the Language Environment condition manager processing the condition.

TRAP(ON) Fully enables the Language Environment condition handler. This causes the Language Environment condition handler to intercept error conditions and routine interrupts.

When TRAP(ON, NOSPIE) is specified, Language Environment handles all program interrupts and abends through an ESTAE. Use this feature when you do not want Language Environment to issue an ESPIE macro.

During normal operation, you should use TRAP(ON) when running your applications.

TRAP(OFF) Disables the Language Environment condition handler from handling abends and program checks/interrupts. ESPIE is not issued with TRAP(OFF), it is still possible to invoke the condition handler through the CEESGL callable service and pass conditions to registered user-written condition handlers.

Specify TRAP(OFF) when you do not want Language Environment to issue an ESTAE or an ESPIE.

When TRAP(OFF), TRAP(OFF,SPIE), or TRAP(OFF,NOSPIE) is specified and either a program interrupt or abend occurs, the user exit for termination is ignored.

TRAP(OFF) can cause several unexpected side effects. For further information, see the TRAP run-time option in *z/OS Language Environment Programming Reference*.

USRHDLR Specifies the behavior of two user-written condition handlers. The first handler specified will be registered at stack frame 0. The second handler specified will be registered before any other user-written condition handlers, once the handler is enabled by a condition.

When you specify USRHDLR(lastname,supername), lastname gets control at stack frame 0. Supername will get get control first, before any user-written condition handlers but after supername has gone through the enablement phase, when a condition occurs.

XUFLOW Specifies whether an exponent underflow causes a routine interrupt.

Customizing condition handlers

User-written condition handlers permit you to customize condition handling for certain conditions. You can register a user-written condition handler for the current stack frame by using the CEEHDLR callable service. You can use the Language Environment USRHDLR run-time option to register a user-written condition handler for stack frame 0. You can also use USRHDLR to register a user-written condition handler before any other user condition handlers.

When the Language Environment condition manager encounters the condition, it requests that the condition handler associated with the current stack frame handle the condition. If the condition is not handled, the Language Environment condition manager percolates the condition to the next (earlier) stack frame, and so forth to earlier stack frames until the condition has been handled. Conditions that remain unhandled after the first (earliest) stack frame has been reached are presented to the Language Environment condition handler. One of the following Language Environment default actions is then taken, depending on the severity of the condition:

- Resume
- Percolate
- Promote

- Fix-up and resume

For more information about user-written condition handlers and the Language Environment condition manager, see *z/OS Language Environment Programming Guide*.

Invoking the assembler user exit

For debugging purposes, the CEEBXITA assembler user exit can be invoked during:

- Enclave initialization
- Enclave termination
- Process termination

The functions of the CEEBXITA user exit depend on when the user exit is invoked and whether it is application-specific or installation-wide. Application-specific user exits must be linked with the application load module and run only when that application runs. Installation-wide user exits must be linked with the Language Environment initialization/termination library routines and run with all Language Environment library routines. Because an application-specific user exit has priority over any installation-wide user exit, you can customize a user exit for a particular application without affecting the user exit for any other applications.

At enclave initialization, the CEEBXITA user exit runs prior to the enclave establishment. Thus you can modify the environment in which your application runs in the following ways:

- Specify run-time options
- Allocate data sets/files in the user exit
- List abend codes to be passed to the operating system
- Check the values of routine arguments

At enclave termination, the CEEBXITA user exit runs prior to the termination activity. Thus, you can request an abend and perform specified actions based on received return and reason codes. (This does not apply when Language Environment terminates with an abend.)

At process termination, the CEEBXITA user exit runs after the enclave termination activity completes. Thus you can request an abend and deallocate files.

The assembler user exit must have an entry point of CEEBXITA, must be reentrant, and must be capable of running in AMODE(ANY) and RMODE(ANY).

You can use the assembler user exit to establish enclave termination behavior for an enclave ending with an unhandled condition of severity 2 or greater in the following ways:

- If you do not request an abend in the assembler user exit for the enclave termination call, Language Environment honors the setting of the ABTERMENC option to determine how to end the enclave.
- If you request an abend in the assembler user exit for the enclave termination call, Language Environment issues an abend to end the enclave.

For more information on the assembler user exit, see *z/OS Language Environment Programming Guide*.

Establishing enclave termination behavior for unhandled conditions

To establish enclave termination behavior when an unhandled condition of severity 2 or greater occurs, use one of the following methods:

- The assembler user exit (see “Invoking the assembler user exit” on page 23 and *z/OS Language Environment Programming Guide*)
- POSIX signal default action (see *z/OS Language Environment Programming Guide*)
- The ABTERMENC run-time option (discussed below)

The ABTERMENC run-time option sets the enclave termination behavior for an enclave ending with an unhandled condition of severity 2 or greater.

If you specify the IBM-supplied default suboption ABEND, Language Environment issues an abend to end the enclave regardless of the setting of the CEEAUE_ABND flag. Additionally, the assembler user exit can alter the abend code, abend reason code, abend dump attribute, and the abend task/step attribute. For more information on using ABTERMENC, see *z/OS Language Environment Programming Reference*, and for more information on the assembler user exit, see *z/OS Language Environment Programming Guide*.

If you specify the RETCODE suboption, Language Environment uses the CEEAUE_ABND flag value set by the assembler user exit (which is called for enclave termination) to determine whether or not to issue an abend to end the enclave when an unhandled condition of severity 2 or greater occurs.

Using messages in your routine

You can create messages and use them in your routine to indicate the status and progress of the routine during run time, and to display variable values. The process of creating messages and using them requires that you create a message source file, and convert the source file into loadable code for use in your routine.

You can use the Language Environment callable service CEEMOUT to direct user-created message output to the Language Environment message file. To direct the message output to another destination, use the Language Environment MSGFILE run-time option to specify the ddname of the file.

When multiple Language Environment environments are running in the same address space and the same MSGFILE ddname is specified, writing contention can occur. To avoid contention, use the MSGFILE suboption ENQ. ENQ tells Language Environment to perform serialization around writes to the MSGFILE ddname specified which eliminates writing contention. Writing contention can also be eliminated by specifying unique MSGFILE ddnames.

Each Language Environment-conforming language also provides ways to display both user-created and run-time messages. (For an explanation of Language Environment run-time messages, see “Interpreting run-time messages” on page 30.)

The following sections discuss how to create messages in each of the HLLs. For a more detailed explanation of how to create messages and use them in C, C++, COBOL, Fortran, or PL/I routines, see *z/OS Language Environment Programming Guide*.

C/C++

For C/C++ routines, output from the `printf` function is directed to `stdout`, which is associated with `SYSPRINT`. All C/C++ run-time messages and perror() messages are directed to `stderr`. `stderr` corresponds to the ddname associated with the Language Environment MSGFILE run-time option. The destination of the `printf` function output can be changed by using the redirection `1>&2` at routine invocation to redirect `stdout` to the `stderr` destination. Both streams can be controlled by the MSGFILE run-time option.

COBOL

For COBOL programs, you can use the DISPLAY statement to display messages. Output from the DISPLAY statement is directed to SYSOUT. SYSOUT is the IBM-supplied default for the Language Environment message file. The OUTDD compiler option can be used to change the destination of the DISPLAY messages.

Fortran

For Fortran programs, run-time messages, output written to the print unit, and other output (such as output from the SDUMP callable service) are directed to the file specified by the MSGFILE run-time option. If the print unit is different than the error message unit (PRTUNIT and ERRUNIT run-time options have different values), however, output from the PRINT statement won't be directed to the Language Environment message file.

PL/I

Under PL/I, run-time messages are directed to the file specified in the Language Environment MSGFILE run-time option, instead of the PL/I SYSPRINT STREAM PRINT file. User-specified output is still directed to the PL/I SYSPRINT STREAM PRINT file. To direct this output to the Language Environment MSGFILE file, specify the run-time option MSGFILE(SYSPRINT).

Using condition information

If a condition that might require attention occurs while an application is running, Language Environment builds a condition token. The condition token contains 12 bytes (96 bits) of information about the condition that Language Environment or your routines can use to respond appropriately. Each condition is associated with a single Language Environment run-time message.

You can use this condition information in two primary ways:

- To specify the feedback code parameter when calling Language Environment services (see "Using the feedback code parameter").
- To code a symbolic feedback code in a user-written condition handler (see "Using the symbolic feedback code" on page 27).

Using the feedback code parameter

The feedback code is an optional parameter of the Language Environment callable services. (For COBOL/370 programs, you must provide the **fc** parameter in each call to a Language Environment callable service. For C/C++, Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, and PL/I routines, this parameter is optional. For more information about **fc** and condition tokens, see *z/OS Language Environment Programming Guide*.)

When you provide the feedback code (**fc**) parameter, the callable service in which the condition occurs sets the feedback code to a specific value called a condition token.

The condition token does not apply to asynchronous signals. For a discussion of the distinctions between synchronous signals and asynchronous signals with POSIX(ON), see *z/OS Language Environment Programming Guide*.

When you do not provide the **fc** parameter, any nonzero condition is signaled and processed by Language Environment condition handling routines. If you have registered a user-written condition handler, Language Environment passes control to the handler, which determines the next action to take. If the condition remains unhandled, Language Environment writes a message to the Language Environment message file. The message is the translation of the condition token into English (or another supported national language).

Language Environment provides callable services that can be used to convert condition tokens to routine variables, messages, or signaled conditions. The following table lists these callable services and their functions.

CEEMSG Transforms the condition token into a message and writes the message to the message file.

CEEMGET Transforms the condition token into a message and stores the message in a buffer.

CEEDCOD Decodes the condition token; that is, separates it into distinct user-supplied variables. Also, if a language does not support structures, CEEDCOD provides direct access to the token.

CEESGL Signals the condition. This passes control to any registered user-written condition handlers. If a user-written condition handler does not exist, or the condition is not handled, Language Environment by default writes the corresponding message to the message file and terminates the routine for severity 2 or higher. For severity 0 and 1, Language Environment continues without writing a message. COBOL, however, issues severity 1 messages before continuing. CEESGL can signal a POSIX condition. For details, see *z/OS Language Environment Programming Guide*.

There are two types of condition tokens. Case 1 condition tokens contain condition information, including the Language Environment message number. All Language Environment callable services and most application routines use case 1 condition tokens. Case 2 condition tokens contain condition information and a user-specified class and cause code. Application routines, user-written condition handlers, assembler user exits, and some operating systems can use case 2 condition tokens.

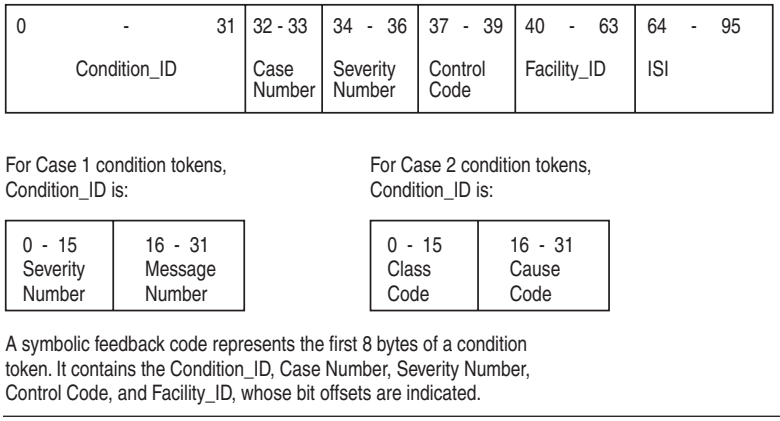

Figure 4. Language Environment condition token

For example, in the condition token: X'0003032D 59C3C5C5 00000000'

- X'0003' is severity.
- X'032D' is message number 813.
- X'59' are hexadecimal flags for case, severity, and control.
- X'C3C5C5' is the CEE facility ID.
- X'00000000' is the ISI. (In this case, no ISI was provided.)

If a Language Environment traceback or dump is generated while a condition token is being processed or when a condition exists, Language Environment writes the run-time message to the condition section of the traceback or dump. If a condition is detected when a callable service is invoked without a feedback code, the condition token is passed to the Language Environment condition manager. The condition manager polls active condition handlers for a response. If a condition of severity 0 or 1 remains unhandled, Language Environment resumes without issuing a message. Language Environment does issue messages, however, for COBOL severity 1 conditions. For unhandled conditions of severity 2 or greater, Language Environment issues a message and terminates. For a list of Language Environment run-time messages and corrective information, see *z/OS Language Environment Run-Time Messages*.

If a second condition is raised while Language Environment is attempting to handle a condition, the message `CEE0374C CONDITION = <message no.>` is displayed using a write-to-operator (WTO). The message number in the CEE0374C message indicates the original condition that was being handled when the second condition was raised. This can happen when a critical error is signaled (for example, when internal control blocks are damaged).

If the output for this error message appears several times in sequence, the conditions appear in order of occurrence. Correcting the earliest condition can cause your application to run successfully.

Using the symbolic feedback code

The symbolic feedback code represents the first 8 bytes of a 12-byte condition token. You can think of the symbolic feedback code as the nickname for a condition. As such, the symbolic feedback code can be used in user-written condition handlers to screen for a given condition, even if it occurs at different locations in an application.

For more details on symbolic feedback codes, see *z/OS Language Environment Programming Guide*.

Chapter 2. Classifying errors

This chapter describes errors that commonly occur in Language Environment routines. It also explains how to use run-time messages and abend codes to obtain information about errors in your routine.

Identifying problems in routines

The following sections describe how you can identify errors in Language Environment routines. Included are common error symptoms and solutions.

Language Environment module names

You can identify Language Environment-supplied module elements by any of the following three-character prefixes:

- CEE (Language Environment)
- CEL (Language Environment and C/C++ run-time library)
- EDC (C/C++)
- FOR (Fortran)
- IBM (PL/I)
- IGZ (COBOL)

Module elements or text files with other prefixes are not part of the Language Environment product.

Common errors in routines

These common errors have simple solutions:

- If you do not have enough virtual storage, increase your region size or decrease your storage usage (stack size) by using the storage-related run-time options and callable services. (See “Controlling storage allocation” on page 11 for information about using storage in routines.)
- If you do not have enough disk space, increase your disk allocation.
- If executable files are not available, check your executable library to ensure that they are defined. For example, check your STEPLIB or JOBLIB definitions.

If your error is not caused by any of the items listed above, examine your routine or routines for changes since the last successful run. If there have been changes, review these changes for errors that might be causing the problem. One way to isolate the problem is to branch around or comment out recent changes and rerun the routine. If the run is successful, the error can be narrowed to the scope of the changes.

Duplicate names shared between Fortran routines and C library routines can produce unexpected results. Language Environment provides several cataloged procedures to properly resolve duplicate names. For more information on how to avoid name conflicts, see *z/OS Language Environment Programming Guide*.

Changes in optimization levels, addressing modes, and input/output file formats can also cause unanticipated problems in your routine.

In most cases, generated condition tokens or run-time messages point to the nature of the error. The run-time messages offer the most efficient corrective action. To

help you analyze errors and determine the most useful method to fix the problem, Table 3 lists common error symptoms, possible causes, and programmer responses.

Table 3. Common error symptoms, possible causes, and programmer responses

Error Symptom	Possible Cause	Programmer Response
Numbered run-time message appears	Condition raised in routine	For any messages you receive, read the Programmer Response. For information about message structure, see “Interpreting run-time messages” below.
User abend code < 4000	a) A non-Language Environment abend occurred b) The assembler user exit requested an abend for an unhandled condition of severity ≥2	See the Language Environment abend codes in *z/OS Language Environment Run-Time Messages*. Check for a subsystem-generated abend or a user-specified abend.
User abend code ≥ 4000	a) Language Environment detected an error and could not proceed b) An unhandled software-raised condition occurred and ABTERMENC(ABEND) was in effect c) The assembler user exit requested an abend for an unhandled condition of severity 4	For any abends you receive, read the appropriate explanation listed in the abend codes section of *z/OS Language Environment Run-Time Messages*.
System abend with TRAP(OFF)	Cause depends on type of malfunction	Respond appropriately. Refer to the messages and codes book of the operating system.
System abend with TRAP(ON)	System-detected error	Refer to the messages and codes book of the operating system.
No response (wait/loop)	Application logic failure	Check routine logic. Ensure ERRCOUNT and DEPTHCONDLMT run-time options are set to a nonzero value.
Unexpected message (message received was not from most recent service)	Condition caused by something related to current service	Generate a traceback using CEE3DMP.
Incorrect output	Incorrect file definitions, storage overlay, incorrect routine mask setting, references to uninitialized variables, data input errors, or application routine logic error	Correct the appropriate parameters.
No output	Incorrect ddname, file definitions, or message file setting	Correct the appropriate parameters.
Nonzero return code from enclave	Unhandled condition of severity 2, 3, or 4, or the return code was issued by the application routine	Check the Language Environment message file for run-time message.
Unexpected output	Conflicting library module names	Refer to the name conflict resolution steps outlined in *z/OS Language Environment Programming Guide*.

Interpreting run-time messages

The first step in debugging your routine is to look up any run-time messages. To find run-time messages, check the message file:

- On z/OS, run-time messages are written by default to ddname SYSOUT. If SYSOUT is not specified, then the messages are written to SYSOUT=*.
- On CICS, the run-time messages are written to the CESE transient data QUEUE.

The default message file ddname can be changed by using the MSGFILE run-time option. For information about displaying run-time messages for C/C++, COBOL, Fortran, or PL/I routines, see *z/OS Language Environment Programming Guide*.

Run-time messages provide users with additional information about a condition, and possible solutions for any errors that occurred. They can be issued by Language Environment common routines or language-specific run-time routines and contain a message prefix, message number, severity code, and descriptive text.

In the following example Language Environment message:

```
CEE3206S The system detected a specification exception.
```

- The message prefix is CEE.
- The message number is 3206.
- The severity code is S.
- The message text is “The system detected a specification exception”.

Language Environment messages can appear even though you made no explicit calls to Language Environment services. C/C++, COBOL, and PL/I run-time library routines commonly use the Language Environment services. This is why you can see Language Environment messages even when the application routine does not directly call common run-time services.

Message prefix

The message prefix indicates the Language Environment component that generated the message. The message prefix is the first three characters of the message number and is also the facility ID in the condition token. See the following table for more information about Language Environment run-time messages.

Message Prefix	Language Environment Component
CEE	Common run time
EDC	C/C++ run time
FOR	Fortran run time
IBM	PL/I run time
IGZ	COBOL run time

The messages for the various components can be found in *z/OS Language Environment Run-Time Messages* and in *z/OS MVS Diagnosis: Reference*.

Message number

The message number is the 4-digit number following the message prefix. Leading zeros are inserted if the message number is less than four digits. It identifies the condition raised and references additional condition and programmer response information.

Severity code

The severity code is the letter following the message number and indicates the level of attention called for by the condition. Messages with severity of I are informational messages and do not usually require any corrective action. In general, if more than one run-time message appears, the first noninformational message indicates the

problem. For a complete list of severity codes, severity values, condition information, and default actions, see *z/OS Language Environment Programming Guide*.

Message text

The message text provides a brief explanation of the condition.

Understanding abend codes

Under Language Environment, abnormal terminations generate abend codes. There are two types of abend codes: 1) user (Language Environment and user-specified) abends and 2) system abends. User abends follow the format of U*dddd*, where *dddd* is a decimal user abend code. System abends follow the format of S*hhh*, where *hhh* is a hexadecimal abend code. Language Environment abend codes are usually in the range of 4000 to 4095. However, some subsystem abend codes can also fall in this range. User-specified abends use the range of 0 to 3999.

Example abend codes are:

```
User (Language Environment) abend code:U4041
User-specified abend code:U0005
System abend code:S80A
```

The Language Environment callable service CEE3ABD terminates your application with an abend. You can set the `clean-up` parameter value to determine how the abend is processed and how Language Environment handles the raised condition. For more information about CEE3ABD and `clean-up`, see *z/OS Language Environment Programming Reference*.

You can specify the ABTERMENC run-time option to determine what action is taken when an unhandled condition of severity 2 or greater occurs. For more information on ABTERMENC, see “Establishing enclave termination behavior for unhandled conditions” on page 24, as well as *z/OS Language Environment Programming Reference*.

User abends

If you receive a Language Environment abend code, see *z/OS Language Environment Run-Time Messages* for a list of abend codes, error descriptions, and programmer responses.

System abends

If you receive a system abend code, look up the code and the corresponding information in the publications for the system you are using.

When a system abend occurs, the operating system can generate a system dump. System dumps are written to ddname SYSMDUMP, SYSABEND, or SYSUDUMP. If the DYNDUMP run-time option is used, the system dump can be written without the ddname specified. System dumps show the memory state at the time of the condition. See “Generating a system dump” on page 80 for more information about system dumps.

Using edcmtext to obtain information about errno2 values

Language Environment provides the **edcmtext** utility (similar to **bpxmtext**), which allows faster error resolution when an errno2 is encountered in Language Environment. Use the **edcmtext** utility to display errno2 reason code text. This utility produces a description and action for the errno2 value.

The **bpmtext** utility calls **edcmtext** when the errno2 value is in the range reserved for the C run-time library or **edcmtext** can be invoked directly with the errno2 value as input.

Format

z/OS UNIX environment:

edcmtext *errno2_value*

TSO/E environment:

EDCMTEXT *errno2_value*

Description

edcmtext displays the description and action text for C/C++ run-time library errno2 values, no other values are supported by this command. This command is intended as an aid for problem determination.

errno2_value is specified as 8 hexadecimal characters.

The user can specify one of the following in place of a errno2 value to view a help dialog: *-h*, *help*, *?*.

The user can specify the **-U** option to display the output in uppercase.

Usage notes

errno2_values are also accepted in mixed case and with hex digits prefixed with the ″0x″.

The range of values for the C/C++ run-time library is 0X'C0000000' through 0X'CFFFFFFF'.

The utility **bpmtext** displays the description and action text for reason codes returned from the kernel, in addition to *errno2_values* returned from the C/C++ run-time library. The user should use **bpxmtext** when the source of the *errno2_values* is unknown. For further information about **bpxmtext**, see *z/OS UNIX System Services Command Reference*.

Message returns

If the user specifies a *-h*, *help* or *?* in place of the *errno2_value*, the following message is displayed:

```
Usage: edcmtext errno2_value
```

If no text is available for the *errno2_value*, the following message is displayed:

```
errno2_value: No information is currently available for this errno2_value.
```

If the *errno2_value* is not comprised of 1-8 hex digits, the following message is displayed:

```
Usage: edcmtext errno2_value
```

If the *errno2_value* is not in the C/C++ run-time library range, the following message is displayed:

```
Notice: The errn2_value is not in the C/C++ run-time library range.
```

If the environment that *edcmtext* is being run in is not TSO/E or z/OS UNIX the following message is displayed:

```
Error: The environment is not TSO/E or z/OS UNIX.
```

Examples

The command:

```
edcmtext C00B0021
```

produces data displayed in the following format:

```
JrEdc1opsEinval01: The mode argument passed to fopen() or freopen() did not begin
with r, w, or a.

Action: Correct the mode argument.  The first keyword of the mode argument must be
the open mode.  Ensure the open mode is specified first and begins with r, w, or a.

Source: edc1opst.c
```

Exit Values

0	Successful completion
2	Failure due to an argument that is not 1–8 hex digits
8	Bad Input due to an *errno2_value* out of the C/C++ run-time range.
14	Environment not TSO/E or z/OS UNIX
>20	Contact IBM due to Internal Error

Chapter 3. Using Language Environment debugging facilities

This chapter describes methods of debugging routines in Language Environment. Currently, most problems in Language Environment and member language routines can be determined through the use of a debugging tool or through information provided in the Language Environment dump.

Debug tools

Debug tools are designed to help you detect errors early in your routine. IBM offers Debug Tool, a comprehensive compile, edit, and debug product that is provided with the C/C++ for MVS/ESA, Enterprise COBOL for z/OS, COBOL for OS/390 & VM, COBOL for MVS & VM, PL/I for MVS & VM, Enterprise PL/I for z/OS, and VisualAge for Java compiler products. IBM Debug Tool for z/OS is also available as a standalone product for debugging XL C/C++ applications. For more information on Debug Tool, see http://www.ibm.com/software/awdtools/debugtool/..

You can use the IBM Debug Tool to examine, monitor, and control how your routines run, and debug your routines interactively or in batch mode. Debug Tool also provides facilities for setting breakpoints and altering the contents and values of variables. Language Environment run-time options can be used with Debug Tool to debug or analyze your routine. See the Debug Tool publications for a detailed explanation of how to invoke and run Debug Tool. For more information, see http://www.ibm.com/software/awdtools/debugtool/.

You can use IBM WebSphere® Developer Debugger for System z™ to get a workstation graphical interface to IBM Debug Tool for z/OS. For more information, see http://www-306.ibm.com/software/awdtools/debugtool/tools/wddsz/.

You can also use **dbx** to debug Language Environment applications, including C/C++ programs. *z/OS UNIX System Services Command Reference* has information on **dbx** subcommands, while *z/OS UNIX System Services Programming Tools* contains usage information.

Language Environment dump service, CEE3DMP

The following sections provide information about using the Language Environment dump service, and describe the contents of the Language Environment dump.

Below is a list of methods to invoke the Language Environment dump service:
- CEE3DMP callable service (non-64-bit only)
- TERMTHDACT run-time option
- HLL-specific functions

Generating a Language Environment dump with CEE3DMP

For non-64-bit, the CEE3DMP callable service generates a dump of the run-time environment for Language Environment and the member language libraries at the point of the CEE3DMP call. You can call CEE3DMP directly from an application routine.

Depending on the CEE3DMP options you specify, the dump can contain information about conditions, tracebacks, variables, control blocks, stack and heap storage, file status and attributes, and language-specific information.

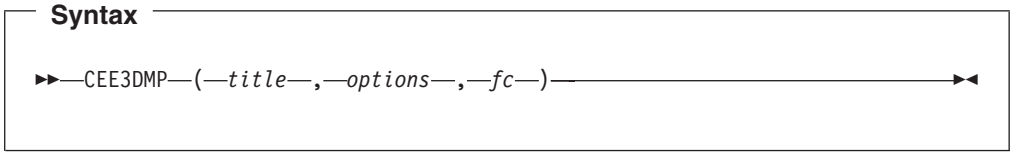
All output from CEE3DMP is written to the default ddname CEEDUMP. CEEDUMP, by default, sends the output to the SDSF output queue. You can direct the output from the CEEDUMP to a specific sysout class by using the environment variable, _CEE_DMPTARG=SYSOUT(x), where x is the output class.

Under z/OS UNIX, if the application is running in an address-space created as a result of a `fork()`, `spawn()`, `spawnp()`, `vfork()`, or one of the exec family of functions, then the CEEDUMP is placed in the HFS in one of the following directories in the specified order:

1. the directory found in environment variable *_CEE_DMPTARG*, if found
2. the current working directory, if this is not the root directory (/), the directory is writable, and the CEEDUMP pathname does not exceed 1024 characters.
3. the directory found in environment variable *TMPDIR* (an environment variable that indicates the location of a temporary directory if it is not /tmp)
4. the **/tmp** directory.

The syntax for CEE3DMP is:

Syntax



title
An 80-byte fixed-length character string that contains a title that is printed at the top of each page of the dump.

options
A 255-byte fixed-length character string that contains options describing the type, format, and destination of dump information. The options are declared as a string of keywords separated by blanks or commas. Some options also have suboptions that follow the option keyword, and are contained in parentheses. The last option declaration is honored if there is a conflict between it and any preceding options.

fc (output)
A 12-byte feedback token code that indicates the result of a call to CEE3DMP. If specified as an argument, feedback information, in the form of a condition token, is returned to the calling routine. If not specified, and the requested operation was not successfully completed, the condition is signaled to the condition manager.

Following is a list of CEE3DMP options and related information:

Table 4. CEE3DMP options

Dump Options	Abbreviation	Action Taken
ENCLAVE(ALL)	ENCL	Dumps all enclaves associated with the current process. (In ILC applications in which a C/C++ routine calls another member language routine, and that routine in turn calls CEE3DMP, traceback information for the C/C++ routine is not provided in the dump.) This is the default setting for ENCLAVE.

Table 4. CEE3DMP options (continued)

Dump Options	Abbreviation	Action Taken
ENCLAVE(CURRENT)	ENCL(CUR)	Dumps the current enclave.
ENCLAVE(n)	ENCL(n)	Dumps a fixed number of enclaves, indicated by *n*.
THREAD(ALL)	THR(ALL)	Dumps all threads in this enclave (including in a PL/I multitasking environment).
THREAD(CURRENT)	THR(CUR)	Dumps the current thread in this enclave.
TRACEBACK	TRACE	Includes a traceback of all active routines. The traceback shows transfer of control from either calls or exceptions. Calls include PL/I transfers of control from BEGIN-END blocks or ON-units.
NOTRACEBACK	NOTRACE	Does not include a traceback of all active routines.
FILES	FILE	Includes attributes of all open files. File control blocks are included when the BLOCKS option is also specified. File buffers are included when the STORAGE option is specified.
NOFILES	NOFILE	Does not include file attributes.
VARIABLES	VAR	Includes a symbolic dump of all variables, arguments, and registers.
NOVARIABLES	NOVAR	Does not include variables, arguments, and registers.
BLOCKS	BLOCK	Dumps control blocks from Language Environment and member language libraries. Global control blocks, as well as control blocks associated with routines on the call chain, are printed. Control blocks are printed for the routine that called CEE3DMP. The dump proceeds up the call chain for the number of routines specified by the STACKFRAME option (see below). Control blocks for files are also dumped if the FILES option was specified. See the FILES option above for more information. If the TRACE run-time option is set to ON, the trace table is dumped if BLOCKS is specified. If the Heap Storage Diagnostics report is requested via the HEAPCHK run-time option, the report is displayed when BLOCKS is specified.
NOBLOCKS	NOBLOCK	Does not include control blocks.
STORAGE	STOR	Dumps the storage used by the routine. The number of routines dumped is controlled by the STACKFRAME option.
NOSTORAGE	NOSTOR	Suppresses storage dumps.

Table 4. CEE3DMP options (continued)

Dump Options	Abbreviation	Action Taken
STACKFRAME(ALL)	SF(ALL)	Dumps all stack frames from the call chain. This is the default setting for STACKFRAME.
STACKFRAME(n)	SF(n)	Dumps a fixed number of stack frames, indicated by *n*, from the call chain. The specific information dumped for each stack frame depends on the VARIABLES, BLOCK, and STORAGE options declarations. The first stack frame dumped is the caller of CEE3DMP, followed by its caller, and proceeding backward up the call chain.
PAGESIZE(n)	PAGE(n)	Specifies the number of lines on each page of the dump.
FNAME(s)	FNAME(s)	Specifies the ddname of the file to which the dump is written.
CONDITION	COND	Dumps condition information for each condition active on the call chain.
NOCONDITION	NOCOND	For each condition active on the call chain, does not dump condition information.
ENTRY	ENT	Includes a description of the program unit that called CEE3DMP and the registers on entry to CEE3DMP.
NOENTRY	NOENT	Does not include a description of the program unit that called CEE3DMP or registers on entry to CEE3DMP.
GENOPTS	GENO	Generate a run-time options report in the dump output. This will be the default if an unhandled condition occurs, and a CEEDUMP is generated due to the setting of the TERMTHDACT run-time option setting.
NOGENOPTS	NOGENO	Do not generate a run-time options report in the dump output. NOGENOPTS is the default for user-called dumps.
REGSTOR(reg_stor_amount)	REGST(reg_ stor_amount)	Controls the amount of storage to be dumped around registers. Default is 96 bytes. Specify REGSTOR(0) if no storage around registers is required.
Note: On CICS, only ENCLAVE(CURRENT) and ENCLAVE(1) settings are supported.		

The IBM-supplied default settings for CEE3DMP are:

```
ENCLAVE(ALL) TRACEBACK
THREAD(CURRENT) FILES VARIABLES NOBLOCKS NOSTORAGE
STACKFRAME(ALL) PAGESIZE(60) FNAME(CEEDUMP)
CONDITION ENTRY NOGENOPTS REGSTOR(96)
```

For additional information about the CEE3DMP callable service and dump options, see *z/OS Language Environment Programming Reference*. For an example of a Language Environment dump, see “Understanding the Language Environment dump” on page 43.

Generating a Language Environment dump with TERMTHDACT

The TERMTHDACT run-time option produces a dump during program checks, abnormal terminations, or calls to the CEESGL service. You must use TERMTHDACT(DUMP) in conjunction with TRAP(ON) to generate a Language Environment dump.

You can use TERMTHDACT to produce a traceback, Language Environment dump, or user address space dump when a thread ends abnormally because of an unhandled condition of severity 2 or greater. If this is the last thread in the process, the enclave goes away. A thread terminating in a non-POSIX environment is analogous to an enclave terminating because Language Environment Version 1 supports only single threads. For information on enclave termination, see *z/OS Language Environment Programming Guide*.

The TERMTHDACT suboptions QUIET, MSG, TRACE, DUMP, UAONLY, UATRACE, UADUMP, and UAIMM control the level of information available. Following are the suboptions, the levels of information produced, and the destination of each.

Table 5. TERMTHDACT suboptions, level of information, and destinations

Suboption	Level of Information	Destination
QUIET	No information	No destination.
MSG	Message	Terminal or ddname specified in MSGFILE run-time option.
TRACE	Message and Language Environment dump containing only a traceback	Message goes to terminal or ddname specified in MSGFILE run-time option. Traceback goes to CEEDUMP file.
DUMP	Message and complete Language Environment dump	Message goes to terminal or ddname specified in MSGFILE run-time option. Language Environment dump goes to CEEDUMP file.
UAONLY	SYSMDUMP, SYSABEND dump, or SYSUDUMP depending on the DD card used in the JCL in z/OS. In CICS, a transaction dump is created. In non-CICS you will get a system dump of your user address space if the appropriate DD statement is used. **Note:** A Language Environment dump is not generated.	Language Environment generates a U4039 abend which allows a system dump of the user address space to be generated. For z/OS, the system dump is written to the ddname specified; for CICS the transaction dump goes to DFHDMPA or the DFHDMPB data set.
UATRACE	Message, Language Environment dump containing only a traceback, and a system dump of the user address space	Message goes to terminal or ddname specified in MSGFILE run-time option. Traceback goes to CEEDUMP file. Language Environment generates a U4039 abend which allows a system dump of the user address space to be generated. For z/OS, the system dump is written to the ddname specified; for CICS the transaction dump goes to DFHDMPA or the DFHDMPB data set.

Table 5. TERMTHDACT suboptions, level of information, and destinations (continued)

Suboption	Level of Information	Destination
UADUMP	Message, Language Environment dump, and SYSMDUMP, SYSABEND dump, or SYSUDUMP depending on the DD card used in the JCL in z/OS. In CICS, a transaction dump is created.	Message goes to terminal or ddname specified in MSGFILE run-time option. Language Environment dump goes to CEEDUMP file. Language Environment generates a U4039 abend which allows a system dump of the user address space to be generated. For z/OS, the system dump is written to the ddname specified; for CICS the transaction dump goes to DFHDMPA or the DFHDMPB data set.
UAIMM	Language Environment generates a system dump of the original abend/program interrupt of the user address space. In CICS, a transaction dump is created. In non-CICS you will get a system dump of your user address space if the appropriate DD statement is used. After the dump is taken by the operating system, Language Environment condition manager continues processing. **Note:** Under CICS, UAIMM yields UAONLY behavior. Under non-CICS, TRAP(ON,NOSPIE) must be in effect. When TRAP(ON,SPIE) is in effect, UAIMM yields UAONLY behavior. For software raised conditions or signals, UAIMM behaves the same as UAONLY.	Message goes to terminal or ddname specified in MSGFILE run-time option. User address space dump goes to ddname specified for z/OS; or a CICS transaction dump goes to the DFHDMPA or DFHDMPB data set.

The TRACE and UATRACE suboptions of TERMTHDACT use these dump options:

- CONDITION
- ENCLAVE(ALL)
- FILES
- FNAME(CEEDUMP)
- GENOPTS
- NOBLOCKS
- NOENTRY
- NOSTORAGE
- STACKFRAME(ALL)
- THREAD(ALL)
- TRACEBACK
- VARIABLES

The DUMP and UADUMP suboptions of TERMTHDACT use these dump options:

- BLOCKS
- CONDITION
- ENCLAVE(ALL)
- FILES
- FNAME(CEEDUMP)
- GENOPTS
- NOENTRY

- STACKFRAME(ALL)
- STORAGE
- THREAD(CURRENT)
- TRACEBACK
- VARIABLES

Although you can modify CEE3DMP options, you cannot change options for a traceback or dump produced by TERMTHDACT.

Considerations for setting TERMTHDACT options

The output of TERMTHDACT may vary depending upon which languages and subsystems are processing the request. This section describes the considerations associated with issuing the TERMTHDACT suboptions.

- COBOL Considerations
  - The following TERMTHDACT suboptions for COBOL are recommended, UAONLY, UATRACE, and UADUMP. A system dump will always be generated when one of these suboptions is specified.
- PL/I Considerations
  - After a normal return from a PL/I ERROR ON-unit, or from a PL/I FINISH ON-unit, Language Environment considers the condition unhandled. If a GOTO is not performed and the resume cursor is not moved, then the thread terminates. The TERMTHDACT setting guides the amount of information that is produced, so the message is not presented twice.
- PL/I MTF Considerations
  - TERMTHDACT applies to a task that terminates abnormally due to an unhandled condition of severity 2 or higher that is percolated beyond the initial routine's stack frame. All active subtasks that were created from the incurring task will terminate abnormally, but the enclave will continue to run.
- z/OS UNIX Considerations
  - The TERMTHDACT option applies when a thread terminates abnormally. Abnormal termination of a single thread causes termination of the entire enclave. If an unhandled condition of severity 2 or higher percolates beyond the first routine's stack frame the enclave terminates abnormally.
  - If an enclave terminates due to a POSIX default signal action, then TERMTHDACT applies to conditions that result from software signals, program checks, or abends.
  - If running under a shell and Language Environment generates a system dump, then a storage dump is generated to a file based on the kernel environment variable, _BPXK_MDUMP.
- CICS Considerations
  - TERMTHDACT output is written either to a transient data queue named CESE, or to the CICS transaction dump, depending on the setting of the CESE|CICSDDS suboption of the TERMTHDACT run-time option. Table 6 on page 42 shows the behavior of CESE|CICSDDS when they are used with the other suboptions of TERMTHDACT.
  - Since Language Environment does not own the ESTAE, the suboption UAIMM will be treated as UAONLY.
  - All associated Language Environment dumps will be suppressed if termination processing is the result of an EXEC CICS ABEND with NODUMP.

Table 6. Condition handling of 0Cx abends

Options	**TERMTHDACT(*X*,CESE,)**	**TERMTHDACT(*X*,CICSDDS,)**
QUIET	• No output.	• No output.
MSG	• Message written to CESE queue or MSGFILE.	• Message written to CESE queue or MSGFILE.
TRACE	• The traceback is written to the CESE queue, followed by U4038 abend with nodump option.	• Language Environment will write traceback, variables, COBOL working storage, C writeable static. The member handlers will be invoked to provide the desired output to the new transaction server queue (which CICS will read and write to CICS transaction dump later). • U4039 abend to force CICS transaction dump followed by U4038 abend with nodump option. • Message to CESE or MSGFILE.
DUMP	• CEEDUMP to CESE queue followed by U4038 abend with nodump option.	• CEEDUMP to new transaction server queue which CICS will read and write to CICS transaction dump later. • U4039 abend to force CICS transaction dump followed by U4038 abend with nodump option. • Message to CESE or MSGFILE.
UATRACE	• U4039 abend with traceback to CESE queue followed by U4038 abend with nodump option.	• Language Environment will write traceback, variables, COBOL working storage, C writeable statics. The member handlers will be invoked to provide the desired output to the new transaction server queue (which CICS will read and write to CICS transaction dump later). • U4039 abend to force CICS transaction dump followed by U4038 abend with nodump option. • Message to CESE or MSGFILE.
UADUMP	• U4039 abend with CEEDUMP to CESE queue followed by U4038 abend with nodump option.	• CEEDUMP to new transaction server queue which CICS will read and write to CICS transaction dump later. • U4039 abend to force CICS transaction dump followed by U4038 abend with nodump option. • Message to CESE or MSGFILE.
UAONLY	• U4039 abend followed by U4038 abend with nodump option.	• U4039 abend followed by U4038 abend with nodump option. • No CEEDUMP information is generated. • Same as CESE.
UAIMM	• U4039 abend followed by U4038 abend with nodump option.	• U4039 abend followed by U4038 abend with nodump option. • No CEEDUMP information is generated. • Same as CESE.

Note: Program checks and other abends will cause CICS to produce a CICS transaction dump.

For more information about the TERMTHDACT run-time option, see *z/OS Language Environment Programming Reference*.

Generating a Language Environment dump with language-specific functions

In addition to the CEE3DMP callable service and the TERMTHDACT run-time option, you can use language-specific routines such as C functions, the Fortran SDUMP service, and the PL/I PLIDUMP service to generate a dump.

C/C++ routines can use the functions `cdump()`, `csnap()`, and `ctrace()` to produce a Language Environment dump. All three functions call the CEE3DMP callable service, and each function includes an options string consisting of different CEE3DMP options that you can use to control the information contained in the dump. For more information on these functions, see “Generating a Language Environment dump of a C/C++ routine” on page 155.

Fortran programs can call SDUMP, DUMP/PDUMP, or CDUMP/CPDUMP to generate a Language Environment dump. CEE3DMP cannot be called directly from a Fortran program. For more information on these functions, see “Generating a Language Environment dump of a Fortran routine” on page 235.

PL/I routines can call PLIDUMP instead of CEE3DMP to produce a dump. PLIDUMP includes options that you can specify to obtain a variety of information in the dump. For a detailed explanation about PLIDUMP, see “Generating a Language Environment dump of a PL/I for MVS & VM routine” on page 259.

Understanding the Language Environment dump

The Language Environment dump service generates output of data and storage from the Language Environment run-time environment on an enclave basis. This output contains the information needed to debug most basic routine errors.

Figure 7 on page 48 illustrates a dump for enclave main. The example assumes full use of the CEE3DMP dump options. Ellipses are used to summarize some sections of the dump and information regarding unhandled conditions may not be present at all. Sections of the dump are numbered to correspond with the descriptions given in “Sections of the Language Environment dump” on page 56.

The CEE3DMP was generated by the C program CELSAMP shown in Figure 5 on page 44. CELSAMP uses the DLL CELDLL shown in Figure 6 on page 47.

[20]CEE3846I CEEDUMP Processing completed.
```

Figure 7. Example dump using CEE3DMP (Part 9 of 9)

Sections of the Language Environment dump

The sections of the dump listed here appear independently of the Language Environment-conforming languages used. Each conforming language adds language-specific storage and file information to the dump.

For a detailed explanation of language-specific dump output:

- For C/C++ routines, see “Finding C/C++ information in a Language Environment dump” on page 166.
- For COBOL routines, see “Finding COBOL information in a dump” on page 215.
- For Fortran routines, see “Finding Fortran information in a Language Environment dump” on page 241.
- For PL/I routines, see “Finding PL/I for MVS & VM information in a dump” on page 261.

[1] Page Heading

The page heading section appears on the top of each page of the dump and contains:

- CEE3DMP identifier
- Title

  For dumps generated as a result of an unhandled condition, the title is “Condition processing resulted in the Unhandled condition.”
- Product abbreviation of Language Environment
- Version number
- Release number
- Date
- Time
- Page number

The contents of the second line of the page heading vary depending on the environment in which the CEEDUMP is issued.

For CEEDUMPs produced under a batch environment, the following items are displayed:

- ASID: Describes the address space ID.
- Job ID: Describes the JES Job ID.
- Job name: Describes the job name.
- Step name: Describes the job's step name in which the CEEDUMP was produced.
- UserID: Describes the TSO userid who issued the job.

For jobs running with POSIX(ON), the following additional items are displayed:

- PID: Displays the associated process ID.
- Parent PID: Displays the associated parent PID.

For CEEDUMPs produced under the z/OS UNIX shell, the following items are displayed:

- ASID: Describes the address space ID.
- PID: Displays the associated process ID.
- Parent PID: Displays the associated parent PID.
- User name: Contains the userid associated to the CEEDUMP.

For CEEDUMPs produced under CICS, the following items are displayed:

- Transaction ID and task number.

[2] CEE3845I CEEDUMP Processing started.

Message CEE3845I identifies the start of the Language Environment dump processing. Similarly, message CEE3846I identifies the end of the dump processing, Message number CEE3845I can be used to locate the start of the next CEEDUMP report when scanning forward in a data set that contains several CEEDUMP reports.

[3] Caller Program Unit and Offset

This information identifies the routine name and offset in the calling routine of the call to the dump service.

[4] Registers on Entry to CEE3DMP

This section of the dump shows data at the time of the call to the dump service.

- Program mask

  The program mask contains the bits for the fixed-point overflow mask, decimal overflow mask, exponent underflow mask, and significance mask.

- General purpose registers (GPRs) 0–15

  On entry to CEE3DMP, the GPRs contain:

GPR 0	Working register
GPR 1	Pointer to the argument list
GPR 2–11	Working registers
GPR 12	Address of CAA
GPR 13	Pointer to caller's stack frame
GPR 14	Address of next instruction to run if the ALL31 run-time option is set to ON
GPR 15	Entry point of CEE3DMP

- Floating point registers (FPRs) 0 through 15

- Storage pointed to by General Purpose Registers

  Treating the contents of each register as an address, 32 bytes before and 64 bytes after the address are shown.

[5] - [17] Enclave Information

These sections show information that is specific to an enclave. When multiple enclaves are dumped, these sections will appear for each enclave.

[5] Enclave Identifier

This statement names the enclave for which information in the dump is provided. If multiple enclaves exist, the dump service generates data and storage information for the most current enclave, followed by previous enclaves in a last-in-first-out (LIFO) order. For more information about dumps for multiple enclaves, see “Multiple enclave dumps” on page 78.

[6] - [12] Thread Information

These sections show information that is specific to a thread. When multiple threads are dumped, these sections will appear for each thread.

[6] Information for thread

This section shows the system identifier for the thread. Each thread has a unique identifier.

[7] Traceback

In a multithread case, the traceback reflects only the current thread. For all active routines, the traceback section shows routine information in three parts. The first part contains:

- DSA number

  A number assigned to the information for this active routine by dump processing. The number is used to associate information from the first part of the traceback with information in the second and third parts of the traceback.
- Entry

  For COBOL, Fortran, PL/I, and Enterprise PL/I for z/OS routines, this is the entry point name. For C/C++ routines, this is the function name. If a function name or entry point was not specified for a particular routine, the string ’** NoName **’ will appear.
- Entry point offset
- Statement number

  Refers to the line number in the source code (program unit) in which a call was made or an exception took place (see Status column). The statement number appears only if your routine was compiled with the options required to generate statement numbers.
- Load module

  The load module name displayed can be a partitioned data set member or an UNIX executable file. The load module name is also displayed in the third part of the traceback.
- Program unit

For COBOL programs, program unit is the PROGRAM-ID name. For C, Fortran, and PL/I routines, program unit is the compile unit name. For Language Environment-conforming assemblers, program unit is either the EPNAME = value on the CEEPPA macro, or a fully qualified path name.

If the program unit name is available to Language Environment (for example, for C/C++, the routine was compiled with TEST(SYM)), the program unit name will appear under this column, according to the following rules:

- If your compiled routine is in a partitioned data set, only the member will be output.
- If your compiled routine is in a sequential data set, only the last qualifier will be shown.
- If your compiled routine is in an UNIX filename, only what fits of the filename will be displayed in a line.

- Service level

  The latest service level applied to the compile unit (for example, for IBM products, it would be the PTF number).
- Status

  Routine status can be 'call' or 'exception'.

The second part contains:

- DSA number

  A number assigned to the information for this active routine by dump processing. The number is used to associate information from the first part of the traceback with information in the second and third parts of the traceback.
- Stack frame (DSA) address
- Entry point address
- Program unit address
- Program unit offset

  The offset of the last instruction to run in the routine. If the offset is a negative number, zero, or a very large positive number, the routine associated with the offset probably did not allocate a save area or could have been called using SVC-assisted linkage. Adding the program unit address to the offset gives the location of the current instruction in the routine. This offset is from the starting address of the routine.
- Compile Date

  Contains the year, month and day in which the routine was compiled.
- Attributes

  The available compilation attributes of the compile unit including:

  - A label identifying the LE-supported language such as COBOL, ENT PL/I, C/C++, and so on.
  - Compilation attributes such as EBCDIC, ASCII, IEEE or hexadecimal floating point (HFP). The compilation attributes will only be displayed if there is enough information available.
  - If the CEEDUMP was created under a POSIX environment, POSIX will be displayed.

The third part of the traceback, which is also referred to as 'Fully Qualified Names' section, contains the following:

- DSA number
- Entry
- Program unit

Similar to the Program Unit column in part 1 except that the server name and the complete program unit (PU) name will be displayed. A PU name will appear here only if it is available to Language Environment.

- Load Module

  The complete pathname of a load module name residing in an UNIX filename will be displayed here if available. The load module's full pathname will be displayed if the PATH environment variable is set such that the pathname of the load module's directory appears before the current directory (.). For load modules found in data sets, the same output shown in the traceback part 1 will also be displayed here.

[8] Condition Information for Active Routines

This section displays the following information for all conditions currently active on the call chain:

- Statement showing failing routine and stack frame address of routine
- Condition information block (CIB) address
- Current condition, in the form of a Language Environment message for the condition raised or a Language Environment abend code, if the condition was caused by an abend
- Location

  For the failing routine, this is the program unit, entry routine, statement number, and offset.
- Machine state, which shows:
  - Instruction length counter (ILC)
  - Interruption code
  - *Program status word (PSW)*
  - Contents of GPRs 0–15
  - Storage dump near condition (2 hex-bytes of storage near the PSW)
  - Storage pointed to by General Purpose Registers

  These values are the current values at the time the condition was raised.

[9] Parameters, Registers, and Variables for Active Routines

For each active routine, this section shows:

- Routine name and stack frame address
- Arguments

  For C/C++ and Fortran, arguments are shown here rather than with the local variables. For COBOL, arguments are shown as part of local variables. PL/I arguments are not displayed in the Language Environment dump.
- Saved registers

  This lists the contents of GPRs 0–15 at the time the routine transferred control.
- Storage pointed to by the saved registers

  Treating the saved contents of each register as an address, 32 bytes before and 64 bytes after the address shown.
- Local variables

  This section displays the local variables and arguments for the routine. This section also shows the variable type. Variables are displayed only if the symbol tables are available. To generate a symbol table and display variables, use the following compile options:
  - For C, use TEST(SYM).

- For C++, use TEST.
- For VS COBOL II, use FDUMP.
- For COBOL/370, use TEST(SYM).
- For COBOL for OS/390 & VM, use TEST(SYM).
- For Enterprise COBOL for z/OS, use TEST(SYM)
- For Fortran, use SDUMP.
- For PL/I, arguments and variables are not displayed.

[10] Control Blocks for Active Routines

For each active routine controlled by the STACKFRAME option, this section lists contents of related control blocks. The Language Environment-conforming language determines which language-specific control blocks appear. The possible control blocks are:

- Stack frame
- Condition information block
- Language-specific control blocks

[11] Storage for Active Routines

This displays local storage for each active routine. The storage is dumped in hexadecimal, with EBCDIC translations on the right side of the page. There can be other information, depending on the language used. For C/C++ routines, this is the stack frame storage. For COBOL programs, this is language-specific information, WORKING-STORAGE, and LOCAL-STORAGE.

[12] Control Blocks Associated with the Thread

This section lists the contents of the Language Environment common anchor area (CAA), thread synchronization queue element (SQEL), DLL failure data, and dummy stack frame. Other language-specific control blocks can appear in this section. DLL failure data is described in “Using the DLL failure control block” on page 78.

[13] Enclave variables:

This section displays language specific global variables. This section also shows the variable type. Variables are displayed only if the symbol tables are available.

[14] Enclave Control Blocks

This section lists the contents of the Language Environment enclave data block (EDB) and enclave member list (MEML). The information presented may vary depending on which run-time options are set.

- If the POSIX run-time option is set to ON, this section lists the contents of the mutex and condition variable control blocks, the enclave level latch table, and the thread synchronization trace block and trace table.
- If DLLs have been loaded, this section shows information for each DLL including the DLL name, load address, use count, writeable static area (WSA) address, and the thread id of the thread that loaded the DLL.
- If the HEAPCHK run-time option is set to ON, this section shows the contents of the HEAPCHK options control block (HCOP) and the HEAPCHK element tables (HCEL). A HEAPCHK element table contains the location and length of all allocated storage elements for a heap in the order that they were allocated.

- When the *call-level* suboption of the HEAPHCK run-time option is set, any unfreed storage, which would indicate a storage leak, would be displayed in this area. The traceback could then be used to identify the program which did not free the storage.
- If the TRACE run-time option is set to ON, this section shows the contents of the Language Environment trace table.

Other language-specific control blocks can appear in this section.

[15] Enclave Storage

This section shows the Language Environment heap storage. For C/C++ and PL/I routines, heap storage is the dynamically allocated storage. For COBOL programs, it is the storage used for WORKING-STORAGE data items. This section also shows the writeable static area (WSA) storage for program objects. Other language-specific storage can appear in this section.

[17] Run-Time Options Report

This section lists the Language Environment run-time options in effect when the routine was executed.

[18] Process Control Blocks

This section lists the contents for the Language Environment process control block (PCB), process member list (MEML), and if the POSIX run-time option is set to ON, the process level latch table. Other language-specific control blocks can appear in this section.

[19] Additional Language Specific Information:

This section displays any additional information not included in other sections. For C/C++, it shows the thread id of the thread that generated the dump and the settings of the errno and errnojr variables for that thread.

[20] CEE3846I CEEDUMP Processing completed.

Message CEE3846I identifies the end of the Language Environment dump processing. Similarly, message CEE3845I identifies the start of the dump processing, Message number CEE3846I can be used to locate the end of the previous CEEDUMP report when scanning backward in a data set that contains several CEEDUMP reports.

Debugging with specific sections of the Language Environment dump

The following sections describe how you can use particular blocks of the dump to help you debug errors.

The tracebacks, condition information, and data values section

The CEE3DMP call with dump options TRACEBACK, CONDITION, and VARIABLES generates output that contains a traceback, information about any conditions, and a list of arguments, registers, and variables.

The traceback, condition, and variable information provided in the Language Environment dump can help you determine the location and context of the error without any additional information. The traceback section includes a sequential list for all active routines and the routine name, statement number, and offset where the

exception occurred. The condition information section displays a message describing the condition and the address of the condition information block. The arguments, registers, and variables section shows the values of your arrays, structures, arguments, and data during the sequence of calls in your application. Static data values do not appear. Single quotes indicate character fields.

These sections of the dump are shown in Figure 7 on page 48.

The upward-growing (non-XPLINK) stack frame section

The stack frame, also called dynamic save area (DSA), for each active routine is listed in the full dump.

A stack frame chain is associated with each thread in the run-time environment and is acquired every time a separately compiled procedure or block is entered. A stack frame is also allocated for each call to a Language Environment service. All stack frames are back-chained with a stopping stack frame (also called a dummy DSA) as the first stack frame on the stack. Register 13 addresses the recently active stack frame or a standard register save area (RSA). The standard save area back chain must be initialized, and it holds the address of the previous save area. Not all Language Environment-conforming compilers set the forward chain; thus, it cannot be guaranteed in all instances. Calling routines establish the member-defined fields.

When a routine makes a call, registers 0–15 contain the following values:

- R1 is a pointer to parameter list or 0 if no parameter list passed.
- R0, R2–R11 is unreferenced by Language Environment. Caller's values are passed transparently.
- R12 is the pointer to the CAA if entry to an external routine.
- R13 is the pointer to caller's stack frame.
- R14 is the return address.
- R15 is the address of the called entry point.

With an optimization level other than 0, C/C++ routines save only the registers used during the running of the current routine. Non-Language Environment RSAs can be in the save area chain. The length of the save area and the saved register contents do not always conform to Language Environment conventions. For a detailed description of stack frames Language Environment storage management, see *z/OS Language Environment Programming Guide*. Figure 8 on page 64 shows the format of the upward-growing stack frame.

Note: The *Member-defined* fields are reserved for the specific higher level language.

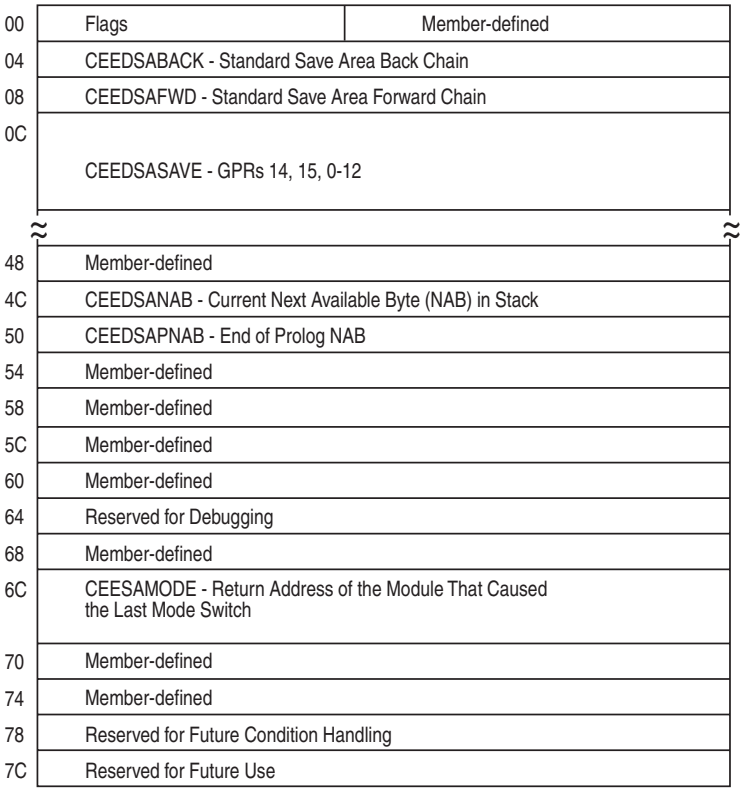

Figure 8. Upward-growing (non-XPLINK) stack frame format

The downward-growing (XPLINK) stack frame section

Figure 9 on page 65 shows the format of the downward-growing stack frame.

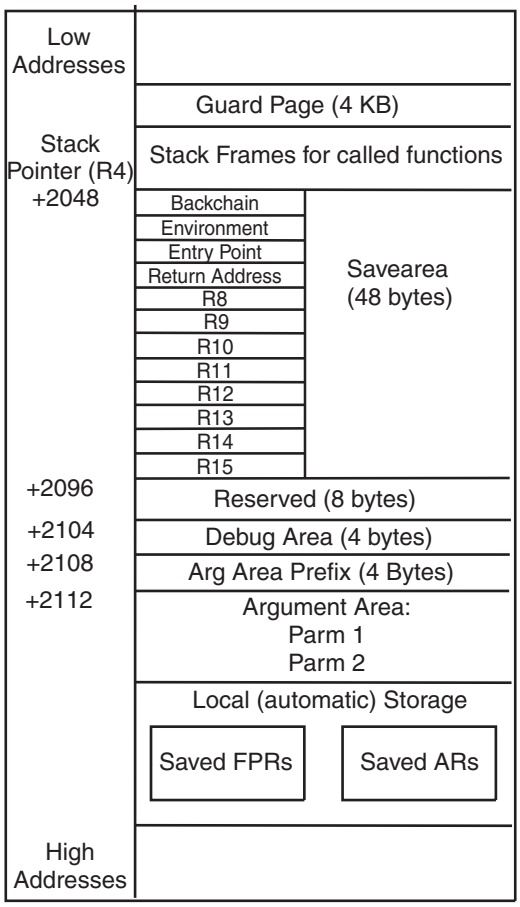

Figure 9. Downward-growing (XPLINK) stack frame format

For detailed information about the downward-growing stack, register conventions and parameter passing conventions, see *z/OS Language Environment Programming Guide*.

The Common Anchor Area

Each thread is represented by a common anchor area (CAA), which is the central communication area for Language Environment. All thread- and enclave-related resources are anchored, provided for, or can be obtained through the CAA. The CAA is generated during thread initialization and deleted during thread termination. When calling Language Environment-conforming routines, register 12 points to the address of the CAA.

Use CAA fields as described. Do not modify fields and do not use routine addresses as entry points, except as specified. Fields marked ‘Reserved’ exist for migration of specific languages, or internal use by Language Environment. Language Environment defines their location in the CAA, but not their use. Do not use or reference them except as specified by the language that defines them.

Figure 10 on page 66 shows the format of the Language Environment CAA.

-18	CEECAAEYE	CL8'CEECAA '		
-0C - -01	Reserved

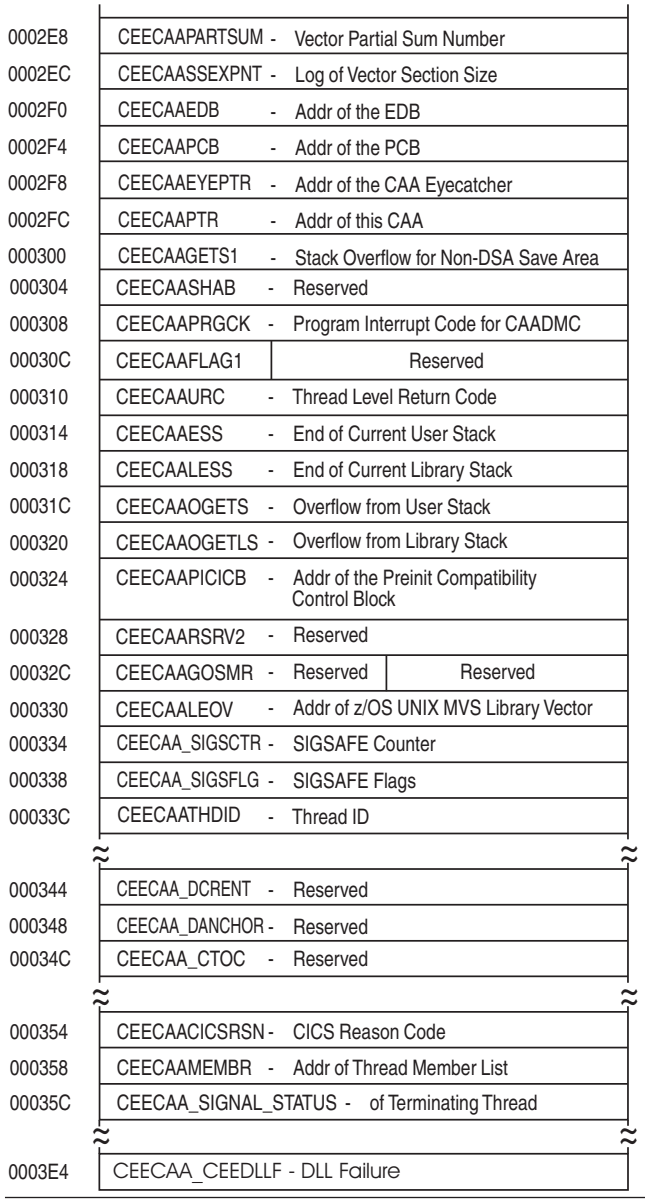

Figure 10. Common anchor area (Part 2 of 2)

Table 7 contains a list of CAA fields:

Table 7. List of CAA fields

CAA Field	Explanation
CEECAA_CEEDLLF	Address of the newest CEEDLLF control block.

Table 7. List of CAA fields (continued)

CAA Field	Explanation
CEECAAFLAG0	CAA flag bits. The bits are defined as follows: **Bit** **Description** **0–5** Reserved **6** CEECAAXHDL. A flag used by the condition handler. If the flag is set to 1, the application requires immediate return/percolation to the system on any interrupt or condition handler event. **7** Reserved
CEECAALANGP	PL/I language compatibility flags external to Language Environment. The bits are defined as follows: **Bit** **Description** **0–3** Reserved **4** CEECAATHFN. A flag set by PL/I to indicate a PL/I FINISH ON-unit is active. If the flag is set to 1, no PL/I FINISH ON-unit is active. If the flag is set to 0, a PL/I FINISH ON-unit could be active. **5–7** Reserved
CEECAABOS	Start of the current storage segment. This field is initially set during thread initialization. It indicates the start of the current stack storage segment. It is altered when the current stack storage segment is changed.
CEECAAEOS	This field is used to determine if a stack overflow routine must be called when allocating storage from the user stack. Normally, the value of this field will represent the end of the current user stack segment. However, its value can also be zero to force the call of a stack overflow routine for every allocation of storage from the user stack. This field is used by function prologs that do not use FASTLINK linkage conventions.
CEECAATORC	Thread level return code. The thread level return code set by CEESRC callable service.
CEECAATOVF	Address of stack overflow routine.
CEECAAATTN	Address of the Language Environment attention handling routine. The address of the Language Environment attention handling routine supports common run-time environment's polling code convention for attention processing.
CEECAAHLLEXIT	Address of the Exit List Control Block set by the HLL user exit CEEBINT.
CEECAAHOOKS	Hook area. This is the start of 18 fullword execute hooks. Language Environment initializes each fullword to X'07000000'. The hooks can be altered to support various debugging hook mechanisms.

Table 7. List of CAA fields (continued)

CAA Field	Explanation
CEECAASYSTM	Underlying operating system. The value indicates the operating system supporting the active environment. **Value** **Operating System** **0** Undefined. This value should not appear after Language Environment is initialized. **1** Unsupported **3** z/OS
CEECAAHRDWR	Underlying hardware. This value indicates the type of hardware on which the routine is running. **Value** **Hardware** **0** Undefined. This value should not appear after Language Environment is initialized. **1** Unsupported **2** System/370™, non-XA **3** System/370, XA **4** System/370, ESA
CEECAASBSYS	Underlying subsystem. This value indicates the subsystem (if any) on which the routine is running. **Value** **Subsystem** **0** Undefined. This value should not occur after Language Environment is initialized. **1** Unsupported **2** None. The routine is not running under a Language Environment-recognized subsystem. **3** TSO **4** IMS™ **5** CICS
CEECAAFLAG2	CAA Flag 2. **Bit** **Description** **0** Bimodal addressing is available. **1** Vector hardware is available. **2** Thread terminating. **3** Initial thread **4** Library trace is active. The TRACE run-time option was set. **5** Reserved **6** CEECAA_ENQ_Wait_Interruptible. Thread is in an enqueue wait. **7** Reserved

Table 7. List of CAA fields (continued)

CAA Field	Explanation
CEECAALEVEL	Language Environment level identifier. This contains a unique value that identifies each release of Language Environment. This number is incremented for each new release of Language Environment.
CEECAA_PM	Image of current program mask.
CEECAAGETLS	Address of stack overflow for library routines.
CEECAACELV	Address of the Language Environment library vector. This field is used to locate dynamically loaded Language Environment routines.
CEECAAGETS	Address of the Language Environment prolog stack overflow routine. The address of the Language Environment get stack storage routine is included in prolog code for fast reference.
CEECAALBOS	Start of the library stack storage segment. This field is initially set during thread initialization. It indicates the start of the library stack storage segment. It is altered when the library stack storage segment is changed.
CEECAALEOS	This field is used to determine if a stack overflow routine must be called when allocating storage from the library stack. Normally, the value of this field will represent the end of the current library stack segment. However, its value can also be zero to force the call of a stack overflow routine for every allocation of storage from the library stack. This field is used by function prologs that do not use FASTLINK linkage conventions.
CEECAALNAB	Next available library stack storage byte. This contains the address of the next available byte of storage on the library stack. It is modified when library stack storage is obtained or released.
CEECAADMC	Language Environment shunt routine address. Its value is initially set to 0 during thread initialization. If it is nonzero, this is the address of a routine used in specialized exception processing.
CEECAAACD	Most recent CAASHAB abend code.
CEEAAABCODE	Most recent abend completion code.
CEECAAARS	Most recent CAASHAB reason code.
CEECAAARSNCODE	Most recent abend reason code.
CEECAAERR	Address of the current condition information block. After completion of initialization, this always points to a condition information block. During exception processing, the current condition information block contains information about the current exception being processed. Otherwise, it indicates no exception being processed.
CEECAAGETSX	Address of the user stack extender routine. This routine is called to extend the current stack frame in the user stack. Its address is in the CEECAA for performance reasons.
CEECAADDSA	Address of the Language Environment dummy DSA. This address determines whether a stack frame is the dummy DSA, also known as the zeroth DSA.

Table 7. List of CAA fields (continued)

CAA Field	Explanation
CEECAASECTSIZ	Vector section size. This field is used by the vector math services.
CEECAAPARTSUM	Vector partial sum number. This field is used by the vector math services.
CEECAASSEXPNT	Log of the vector section size. This field is used by the vector math services.
CEECAAEDB	Address of the Language Environment EDB. This field points to the encompassing EDB.
CEECAAPCB	Address of the Language Environment PCB. This field points to the encompassing PCB.
CEECAAEYEPTR	Address of the CAA eye catcher. The CAA eye catcher is CEECAA. This field can be used for validation of the CAA.
CEECAAPTR	Address of the CAA. This field points to the CAA itself and can be used in validation of the CAA.
CEECAAGETS1	Non-DSA stack overflow. This field is the address of a stack overflow routine, which cannot guarantee that the current register 13 is pointing at a stack frame. Register 13 must point, at a minimum, to a save area.
CEECAASHAB	ABEND shunt routine. Its value is initially set to zero during thread initialization. If it is nonzero, this is the address of a routine used in specialized exception processing for ABENDs that are intercepted in the ESTAE exit.
CEECAAPRGCK	Routine interrupt code for CEECAADMC. If CEECAADMC is nonzero, and a routine interrupt occurs, this field is set to the routine interrupt code and control is passed to the address in CEECAAMDC.
CEECAAFLAG1	CAA flag bits. The bits are defined as follows: **Bit** — **Description** **0** — CEECAASORT. A call to DFSORT™ is active. **1** — CEECAA_USE_OLD_STK. Use the old stack. **2–7** — Reserved
CEECAAURC	Thread level return code. This is the common place for members to set the return codes for subroutine-to-subroutine return code processing.
CEECAAESS	This field is used to determine if a stack overflow routine must be called when allocating storage from the user stack. Normally, the value of this field will represent the end of the current user stack segment. However, its value can also be zero to force the call of a stack overflow routine for every allocation of storage from the user stack. This field is used by function prologs that use FASTLINK linkage conventions.

Table 7. List of CAA fields (continued)

CAA Field	Explanation
CEECAALESS	This field is used to determine if a stack overflow routine must be called when allocating storage from the library stack. Normally, the value of this field will represent the end of the current library stack segment. However, its value can also be zero to force the call of a stack overflow routine for every allocation of storage from the library stack. This field is used by function prologs that use FASTLINK linkage conventions.
CEECAAOGETS	Overflow from user stack allocations.
CEECAAOGETLS	Overflow from library stack allocations.
CEECAARSRV1	Reserved.
CEECAAPICICB	Address of the preinitialization compatibility control block.
CEECAAOGETSX	User DSA exit from OPLINK.
CEECAARSRV2	Reserved.
CEECAAGOSMR	Go some more—Used CEEHTRAV multiple.
CEECAALEOV	This field is the address of the Language Environment library vector for z/OS UNIX support.
CEECAA_SIGSCTR	SIGSAFE counter.

Table 7. List of CAA fields (continued)

CAA Field	Explanation	
CEECAA_SIGSFLG	SIGSAFE flags. SIGSAFE flags indicate the signal safety of the library.	
	Bit	**Description**
	0	CEECAA_SIGPUTBACK. The signal cannot be delivered, therefore the signal is put back to the kernel.
	1	CEECAA_SA_RESTART. Indicates that a signal registered with the SA_RESTART flag interrupted the last kernel call, and the signal catcher returned.
	2	Reserved
	3	CEECAA_SIGSAFE. It is safe to deliver the signal, while in library code.
	4	CEECAA_CANCELSAFE. It is safe to deliver the cancel signal, while in library code.
	5	CEECAA_SIGRESYNCH. CEECAA_sigputsynch flag was on last time CEEOSIGR resolicited a signal.
	6	CEECAA_FRZ_UNSAFE. This thread is in an unsafe state to be frozen.
	7	CEECAA_NOAPPREGS. User application registers may be saved in a nonstandard place.
	8	CEECAA_EINTR_RSOL. Secondary Signal resolicitation is in progress, after EINTR errno from inner function.
	9	CEECAA_EINTR_PUTB. Secondary resolicited signal has been put back.
	10	CEECAA_EINTR_REST. User signal catcher returned after catching secondary resolicited signal with SA_RESTART in effect.
	11	CEECAA_EINTR_SIGG. Stray signal interrupted CEEOSIGG while secondary signal resolicitation was in progress.
CEECAATHDID	Thread id. This field is the thread identifier.	
CEECAA_DCRENT	DCE's read/write static external anchor.	
CEECAA_DANCHOR	DCE's per-thread anchor.	
CEECAA_CTOC	TOC anchor for CRENT.	
CEECAACICSRSN	CICS reason code from member language.	
CEECAAMEMBR	Address of thread-level member list.	
CEECAA_SIGNAL_STATUS	Signal status of the terminating thread member list.	

For information about the DLL failure control block, CEEDLLF, see *z/OS Language Environment Vendor Interfaces*.

The condition information block

The Language Environment condition manager creates a condition information block (CIB) for each condition encountered in the Language Environment environment. The CIB holds data required by the condition handling facilities and pointers to locations of other data. The address of the current CIB is located in the CAA.

For COBOL, Fortran, and PL/I applications, Language Environment provides macros (in the SCEESAMP data set) that map the CIB. For C/C++ applications, the macros are in `leawi.h`.

Figure 11 on page 75 shows the condition information block.

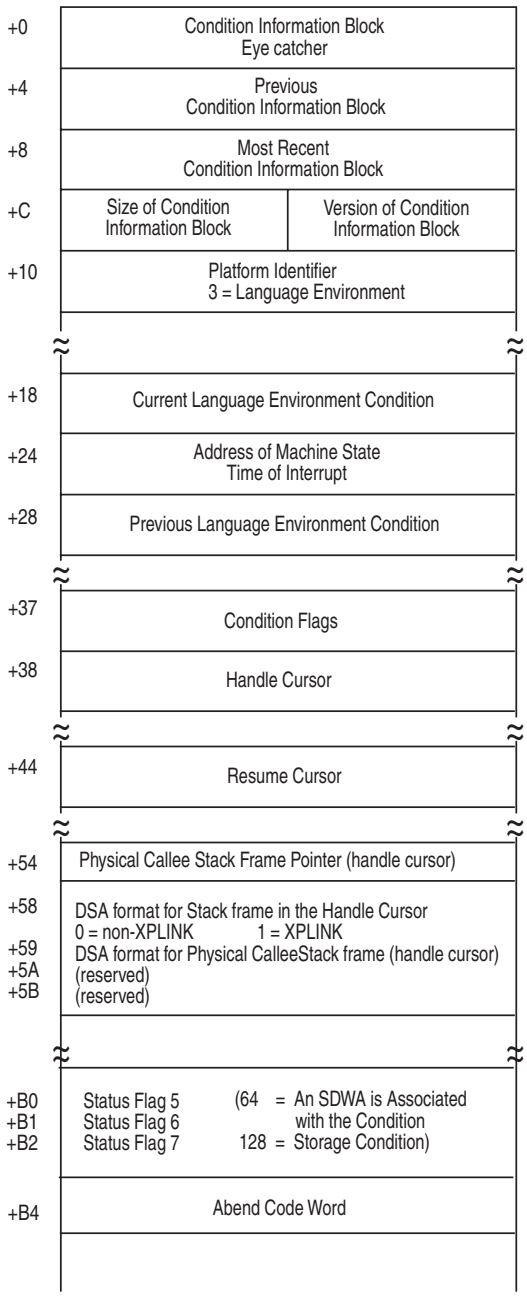

Figure 11. Condition information block (Part 1 of 2)

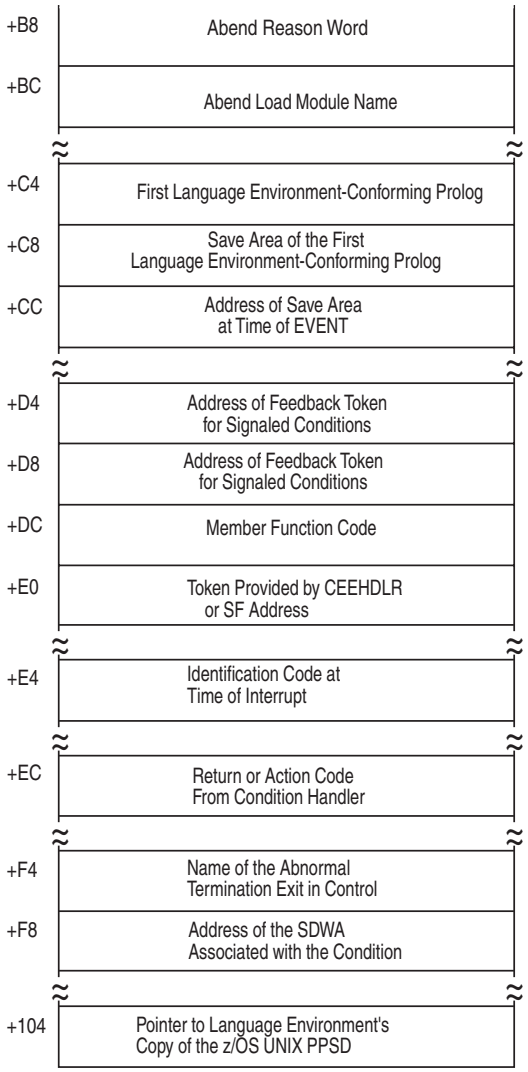

Figure 11. Condition information block (Part 2 of 2)

The flags for Condition Flag 4:

2 The resume cursor has been moved
4 Message service has processed the condition
8 The resume cursor has been moved explicitly

The flags for Status Flag 5, Language Environment events:

1 Caused by an attention interrupt
2 Caused by a signaled condition
4 Caused by a promoted condition
8 Caused by a condition management raised TIU
32 Caused by a condition signaled via CEEOKILL [1]
64 Caused by a program check
128 Caused by an abend

The flags for Status Flag 6, Language Environment actions:

1. The signaled-via-CEEOKILL flag is always set with the signaled flag; thus, a signaled condition can have a value of either 2 or 34. (The value is 2 if the signaled condition does not come through CEEOKILL. If it comes through CEEOKILL, its value is 2+32=34.)

2 Doing stack frame zero scan
4 H-cursor pointing to owning SF
8 Enable only pass (no condition pass)
16 MRC type 1
32 Resume allowed
64 Math service condition
128 Abend reason code valid

The language-specific function codes for the CIB:
X'1' For condition procedure
X'2' For enablement
X'3' For stack frame zero conditions

Using the machine state information block

The Language Environment machine state information block contains condition information pertaining to the hardware state at the time of the error. Figure 12 shows the machine state information block.

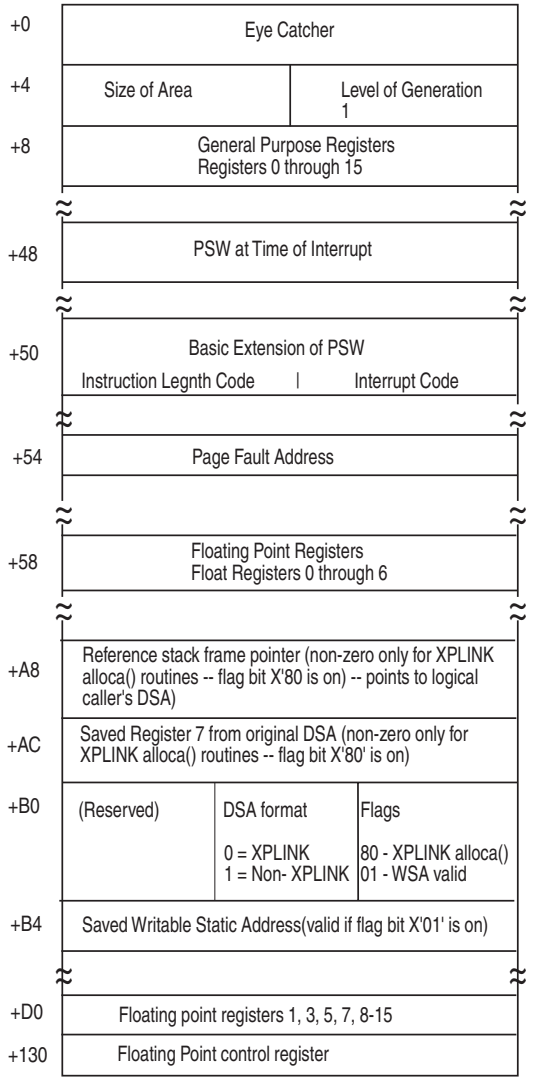

Figure 12. Machine state information block

Using the DLL failure control block

The CEEDLLF control block contains error diagnostics corresponding to an implicit or explicit DLL failure. Diagnostics describing up to 10 of the most recent DLL failures are available in a circular list of CEEDLLF control blocks. When viewing a dump, the in-use CEEDLLF control blocks are displayed from newest to oldest.

See *z/OS Language Environment Vendor Interfaces* for the contents of CEEDLLF fields.

Multiple enclave dumps

If multiple enclaves are used, the dump service generates data and storage information for the most current enclave and moves up the chain of enclaves to the starting enclave in a LIFO order. For example, if two enclaves are used, the dump service first generates output for the most current enclave. Then the service creates output for the previous enclave. A thread terminating in a non-POSIX environment is analogous to an enclave terminating because Language Environment Version 1 supports only single threads.

Figure 13 on page 79 illustrates the information available in the Language Environment dump and the order of information for multiple enclaves.

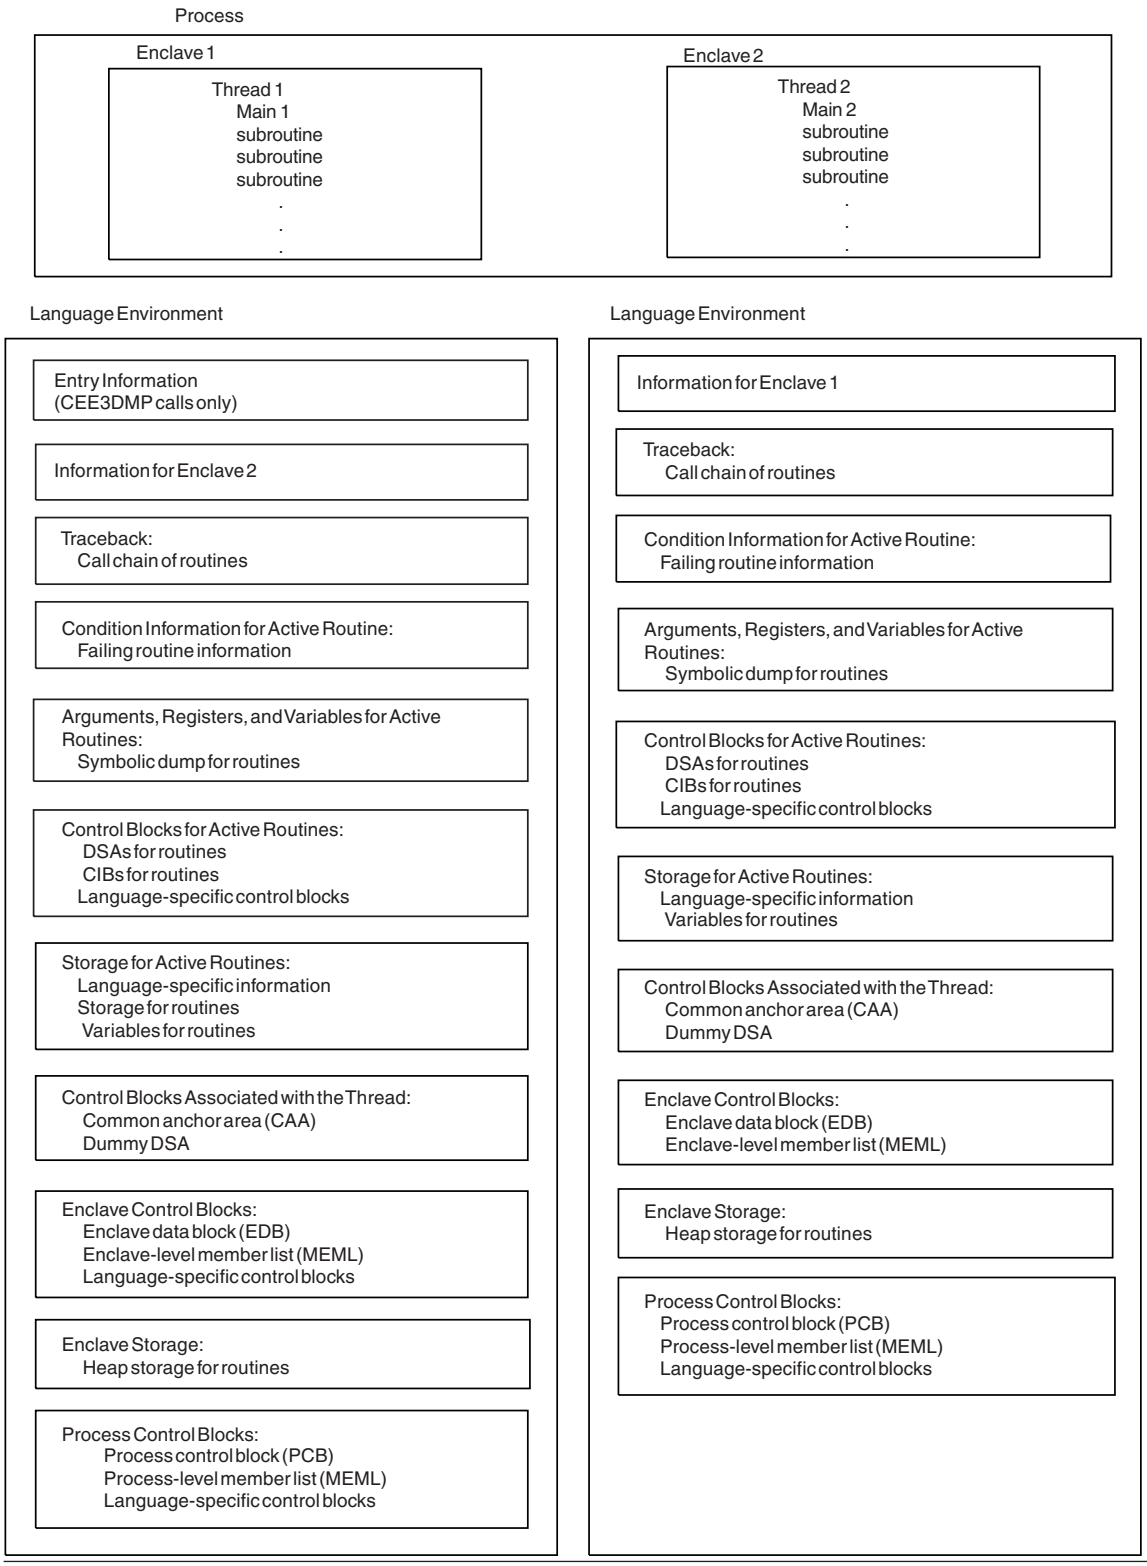

Figure 13. Language Environment dump of multiple enclaves

Generating a system dump

A system dump contains the storage information needed to diagnose errors. You can use Language Environment to generate a system dump through any of the following methods:

DYNDUMP(*hlq*,DYNAMIC,TDUMP)
: You can use the DYNDUMP run-time option to obtain IPCS-readable dumps of user applications that would ordinarily be lost due to the absence of a SYSMDUMP, SYSUDUMP, or SYSABEND DD statement.

TERMTHDACT(UAONLY, UATRACE, or UADUMP)
: You can use these run-time options, with TRAP(ON), to generate a system dump if an unhandled condition of severity 2 or greater occurs. For further details regarding the level of dump information produced by each of the TERMTHDACT suboptions, see “Generating a Language Environment dump with TERMTHDACT” on page 39.

TRAP(ON,NOSPIE) TERMTHDACT(UAIMM)
: TRAP(ON,NOSPIE) TERMTHDACT(UAIMM) generates a system dump of the user address space of the original abend or program interrupt prior to the Language Environment condition manager processing the condition.

ABPERC(abcode)
: The ABPERC run-time option specifies one abend code that is exempt from the Language Environment condition handler. The Language Environment condition handler percolates the specified abend code to the operating system. The operating system handles the abend and generates a system dump.

  ABPERC is ignored under CICS.

Abend Codes in Initialization Assembler User Exit
: Abend codes listed in the initialization assembler user exit are passed to the operating system. The operating system can then generate a system dump.

CEE3ABD
: You can use the CEE3ABD callable service to cause the operating system to handle an abend.

Refer to system or subsystem documentation for detailed system dump information.

The method for generating a system dump varies for each of the Language Environment run-time environments. The following sections describe the recommended steps needed to generate a system dump in a batch, IMS, CICS, and z/OS UNIX shell run-time environments. Other methods may exist, but these are the recommended steps for generating a system dump.

For details on setting Language Environment run-time options, see *z/OS Language Environment Programming Guide*.

Steps for generating a system dump in a batch run-time environment

Perform the following steps to generate a system dump in a batch run-time environment:

1. Specify run-time options TERMTHDACT(UAONLY, UADUMP, UATRACE, or UAIMM), and TRAP(ON). If you specify the suboption UAIMM then you must set TRAP(ON,NOSPIE). The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details on the TERMTHDACT suboptions, see "Generating a Language Environment dump with TERMTHDACT" on page 39.
2. Decide whether to include a SYSMDUMP DD card or use the DYNDUMP run-time option.
   - Include a SYSMDUMP DD card with the desired data set name and DCB information:

     `LRECL=4160, BLKSIZE=4160, and RECFM=FBS.`
   - Specify the DYNDUMP run-time option with the following information:

     `DYNDUMP (hlq,DYNAMIC,TDUMP)`
3. Rerun the program.

When you are done, you have a generated system dump in a batch run-time environment.

Steps for generating a system dump in an IMS run-time environment

Perform the following steps to generate a system dump in an IMS run-time environment:

1. Specify run-time options TERMTHDACT(UAONLY, UADUMP, UATRACE, or UAIMM), ABTERM(ABEND), and TRAP(ON). If you specify the suboption UAIMM, then you must set TRAP(ON,NOSPIE). The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details on the TERMTHDACT suboptions, see "Generating a Language Environment dump with TERMTHDACT" on page 39.

   Restriction: In an IMS environment, you can only use CEEUOPT, CEEDOPT, or CEEROPT to change run-time options. CEEUOPT cannot be used by OS/VS COBOL or non-Language Environment assembler.
2. Decide whether to include a SYSMDUMP DD card or use the DYNDUMP run-time option.
   - Include a SYSMDUMP DD card with the desired data set name and DCB information:

     `LRECL=4160, BLKSIZE=4160, and RECFM=FBS.`
   - Specify the DYNDUMP run-time option with the following information:

     `DYNDUMP (hlq,DYNAMIC,TDUMP)`
3. Rerun the program.

When you are done, you have a generated system dump in an IMS run-time environment.

Steps for generating a system dump in a CICS run-time environment

Before you begin: Under CICS, a system dump provides the most useful information for diagnosing problems. However, if you have a Language Environment U4038 abend, CICS will not generate a system dump. In order to generate diagnostic information for a CICS run-time environment with a Language Environment U4038 abend, you must create a Language Environment U4039

abend. For instructions on how to create a Language Environment U4039 abend, see “Steps for generating a Language Environment U4039 abend.”

Note: DYNDUMP is ignored in a CICS environment.

Perform the following steps to generate a system dump in a CICS run-time environment:

1. Specify run-time options TERMTHDACT(UAONLY, UADUMP, or UATRACE), ABTERM(ABEND), and TRAP(ON). The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details on the TERMTHDACT suboptions, see “Generating a Language Environment dump with TERMTHDACT” on page 39.
2. Update the transaction dump table with the CICS supplied CEMT command:

   ```
   CEMT SET TRD(40XX) SYS ADD
   ```

   Result: You will see CEMT output.

   Example:

   ```
   STATUS: RESULTS - OVERTYPE TO MODIFY
   Trd(4088)  Sys    Loc Max( 999 )  Cur(0000)
   ```
3. Rerun the program.

When you are done, you have a generated system dump in a CICS run-time environment.

Steps for generating a Language Environment U4039 abend

If you have a Language Environment U4038 abend, CICS will not generate a system dump. In order to generate diagnostic information, you must create a Language Environment U4039 abend by performing the following steps:

1. Specify DUMP=YES in CICS DFHSIT.
2. Relink your program by including CEEUOPT.

   Restriction:CEEUOPT cannot be used by OS/VS COBOL or non-Language Environment assembler.
3. Take CEECOPT from SCEESAMP and modify the Language Environment run-time options TERMTHDACT(UAONLY, UATRACE, or UADUMP), ABTERM(ABEND), and TRAP(ON).

   Result: By setting these run-time options, a Language Environment U4039 abend occurs which generates a system dump.
4. Rerun the program.

Note: In the CICS run-time environment, the TERMTHDACT suboption UAIMM is processed the same as UAONLY.

Steps for generating a system dump in a z/OS UNIX shell

Perform the following steps to generate a system dump from a z/OS UNIX shell:

- Using _BPXK_MDUMP
  1. Specify where to write the system dump
     - To write the system dump to a z/OS data set, issue the command:

       ```
       export _BPXK_MDUMP=filename
       ```

       where *filename* is a fully qualified data set name with DCB information: LRECL=4160, BLKSIZE=4160, and RECFM=FBS.

       Example:

```
export _BPXK_MDUMP=hlq.mydump
```

– To write the system dump to an HFS file, issue the command:

```
export _BPXK_MDUMP=filename
```

where *filename* is a fully qualified HFS filename.

Example:

```
export _BPXK_MDUMP=/tmp/mydump.dmp
```

2. Specify Language Environment run-time options:

```
export _CEE_RUNOPTS="termthdact(suboption)"
```

where *suboption* = UAONLY, UADUMP, UATRACE, or UAIMM. If UAIMM is set, TRAP(ON,NOSPIE) must also be set. The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details regarding the TERMTHDACT suboptions, see "Generating a Language Environment dump with TERMTHDACT" on page 39.

3. Rerun the program.

When you are done, the system dump is written to the data set name or HFS file name specified.

For additional BPXK_MDUMP information see *z/OS UNIX System Services Command Reference*.

- Using DYNDUMP

1. Specify Language Environment run-time options:

```
export _CEE_RUNOPTS="termthdact(suboption),DYNDUMP(hlq,DYNAMIC,TDUMP)"
```

where:

– *suboption* = UAONLY, UADUMP, UATRACE, or UAIMM. If UAIMM is set, TRAP(ON,NOSPIE) must also be set. The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details regarding the TERMTHDACT suboptions, see "Generating a Language Environment dump with TERMTHDACT" on page 39.

– *hlq* is the high level qualifier for the dump data set to be created.

2. Rerun the program.

When you are done, the system dump is written to the name generated by the DYNDUMP run-time option.

For additional DYNDUMP information see *z/OS Language Environment Programming Reference*.

Note: You can also specify the signal SIGDUMP on the kill command to generate a system dump of the user address space. For more information regarding the SIGDUMP signal, see *z/OS UNIX System Services Command Reference*.

Formatting and analyzing system dumps

You can use the interactive problem control system (IPCS) to format and analyze system dumps. Language Environment provides an IPCS Verbexit LEDATA that can be used to format Language Environment control blocks.

For more information on using IPCS, refer to *z/OS MVS IPCS User's Guide*.

Preparing to use the Language Environment support for IPCS

Guidelines: Use the following guidelines before you use IPCS to format Language Environment control blocks:

- Ensure that your IPCS job can find the CEEIPCSP member.

  IPCS provides an exit control table with imbed statements to enable other products to supply exit control information. The IPCS default table, BLSCECT, normally in the SYS1.PARMLIB library, has the following entry for Language Environment:

  ```
  IMBED MEMBER(CEEIPCSP) ENVIRONMENT(IPCS)
  ```

  The Language Environment-supplied CEEIPCSP member, installed in the SYS1.PARMLIB library, contains the Language Environment-specific entries for the IPCS exit control table.
- Provide an IPCSPARM DD statement to specify the libraries containing the IPCS control tables.

  Example:

  ```
  //IPCSPARM  DD  DSN=SYS1.PARMLIB,DISP=SHR
  ```
- Ensure that your IPCS job can find the Language Environment-supplied ANALYZE exit routines installed in the SYS1.MIGLIB library.
- To aid in debugging system or address space hang situations, Language Environment mutexes, latches and condition variables can be displayed if the CEEIPSCP member you are using is updated to identify the Language Environment ANALYZE exit, by including the following statement:

  ```
  EXIT EP(CEEEANLZ) ANALYZE
  ```

Language Environment IPCS Verbexit – LEDATA

Use the LEDATA Verbexit to format data for Language Environment. This Verbexit provides information about the following topics:

- A summary of Language Environment at the time of the dump
- Run-time Options
- Storage Management Control Blocks
- Condition Management Control Blocks
- Message Handler Control Blocks
- C/C++ Control Blocks
- COBOL Control Blocks

Format

Syntax

```
VERBEXIT LEDATA [ 'parameter[,parameter]...']
   Report Type Parameters:
      [ SUM ]
      [ HEAP | STACK | SM ]
      [ HPT(value) ]
      [ CM ]
      [ MH ]
      [ CEEDUMP ]
      [ PTBL(value) ]
      [ ALL ]
   Data Selection Parameters:
      [ DETAIL | EXCEPTION ]
   Control Block Selection Parameters:
      [ CAA(caa-address) ]
      [ DSA(dsa-address) ]
      [ TCB(tcb-address) ]
      [ ASID(address-space-id) ]
      [ NTHREADS(value) ]
```

Parameters

Report type parameters

Use these parameters to select the type of report. You can specify as many reports as you wish. If you omit these parameters, the default is SUMMARY.

SUMmary

Requests a summary of the Language Environment at the time of the dump. The following information is included:

- TCB address
- Address Space Identifier
- Language Environment Release
- Active members
- Formatted CAA, PCB, RCB, EDB and PMCB
- Run-time Options in effect

HEAP | STACK | SM

HEAP

Requests a report on Storage Management control blocks pertaining to HEAP storage, as well as a detailed report on heap segments. The detailed report includes information about the free storage tree in the heap segment, and information about each allocated storage element.

Note: Language Environment does not provide support for alternative Vendor Heap Manager (VHM) data.

STACK

Requests a report on Storage Management control blocks pertaining to STACK storage.

SM
Requests a report on Storage Management control blocks. This is the same as specifying both HEAP and STACK.

HPT(value)
Requests that the heappools trace (if available) be formatted. If the value is 0 or *, the trace for every heappools poolid is formatted. If the value is a single number (1-12), the trace for the specific heappools poolid is formatted.

CM
Requests a report on Condition Management control blocks.

MH
Requests a report on Message Handler control blocks.

CEEdump
Requests a CEEDUMP-like report. Currently this includes the traceback, the Language Environment trace, and thread synchronization control blocks at process, enclave and thread levels.

PTBL(value)
Requests that PreInit tables be formatted according to the following values:,

CURRENT
If current is specified, the PreInit table associated with the current or specified TCB is displayed.

address
If an address is specified, the PreInit table at that address is specified.

***** All active and dormant PreInit tables within the current address space are displayed; this option is time-consuming.

ACTIVE
The PreInit tables for all TCBs in the address space are displayed.

ALL
Requests all above reports, as well as C/C++ and COBOL reports.

Data selection parameters

Data selection parameters limit the scope of the data in the report. If no data selection parameter is selected, the default is DETAIL.

DETail
Requests formatting all control blocks for the selected components. Only significant fields in each control block are formatted.

Note: For the Heap and Storage Management Reports, the DETAIL parameter will provide a detailed heap segment report for each heap segment in the dump. The detailed heap segment report includes information on the free storage tree in the heap segments, and all allocated storage elements. This report will also identify problems detected in the heap management data structures. For more information about the Heap Reports, see “Understanding the HEAP LEDATA output” on page 105.

EXCeption
Requests validating all control blocks for the selected components. Output is only produced naming the control block and its address for the first control block in a chain that is invalid. Validation consists of control block header verification at the very least.

Note: For the Summary, CEEDUMP, C/C++, and COBOL reports, the EXCEPTION parameter has not been implemented. For these reports, DETAIL output is always produced.

Control block selection parameters

Use these parameters to select the CAA and DSA control blocks used as the starting points for formatting.

CAA(caa-address)
specifies the address of the CAA. If not specified, the CAA address is obtained from the TCB.

DSA(dsa-address)
specifies the address of the DSA. If not specified, the DSA address is assumed to be the register 13 value for the TCB.

TCB(tcb-address)
specifies the address of the TCB. If not specified, the TCB address of the current TCB from the CVT is used.

ASID(address-space-id)
specifies the hexadecimal address space id. If not specified, the IPCS default address space id is used. This parameter is not needed when the dump only has one address space.

NTHREADS(value)
specifies the number of TCBs for which the traceback will be displayed. If NTHREADS is not specified, *value* will default to (1). If *value* is specified as asterisk (*), all TCBs will be displayed.

Understanding the Language Environment IPCS Verbexit LEDATA output

The Language Environment IPCS Verbexit LEDATA generates formatted output of the Language Environment run-time environment control blocks from a system dump. Figure 14 on page 88 illustrates the output produced when the LEDATA Verbexit is invoked with the ALL parameter. The system dump being formatted was obtained by specifying the TERMTHDACT(UADUMP) run-time option when running the program CELSAMP in Figure 5 on page 44. “Sections of the Language Environment LEDATA Verbexit formatted output” on page 99 describes the information contained in the formatted output. Ellipses are used to summarize some sections of the dump.

For easy reference, the sections of the following dump are numbered to correspond with the descriptions in “Sections of the Language Environment LEDATA Verbexit formatted output” on page 99.

```

```
Summary of analysis for Heap Segment 20FE4018:
   Amounts of identified storage:  Free:00002DD8  Allocated:00005208  Total:00007FE0
   Number of identified areas   :  Free:       1  Allocated:       5  Total:       6
   00000000 bytes of storage were not accounted for.
   No errors were found while processing this heap segment.
   This is the last heap segment in the current heap.

Figure 14. Example of formatted output from LEDATA Verbexit (Part 12 of 12)

Sections of the Language Environment LEDATA Verbexit formatted output

The sections of the output listed here appear independently of the Language Environment-conforming languages used.

[1] - [9] Summary

These sections are included when the SUMMARY parameter is specified on the LEDATA invocation.

[1] Summary Header

The summary header section contains:
- Address of Thread control block (TCB)
- Release number
- Address Space ID (ASID)

[2] Active Members List

This list of active members is extracted from the enclave member list (MEML).

[3] CEECAA

This section formats the contents of the Language Environment common anchor area (CAA). See "The Common Anchor Area" on page 65 for a description of the fields in the CAA.

[4] CEEDLLF

This section formats the contents of all Language Environment CEEDLLF (DLLF) control blocks that are in use. See *z/OS Language Environment Vendor Interfaces* for more information about the CEEDLLF control block chain.

[5] CEEPCB

This section formats the contents of the Language Environment process control block (PCB), and the process level member list.

[6] CEERCB

This section formats the contents of the Language Environment region control block (RCB).

[7] CEEEDB

This section formats the contents of the Language Environment enclave data block (EDB), and the enclave level member list.

[8] PMCB

This section formats the contents of the Language Environment program management control block (PMCB).

[9] Run-Time Options

This section lists the run-time options in effect at the time of the dump, and indicates where they were set.

[10] Heap Storage Control Blocks

This section is included when the HEAP or SM parameter is specified on the LEDATA invocation.

This section formats the Enclave-level storage management control block (ENSM) and for each different type of heap storage:
- Heap control block (HPCB)

- Chain of heap anchor blocks (HANC). A HANC immediately precedes each segment of heap storage.

This section includes a detailed heap segment report for each segment in the dump. For more information about the detailed heap segment report, see "Understanding the HEAP LEDATA output" on page 105.

[11] Stack Storage Control Blocks

This section is included when the STACK or SM parameter is specified on the LEDATA invocation.

This section formats:

- Storage management control block (SMCB)
- Chain of dynamic save areas (DSA)

  Refer to "The upward-growing (non-XPLINK) stack frame section" on page 63 or "The downward-growing (XPLINK) stack frame section" on page 64 for a description of the fields in the DSA.
- Chain of stack segment headers (STKH)

  An STKH immediately precedes each segment of stack storage.

[12] Condition Management Control Blocks

This section is included when the CM parameter is specified on the LEDATA invocation.

This section formats the chain of Condition Information Block Headers (CIBH) and Condition Information Blocks. The Machine State Information Block is contained with the CIBH starting with the field labeled MCH_EYE. Refer to "The condition information block" on page 74 for a description of fields in these control blocks.

[13] Message Processing Control Blocks

This section is included when the MH parameter is specified on the LEDATA invocation.

[14] - [21] CEEDUMP Formatted Control Blocks

These sections are included when the CEEDUMP parameter is specified on the LEDATA invocation.

[14]-[17] NTHREADS information

One or more instances of these sections are included when the NTHREADS() parameter is specified on the LEDATA invocation. For a description of NTHREADS, see "Report type parameters" on page 85.

[14] Enclave Identifier

This statement names the enclave for which information is provided.

[15] Information for thread

This section shows the system identifier for the thread. Each thread has a unique identifier.

[16] Registers and PSW

This section displays the register and program status word (PSW) values that were used to create the traceback. These values may come from the TCB, the RTM2 work area, a linkage stack entry or output from the BPXGMSTA service. This section is not displayed when the DSA() parameter is specified on the LEDATA invocation.

[17] Traceback

For all active routines in a particular thread, the traceback section shows routine information in two parts. The first part contains the following items:

- DSA number

  A number assigned to the information for this active routine by dump processing. The number is used to associate information from the first part of the traceback with information in the second part of the traceback.
- Entry

  For COBOL, Fortran, and PL/I routines, this is the entry point name. For C/C++ routines, this is the function name. If a function name or entry point was not specified for a particular routine, the string '** NoName **' will appear.
- Entry point offset
- Statement number

  This field contains no Language Environment data.
- Load module
- Program unit

  The primary entry point of the external procedure. For COBOL programs, this is the PROGRAM-ID name. For C, Fortran, and PL/I routines, this is the compile unit name. For Language Environment-conforming assemblers, this is the EPNAME = value on the CEEPPA macro.
- Service level

  The latest service level applied to the compile unit (for example, for IBM products, it would be the PTF number).
- Status

  Routine status can be call, exception, or running.

The second part contains the following items:

- DSA number

  A number assigned to the information for this active routine by dump processing. The number is used to associate information from the first part of the traceback with information in the second part of the traceback.
- Stack frame (DSA) address
- Entry point address
- Program unit address
- Program unit offset

  The offset of the last instruction to run in the routine. If the offset is a negative number, zero, or a very large positive number, the routine associated with the offset probably did not allocate a save area, or the routine could have been called using SVC-assisted linkage. Adding the program unit address to the offset gives you the location of the current instruction in the routine. This offset is from the starting address of the routine.

- Compile Date

  Contains the year, month and day in which the routine was compiled.
- Attributes

  The available compilation attributes of the compile unit including:
  - A label identifying the LE-supported language such as COBOL, ENT PL/I, C/C++, and so on.
  - Compilation attributes such as EBCDIC, ASCII, IEEE, or hexadecimal floating point (HFP). The compilation attributes will only be displayed if there is enough information available.
  - POSIX, If the CEEDUMP was created under a POSIX environment.

[18] Control Blocks Associated with the Thread

This section lists the contents of the thread synchronization queue element (SQEL).

[19] Enclave Control Blocks

If the POSIX run-time option was set to ON, this section lists the contents of the mutex and condition variable control blocks, the enclave level latch table, and the thread synchronization trace block and trace table. If the HEAPCHK run-time option is set to ON, this section lists the contents of the HEAPCHK options control block (HCOP) and the HEAPCHK element tables (HCEL). A HEAPCHK element table contains the location and length of all allocated storage elements for a heap in the order that they were allocated.

[20] Language Environment Trace Table

If the TRACE run-time option was set to ON, this section shows the contents of the Language Environment trace table.

[21] Process Control Blocks

If the POSIX run-time option was set to ON, this section lists the contents of the process level latch table.

[22] Preinitialization Information

This section is included when the PTBL parameter is specified on the LEDATA invocation.

This section formats information related to preinitialization. See PTBL LEDATA output for more information. If the preinitialization service CEEPIPI was not used to initialize this environment, the message: `No PIPICB associated with CAA` is displayed instead.

PTBL LEDATA output

The Language Environment IPCS Verbexit LEDATA command generates formatted output of PreInit tables when the PTBL or ALL parameter are specified. If ALL is specified, PTBL defaults to CURRENT value. Figure 15 on page 104 illustrates the output produced when the Verbexit LEDATA command is invoked with the PTBL parameter.

```

Figure 15. Example of formatted PTBL output from LEDATA Verbexit (Part 2 of 2)

Understanding the HEAP LEDATA output

The Language Environment IPCS Verbexit LEDATA generates a detailed heap segment report when the HEAP option is used with the DETAIL option, or when the SM,DETAIL option is specified. The detailed heap segment report is useful when trying to pinpoint damage because it provides very specific information. The report describes the nature of the damage, and specifies where the actual damage occurred. The report can also be used to diagnose storage leaks, and to identify heap fragmentation. Figure 16 on page 106 illustrates the output produced by specifying the HEAP option. “Heap report sections of the LEDATA output” on page 109 describes the information contained in the formatted output.

For easy reference, the sections of the dump are numbered to correspond with the description of each section that follows. Ellipses are used to summarize some sections of the dump.

Note: Language Environment does not provide support for alternative Vendor Heap Manager (VHM) data. LEDATA verb exit will state that an alternative VHM is in use.

Exiting Language Environment Data
```

Figure 16. Example formatted detailed heap segment report from LEDATA Verbexit (Part 4 of 4)

Heap report sections of the LEDATA output

The Heap Report sections of the LEDATA output provide information for each heap segment in the dump. The detailed heap segment reports include information on the free storage tree in the heap segments, the allocated storage elements, and the cause of heap management data structure problems.

[1]Free Storage Tree Report

Within each heap segment, Language Environment keeps track of unallocated storage areas by chaining them together into a tree. Each free area represents a node in the tree. Each node contains a header, which points to its left and right child nodes. The header also contains the length of each child.

The LEDATA HEAP option formats the free storage tree within each heap, and validates all node addresses and lengths within each node. Each node address is validated to ensure that it:

- Falls on a doubleword boundary
- Falls within the current heap segment
- Does not point to itself
- Does not point to a node that was previously traversed

Each node length is validated to ensure that it:

- Is a multiple of 8
- Is not larger than the heap segment length
- Does not cause the end of the node to fall outside of the current heap segment
- Does not cause the node to overlap another node

If the formatter finds a problem, then it will place an error message describing the problem directly after the formatted line of the node that failed validation

[2]Heap Segment Map Report

The LEDATA HEAP option produces a report that lists all of the storage areas within each heap segment, and identifies the area as either allocated or freed. For each

allocated area the contents of the first X'20' bytes of the area are displayed in order to help identify the reason for the storage allocation.

Each allocated storage element has an 8 byte prefix used by Language Environment to manage the area. The first fullword contains a pointer to the start of the heap segment. The second fullword contains the length of the allocated storage element. The formatter validates this header to ensure that its heap segment pointer is valid. The length is also validated to ensure that it:

- Is a multiple of 8
- Is not zero
- Is not larger than the heap segment length
- Does not cause the end of the element to fall outside of the current heap segment
- Does not cause the element to overlap a free storage node

If the heap_free_value of the STORAGE run-time option was specified, then the formatter also checks that the free storage within each free storage element is set to the requested heap_free_value. If a problem is found, then an error message describing the problem is placed after the formatted line of the storage element that failed validation.

Diagnosing heap damage problems

Heap storage errors can occur when an application allocates a heap storage element that is too small for it to use, and therefore, accidently overlays heap storage. If this situation occurs then some of the typical error messages generated are:

- The node address does not represent a valid node within the heap segment
- The length of the segment is not valid, or
- The heap segment pointer is not valid.

If one of the above error messages is generated by one of the reports, then examine the storage element that immediately precedes the damaged node to determine if this storage element is owned by the application program. Check the size of the storage element and ensure that it is sufficient for the program's use. If the size of the storage element is not sufficient then adjust the allocation size.

If an error occurs indicating that the node's pointers form a circular loop within the free storage tree, then check the Free Storage Tree Report to see if such a loop exists. If a loop exists, then contact the IBM support center for assistance because this may be a problem in the Language Environment heap management routines.

Additional diagnostic information regarding heap damage can be obtained by using the HEAPCHK run-time option. This option provides a more accurate time perspective on when the heap damage actually occurred, which could help to determine the program that caused the damage. For more information on HEAPCHK, see *z/OS Language Environment Programming Reference*.

Diagnosing storage leak problems

A storage leak occurs when a program does not return storage back to the heap after it has finished using it. To determine if this problem exists, do one of the following:

- The *call-level* suboption of the HEAPCHK run-time option causes a report to be produced in the CEEDUMP. Any still-allocated (that is, not freed) storage identified by HEAPCHK is listed in the report, along with the corresponding traceback. This shows any storage that wasn't freed, as well as all the calls that

were involved in allocating the storage. For more information about the HEAPCHK run-time option, see *z/OS Language Environment Programming Reference* .

- Examine the Heap Segment Map report to see if any data areas, within the allocated storage elements, appear more frequently than expected. If they do, then check to see if these data areas are still being used by the application program. If the data areas are not being used, then change the program to free the storage element after it is done with it.

Diagnosing heap fragmentation problems

Heap fragmentation occurs when allocated storage is interlaced with many free storage areas that are too small for the application to use. Heap fragmentation could indicate that the application is not making efficient use of its heap storage. Check the Heap Segment Map report for frequent free storage elements that are interspersed with the allocated storage elements.

Understanding the HEAPPOOLS trace LEDATA output

The Language Environment IPCS Verbexit LEDATA generates a detailed HEAPPOOLS trace report when the HPT option is used. The argument *value* is the id of the pool to be formatted in the report.

Figure 17. Example formatted detailed HEAPPOOLS trace report from LEDATA Verbexit (Part 2 of 2)

[1] Trace Header

HEAPPOOLS trace header information.

[2] Pool Information

Information includes the number of the pool (POOLID) which is currently being formatted, the ASID, and the number of entries formatted and the total number of entries taken.

Note: The trace wraps for each poolid after 1024 enties have been taken.

[3] Timestamp

The time this trace entry was taken.

Note: The trace entries are formatted in reverse order (most recent trace entry first).

[4] Trace Table Entry contents

The individual trace entry:

- The TYPE - GET or FREE.
- The Cell within the pool being acted upon.
- The CPU and TCB which requested or freed the cell.
- A traceback at the time of the request. The number of entries in this traceback is limited by the HEAPCHK run-time option.

Understanding the C/C++-specific LEDATA output

The Language Environment IPCS Verbexit LEDATA generates formatted output of C/C++-specific control blocks from a system dump when the ALL parameter is specified and C/C++ is active in the dump. Figure 18 on page 114 illustrates the C/C++-specific output produced. The system dump being formatted was obtained by specifying the TERMTHDACT(UADUMP) run-time option when running the program CELSAMP Figure 5 on page 44. “C/C++-specific sections of the LEDATA output” on page 118 describes the information contained in the formatted output. Ellipses are used to summarize some sections of the dump.

For easy reference, the sections of the dump are numbered to correspond with the description of each section that follows.

```

Figure 18. Example formatted C/C++ output from LEDATA Verbexit (Part 5 of 5)

C/C++-specific sections of the LEDATA output

For the LEDATA output:

[1] CGEN

This section formats the C/C++-specific portion of the Language Environment common anchor area (CAA).

[2] CGENE

This section formats the extension to the C/C++-specific portion of the Language Environment common anchor area (CAA).

[3] CEDB

This section formats the C/C++-specific portion of the Language Environment enclave data block (EDB).

[4] CTHD

This section formats the C/C++ thread-level control block (CTHD).

[5] CPCB

This section formats the C/C++-specific portion of the Language Environment process control block (PCB).

[6] CIO

This section formats the C/C++ IO control block (CIO).

[7] File Control Blocks

This section formats the C/C++ file control block (FCB). The FCB and its related control blocks represent the information needed by each open stream.

Related Control Blocks

FSCE The file specific category extension control block. The FSCE represents the specific type of IO being performed. The following is a list of FSCEs that may be formatted.

OSNS — OS no seek

OSFS — OS fixed text

OSVF — OS variable text

OSUT — OS undefined format text

Other FSCEs will be displayed using a generic overlay.

OSIO The OS IO interface control block.

DCB The data control block. For more information about the DCB, refer to *z/OS DFSMS Macro Instructions for Data Sets*.

DCBE The data control block extension. For more information about the DCBE, refer to *z/OS DFSMS Macro Instructions for Data Sets*.

JFCB The job file control block (JFCB). For more information about the JFCB, refer to *z/OS MVS Data Areas, Vol 3 (IVT-RCWK)*.

Understanding the COBOL-specific LEDATA output

The Language Environment IPCS Verbexit LEDATA generates formatted output of COBOL-specific control blocks from a system dump when the ALL parameter is specified and COBOL is active in the dump. Figure 19 on page 120 illustrates the COBOL-specific output produced. The system dump being formatted was obtained by specifying the TERMTHDACT(UADUMP) run-time option. “COBOL-specific sections of the LEDATA Output” on page 121 describes the information contained in the formatted output.

For easy reference, the sections of the dump are numbered to correspond with the description of each section that follows.

```

Exiting COBOL Environment Data
```

Figure 19. Example formatted COBOL output from LEDATA Verbexit (Part 2 of 2)

COBOL-specific sections of the LEDATA Output

For the LEDATA output:

[1] RUNCOM

This section formats the COBOL enclave-level control block (RUNCOM).

[2] THDCOM

This section formats the COBOL process-level control block (THDCOM).

[3] COBCOM

This section formats the COBOL region-level control block (COBCOM).

[4] CLLE

This section formats the COBOL loaded program control blocks (CLLE).

[5] TGT

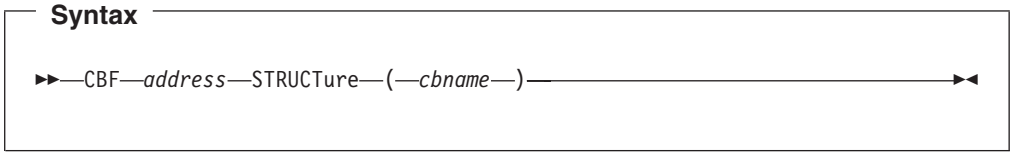
This section formats the COBOL TGT control blocks.

Formatting individual control blocks

In addition to the full LEDATA output which contains many formatted control blocks, the IPCS Control block formatter can also format individual Language Environment control blocks.

The IPCS cbf command can be invoked from the ″IPCS Subcommand Entry″ screen, option 6 of the ″IPCS PRIMARY OPTION MENU″.

Syntax



address
The address of the control block in the dump. This is determined by browsing the dump or running the LEDATA verb exit.

cbname
The name of the control block to be formatted. The control blocks that can be individually formatted are listed in Table 8 on page 123. In general, the name of each control block is similar to that used by the LEDATA verb exit and is generally found in the control block's eyecatcher field. However, all control block names are prefixed with CEE in order to uniquely define the Language Environment control block names to IPCS.

For an example of the display which is the result of the command, see Figure 20 on page 123 :

Requesting a Language Environment trace for debugging

Language Environment provides an in-storage, wrapping trace facility that can reconstruct the events leading to the point where a dump is taken. The trace facility can record two types of events: entry and exit library calls and, if the POSIX run-time option is set to ON, user mutex and condition variable activity such as init, lock/unlock, and wait. Language Environment produces a trace table in its dump report under the following conditions:

- The CEE3DMP callable service is invoked with the BLOCKS option and the TRACE run-time option is set to ON.
- The TRACE run-time option is set to NODUMP and the TERMTHDACT run-time option is set to DUMP, UADUMP, TRACE, or UATRACE.
- The TRACE run-time option is set to DUMP (the default).

For more information about the CEE3DMP callable service, the TERMTHDACT run-time option, or the TRACE run-time option, see *z/OS Language Environment Programming Reference*.

The TRACE run-time option activates Language Environment run-time library tracing and controls the size of the trace buffer, the type of trace events to record, and it determines whether a dump containing only the trace table should be unconditionally taken when the application (enclave) terminates. The trace table contents can be written out either upon demand or at the termination of an enclave.

The contents of the Language Environment dump depend on the values set in the TERMTHDACT run-time option. Under abnormal termination, the following dump contents are generated:

- TERMTHDACT(QUIET) generates a Language Environment dump containing the trace table only

- TERMTHDACT(MSG) generates a Language Environment dump containing the trace table only
- TERMTHDACT(TRACE) generates a Language Environment dump containing the trace table and the traceback
- TERMTHDACT(DUMP) generates a Language Environment dump containing thread/enclave/process storage and control blocks (the trace table is included as an enclave control block)
- TERMTHDACT(UAONLY) generates a system dump of the user address space
- TERMTHDACT(UATRACE) generates a Language Environment dump that contains traceback information, and a system dump of the user address space
- TERMTHDACT(UADUMP) generates a Language Environment dump containing thread/enclave/process storage and control blocks (the trace table is included as an enclave control block), and a user address space dump
- TERMTHDACT(UAIMM) generates a system dump of the user address space of the original abend or program interrupt that occurred prior to the Language Environment condition manager processing the condition.

Note: Under CICS, UAIMM yields UAONLY behavior. Under non-CICS, TRAP(ON,NOSPIE) must be in effect. When TRAP(ON,SPIE) is in effect, UAIMM yields UAONLY behavior. For software raised conditions or signals, UAIMM behaves the same as UAONLY.

Under normal termination, the following dump contents are generated:

- Independent of the TERMTHDACT setting, Language Environment generates a dump containing the trace table only based on the TRACE run-time option

Language Environment quiesces all threads that are currently running except for the thread that issued the call to CEE3DMP. When you call CEE3DMP in a multithread environment, only the current thread is dumped. Enclave- and process-related storage could have changed from the time the dump request was issued.

Locating the trace dump

If your application calls CEE3DMP, the Language Environment dump is written to the file specified in the FNAME parameter of CEE3DMP (the default is CEEDUMP).

If your application is running under TSO or batch, and a CEEDUMP DD is not specified, Language Environment writes the CEEDUMP to the batch log (SYSOUT=* by default). You can change the SYSOUT class by specifying a CEEDUMP DD, or by setting the environment variable, *_CEE_DMPTARG=SYSOUT(x)*, where x is the preferred SYSOUT class.

If your application is running under z/OS UNIX and is either running in an address space you issued a `fork()` to, or if it is invoked by one of the `exec` family of functions, the dump is written to the hierarchical file system (HFS). Language Environment writes the CEEDUMP to one of the following directories in the specified order:

1. The directory found in environment variable *_CEE_DMPTARG*, if found
2. The current working directory, if the directory is not the root directory (/), the directory is writable, and the CEEDUMP path name does not exceed 1024 characters
3. The directory found in environment variable *TMPDIR* (an environment variable that indicates the location of a temporary directory if it is not /tmp)
4. The **/tmp** directory

The name of this file changes with each dump and uses the following format:
`/path/Fname.Date.Time.Pid`

path The path determined from the above algorithm.

Fname The name specified in the FNAME parameter on the call to CEE3DMP (default is CEEDUMP).

Date The date the dump is taken, appearing in the format `YYYYMMDD` (such as 20040918 for September 18, 2004).

Time The time the dump is taken, appearing in the format `HHMMSS` (such as 175501 for 05:55:01 p.m.).

Pid The process ID the application is running in when the dump is taken.

Using the Language Environment trace table format in a dump report

The Language Environment trace table is established unconditionally at enclave initialization time if the TRACE run-time option is set to ON. All threads in the enclave share the trace table; there is no thread-specific table, nor can the table be dynamically extended or enlarged.

Understanding the trace table entry (TTE)

Each trace table entry is a fixed-length record consisting of a fixed-format portion (containing such items as the timestamp, thread ID, and member ID) and a member-specific portion. The member-specific portion has a fixed length, of which some (or all) can be unused. For information about how participating products use the trace table entry, refer to the product-specific documentation. The format of the trace table entry is as follows:

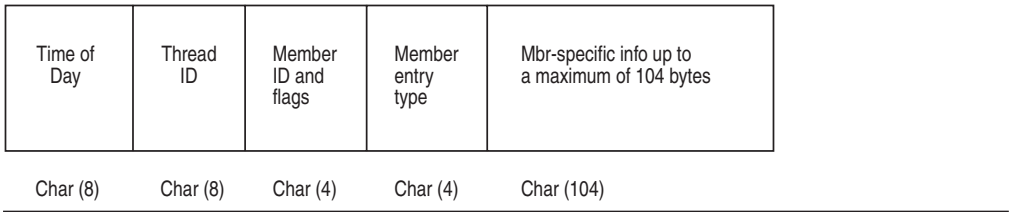

Figure 21. Format of the trace table entry

Following is a definition of each field:

Time The 64-bit value obtained from a store clock (STCK).

Thread ID The 8-byte thread ID of the thread that is adding the trace table entry.

Member ID and Flags
Contains 2 fields:

Member ID The 1-byte member ID of the member making the trace table entry, as follows:

ID	Name
01	CEL
03	C/C++
05	COBOL
07	Fortran

08	DCE
10	PL/I
12	Sockets

Flags 24 flags reserved for internal use.

Member Entry Type
A number that indicates the type of the member-specific trace information that follows the field.

To uniquely identify the information contained in a specific TTE, you must consider Member ID as well as Member Entry Type.

Member-Specific Information
Based on the member ID and the member entry type, this field contains the specific information for the entry, up to 104 bytes.

For C/C++, the entry type of 1 is a record that records an invocation of a base C run-time library function. The entry consists of the name of the invoking function and the name of the invoked function. Entry type 2 is a record that records the return from the base library function. It contains the returned value and the value of errno.

Member-specific information in the trace table entry

Global tracing is activated by using the LE=n suboption of the TRACE run-time option. This requests all Language Environment members to generate trace records in the trace table.

The settings for the global trace events are:

Level	Description
0	No global trace
1	Trace all run-time library (RTL) function entry and exits
2	Trace all RTL mutex init/destroy and lock/unlock
3	Trace all RTL function entry and exits, and all mutex init/destroy and lock/unlock
8	Trace all RTL storage allocation/deallocation
20	Trace all XPLINK/non-XPLINK transitions for AMODE 31 only. If `#pragma` linkage (xxxxxxxx, OS_UPSTACK) is specified, no transitions are recorded.

When LE=1 is specified: The following C/C++ records may be generated.

Table 9. LE=1 entry records

Member ID	Record Type	Description
03	00000001	Base C Library function Entry
03	00000002	Base C Library function Exit
03	00000003	Posix C Library function Entry
03	00000004	Posix C Library function Exit
03	00000005	XPLINK Base or Posix C Library function Entry
03	00000006	XPLINK Base or Posix C Library function Exit

For a detailed description of these records, see “C/C++ contents of the Language Environment trace tables” on page 177.

When LE=2 is specified: The following Language Environment records may be generated.

Table 10. LE=2 entry records

Member ID	Record Type	Class	Event	Description
01	00000101	LT	A	Latch Acquire
01	00000102	LT	R	Latch Release
01	00000103	LT	W	Latch Wait
01	00000104	LT	AW	Latch Acquire after Wait
01	00000106	LT	I	Latch Increment (Recursive)
01	00000107	LT	D	Latch Decrement (Recursive)
01	000002FC	LE	EUO	Latch unowned (not released)
01	000002FD	LE	EO	Latch already owned (not acquired)
01	00000301	MX	A	Mutex acquire
01	00000302	MX	R	Mutex release
01	00000303	MX	W	Mutex wait
01	00000304	MX	AW	Mutex acquire after wait
01	00000305	MX	B	Mutex busy (Trylock failed)
01	00000306	MX	I	Mutex increment (recursive)
01	00000307	MX	D	Mutex decrement (recursive)
01	00000315	MX	IN	Mutex initialize
01	00000316	MX	DS	Mutex destroy
01	0000031D	MX	BI	Shared memory lock init
01	0000031E	MX	BD	Shared memory lock destroy
01	0000031F	MX	BO	shared memory lock obtain
01	00000320	MX	BC	Shared memory lock obtain on condition
01	00000321	MX	BR	Shared memory lock release
01	00000324	MX	CIN	Call to SMC_INIT
01	00000325	MX	CSD	Call to SMC_DESTROY
01	00000326	MX	CSO	Shared resource obtain
01	00000327	MX	CSR	Shared resource release
01	00000328	MX	CST	Call to SMC_SetupToWait
01	00000329	MX	CSP	Call to SMC_POST
01	000004CC	ME	FFR	Error - Forced release (shared mutex)
01	000004CD	ME	FFD	Error - Forced decrement (shared mutex)
01	000004CE	ME	FBD	Error - BPX_SMC(DESTROY) error return
01	000004CF	ME	FBU	Error - BPX_SMC(fail) returns EBUSY
01	000004D0	ME	FIV	Error - BPX_SMC(fail) returns EINVAL
01	000004D4	ME	FDU	Error - Destroy failed (uninitialized) (shared mutex/CV)
01	000004D5	ME	FP	Error - Program check (shared mutex/CV)
01	000004DB	ME	ESC	Error - BPX1SMC error return

Table 10. LE=2 entry records (continued)

Member ID	Record Type	Class	Event	Description
01	000004DE	ME	EDL	Shared memory lock returns deadlock
01	000004DF	ME	EIV	Shared memory lock returns invalid
01	000004E0	ME	EPM	Shared memory lock returns eperm
01	000004E1	ME	EAG	Shared memory lock returns eagain
01	000004E2	ME	EBU	Shared memory lock returns ebusy
01	000004E3	ME	ENM	Shared memory lock returns enomem
01	000004E4	ME	EBR	Shared memory lock release error
01	000004E5	ME	EBC	Shared memory lock obtain condition error
01	000004E6	ME	EBO	Shared memory lock obtain error
01	000004E7	ME	EBD	Shared memory lock destroy error
01	000004E8	ME	EBI	Shared memory lock initialize error
01	000004E9	ME	EFR	Mutex forced release
01	000004EA	ME	EFD	Mutex forced decrement
01	000004EB	ME	EDD	Mutex destroy failed (damage)
01	000004EC	ME	EDB	Mutex destroy failed (busy)
01	000004ED	ME	EIA	Mutex initialize failed (attribute)
01	000004EE	ME	EIS	Mutex initialize failed (storage)
01	000004EF	ME	EF	Mutex release (forced by quiesce)
01	000004F0	ME	EP	Mutex program check
01	000004FA	ME	EDU	Mutex destroy failed (uninitialized)
01	000004FB	ME	EUI	Mutex uninitialized
01	000004FC	ME	EUO	Mutex unowned (not released)
01	000004FD	E	EO	Mutex already owned (not acquired)
01	000004FE	ME	EIN	Mutex initialization failed (duplicate)
01	00000508	CV	MR	CV release mutex
01	00000509	CV	MA	CV reacquire mutex
01	0000050A	CV	MW	CV mutex wait
01	0000050B	CV	MAW	CV reacquire mutex after wait
01	0000050C	CV	CW	CV condition wait
01	0000050D	CV	CTW	CV condition timeout
01	0000050E	CV	CWP	CV wait posted
01	0000050F	CV	CWI	CV wait interrupted
01	00000510	CV	CTO	CV wait timeout
01	00000511	CV	CSS	CV condition signal success
01	00000512	CV	CSM	CV condition signal miss
01	00000513	CV	CBS	CV condition broadcast success
01	00000514	CV	CBM	CV condition broadcast miss
01	00000515	CV	IN	CV initialize
01	00000516	CV	DS	CV destroy

Table 10. LE=2 entry records (continued)

Member ID	Record Type	Class	Event	Description
01	00000522	CV	CIN	Call to SMC_INIT
01	00000523	CV	CSD	Call to SMC_DESTROY
01	00000529	CV	CSP	Call to SMC_POST
01	0000052A	CV	CSB	Call to SMC_POSTALL
01	0000052B	CV	CSW	Call to SMC_WAIT
01	0000052C	CV	DBM	Shared condition broadcast - miss
01	0000052D	CV	DBS	Shared condition broadcast - success
01	0000052E	CV	DDS	Destroy (shared mutex/CV)
01	0000052F	CV	DIN	Initialize (shared mutex/CV)
01	00000530	CV	DSM	Condition signal - miss (shared CV)
01	00000531	CV	DSS	Condition signal - success (shared CV)
01	00000532	CV	DWI	Wait interrupted (shared CV)
01	00000533	CV	DTO	Wait timeout (shared CV)
01	00000534	CV	DWP	Wait posted (shared CV)
01	000006CB	CE	FBT	Error - Invalid system TOD (shared)
01	000006D1	CE	FRM	Error - Recursive mutex (shared)
01	000006D2	CE	FUO	Error - Shared mutex unowned
01	000006D3	CE	FDB	Error - Destroy failed (busy) (shared mutex/CV)
01	000006D4	CE	FDU	Error - Destroy failed (unitialized) (shared mutex/CV)
01	000006D5	CE	FP	Error - Program check (shared mutex/CV)
01	000006D6	CE	FUI	Error - Shared mutex or CV unitialized
01	000006D7	CE	ENV	Error - BPX1SMC(fail) returns EINVAL
01	000006D8	CE	EPE	Error - BPX1SMC(fail) returns EPERM
01	000006D9	CE	EAN	Error - BPX1SMC(fail) returns EAGAIN
01	000006DA	CE	EIB	Error - BPX1SMC failed (EBUSY)
01	000006DB	CE	ESC	Error - BPX1SMC failed
01	000006EB	CE	EDD	CV destroy failed (damage)
01	000006EC	CE	EDB	CV destroy failed (busy)
01	000006ED	CE	EIA	CV initialization failed (attribute)
01	000006EE	CE	EIS	CV initialization failed (storage)
01	000006EF	CE	EF	CV forced by quiesce
01	000006F0	CE	EP	CV program check
01	000006F1	CE	EBT	CV invalid system TOD
01	000006F2	CE	EBN	CV invalid timespec (nanoseconds)
01	000006F3	CE	EBS	CV invalid timespec (seconds)
01	000006F4	CE	EPO	CV condition post callable service fail
01	000006F5	CE	ETW	CV condition timed wait callable service fail
01	000006F6	CE	EWA	CV condition wait callable service fail

Table 10. LE=2 entry records (continued)

Member ID	Record Type	Class	Event	Description
01	000006F7	CE	ESE	CV condition setup callable service fail
01	000006F8	CE	ERM	CV recursive mutex
01	000006F9	CE	EWM	CV wrong mutex
01	000006FA	CE	EDU	CV destroy failed (uninitialized)
01	000006FB	CE	EUI	CV mutex or CV uninitialized
01	000006FC	CE	EUO	CV mutex unowned
01	000006FE	CE	EIN	CV initialization failed (duplicate)
01	00000702	RW	R	Release
01	00000704	RW	AW	Acquire after wait
01	00000706	RW	I	Increment (recursive)
01	00000707	RW	D	Decrement (recursive)
01	00000715	RW	IN	Initialize
01	00000716	RW	DS	Destroy
01	00000717	RW	RA	Read acquire
01	00000718	RW	WA	Write acquire
01	00000719	RW	RB	Read busy (tryread failed)
01	0000071A	RW	WB	Write busy (trywrite failed)
01	0000071B	RW	RW	Read wait
01	0000071C	RW	WW	Write wait
01	0000071D	RW	BI	Call to SLK_INIT

01	000008E6	RE	EBO	Error - BPX1SLK(OBTAIN) error return
01	000008E7	RE	EBD	Error - BPX1SLK(DESTROY) error return
01	000008E8	RE	EBI	Error - BPX1SLK(INIT) error return
01	000008E9	RE	EFR	Error - Forced release
01	000008EA	RE	EFD	Error - Forced decrement

Table 10. LE=2 entry records (continued)

Member ID	Record Type	Class	Event	Description
01	000008ED	RE	EIA	Error - Initialization failed (attribute)
01	000008EE	RE	EIS	Error - Initialization failed (storage)
01	000008EF	RE	EF	Error - Forced by quiesce
01	000008F0	RE	EP	Error - Program check
01	000008FB	RE	EUI	Error - Uninitialized
01	000008FC	RE	EUO	Error - Unowned (not released)
01	000008FD	RE	EO	Error - Already owned (not acquired)
01	000008FE	RE	EIN	Error - Initialization failed (duplicate)

The format for the Mutex – Condition Variable – Latch entries in the trace table is:

Table 11. Format of the mutex/CV/latch records

Class	Source		Event		Object Addr	Name1	Name2
unused							

Where each field represents:

Class Two character EBCDIC representation of the trace class.

- **LT** Latch
- **LE** Latch Exception
- **MX** Mutex
- **ME** Mutex Exception
- **CV** Condition Variable
- **CE** Condition Variable Exception

Source
One character EBCDIC representation of the event.

- **C** C/C++
- **D** DCE
- **S** Sockets

Blank Blank character

Event Two character EBCDIC representation of the event. See Table 10 on page 128.

Object address
Fullword address of the mutex object.

Name 1
Optional eight character field containing the name of the function or object to be recorded.

Name 2
Optional eight character field containing the name of the function or object to be recorded.

When LE=3 is specified: The trace table will include the records generated by both LE=1 and LE=2.

When LE=8 is specified: The trace table will contain only storage allocation records. Currently this is only supported by C/C++.

Table 12. LE=8 entry records

Member ID	Record Type	Description
03	00000001	Storage allocation entry
03	00000001	Storage allocation exit

For a detailed description of these records, see “C/C++ contents of the Language Environment trace tables” on page 177.

When LE=20 is specified: The following C/C++ records might be generated.

Table 13. LE=20 entry records

Member ID	Record Type	Description
03	00000007	XPLINK calls non-XPLINK entry
03	00000008	non-XPLINK calls XPLINK entry

For a detailed description of these records, see “C/C++ contents of the Language Environment trace tables” on page 177.

Sample dump for the trace table entry

The following is an example of a dump of the trace table when you specify the LE=1 suboption (the library call/return trace):

```

Figure 22. Trace table in dump output

Part 2. Debugging language-specific routines

This part provides specific information for debugging applications written in C/C++, COBOL, Fortran, and PL/I. It also discusses techniques for debugging under CICS.

Chapter 4. Debugging C/C++ routines

This chapter provides specific information to help you debug applications that contain one or more C/C++ routines. It also provides information about debugging C/C++ applications compiled with XPLINK. It includes the following topics:

- Debugging C/C++ I/O routines
- Using C/C++ compiler listings
- Generating a Language Environment dump of a C/C++ routine
- Generating a Language Environment dump of a C/C++ routine with XPLINK
- Finding C/C++ information in a Language Environment dump
- Debugging example of C/C++ routines
- Debugging example of C/C++ routines with XPLINK

There are several debugging features that are unique to C/C++ routines. Before examining the C/C++ techniques to find errors, you might want to consider the following areas of potential problems:

- If you suspect that you are using uninitialized storage, you may want to use the `STORAGE` run-time option.
- If you are using the `fetch()` function, refer to *z/OS XL C/C++ Programming Guide* to ensure that you are creating the fetchable module correctly.
- If you are using `DLL`s, refer to *z/OS XL C/C++ Programming Guide* to ensure that you are using the DLL correctly.
- For non-System Programming C routines, ensure that the entry point of the load module is CEESTART.
- You should avoid:
  - Incorrect casting
  - Referencing an array element with a subscript outside the declared bounds
  - Copying a string to a target with a shorter length than the source string
  - Declaring but not initializing a pointer variable, or using a pointer to allocated storage that has already been freed

  If a routine exception occurred and you need more information than the condition handler provided, run your routine with the following run-time options, TRAP(ON, NOSPIE) and TERMTHDACT(UAIMM). Setting these run-time options generates a system dump of the user address space of the original abend or program interrupt prior to the Language Environment condition manager processing the condition. After the system dump is taken by the operating system the Language Environment condition manager continues processing.

Debugging C/C++ programs

You can use C/C++ conventions such as `__amrc` and `perror()` when you debug C/C++ programs.

Using the __amrc and __amrc2 structures to debug input/output

`__amrc`, a structure defined in **stdio.h**, can help you determine the cause of errors resulting from an I/O operation, because it contains diagnostic information (for example, the return code from a failed VSAM operation).

There are two structures:

- `__amrc` (defined by type `__amrc_type`
- `__amrc2` (defined by type `__amrc2_type`)

The __amrc2_type structure contains secondary information that C can provide.

Because any I/O function calls, such as printf(), can change the value of __amrc or __amrc2, make sure you save the contents into temporary structures of __amrc_type and __amrc2_type respectively, before dumping them.

Figure 23 shows the structure as it appears in **stdio.h**.

```
    typedef struct __amrctype {

[1]    union {

[2]       long int __error;
          struct {
            unsigned short __syscode,
                           __rc;
[3]       } __abend;
          struct {
             unsigned char __fdbk_fill,
                           __rc,
                           __ftncd,
                           __fdbk;
[4]       } __feedback;
          struct {
             unsigned short __svc99_info,
                            __svc99_error;
[5]       } __alloc;
[1]    } __code;
[6]    unsigned long __RBA;
[7]    unsigned int      __last_op;
       struct {
        unsigned long  __len_fill; /* __len + 4       */
        unsigned long  __len;
        char           __str[120];
        unsigned long  __parmr0;
        unsigned long  __parmr1;
        unsigned long  __fill2[2];
        char           __str2[64];
[8]    } __msg;
[9]  #if __EDC_TARGET >= 0x22080000
 unsigned char        __rplfdbwd[4];
 #endif
 [10] #if __EDC_TARGET >= 0x41080000
   #ifdef  __LP64
     unsigned long __XRBA;
   #elif defined(__LL)
     unsigned long long __XRBA;
   #else
     unsigned int __XRBA1;
     unsigned int __XRBA2;
   #endif
 unsigned char        __amrc_noseek_to_seek;
 char                 __amrc_pad[23];
 #endif
 } __amrc_type;
```

Figure 23. __amrc structure

Figure 24 on page 139 shows the __amrc2 structure as it appears in **stdio.h**.

```
    struct {
[11]       long int   __error2;
                            char       __pad__error2[4];
[12]      FILE      *__fileptr;
[13]      long int   __reserved{6};
    }
```

Figure 24. __amrc2 structure

[1] union { ... } __code
The error or warning value from an I/O operation is in __error, __abend, __feedback, or __alloc. Look at __last_op to determine how to interpret the __code union.

[2] __error A structure that contains error codes for certain macros or services your application uses. Look at __last_op to determine the error codes. __syscode is the system abend code.

[3] __abend A structure that contains the abend code when errno is set to indicate a recoverable I/O abend. __rc is the return code. For more information on abend codes, see *z/OS MVS System Codes*.

[4] __feedback A structure that is used for VSAM only. The __rc stores the VSAM register 15, __fdbk stores the VSAM error code or reason code, and __RBA stores the RBA after some operations.

[5] __alloc A structure that contains errors during fopen or freopen calls when defining files to the system using SVC 99.

[6] __RBA The RBA value returned by VSAM after an ESDS or KSDS record is written out. For an RRDS, it is the calculated value from the record number. It can be used in subsequent calls to flocate.

[7] __last_op A field containing a value that indicates the last I/O operation being performed by C/C++ at the time the error occurred. These values are shown in Table 14 on page 140.

[8] __msg May contain the system error messages from read or write operations emitted from the DFSMS/MVS® SYNADAF macro instruction. Because the message can start with a hexadecimal address followed by a short integer, it is advisable to start printing at MSG+6 or greater so the message can be printed as a string. Because the message is not null-terminated, a maximum of 114 characters should be printed. This can be accomplished by specifying a printf format specifier as %.114s.

[9] __amrc_noseek_to_seek
This field contains the reason for the switch from QSAM (noseek) to BSAM with NOTE and POINT macros requested (seek) by the XL C/C++ Run-Time Library. This field is set when system-level I/O macro processing triggers an ABEND condition. The macro name values (defined in stdio.h) for this field are as follows:

Macro	Definition
__AM_BSAM_NOSWITCH	No switch was made.
__AM_BSAM_UPDATE	The data set is open for update

Macro	Definition
__AM_BSAM_BSAMWRITE	The data set is already open for write (or update) in the same C process.
__AM_BSAM_FBS_APPEND	The data set is recfm=FBS and open for append
__AM_BSAM_LRECLX	The data set is recfm=LRECLX (used for VBS data sets where records span the largest blocksize allowed on the device)
__AM_BSAM_PARTITIONED_DIRECTORY	The data set is the directory for a regular or extended partitioned data set
__AM_BSAM_PARTITIONED_INDIRECT	The data set is a member of a partitioned data set, and the member name was not specified at allocation

[10] __XRBA This is the 8 byte relative byte address returned by VSAM after an ESDS or KSDS record is written out. For an RRDS, it is the calculated value from the record number. It may be used in subsequent calls to `flocate()`.

[11] __error2 A secondary error code. For example, an unsuccessful rename or remove operation places its reason code here.

[12] __fileptr A pointer to the file that caused a SIGIOERR to be raised. Use an `fldata()` call to get the actual name of the file.

[13] __reserved
Reserved for future use.

__last_op values

The `__last_op` field is the most important of the `__amrc` fields. It defines the last I/O operation C/C++ was performing at the time of the I/O error. You should note that the structure is neither cleared nor set by non-I/O operations, so querying this field outside of a `SIGIOERR` handler should only be done immediately after I/O operations. Table 14 lists `__last_op` values you could receive and where to look for further information.

Table 14. __last_op values and diagnosis information

Value	Further Information
`__IO_INIT`	Will never be seen by `SIGIOERR` exit value given at initialization.
`__BSAM_OPEN`	Sets __error with return code from OS OPEN macro.
`__BSAM_CLOSE`	Sets __error with return code from OS CLOSE macro.
`__BSAM_READ`	No return code (either __abend (errno == 92) or __msg (errno == 66) filled in).
`__BSAM_NOTE`	NOTE returned 0 unexpectedly, no return code.
`__BSAM_POINT`	This will not appear as an error lastop.
`__BSAM_WRITE`	No return code (either __abend (errno == 92) or __msg (errno == 65) filled in).
`__BSAM_CLOSE_T`	Sets __error with return code from OS CLOSE TYPE=T.
`__BSAM_BLDL`	Sets __error with return code from OS BLDL macro.
`__BSAM_STOW`	Sets __error with return code from OS STOW macro.
`__TGET_READ`	Sets __error with return code from TSO TGET macro.
`__TPUT_WRITE`	Sets __error with return code from TSO TPUT macro.

Table 14. __last_op values and diagnosis information (continued)

Value	Further Information
__IO_DEVTYPE	Sets __error with return code from I/O DEVTYPE macro.
__IO_RDJFCB	Sets __error with return code from I/O RDJFCB macro.
__IO_TRKCALC	Sets __error with return code from I/O TRKCALC macro.
__IO_OBTAIN	Sets __error with return code from I/O CAMLST OBTAIN.
__IO_LOCATE	Sets __error with return code from I/O CAMLST LOCATE.
__IO_CATALOG	Sets __error with return code from I/O CAMLST CAT. The associated macro is CATALOG.
__IO_UNCATALOG	Sets __error with return code from I/O CAMLST UNCAT. The associated macro is CATALOG.
__IO_RENAME	Sets __error with return code from I/O CAMLST RENAME.
__SVC99_ALLOC	Sets __alloc structure with info and error codes from SVC 99 allocation.
__SVC99_ALLOC_NEW	Sets __alloc structure with info and error codes from SVC 99 allocation of NEW file.
__SVC99_UNALLOC	Sets __unalloc structure with info and error codes from SVC 99 unallocation.
__C_TRUNCATE	Set when C or C++ truncates output data. Usually this is data written to a text file with no newline such that the record fills up to capacity and subsequent characters cannot be written. For a record I/O file this refers to an `fwrite()` writing more data than the record can hold. Truncation is always rightmost data. There is no return code.
__C_FCBCHECK	Set when C or C++ FCB is corrupted. This is due to a pointer corruption somewhere. File cannot be used after this.
__C_DBCS_TRUNCATE	This occurs when writing DBCS data to a text file and there is no room left in a physical record for anymore double byte characters. A new-line is not acceptable at this point. Truncation will continue to occur until an SI is written or the file position is moved. Cannot happen if MB_CUR_MAX is 1.
__C_DBCS_SO_TRUNCATE	This occurs when there is not enough room in a record to start any DBCS string or else when a redundant SO is written to the file before an SI. Cannot happen if MB_CUR_MAX is 1.
__C_DBCS_SI_TRUNCATE	This occurs only when there was not enough room to start a DBCS string and data was written anyways, with an SI to end it. Cannot happen if MB_CUR_MAX is 1.
__C_DBCS_UNEVEN	This occurs when an SI is written before the last double byte character is completed, thereby forcing C or C++ to fill in the last byte of the DBCS string with a padding byte X'FE'. Cannot happen if MB_CUR_MAX is 1.
__C_CANNOT_EXTEND	This occurs when an attempt is made to extend a file that allows writing, but cannot be extended. Typically this is a member of a partitioned data set being opened for update.
__VSAM_OPEN_FAIL	Set when a low level VSAM OPEN fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_OPEN_ESDS	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_OPEN_RRDS	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.

Table 14. __last_op values and diagnosis information (continued)

Value	Further Information
__VSAM_OPEN_KSDS	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_OPEN_ESDS_PATH	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_OPEN_KSDS_PATH	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_MODCB	Set when a low level VSAM MODCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_TESTCB	Set when a low level VSAM TESTCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_SHOWCB	Set when a low level VSAM SHOWCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_GENCB	Set when a low level VSAM GENCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_GET	Set when the last op was a low level VSAM GET; if the GET fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_PUT	Set when the last op was a low level VSAM PUT; if the PUT fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_POINT	Set when the last op was a low level VSAM POINT; if the POINT fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_ERASE	Set when the last op was a low level VSAM ERASE; if the ERASE fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_ENDREQ	Set when the last op was a low level VSAM ENDREQ; if the ENDREQ fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_CLOSE	Set when the last op was a low level VSAM CLOSE; if the CLOSE fails, sets __rc and __fdbk in the __amrc struct.
__QSAM_GET	__error is not set (if abend (errno == 92), __abend is set, otherwise if read error (errno == 66), look at __msg.
__QSAM_PUT	__error is not set (if abend (errno == 92), __abend is set, otherwise if write error (errno == 65), look at __msg.
__QSAM_TRUNC	This is an intermediate operation. You will only see this if an I/O abend occurred.
__QSAM_FREEPOOL	This is an intermediate operation. You will only see this if an I/O abend occurred.
__QSAM_CLOSE	Sets __error to result of OS CLOSE macro.
__QSAM_OPEN	Sets __error to result of OS OPEN macro.
__CMS_OPEN	Sets __error to result of FSOPEN.
__CMS_CLOSE	Sets __error to result of FSCLOSE.
__CMS_READ	Sets __error to result of FSREAD.
__CMS_WRITE	Sets __error to result of FSWRITE.
__CMS_STATE	Sets __error to result of FSSTATE.
__CMS_ERASE	Sets __error to result of FSERASE.
__CMS_RENAME	Sets __error to result of CMS RENAME command.
__CMS_EXTRACT	Sets __error to result of DMS EXTRACT call.
__CMS_LINERD	Sets __error to result of LINERD macro.

Table 14. __last_op values and diagnosis information (continued)

Value	Further Information
__CMS_LINEWRT	Sets __error to result of LINEWRT macro.
__CMS_QUERY	__error is not set.
__HSP_CREATE	Indicates last op was a DSPSERV CREATE to create a hiperspace for a hiperspace memory file. If CREATE fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_DELETE	Indicates last op was a DSPSERV DELETE to delete a hiperspace for a hiperspace memory file during termination. If DELETE fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_READ	Indicates last op was a HSPSERV READ from a hiperspace. If READ fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_WRITE	Indicates last op was a HSPSERV WRITE to a hiperspace. If WRITE fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_EXTEND	Indicates last op was a HSPSERV EXTEND during a write to a hiperspace. If EXTEND fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__CICS_WRITEQ_TD	Sets __error with error code from EXEC CICS WRITEQ TD.
__LFS_OPEN	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_CLOSE	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_READ	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_WRITE	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_LSEEK	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_FSTAT	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

Displaying an error message with the perror() function

To find a failing routine, check the return code of all function calls. After you have found the failing routine, use the `perror()` function after the routine to display the error message. `perror()` displays the string that you pass to it and an error message corresponding to the value of `errno`. `perror()` writes to the standard error stream (`stderr`). By default, the errno2 value will be appended to the end of the perror() string.

If you do not want the errno2 value appended to the `perror()` string, set the _EDC_ADD_ERRNO2 environment variable to 0.

Figure 25 is an example of a routine using `perror()`.

```
#include <stdio.h>
int main(void){
   FILE *fp;

   fp = fopen("myfile.dat", "w");
   if (fp == NULL)
      perror("fopen error");
}
```

Figure 25. Example of a routine using perror()

Using __errno2() to diagnose application problems

Use the __errno2() function when diagnosing problems in an application program. This function enables z/OS XL C/C++ application programs to access additional diagnostic information, `errno2` (`errnojr`), associated with `errno`. The __`errno2` may be set by the z/OS XL C/C++ run-time library, z/OS UNIX callable services, or other callable services. The `errno2` is intended for diagnostic display purposes only and is not a programming interface.

Note: Not all functions set `errno2` when `errno` is set. In the cases where `errno2` is not set, the __errno2() function may return a residual value. You may use the __err2ad() function to clear `errno2` to reduce the possibility of a residual value being returned.

Figure 26 on page 145 is an example of a routine using __`errno2()` and Figure 27 on page 145 shows the sample output from that routine.

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>

int main(void) {
  FILE *f;
  f = fopen("testfile.dat", "r")
  if (f==NULL) {
      perror("fopen() failed");
      printf("__errno2 = %08x\n", __errno2());
   }
   return 0;
}
```

Figure 26. Example of a routine using __errno2()

```
fopen() failed: EDC5129I No such file or directory. (errno2=0x05620062)
__errno2 = 05620062
```

Figure 27. Sample output of a routine using __errno2()

Figure 28 is an example of a routine using the environment variable _EDC_ADD_ERRNO2 and Figure 29 shows the sample output from that routine.

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void) {
  FILE *fp;
  /* do NOT add errno2 to perror message */
  setenv("_EDC_ADD_ERRNO2", "0", 1);
  fp = fopen("testfile.dat", "r");
  if (fp == NULL)
      perror("fopen() failed");
  return 0;
}
```

Figure 28. Example of a routine using _EDC_ADD_ERRNO2

```
fopen() failed: EDC5129I No such file or directory.
```

Figure 29. Sample output of a routine using _EDC_ADD_ERRNO2

Figure 30 on page 146 is an example of a routine using __err2ad() in combination with __errno2() and Figure 31 on page 146 shows the sample output from that routine.

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void) {
  FILE *f;
  setenv("_EDC_ADD_ERRNO2", "0", 1);
  f = fopen("testfile.dat", "r");
  if (f == NULL) {
    perror("fopen() failed");
    printf("__errno2 = %08x\n", __errno2());
  }
  /* reset errno2 to zero */
  *__err2ad() = 0x0;
  printf("__errno2 = %08x\n", __errno2());
  f = fopen(*testfile.dat", "r");

  if (fp == NULL) {
    perror("fopen() failed");
    printf(*__errno2 = %08x\n", __errno2());
  }
  return 0;
}
```

Figure 30. Example of a routine using __err2ad() in combination with __errno2()

```
fopen() failed: EDC5129I  No such file or directory.
__errno2 = 05620062
__errno2 = 00000000
fopen() failed: EDC5129I  No such file or directory.
__errno2 = 05620062
```

Figure 31. Sample output of routine using __err2ad() in combination with __errno2()

For more information about _EDC_ADD_ERRNO2, see *z/OS XL C/C++ Programming Guide*.

For more information about __errno2() and __err2ad(), see *z/OS XL C/C++ Run-Time Library Reference*.

Diagnosing DLL problems

Use the _EDC_DLL_DIAG environment variable to diagnose DLL problems. For more information, see *z/OS XL C/C++ Programming Guide*

You can also see the diagnosis output in CEEDUMP and Verbexit LEDATA reports. For more information, see “Using the DLL failure control block” on page 78.

Using C/C++ listings

For a detailed description of available listings, see *z/OS XL C/C++ User’s Guide*.

Finding variables

You can determine the value of a variable in the routine at the point of interrupt by using the compiled code listing as a guide to its address, then finding this address in the Language Environment dump. The method you use depends on the storage class of variable.

This method is generally used when no symbolic variables have been dumped (by using the TEST compiler option).

It is possible for the routine to be interrupted before the value of the variable is placed in the location provided for it. This can explain unexpected values in the dump.

Steps for finding automatic variables

Perform the following steps to find automatic variables in the Language Environment dump:

1. Identify the start of the stack frame. If a dump has been taken, each stack frame is dumped. The stack frames can be cross-referenced to the function name in the traceback.
2. Determine the value of the base register (in this example, GPR13) in the Saved Registers section for the function you are interested in.
3. Find the offset of the variable (which is given in decimal) in the storage offset listing.

   Example:

   ```
   aa1    85-0:85   Class = automatic, Offset = 164(r13),    Length = 40
   ```

4. Add this base address to the offset of the variable.

When you are done, the contents of the variable can be read in the DSA Frame section corresponding to the function the variable is contained in.

Locating the Writable Static Area (WSA)

The Writable Static Area (WSA) address is the base address of the writable static area which is available for all C and C++ programs except C programs compiled with the NORENT compiler option. If you have C code compiled with the RENT option or C++ code (hereafter called RENT code) you must determine the base address of the WSA if you want to calculate the address of a static or external variable. Use the following table to determine where to find the WSA base address:

Table 15. Finding the WSA base address

If you want the WSA base address for:	Locate the WSA base address in:
application code	the WSA address field in the Enclave Control Blocks section
a fetched module	the WSA address field of the Fetch() Information section for the fetch() function pointer for which you are interested
a DLL	the corresponding WSA address in the DLL Information section

Use the WSA base address to locate the WSA in the Enclave Storage section.

Steps for finding the static storage area

If you have C code compiled with the NORENT option (hereafter called NORENT code) you must determine the base address of the static storage area if you want to calculate the address of a static or external variable.

Perform the following steps to find the static storage area:

1. Name the static storage area CSECT by using the `pragma csect` directive. Once this is done, a CSECT is generated for the static storage area for each source file.
2. Determine the origin and length of the CSECT from the linker map.
3. Locate the external variables corresponding to the CSECT with the same name.
4. Determine the origin and length of the external variable CSECT from the linker map.

Notes:

1. Address calculation for static and external variables uses the static storage area as a base address with 1 or more offsets added to this address.
2. The storage associated with these CSECTs is not dumped when an exception occurs. It is dumped when `cdump` or CEE3DMP is called, but it is written to a separate ddname called CEESNAP. For information about `cdump`, CEE3DMP, and enabling the CEESNAP ddname, see “Generating a Language Environment dump of a C/C++ routine” on page 155.

Steps for finding RENT static variables

Before you begin: You need to know the WSA. To find this information, see “Locating the Writable Static Area (WSA)” on page 147. For this procedure’s example, assume that the address of writable static is X'02D66E40'.

Perform the following steps to find RENT static variables:

1. Find the offset of `@STATIC` (associated with the file where the static variable is located) in the Writable Static Map section of the prelinker map.

   Example:

```
=========================================================================
|                        Writable Static Map                            |
=========================================================================

  OFFSET    LENGTH  FILE ID  INPUT NAME

       0         1   00001   DFHC0011
       4         1   00001   DFHC0010
       8         2   00001   DFHDUMMY
       C         2   00001   DFHB0025
      10         2   00001   DFHB0024
      14         2   00001   DFHB0023
      18         2   00001   DFHB0022
      1C         2   00001   DFHB0021
      20         2   00001   DFHB0020
      24         2   00001   DFHEIB0
      28         4   00001   DFHEIPTR
      2C         4   00001   DFHCP011
      30         4   00001   DFHCP010
      34         4   00001   DFHBP025
      38         4   00001   DFHBP024
      3C         4   00001   DFHBP023
      40         4   00001   DFHBP022
      44         4   00001   DFHBP021
      48         4   00001   DFHBP020
      4C         4   00001   DFHEICB
      50         4   00001   DFHEID0
      54         4   00001   DFHLDVER
      58       278   00001   @STATIC
     720        30   00002   @STATIC
```

Figure 32. Writable static map produced by prelinker

In this Writable Static Map section of a prelinker map the offset is X'58'.

2. Add the offset to the WSA to get the base address of static variables.

   Example: X'02D66E40' + X'58' = X'2D66E98'

3. Find the offset of the static variable in the partial storage offset compiler listing.

   Example:

   ```
   sa0  66-0:66 Class = static, Location = WSA + @STATIC + 96, Length = 4
   ```

   The offset is 96 (X'60').

4. Add the offset of the static variable in the partial storage offset compiler listing (found in step 3) to the base address of static variables (calculated in step 2).

   Example: X'2D66E98' + X'60' = X'2D66EF8'

When you are done, you have the address of the value of the static variable in the Language Environment dump.

Figure 33 on page 150 shows the path to locate RENT C++ and C static variables by adding the address of writable static, the offset of @STATIC, and the variable offset.

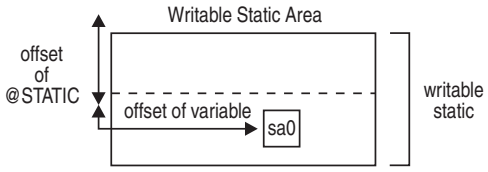

Figure 33. Location of RENT static variable in storage

Steps for finding external RENT variables

Before you begin: You need to know the WSA. To find this information see "Locating the Writable Static Area (WSA)" on page 147. For this procedure's example, the address of writable static is X'02D66E40'.

Perform the following steps to find external RENT variables:

1. Find the offset of the external variable in the Prelinker Writable Static Map.

   Example:
   In this example, the offset for `DFHEIPTR` is X'28'.

```
========================================================================
|                        Writable Static Map                           |
========================================================================

  OFFSET    LENGTH  FILE ID  INPUT NAME

       0         1   00001   DFHC0011
       4         1   00001   DFHC0010
       8         2   00001   DFHDUMMY
       C         2   00001   DFHB0025
      10         2   00001   DFHB0024
      14         2   00001   DFHB0023
      18         2   00001   DFHB0022
      1C         2   00001   DFHB0021
      20         2   00001   DFHB0020
      24         2   00001   DFHEIB0
      28         4   00001   DFHEIPTR
      2C         4   00001   DFHCP011
      30         4   00001   DFHCP010
      34         4   00001   DFHBP025
      38         4   00001   DFHBP024
      3C         4   00001   DFHBP023
      40         4   00001   DFHBP022
      44         4   00001   DFHBP021
      48         4   00001   DFHBP020
      4C         4   00001   DFHEICB
      50         4   00001   DFHEID0
      54         4   00001   DFHLDVER
      58       420   00001   @STATIC
```

Figure 34. Writable static map produced by prelinker

2. Add the offset of the external variable to the address of writable static.

   Example: X'02D66E40' + X'28' = X'2D66E68'

When you are done, you have the address of the value of the external variable in the Language Environment dump.

Steps for finding NORENT static variables

Before you begin: You need to know the name and address of the static storage area. To find this information see “Steps for finding the static storage area” on page 148. For this procedure’s example, the static storage area is called **STATSTOR** and has an address of X'02D66E40'.

Perform the following steps to find external RENT variables:

1. Find the offset of the static variable in the partial storage offset compiler listing.

   Example:

   ```
   sa0   66-0:66   Class = static,   Location = STATSTOR +96,   Length = 4
   ```

   The offset is 96 (X'60').
2. Add the offset to the base address of static variables.

   Example: X'2D66E40' + X'60' = X'2D66EA0'

When you are done, you have the address of the value of the static variable in the Language Environment dump.

Figure 35 shows how to locate NORENT C static variables by adding the Static Storage Area CSECT address to the variable offset.

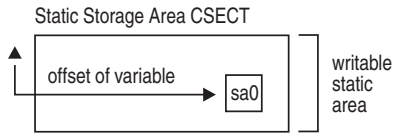

Figure 35. Location of NORENT static variable in storage

Steps for finding external NORENT variables

Before you begin: You need to find the address of the external variable CSECT. To find this information, see “Steps for finding the static storage area” on page 148. For this procedure’s example, the address of the external variable CSECT is X'02D66E40'.

The address of the external variable CSECT is the address of the value of the external variable in the Language Environment dump.

Steps for finding the C/370 parameter list

Perform the following steps to locate a parameter in the Language Environment dump:

1. Indentify the address of the start of the parameter list. A pointer to the parameter list is passed to the called function in register 1. This is the address of the start of the parameter list. Figure 36 on page 152 shows an example code for the parameter variable.

   Example:

```
func0() {
   :
 func1(a1,a2);
   :
}

func1(int ppx, int pp0) {
   :
}
```

Figure 36. Example code for parameter variable

Parameters *ppx* and *pp0* correspond to copies of *a1* and *a2* in the stack frame belonging to `func0`.

2. Use the address of the start of the parameter list to find the register and offset in the partial storage offset listing.

   Example:

   ```
   pp0     62-0:62    Class = parameter,   Location = 4(r1),    Length = 4
   ```

   The offset is 4 (X'4') from register 1.
3. Determine the value of `GPR1` in the Saved Registers section for the function that called the function you are interested in.
4. Add this base address to the offset of the parameter.

When you are done, the contents of the variable can then be read in the DSA frame section corresponding to the function the parameter was passed from.

Steps for finding the C++ parameter list

Before you begin: To locate C++ functions with `extern C` attributes, see "Steps for finding the C/370 parameter list" on page 151.

Perform the following steps to find the C++ parameter list:

1. Indentify the address of the start of the parameter list. A pointer to the parameter list is passed to the called function in register 1. This is the address of the start of the parameter list. Figure 37 shows an example code for the parameter variable.

   Example:

```
func0() {
   :
 func1(a1,a2);
   :
}

func1(int ppx, int pp0) {
   :
 }
```

Figure 37. Example code for parameter variable

Parameters *ppx* and *pp0* correspond to copies of *a1* and *a2* in the stack frame belonging to `func1`.

2. Locate the value of the base register in the Saved Registers section of the function you are interested in.
3. Find the offset of the static variable in the partial storage offset compiler listing.

   Example:

```
ppx    62-0:62    Class = parameter,    Location = 188(r13),    Length = 4
pp0    62-0:62    Class = parameter,    Location = 192(r13),    Length = 4
```

Figure 38. Partial storage offset listing

4. Add the value of the base register to the offset.
5. Locate the parameter.

Restriction: When OPTIMIZE is on, the parameter value might never be stored, since the first few parameters might be passed in registers and there might be no need to save them.

Steps for finding members of aggregates

You can define aggregates in any of the storage classes or pass them as parameters to a called function. The first step is to find the start of the aggregate. You can compute the start of the aggregate as described in previous sections, depending on the type of aggregate used.

The aggregate map provided for each declaration in a routine can further assist in finding the offset of a specific variable within an aggregate. Structure maps are generated using the AGGREGATE compiler option. Figure 39 shows an example of a static aggregate.

```
static struct {
    short int ss01;
    char      ss02[56];
    int       sz0[6];
    int       ss03;
} ss0;
```

Figure 39. Example code for structure variable

Figure 40 on page 154 shows an example aggregate map.

```
================================================================================
| Aggregate map for:  ss0                                                      |
================================================================================
|      Offset      |       Length      | Member Name                           |
|    Bytes(Bits)   |     Bytes(Bits)   |                                       |
====================================================================================
|       0          |         2         |  ss01                                 |
|       2          |        56         |  ss02[56]                             |
|      58          |         2         |  ***PADDING***                        |
|      60          |        24         |  sz0[6]                               |
|      84          |         4         |  ss03                                 |
================================================================================
```

Figure 40. Example of aggregate map

Assume the structure has been compiled as RENT. To find the value of variable *sz0[0]*:

1. Find the address of the writable static. For this example the address of writable static is X'02D66E40'.
2. Find the offset of @STATIC in the Writable Static Map. In this example, the offset is X'58'. Add this offset to the address of writable static. The result is X'2D66E98' (X'02D66E40' + X'58'). Figure 41 shows the Writable Static Map produced by the prelinker.

```
================================================================================
|                          Writable Static Map                                 |
================================================================================

  OFFSET    LENGTH  FILE ID  INPUT NAME

       0         1   00001   DFHC0011
       4         1   00001   DFHC0010
       8         2   00001   DFHDUMMY
       C         2   00001   DFHB0025
      10         2   00001   DFHB0024
      14         2   00001   DFHB0023
      18         2   00001   DFHB0022
      1C         2   00001   DFHB0021
      20         2   00001   DFHB0020
      24         2   00001   DFHEIB0
      28         4   00001   DFHEIPTR
      2C         4   00001   DFHCP011
      30         4   00001   DFHCP010
      34         4   00001   DFHBP025
      38         4   00001   DFHBP024
      3C         4   00001   DFHBP023
      40         4   00001   DFHBP022
      44         4   00001   DFHBP021
      48         4   00001   DFHBP020
      4C         4   00001   DFHEICB
      50         4   00001   DFHEID0
      54         4   00001   DFHLDVER
      58       320   00001   @STATIC
```

Figure 41. Writable static map produced by prelinker

3. Find the offset of the static variable in the storage offset listing. The offset is 96 (X'60'). Following is an example of a partial storage offset listing.

   ```
   ss0     66-0:66    Class = static,    Location = GPR13(96),   Length = 4
   ```

   Add this offset to the result from step 2. The result is X'2D66EF8' (X'2D66E98' + X'60'). This is the address of the value of the static variable in the dump.
4. Find the offset of sz0 in the Aggregate Map, shown in Figure 40 on page 154. The offset is 60.

Add the offset from the Aggregate Map to the address of the ss0 struct. The result is X'60' (X'3C' + X'60'). This is the address of the values of sz0 in the dump.

Finding the timestamp

The timestamp is in the compile unit block. The address for the compile unit block is located at eight bytes past the function entry point. The compile unit block is the same for all functions in the same compilation. The fourth word of the compile unit block points to the timestamp. The timestamp is 16 bytes long and has the following format:

```
YYYYMMDDHHMMSSSS
```

Generating a Language Environment dump of a C/C++ routine

You can use either the CEE3DMP callable service or the `cdump()`, `csnap()`, and `ctrace()` C/C++ functions to generate a Language Environment dump of C/C++ routines. These C/C++ functions call CEE3DMP with specific options.

cdump()

If your routine is running under z/OS or CICS, you can generate useful diagnostic information by using the `cdump()` function. `cdump()` produces a main storage dump with the activation stack. This is equivalent to calling CEE3DMP with the option string: TRACEBACK BLOCKS VARIABLES FILES STORAGE STACKFRAME(ALL) CONDITION ENTRY.

When `cdump()` is invoked from a user routine, the C/C++ library issues an OS SNAP macro to obtain a dump of virtual storage. The first invocation of `cdump()` results in a SNAP identifier of 0. For each successive invocation, the ID is increased by one to a maximum of 256, after which the ID is reset to 0.

The output of the dump is directed to the CEESNAP data set. The DD definition for CEESNAP is as follows:

```
 //CEESNAP DD SYSOUT= *
```

If the data set is not defined, or is not usable for any reason, `cdump()` returns a failure code of 1. This occurs even if the call to CEE3DMP is successful.

If the SNAP is not successful, the CEE3DMP DUMP file displays the following message:

```
Snap was
unsuccessful
```

If the SNAP is successful, CEE3DMP displays this message:

```
 Snap was
successful; snap ID = nnn
```

Where *nnn* corresponds to the SNAP identifier described above. An unsuccessful SNAP does not result in an incrementation of the identifier.

Because `cdump()` returns a code of 0 only if the SNAP was successful or 1 if it was unsuccessful, you cannot distinguish whether a failure of `cdump()` occurred in the call to CEE3DMP or SNAP. A return code of 0 is issued only if both SNAP and CEE3DMP are successful.

Support for SNAP dumps using the `_cdump` function is provided only under z/OS and z/VM. SNAP dumps are not supported under CICS; no SNAP is produced in this environment. A successful SNAP results in a large quantity of output. A routine calling `cdump()` under CICS receives a return code of 0 if the ensuing call to CEE3DMP is successful. In addition to a SNAP dump, a Language Environment formatted dump is also taken.

csnap()

The `csnap()` function produces a condensed storage dump. `csnap()` is equivalent to calling CEE3DMP with the option string: TRACEBACK FILES BLOCKS VARIABLES NOSTORAGE STACKFRAME(ALL) CONDITION ENTRY.

To use these functions, you must add `#include <ctest.h>` to your C/C++ code. The dump is directed to output *dumpname* , which is specified in a `//CEEDUMP DD` statement in MVS/JCL.

`cdump()`, `csnap()`, and `ctrace()` all return a 1 code in the SPC environment because they are not supported in SPC.

Refer to the *z/OS XL C/C++ Run-Time Library Reference* for more details about the syntax of these functions.

ctrace()

The `ctrace()` function produces a traceback and includes the offset addresses from which the calls were made. `ctrace()` is equivalent to calling CEE3DMP with the option string: TRACEBACK NOFILES NOBLOCKS NOVARIABLES NOSTORAGE STACKFRAME(ALL) NOCONDITION NOENTRY.

Sample C routine that calls cdump()

Figure 42 on page 157 shows a sample C routine that uses the `cdump` function to generate a dump.

Figure 47 on page 161 shows the dump output.

```
#include <stdio.h>
#include <signal.h>
#include <stdlib.h>

void hsigfpe(int);
void hsigterm(int);
void atf1(void);

typedef int (*FuncPtr_T)(void);

int st1    =  99;
int st2    = 255;
int xcount =   0;

int main(void) {
  /*
   * 1) Open multiple files
   * 2) Register 2 signals
   * 3) Register 1 atexit function
   * 4) Fetch and execute a module
   */

  FuncPtr_T fetchPtr;
  FILE*     fp1;
  FILE*     fp2;
  int       rc;
  fp1 = fopen("myfile.data", "w");
  if (!fp1) {
    perror("Could not open myfile.data for write");
    exit(101);
  }

  fprintf(fp1, "record 1\n");
  fprintf(fp1, "record 2\n");
  fprintf(fp1, "record 3\n");

  fp2 = fopen("memory.data", "wb,type=memory");
  if (!fp2) {
    perror("Could not open memory.data for write");
    exit(102);
  }
  fprintf(fp2, "some data");
  fprintf(fp2, "some more data");
  fprintf(fp2, "even more data");

  signal(SIGFPE , hsigfpe);
  signal(SIGTERM, hsigterm);

  rc = atexit(atf1);
  if (rc) {
    fprintf(stderr, "Failed on registration of atexit function atf1\n");
    exit(103);
  }
```

Figure 42. Example C routine using cdump() to generate a dump (Part 1 of 2)

```
  fetchPtr = (FuncPtr_T) fetch("MODULE1");
  if (!fetchPtr) {
    fprintf(stderr, "Failed to fetch MODULE1\n");
    exit(104);
  }
  fetchPtr();
  return(0);
}

void hsigfpe(int sig) {
  ++st1;
  return;
}

void hsigterm(int sig) {
  ++st2;
  return;
}

void atf1() {
  ++xcount;
}
```

Figure 42. Example C routine using cdump() to generate a dump (Part 2 of 2)

Figure 43 shows a fetched C module:

```
#include <ctest.h>

#pragma linkage(func1, fetchable)
int func1(void) {
  cdump("This is a sample dump");
  return(0);
}
```

Figure 43. Fetched module for C routine

Sample C++ routine that generates a Language Environment dump

Figure 44 on page 159 shows a sample C++ routine that uses a protection exception to generate a dump.

```
#include <iostream.h>
#include <ctest.h>
#include "stack.h"

int main() {
  cout << "Program starting:\n";
  cerr << "Error report:\n";

  Stack<int> x;
  x.push(1);
  cout << "Top value on stack : " << x.pop() << '\n';
  cout << "Next value on stack: " << x.pop() << '\n';
  return(0);
}
```

Figure 44. Example C++ routine with protection exception generating a dump

Figure 45 shows the template file stack.c

```
#ifndef __STACK__
  #include "stack.h"
#endif

template <class T> T Stack<T>::pop() {
  T value = head->value;
  head = head->next;

  return(value);
}
template <class T> void Stack<T>::push(T value) {
  Node* newNode  = new Node;
  newNode->value = value;
  newNode->next  = head;
  head = newNode;
}
```

Figure 45. Template file STACK.C

Figure 46 on page 160 shows the header file **stack.h**.

```
#ifndef __STACK_
  #define __STACK__
  template <class T> class Stack {
    public:
      Stack() {
        char* badPtr = 0; badPtr -= (0x01010101);
        head = (Node*) badPtr; /* head initialized to 0xFEFEFEFF */
      }
      T pop();
      void push(T);
    private:
      struct Node {
        T value;
        struct Node* next;
      }* head;
  };
#endif
```

Figure 46. Header file STACK.H

Sample Language Environment dump with C/C++-specific information

This sample dump was produced by compiling the routine in Figure 42 on page 157 with the TEST(SYM) compiler option, then running it. Notice the sequence of calls in the traceback section - EDCZMINV is the C-C++ management module that invokes `main` and @@FECBMODULE1 fetches the user-defined function `func1`, which in turn calls the library routine `__cdump`.

If source code is compiled with the `GONUMBER` or `TEST` compile option, statement numbers are shown in the traceback. If source code is compiled with the `TEST(SYM)` compile option, variables and their associated type and value are dumped out. For more information about C/C++-specific information contained in a dump, see “Finding C/C++ information in a Language Environment dump” on page 166.

```
     CEE3DMP V1 R9.0: This is a sample dump                                    01/10/07 1:12:11 PM                Page:    1

Figure 47. Example dump from sample C routine (Part 6 of 6)

Finding C/C++ information in a Language Environment dump

When a Language Environment traceback or dump is generated for a C/C++ routine, information is provided that is unique to C/C++ routines. C/C++-specific information includes:

- Control block information for active routines
- Condition information for active routines
- Enclave level data

Each of the unique C/C++ sections of the Language Environment dump are described.

[1] Storage for Active Routines

The Storage for Active Routines section of the dump shows the DSAs for the active C and C++ routines. To relate a DSA frame to a particular function name, use the address associated with the frame to find the corresponding DSA. In this example, the function `func1` DSA address is X'20FCB468'.

[2] Control Blocks Associated with the Active Thread

In the Control Blocks Associated with the Thread section of the dump, the following information appears:
- Fields from the CAA
- Fields specific from the CTHD and CEDB
- Signal information

[2A] C/C++ CAA Fields

The CAA contains several fields that the C/C++ programmer can use to find information about the run-time environment. For each C/C++ program, there is a C-C++ Specific Thread area and a C-C++ Specific Enclave area.

[2B] C-C++ Specific CAA

The C-C++ specific CAA fields that are of interest to users are described below.

errno value	A variable used to display error information. Its value can be set to a positive number that corresponds to an error message. The functions `perror()` and `strerror()` print the error message that corresponds to the value of `errno`.
Memory file control block	You can use the memory file control block (MFCB) to locate additional information about memory files. This control block resides at the C/C++ thread level. For more information about the MFCB, see 168.
Open FCB chain	A pointer to the start of a linked list of open file control blocks (FCBs). For more information about FCBs, see 168.

[3] Signal Information

When the POSIX(OFF) run-time option is specified, signal information is provided in the dump to aid you in debugging. For each signal that is disabled with `SIG_IGN`, an entry value of 00000001 is made in the first field of the Signal Information field for the specified signal name.

For each signal that has a handler registered, the signal name and the handler name are listed. If the handler is a fetched C function, the value `@@FECB` is entered as the function name and the address of the fetched pointer is in the first field.

If you compile a C routine as `NORENT`, the WSA address is not available (`N/A`). For more information about the `signal` function, see *z/OS XL C/C++ Programming Guide*.

[4] WSA Address

The `WSA Address` is the base address of the writable static area which is available for all C and C++ programs except C programs compiled with the `NORENT` compile option.

[5] atexit() Information

The `atexit()` information lists the functions registered with the `atexit()` function that would be run at normal termination. The functions are listed in chronological order of registration.

If you compile a C routine as NORENT, the WSA address is not available (N/A). For more information about the atexit() function, see *z/OS XL C/C++ Run-Time Library Reference*.

[6] fetch() Information

The fetch() information shows information about modules that you have dynamically loaded using fetch(). For each module that was fetched, the fetch() pointer and the function pointer are included.

```
ptr1 = fetch("MOD");
```

If you compile a C routine as NORENT, the WSA address is not available (N/A). For more information about the fetch() function, see *z/OS XL C/C++ Programming Guide*.

[7] File Control Block Information

This section of the dump includes the file control block (FCB) information for each C/C++ file. The FCB contains file status and attributes for files open during C/C++ active routines. You can use this information to find the data set or file name.

The FCB is a handle that points to the following file information, which is displayed when applicable, for the file:

- Access method control block (ACB) address
- Data control block (DCB) address
- Data control block extension (DCBE) address
- Job file control block (JFCB) address
- RPL address
- Current buffer address
- Saved buffer address
- ddname

Not all FCB fields are always filled in. For example, RPLs are used only for VSAM data sets. The ddname field contains blanks if it is not used.

The save block buffer represents auxiliary buffers that are used to save the contents of the main buffers. Such saving occurs only when a reposition is performed and there is new data; for example, an incomplete text record or an incomplete fixed-block standard (FBS) block in the buffers that cannot be flushed out of the system.

Because the main buffers represent the current position in the file, while the save buffers merely indicate a save has occurred, check the save buffers only if data appears to be missing from the external device and is not found in the main buffers. Also, do not infer that the presence of save buffers means that data present there belongs at the end of the file. (The buffers remain, even when the data is eventually written.)

For information about the job file control block, refer to *z/OS MVS Data Areas, Vol 3 (IVT-RCWK)*.

Memory File Control Block

This section of the dump holds the memory file control block information for each memory file the routine uses. A sample memory file control block is shown in Figure 48.

```

```

Figure 48. Memory file control block

Memory file name The name assigned to this memory file.

First memory data space A dump of the first 1K maximum of actual user data associated with this memory file.

[8] Information for __amrc

__amrc is a structure defined in the **stdio.h** header file to assist in determining errors resulting from I/O operations. The contents of __amrc can be checked for system information, such as the return code for VSAM. Certain fields of the __amrc structure can provide useful information about what occurred previously in your routine.

For more information about __amrc, refer to “Debugging C/C++ programs” on page 137 and to *z/OS XL C/C++ Programming Guide*.

[9] Errno Information

The Errno information shows the thread id of the thread that generated the dump and the settings of the errno and errnojr variables for that thread.

Both the errno and the errnojr variables contain the return code of the last failing z/OS UNIX system service call. These variables provide z/OS UNIX application programs access to diagnostic information returned from an underlying z/OS UNIX callable service. For more information on these return and reason codes, refer to *z/OS UNIX System Services Messages and Codes*.

Additional Floating-Point registers

The Language Environment dump formats Additional Floating Point (AFP™) registers and Floating Point Control (FPC) registers when the AFP suboption of the FLOAT XL C/C++ compiler option is specified and the registers are needed. These floating-point registers are displayed in three sections of the CEEDUMP; Registers on Entry to CEE3DMP; Parameters, Registers, and Variables; and Condition Information for Active Routines. Samples of each section are given. For information on the FLOAT XL C/C++ compiler option, see *z/OS XL C/C++ User's Guide* .

Registers on entry to CEE3DMP: This section of the Language Environment dump displays the twelve floating-point registers. A sample output is shown.

```

Figure 51. Condition information for active routines

Sample Language Environment dump with XPLINK-specific information

The programs `tranmain` shown in Figure 52 on page 172 and `trandll` shown in Figure 53 on page 173 were used to produce a Language Environment dump. The dump shows XPLINK-compiled routines calling NOXPLINK-compiled routines, and NOXPLINK-compiled routines calling XPLINK-compiled routines. The program `tranmain` was compiled XPLINK and `trandll` was compiled NOXPLINK. Each was link-edited as a separate program object with the sidedeck from the other. The Language Environment dump produced by running these program is shown in Figure 54 on page 174. Explanations for some of the sections are in “Finding XPLINK information in a Language Environment dump” on page 176.

```
#pragma runopts(TRACE(ON,1M,NODUMP,LE=1),XPLINK(ON),TERMTHDACT(UADUMP))
#include <stdio.h>
#pragma export(tran2)

int tran1(int, int, int, long double, int);
int tran3(int, int, int, long double, int);

Figure 54. Example dump of calling between XPLINK and non-XPLINK programs (Part 3 of 3)

Finding XPLINK information in a Language Environment dump

[1] Traceback

When an XPLINK-compiled routine calls a NOXPLINK-compiled routine, a glue routine gets control to convert the linkage conventions of the XPLINK caller to those of the NOXPLINK callee. In the sample dump, this routine is CEEVRONU and it appears between `main()` and tran1() and again between `tran2()` and `tran3()`.

When a NOXPLINK-compiled routine calls an XPLINK-compiled routine, a glue routine gets control to convert the linkage conventions of the NOXPLINK caller to those of the XPLINK callee. In the sample dump, this routine is CEEVROND and it appears between EDCZHINV and `main()` and again between `tran1()` and `tran2()`.

[2] Parameters, Registers, and Variables for Active Routines

In this section, each DSA is identified as one of the following:

UPSTACK DSA The DSA format is that for a NOXPLINK-compiled program that uses an upward growing stack.

DOWNSTACK DSA The DSA format is that for ax XPLINK-compiled program that uses an downward growing stack.

TRANSITION DSA The DSA format is that of its callee. A transition DSA can occur between an UPSTACK DSA and a DOWNSTACK DSA where it represents a transition from one linkage convention to another. A transition DSA can also occur between two DOWNSTACK DSAs where it represents a transition from one stack segment to another (a stack overflow).

[3] Control Blocks for Active Routines

In this section, DSAs are formatted. Those previously identified as UPSTACK DSAs will have one format and those identified as DOWNSTACK DSAs will have a different format. Those identified as TRANSITION DSAs will have two parts — the first will be either the downstack or upstack format, the second is unique to transition DSAs and contains information about the transition.

It is important to understand that the registers saved in an upstack DSA are those saved by a routine that the DSA-owning routine called. Typically register 15 is the entry point of the routine that was called, and register 14 is the return address into the DSA-owning routine. In contrast, the registers saved in an downstack DSA are those saved by the DSA-owning routine on entry. Register 7 is the return address back to the caller of the DSA-owning routine. Register 6 may be the entry point of the DSA-owning routine. (This is not true when the Branch Relative and Save instruction is used to implement the call.)

C/C++ contents of the Language Environment trace tables

Language Environment provides four C/C++ trace table entry types that contain character data:

- Trace entry 1 occurs when a base C library function is called.
- Trace entry 2 occurs when a base C library function returns.
- Trace entry 3 occurs when a POSIX C library function is called.
- Trace entry 4 occurs when a POSIX C library function returns.
- Trace entry 5 occurs when an XPLINK base C or POSIX C library function is called.
- Trace entry 6 occurs when an XPLINK base C or POSIX C library function returns.
- Trace entry 7 occurs when an XPLINK function calls a non-XPLINK function.
- Trace entry 8 occurs when a non-XPLINK function calls an XPLINK function.

The format for trace table entry 1 is:

```
NameOfCallingFunction
—>(xxx) NameOfCalledFunction
```

or, for called functions calloc, free, malloc, and realloc:

```
NameOfCallingFunction
—>(xxx) NameOfCalledFunction<(input_parameters)>
```

In addition, when the call is due to one of these C++ operators:

```
-new,
-new[],
-delete,
-delete[]
```

then the C++ operator will appear and the format becomes:

```
NameOfCallingFunction
—>(xxx) NameOfCalledFunction<(input_parameters)>

NameOfC++Operator
```

The format for trace table entry 2 is:

```
<—(xxx) R15=value ERRNO=value
```

The format for trace table entry 3 is:

```
NameOfCallingFunction
—>(xxx) NameOfCalledFunction
```

The format for trace table entry 4 is:

```
<—(xxx) R15=value ERRNO=value ERRNO2=value
```

The format for trace table entry 5 is:

```
NameOfCallingFunction
-->(xxxx) NameOfCalledFunction<(input_parameters)>
```

5 is just like trace table entry 1. The `input_parameters` and `NameOfC++Operator` only appear for the appropriate functions. The angle brackets (<>) indicate that this information does not always appear.

The format for trace table entry 6 is:

```
<--(xxxx) R1=xxxxxxxx R2=xxxxxxxx R3=xxxxxxxx ERRNO=xxxxxxxx ERRNO2=xxxxxxxx
```

In all entry types, (xxx) and (xxxx) are numbers associated with the called library function and are used to associate a specific entry record with its corresponding return record.

For entry types 5 and 6, the number will be the same as the number of the function as seen in the C run-time library definition side-deck, SCEELIB dataset member CELHS003, on the IMPORT statement for that function.

The format for trace table entry 7 is:

```
ModuleNameOfCallingFunction:NameOfCallingXplinkFunction
-->ModuleNameOfCalledFunction:NameOfCalledNonXplinkFunction
```

The format for trace table entry 8 is:

```
ModuleNameOfCallingFunction:NameOfCallingNonXplinkFunction
-->ModuleNameOfCalledFunction:NameOfCalledXplinkFunction
```

For entry types 7 and 8, 16 bytes is for the module name and 32 bytes is for the function name. If the name is longer than 16 or 32 bytes, an extra trace entry is taken. The name is truncated and only the first 32/64(16/32) bytes will appear in the trace table entry. Also, a module name might not always be located, such as when a DLL is freed. If that occurs, ″UNKNOWN″ appears for the module name in the trace table entry.

Figure 55 shows a non-XPLINK trace which has examples of C/C++ trace table entry types 1 thru 4.

```

Debugging examples of C/C++ routines

This section contains examples that demonstrate the debugging process for C/C++ routines. Important areas of the output are highlighted. Data unnecessary to the debugging examples has been replaced by ellipses.

Divide-by-zero error

Figure 58 illustrates a C program that contains a divide-by-zero error. The code was compiled with RENT so static and external variables need to be calculated from the WSA field. The code was compiled with XREF, LIST and OFFSET to generate a listing, which is used to calculate addresses of functions and data. The code was processed by the binder with MAP to generate a binder map, which is used to calculate the addresses of static and external variables.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
int statint = 73;
int fa;
void funcb(int *pp);

int main(void) {
  int aa, bb=1;
  aa = bb;
  funcb(&aa);
  return(99);
}

void funcb(int *pp) {
  int result;
  fa = *pp;
  result = fa/(statint-73);
  return;
}
```

Figure 58. C routine with a divide-by-zero error

To debug this routine, use the following steps:

1. Locate the Original Condition message in the Condition Information for Active Routines section of the dump. In this example, the message is CEE3209S. The system detected a fixed—point divide exception. This message indicates the error was caused by an attempt to divide by zero. For additional information about CEE3209S, see *z/OS Language Environment Run-Time Messages*.

   The traceback section of the dump indicates that the exception occurred at offset X'76' within function funcb. This information is used along with the compiler-generated Pseudo Assembly Listing to determine where the problem occurred.

   If the TEST compiler option is specified, variable information is in the dump. If the GONUMBER compiler option is specified, statement number information is in the dump. Figure 59 on page 185 shows the generated traceback from the dump.

```

Figure 59. Sections of the dump from example C/C++ routine

2. Locate the instruction with the divide-by-zero error in the Pseudo Assembly Listing in Figure 60 on page 186.

   The offset (within `funcb`) of the exception from the traceback (X'76') reveals the divide instruction: `DR  r4,r1` at that location. Instructions X'66' through X'76' refer to the `result = fa/(statint-73);` line of the C/C++ routine.

⋮
```

Figure 60. Pseudo assembly listing

3. Verify the value of the divisor `statint`. The procedure specified below is to be used for determining the value of static variables only. If the divisor is an

automatic variable, there is a different procedure for finding the value of the variable. For more information about finding automatic variables in a dump, see “Steps for finding automatic variables” on page 147.

Because this routine was compiled with the RENT option, find the WSA address in the Enclave Control Blocks section of the dump. In this example, this address is X'20914F50'. Figure 61 shows the WSA address.

```
 Enclave Control Blocks:
.
.
.
   WSA address.................20914F50
.
.
.
```

Figure 61. C/C++ CAA information in dump

4. Routines compiled with the RENT option must also be processed by the binder. The binder produces the Writable Static Map. Find the offset of `statint` in the Writable Static Map in Figure 62. In this example, the offset is X'0'.

```
.
.
---------------
CLASS  C_WSA            LENGTH =       AC  ATTRIBUTES = MRG, DEFER , RMODE=ANY
                        OFFSET =        0 IN SEGMENT 002       ALIGN = DBLWORD
---------------

           CLASS
          OFFSET  NAME               TYPE    LENGTH   SECTION
               0  statint          PART             4  statint
               8  fa               PART             4  fa
              10  environ          PART             4  environ
              18  errno            PART             4  errno
.
.
.
```

Figure 62. Writable static map

5. Add the WSA address of X'20914F50' to the offset of `statint`. The result is X'20914F50'. This is the address of the variable `statint`, which is in the writable static area.

   The writable static area is shown in the Enclave Storage section of the dump.

   For a load module, the writable static area is storage allocated by the C/C++ run-time for the C/C++ user, so it is in the user heap. For a program object, the writable static area is storage allocated by the loader and is shown in the WSA for Program Object(s) section of the dump.

   For this example, the program was built as a program object. The writable static area is displayed in the Enclave Storage section of the dump, shown in Figure 63 on page 188.
6. To find the variable `statint` in the writable static area, locate the closest address listed that is before the address of `statint`. In this case, that address is X'20914F50'. Count across X'00' to location X'20914F50'. The value at that location is X'49' (that is, `statint` is 73), and hence the fixed point divide exception.

```

Figure 63. Enclave storage section of dump

Calling a nonexistent non-XPLINK function

Figure 64 demonstrates the error of calling a nonexistent function. This routine was compiled with the compiler options LIST, OFFSET, and RENT and was run with the option TERMTHDACT(DUMP). The code was processed by the binder with MAP to generate a binder map, which is used to calculate the addresses of static and external variables.

This routine was not compiled with the TEST(ALL) compiler option. As a result, arguments and variables do not appear in the dump.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <signal.h>
void funca(int* aa);
int (*func_ptr)(void)=0;
int main(void) {
  int aa;
  funca(&aa);
  printf("result of funca = %d\n",aa);
  return;
}
void funca(int* aa) {
  *aa = func_ptr();
  return;
}
```

Figure 64. C/C++ example of calling a nonexistent subroutine

To debug this routine, use the following steps:

1. Locate the Original Condition message in the Condition Information for Active Routines section of the dump, shown in Figure 65 on page 189. In this example, the message is `CEE3201S The system detected an operation exception (System Completion Code=0C1).` This message suggests that the error was caused by an attempt to branch to an unknown address. For additional information about CEE3201S, see *z/OS Language Environment Run-Time Messages*.

   The Location section of the dump indicates that the exception occurred at offset X'-20900978' within function `funca` and that there may have been a bad branch from offset X'+0000005A' within function `funca` . The negative offset indicates that the offset cannot be used to locate the instruction that caused the error. Another indication of bad data is the value of X'80000002' in the instruction

address of the PSW. This address indicates that an instruction in the routine branched outside the bounds of the routine.

```

```

Figure 67. Writable static map

4. Add the offset of `FUNC@PTR` (X'0') to the address of WSA (X'20914F58'). The result (X'20914F58') is the address of the function pointer `func_ptr` in the writable static storage area within the heap. This value is 0, indicating the variable is uninitialized.

   Figure 68 on page 191 shows the sections of the dump.

Figure 68. Enclave control blocks and storage sections in dump

Calling a nonexistent XPLINK function

Figure 69 demonstrates the error of calling a nonexistent function. This routine was compiled with the compiler options XPLINK, LIST and RENT and was run with the option TERMTHDACT(DUMP).

This routine was not compiled with the TEST(ALL) compile option. As a result, arguments and variables do not appear in the dump.

```
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <signal.h>
void funca(int* aa);
int (*func_ptr)(void)=0;
int main(void) {
  int aa;
  funca(&aa);
  printf("result of funca = %d\n",aa);
  return;
}
void funca(int* aa) {
  *aa = func_ptr();
  return;
}
```

Figure 69. C/C++ example of calling a nonexistent subroutine

To debug this routine, use the following steps:

1. Locate the Original Condition message in the Condition Information for Active Routines section of the dump, shown in Figure 70 on page 192. In this example, the message is `CEE3201S The system detected an operation exception (System Completion Code=0C1).` This message suggests that the error was caused by an attempt to branch to an unknown address. For additional information about CEE3201S, see *z/OS Language Environment Run-Time Messages*.

   The location section of the dump indicates that the exception occurred at offset X'-20900158' within function `funca` and that there may have been a bad branch from offset X'+0000001C'. The negative offset indicates that the offset cannot be used to locate the instruction that caused the error. Another indication of bad data is the value of X'80000004' in the instruction address of the PSW. This

address indicates that an instruction in the routine branched outside the bounds of the routine.

```

Figure 73. Enclave control blocks and storage sections in dump

Handling dumps written to the z/OS UNIX file system

When a z/OS UNIX C/C++ application program is running in an address space created as a result of a call to `spawnp()`, `vfork()`, or one of the `exec` family of functions, the SYSMDUMP DD allocation information is not inherited. Even though the SYSMDUMP allocation is not inherited, a SYSMDUMP allocation must exist in the parent in order to obtain a HFS storage dump.

Alternatively, you can specify the DYNDUMP run-time option to generate a system dump. For more information, see *z/OS Language Environment Programming Reference*.

If the program terminates abnormally while running in this new address space, the kernel causes an unformatted storage dump to be written to an HFS file in the user's working directory. The file is placed in the current working directory or into /tmp if the current working directory is not defined. The file name has the following format:

`/directory/coredump.pid`

where directory is the current working directory or tmp, and pid is the hexadecimal process ID (PID) for the process that terminated. For details on how to generate the system dump, see “Steps for generating a system dump in a z/OS UNIX shell” on page 82.

To debug the dump, use the MVS Interactive Problem Control System (IPCS). If the dump was written to an HFS file, you must allocate a data set that is large enough and has the correct attributes for receiving a copy of the HFS file. For example, from the ISPF DATA SET UTILITY panel you can specify a volume serial and data set name to allocate. Doing so brings up the DATA SET INFORMATION panel for specifying characteristics of the data set to be allocated. The following filled-in panel shows the characteristics defined for the URCOMP.JRUSL.COREDUMP dump data set:

```
-------------------------  DATA SET INFORMATION  ----------------------
Command ===>

Data Set Name  . . . : URCOMP.JRUSL.COREDUMP

General Data                          Current Allocation
 Management class . . : STANDARD       Allocated cylinders : 30
 Storage class  . . . : OS390          Allocated extents . : 1
  Volume serial . . . : DPXDU1
  Device type . . . . : 3380
 Data class . . . . . :
  Organization  . . . : PS             Current Utilization
  Record format . . . : FB              Used cylinders. . . : 0
  Record length . . . : 4160            Used extents  . . . : 0
  Block size  . . . . : 4160
  1st extent cylinders: 30
  Secondary cylinders : 10
  Data set name type  :

  Creation date . . . : 2001/08/30
  Expiration date . . : ***None***

F1=Help     F2=Split     F3=End       F4=Return    F5=Rfind     F6=Rchange
F7=Up       F8=Down      F9=Swap     F10=Left     F11=Right    F12=Cancel
```

Figure 74. IPCS panel for entering data set information

Fill in the information for your data set as shown, and estimate the number of cylinders required for the dump file you are going to copy.

Use the TSO/E OGET or OCOPY command with the BINARY keyword to copy the file into the data set. For example, to copy the HFS storage dump file `coredump.00060007` into the data set URCOMP.JRUSL.COREDUMP just allocated, a user with the user ID URCOMP enters the following command:

```
OGET '/u/urcomp/coredump.00060007' 'urcomp.jrusl.coredump' BINARY
```

For more information on using the copy commands, see *z/OS UNIX System Services User’s Guide*.

After you have copied the storage dump file to the data set, you can use IPCS to analyze the dump. Refer to “Formatting and analyzing system dumps” on page 83 for information about formatting Language Environment control blocks.

Multithreading consideration

Certain control blocks are locked while a dump is in progress. For example, a `csnap()` of the file control block would prevent another thread from using or dumping the same information. An attempt to do so causes the second thread to wait until the first one completes before it can continue.

Understanding C/C++ heap information in storage reports

Storage reports that contain specific C/C++ heap information can be generated in two ways:

- By setting the Language Environment RPTSTG(ON) run-time option for Language Environment created heaps
- By issuing a stand-alone call to the C function `__uheapreport()` for user–created heaps.

Details on how to request and interpret the reports are provided in the following sections.

Language Environment storage report with HeapPools statistics

To request a Language Environment storage report set RPTSTG(ON). If the C/C++ application specified the HEAPPOOLS(ON) run-time option, then the storage report displays HeapPools statistics. For a sample storage report showing HeapPools statistics for a multithreaded C/C++ application, see Figure 3 on page 14.

The following describes the C/C++ specific heap pool information.

HeapPools storage statistics

The HEAPPOOLS run-time option controls usage of the heap pools storage algorithm at the enclave level. The heap pools algorithm allows for the definition of one to twelve heap pools, each consisting of a number of storage cells of a specified length.

Usage Note: The use of an alternative Vendor Heap Manager (VHM) overrides the use of the HEAPPOOLS run-time option.

HeapPools statistics:

- Pool *p* size: *ssss*
  - *p* — the number of the pool
  - *ssss* — the cell size specified for the pool.
- Successful Get Heap requests: *xxxx-yyyy n*
  - *xxxx* — the low side of the 8 byte range
  - *yyyy* — the high side of the 8 byte range
  - *n* — the number of requests in the 8 byte range.
- Requests greater than the largest cell size — the number of storage requests that are not satisfied by heap pools.

Note: Values displayed in the HeapPools Statistics report are not serialized when collected, therefore the values are not necessarily exact.

HeapPools summary: The HeapPools Summary displays a report of the HeapPool Statistics and provides suggested percentages for current cell sizes as well as suggested cell sizes.

- Specified Cell Size — the size of the cell specified in the HEAPPOOLS run-time option

- Element Size — the size of the cell plus any additional storage needed for control information or to maintain alignment
- Extent Percent — the cell pool percent specified by the HEAPPOOLS run-time option
- Cells Per Extent — the number of cells per extent. This number is calculated using the following formula:

  ```
  Initial Heap Size * (Extent Percent/100))/(Element Size)
  ```

  with a minimum of four cells.

  Note: Having a small number of cells per extent is not recommended since the pool could allocate many extents, which would cause the HeapPool algorithm to perform inefficiently.
- Extents Allocated — the number of times that each pool allocated an extent.

  In order to optimize storage usage, the extents allocated should be either one or two. If the number of extents allocated is too high, then increase the percentage for the pool.
- Maximum Cells Used — the maximum number of cells used for each pool.
- Cells In Use — the number of cells that were never freed.

  Note: A large number in this field could indicate a storage leak.
- Suggested Percentages for current Cell Sizes — percentages calculated to find the optimal size of the cell pool extent. The calculation is based on the following formula:

  ```
  (Maximum Cells Used * (Element Size) * 100) / Initial Heap Size
  With a minimum of 1% and a maximum of 90%
  ```

  Make sure that your cell pool extents are neither too large nor too small. If your percentages are too large then additional, unreferenced virtual storage will be allocated, thereby causing the program to exhaust the region size. If the percentages are too small then the HeapPools algorithm will run inefficiently.
- Suggested Cell Sizes — sizes that are calculated to optimally use storage (assuming that the application will __malloc/__free with the same frequency).

  Note: The suggested cell sizes are given with no percentages because the usage of each new cell pool size is not known. If there are less than 12 cell sizes calculated and the last calculated cell size is smaller than the largest cell size currently in effect, the largest cell size currently in effect will be used for the last suggested cell size.

For more information about stack and heap storage, see *z/OS Language Environment Programming Guide*.

C function __uheapreport() storage report

To generate a user-created heap storage report use the C function, *__uheapreport()*. Use the information in the report to assist with tuning your application's use of the user-created heap.

User-created HeapPools statistics

- Pool *p* size: *ssss*
  - *p* — the number of the pool
  - *ssss* — the cell size specified for the pool.
- Successful Get Heap requests: *xxxx-yyyy n*
  - *xxxx* — the low side of the range

- *yyyy* — the high side of the range
- *n* — the number of requests in the range.

- Requests greater than the largest cell size — the number of storage requests that are not satisfied by heap pools.

Note: Values displayed in the HeapPools Statistics report are not serialized when collected, therefore the values are not necessarily exact.

HeapPools summary

The HeapPools Summary displays a report of the HeapPool Statistics and provides suggested percentages for current cell sizes as well as suggested cell sizes.

- Cell Size — the size of the cell specified on the __ucreate() call
- Extent Percent — the cell pool percent specified on the __ucreate() call
- Cells Per Extent — the number of cells per extent. This number is calculated using the following formula:

  ```
  Initial Heap Size * (Extent Percent/100))/(8 + Cell Size)
  ```

  with a minimum of four cells.
- Extents Allocated — the number of times that each pool allocated an extent.
- Maximum Cells Used — the maximum number of cells used for each pool.
- Cells In Use — the number of cells that were never freed.

  Note: A large number in this field could indicate a storage leak.
- Suggested Percentages for current Cell Sizes — percentages calculated to find the optimal size of the cell pool extent. The calculation is based on the following formula:

  ```
  (Maximum Cells Used * (Cell Size + 8) * 100) / Initial Heap Size
  With a minimum of 1% and a maximum of 90%
  ```

  Make sure that your cell pool extents are neither too large nor too small. If your percentages are too large then additional, unreferenced virtual storage will be allocated, thereby causing the program to exhaust the region size. If the percentages are too small then the HeapPools algorithm will run inefficiently.
- Suggested Cell Sizes — sizes that are calculated to optimally use storage (assuming that the application will __umalloc/__ufree with the same frequency).

  Note: The suggested cell sizes are given with no percentages because the usage of each new cell pool size is not known. If there are less than 12 cell sizes calculated and the last calculated cell size is smaller than the largest cell size currently in effect, the largest cell size currently in effect will be used for the last suggested cell size.

For more information about stack and heap storage, see *z/OS Language Environment Programming Guide*.

For more information on the *__uheapreport()* function, see *z/OS XL C/C++ Run-Time Library Reference*. For tuning tips, see *z/OS Language Environment Programming Guide*.

A sample storage report generated by *__uheapreport()* is shown in Figure 75 on page 199.

```
Storage Report for Enclave  08/30/01 11:42:23 AM
Language Environment V01 R03.00

    HeapPools Statistics:

Figure 75. Storage report generated by __uheapreport()

MEMCHECK VHM memory leak analysis tool

The MEMCHECK VHM memory leak analysis tool is an alternative vendor heap manager used to diagnose memory problems. MEMCHECK VHM performs the following functions:

- check for heap storage leaks, double free, and overlays
- trace user heap storage allocation and deallocation requests

The results are displayed in two reports.

Restrictions

- MEMCHECK VHM works with C/C++ and Enterprise PL/I applications, but is not enabled for COBOL or Fortran.
- MEMCHECK VHM and HEAPPOOLS are mutually exclusive. HEAPPOOLS will be ignored when MEMCHEKC VHM is active.
- MEMCHECK VHM should not be used in PIPI, PICI, CICS, and SPC environments.

Invoking MEMCHECK VHM

As with any alternate vendor heap manager, you must specify the dllname with the environment variable _CEE_HEAP_MANAGER to indicate that MEMCHECK VHM will be used to manage the user heap. Since CEE_HEAP_MANAGER must be set

before any user code gains control, use the ENVAR run-time option to set the variable or set it inside the file specified by the environment variable, _CEE_ENVFILE or _CEE_ENVFILE_S. The format is

```
_CEE_HEAP_MANAGER=dllname
```

There are two DLLs associated with MEMCHECK VHM:

CEL4MCHK
31-bit base and xplink.

CELQMCHK
64-bit.

They use the following events:

_VHM_INIT
replaces C-RTL malloc(), calloc(), realloc(), and free() with the corresponding MEMCHECK VHM functions. This event is only at Language Environment Initialization and only called by Language Environment.

_VHM_TERM
terminates Vendor Heap Manager to free the memcheck storage functions. This event is called only by Language Environment at Language Environment Termination.

_VHM_REPORT
generates the Heap Leak Report and the optional Trace Report. This new event will be called by Language Environment at Language Environment Termination and will write the Heap Leak Report (and the optional Trace Report if the _CEE_MEMCHECK_TRACE environment variable is active) in the output file name specified in _CEE_MEMCHECK_OUTFILENAME. This event can also be called dynamically by the __vhm_event() API.

MEMCHECK VHM environment variables

The MEMCHECK VHM environment variables control the tool, the call levels of the Heap Leak Report and Trace Report, the Overlay Analysis, the pad length added in the user heap allocation for overlay analysis, and the output file name for the reports.

They should be activated through the ENVAR run-time option, the file specified by the _CEE_ENV_FILE environment variable, or using the export command from the USS shell before any user code gets control (prior to the HLL user exit, static constructors, or main getting control). Setting these environment variables once the user code has begun execution will not activate them and the default values will be used.

_CEE_MEMCHECK_DEPTH
Description: Controls the number of call-levels to be generated on the Heap Leak Report.

Valid settings: integer value : the minimum is 1 and the maximum is MAX_CALL_LEVELS (100). If an invalid value is specified, the default value will be used.

Default: 10.

_CEE_MEMCHECK_OVERLAY
Description: Activates the storage overlays analysis beyond the end of the malloc'd storage.

Valid settings: ON to activate the analysis, OFF to deactivate. If an invalid value is specified, the default value will be used.

Default: OFF

_CEE_MEMCHECK_OVERLAYLEN

Description: Sets the pad length added in the user heap allocation for overlay analysis. This environment variable will be used only if _CEE_MEMCHECK_OVERLAY is active.

Valid settings: integer value, multiple of 4 : the minimum is 4 and the maximum is MAX_OVERLAY_LENGTH (80). Non-multiples of 4 will be rounded up to the next multiple.

Default: 4

_CEE_MEMCHECK_TRACE

Description: Enables tracing of all heap storage allocation and deallocation and a Trace Report will be generated at Language Environment Termination.

Valid settings: ON to activate the analysis, OFF to deactivate. If an invalid value is specified, the default value will be used.

Default: OFF

_CEE_MEMTRACE_DEPTH

Description: Controls the number of call-levels to be generated in the Trace Report, on each call to a library function that deals with heap. This environment variable will be used only if _CEE_MEMCHECK_TRACE is active.

Valid settings: integer value: the minimum is 1 and the maximum is MAX_CALL_LEVELS (100). If an invalid value is specified, the default value will be used.

Default: 10

_CEE_MEMCHECK_OUTFILENAME

Description: Sets the name of the fully qualified path name of the file in which the Heap Leak Report and Trace Report should be directed. The report name could be any valid name used in C-RTL fopen() function, then it could also generates the reports in a Data Set.

Valid settings: string value. If an invalid value is specified, the default value will be used.

Default: standard error output

MEMCHECK VHM report sample scenario

In this example, the MEMCHECK VHM tool is used by specifying the environment variables from the USS shell. The user specifies a depth of 8 call levels in the Heap Leak Report and 8 call levels in the Trace Report for 31-bit.

1. `Export _CEE_MEMCHECK_DEPTH=8`

   specifies the depth to trace on storage requests (written to the Heap Leak Report)
2. `Export _CEE_MEMCHECK_TRACE=ON`

   activates the Trace Report option
3. `Export _CEE_MEMTRACE_DEPTH=8`

   specifies the depth to trace on storage requests (written to the Trace Report)
4. `Export _CEE_MEMCHECK_OVERLAY=ON`

   activates the Overlay analysis option

5. `Export _CEE_HEAP_MANAGER=CEL4MCHK`

   activates the tool with the 31-bit DLL (automatically generating the Heap Leak Report)

MEMCHECK VHM report examples

Both reports are written at Language Environment termination (_VHM_TERM event). They are written in the output file name specified in _CEE_MEMCHECK_OUTFILENAME and are consistent with the format of other Language Environment reports.

The Trace Report will be generated at Language Environment termination (_VHM_TERM event) if the _CEE_MEMCHECK_TRACE environment variable is active. The report generates the traceback information of all heap storage allocations and deallocations.

Figure 77. Heap Leak Report generated by MEMCHECK VHM

Note: The following names are used within MEMCHECK to denote special cases and may be displayed in any of the reports:

(unknown)
Name of the routine is not known.

(noname)
Routine does not have a name in the PPA section. (For example, module compiled with **compress** option).

(nospace)
Internal memory space reserved by MEMCHECK is full, so name was not saved for the traceback information. No action is needed from the user.

Chapter 5. Debugging COBOL programs

This chapter provides information for debugging applications that contain one or more COBOL programs. It includes information about:

- Determining the source of error
- Generating COBOL listings and the Language Environment dump
- Finding COBOL information in a dump
- Debugging example COBOL programs

Determining the source of error

The following sections describe how you can determine the source of error in your COBOL program. They explain how to simplify the process of debugging COBOL programs by using features such as the DISPLAY statement, declaratives, and file status keys. The following methods for determining errors are covered:

- Tracing program logic
- Finding and handling input/output errors
- Validating data
- Assessing switch problems
- Generating information about procedures

After you have located and fixed any problems in your program, you should delete all debugging aids and recompile it before running it in production. Doing so helps the program run more efficiently and use less storage.

Tracing program logic

You can add DISPLAY statements to help you trace through the logic of the program in a non-CICS environment. If, for example, you determine that the problem appears in an EVALUATE statement or in a set of nested IF statements, DISPLAY statements in each path tell you how the logic flows. You can also use DISPLAY statements to show you the value of interim results.

For example, to check logic flow, you might insert:

```
DISPLAY "ENTER CHECK PROCEDURE".
       .
       .  (checking procedure routine)
       .
DISPLAY "FINISHED CHECK PROCEDURE".
```

to determine whether you started and finished a particular procedure. After you are sure that the program works correctly, comment out the DISPLAY statement lines by putting asterisks in position 7 of the appropriate lines. For a detailed description of the DISPLAY statement, see *Enterprise COBOL for z/OS Language Reference*.

Scope terminators can also help you trace the logic of your program because they clearly indicate the end of a statement. For a detailed description of scope terminators, see *Enterprise COBOL for z/OS Programming Guide* or *COBOL for OS/390 & VM Programming Guide*.

Finding input/output errors

VSAM file status keys can help you determine whether routine errors are due to the logic of your routine or are I/O errors occurring on the storage media.

To use file status keys as a debugging aid, include a test after each I/O statement to check for a value other than 0 in the file status key. If the value is other than 0, you can expect to receive an error message. You can use a nonzero value to indicate how the I/O procedures in the routine were coded. You can also include procedures to correct the error based on the file status key value.

The file status key values and their associated meanings are described in *Enterprise COBOL for z/OS Language Reference* and in *COBOL for OS/390 & VM Language Reference*.

Handling input/output errors

If you have determined that the problem lies in one of the I/O procedures in your program, you can include the USE EXCEPTION/ERROR declarative to help debug the problem. If the file does not open, the appropriate USE EXCEPTION/ERROR declarative is activated. You can specify the appropriate declarative for the file or for the different open attributes—INPUT, OUTPUT, I/O, or EXTEND.

Code each USE AFTER STANDARD ERROR statement in a separate section immediately after the Declarative Section keyword of the Procedure Division. See the rules for coding such usage statements in *Enterprise COBOL for z/OS Language Reference* or in *COBOL for OS/390 & VM Language Reference*.

Validating data (class test)

If you suspect that your program is trying to perform arithmetic on nonnumeric data or is somehow receiving the wrong type of data on an input record, you can use the class test to validate the type of data. For a detailed discussion of how to use the class test to check for incompatible data, see *Enterprise COBOL for z/OS Programming Guide* or *COBOL for OS/390 & VM Programming Guide* .

Assessing switch problems

Using INITIALIZE or SET statements to initialize a table or data item is useful when you suspect that a problem is caused by residual data left in those fields. If your problem occurs intermittently and not always with the same data, the problem could be that a switch is not initialized, but is generally set to the right value (0 or 1). By including a SET statement to ensure that the switch is initialized, you can determine whether or not the uninitialized switch is the cause of the problem. For a detailed discussion of how to use the INITIALIZE and SET statements, see *Enterprise COBOL for z/OS Programming Guide* or *COBOL for OS/390 & VM Programming Guide*.

Generating information about procedures

You can use the USE FOR DEBUGGING declarative to include COBOL statements in a COBOL program and specify when they should run. Use these statements to generate information about your program and how it is running.

For example, to check how many times a procedure is run, include a special procedure for debugging (in the USE FOR DEBUGGING declarative) that adds 1 to a counter each time control passes to that procedure. The adding-to-a-counter technique can be used as a check for:

- How many times a PERFORM ran. This shows you whether the control flow you are using is correct.
- How many times a loop routine actually runs. This tells you whether the loop is running and whether the number you have used for the loop is accurate.

Code each USE FOR DEBUGGING declarative in a separate section in the DECLARATIVES SECTION of the PROCEDURE DIVISION. See the rules for coding them in *Enterprise COBOL for z/OS Language Reference* or in *COBOL for OS/390 & VM Language Reference*.

You can use debugging lines, debugging statements, or both in your program. Debugging lines are placed in your program, and are identified by a `D` in position 7. Debugging statements are coded in the DECLARATIVES SECTION of the PROCEDURE DIVISION.

- The USE FOR DEBUGGING declaratives must:
  - Be only in the DECLARATIVES SECTION
  - Follow a DECLARATIVES header USE FOR DEBUGGING

  With USE FOR DEBUGGING, the TEST compiler option must have the NONE hook-location suboption specified or the NOTEST compiler option must be specified. The TEST compiler option and the DEBUG run-time option are mutually exclusive, with DEBUG taking precedence.
- Debugging lines must have a `D` in position 7 to identify them.

To use debugging lines and statements in your program, you must include both:

- WITH DEBUGGING MODE in the SOURCE-COMPUTER paragraph in the ENVIRONMENT DIVISION
- The DEBUG run-time option

Figure 78 on page 210 shows how to use the DISPLAY statement and the USE FOR DEBUGGING declarative to debug a program.

```
Environment Division
Source Computer . . . With Debugging Mode.

:
Data Division.

:
  File Section.

  Working-Storage Section.

 *(among other entries you would need:)

  01  Trace-Msg    PIC X(30)
                   Value "  Trace for Procedure-Name : ".
  01  Total        PIC 99  Value Zeros.

 *(balance of Working-Storage Section)

Procedure Division.
Declaratives.
Debug-Declar Section.
    Use For Debugging On 501-Some-Routine.
Debug-Declar-Paragraph.
    Display Trace-Msg, Debug-Name, Total.
Debug-Declar-End.
    Exit.

End Declaratives.

Begin-Program Section.
:
    Perform 501-Some-Routine.

   *(within the module where you want to test, place:)

    Add 1 To Total

  * (whether you put a period at the end depends on
  * where you put this statement.)
```

Figure 78. Example of using the WITH DEBUGGING MODE clause

In the example in Figure 78, portions of a program are shown to illustrate the kind of statements needed to use the USE FOR DEBUGGING declarative. The DISPLAY statement specified in the DECLARATIVES SECTION issues the:

```
Trace For Procedure-Name : 501-Some-Routine nn
```

message every time the PERFORM 501-SOME-ROUTINE runs. The total shown, *nn*, is the value accumulated in the data item named TOTAL.

Another use for the DISPLAY statement technique shown above is to show the flow through your program. You do this by changing the USE FOR DEBUGGING declarative in the DECLARATIVES SECTION to:

```
USE FOR DEBUGGING ON ALL PROCEDURES.
```

and dropping the word TOTAL from the DISPLAY statement.

Using COBOL listings

When you are debugging, you can use one or more of the following listings:
- Sorted Cross-Reference listing
- Data Map listing
- Verb Cross-Reference listing
- Procedure Division Listings

This section gives an overview of each of these listings and specifies the compiler option you use to obtain each listing. For a detailed description of available listings, sample listings, and a complete description of COBOL compiler options, see *Enterprise COBOL for z/OS Programming Guide* or *COBOL for OS/390 & VM Programming Guide*.

Table 16. Compiler-generated COBOL listings and their contents

Name	Contents	Compiler Option
Sorted Cross-Reference Listings	Provides sorted cross-reference listings of DATA DIVISION, PROCEDURE DIVISION, and program names. The listings provide the location of all references to this information.	XREF
Data Map listing	Provides information about the locations of all DATA DIVISION items and all implicitly declared variables. This option also supplies a nested program map, which indicates where the programs are defined and provides program attribute information.	MAP
Verb Cross-Reference listing	Produces an alphabetic listing of all the verbs in your program and indicates where each is referenced.	VBREF
Procedure Division listings	Tells the COBOL compiler to generate a listing of the PROCEDURE DIVISION along with the assembler coding produced by the compiler. The list output includes the assembler source code, a map of the task global table (TGT), information about the location and size of WORKING-STORAGE and control blocks, and information about the location of literals and code for dynamic storage usage.	LIST
Procedure Division listings	Instead of the full PROCEDURE DIVISION listing with assembler expansion information, you can use the OFFSET compiler option to get a condensed listing that provides information about the program verb usage, global tables, WORKING-STORAGE, and literals. The OFFSET option takes precedence over the LIST option. That is, OFFSET and LIST are mutually exclusive; if you specify both, only OFFSET takes effect.	OFFSET

Generating a Language Environment dump of a COBOL program

The two sample programs shown in Figure 79 on page 212 and Figure 80 on page 213 generate Language Environment dumps with COBOL-specific information.

COBOL program that calls another COBOL program

In this example, program COBDUMP1 calls COBDUMP2, which in turn calls the Language Environment dump service CEE3DMP.

```
CBL  TEST(STMT,SYM),RENT
     IDENTIFICATION DIVISION.
       PROGRAM-ID.   COBDUMP1.
       AUTHOR. USER NAME

     ENVIRONMENT DIVISION.

     DATA DIVISION.

     WORKING-STORAGE SECTION.
     01 SOME-WORKINGSTG.
        05 SUB-LEVEL PIC X(80).

     01   SALARY-RECORDA.
      02    NAMEA   PIC X(10).
      02    DEPTA   PIC 9(4).
      02    SALARYA PIC 9(6).

     PROCEDURE DIVISION.
     START-SEC.
         DISPLAY "STARTING TEST COBDUMP1".
         MOVE "THIS IS IN WORKING STORAGE" TO SUB-LEVEL.
         CALL "COBDUMP2" USING SALARY-RECORDA.
         DISPLAY "END OF TEST COBDUMP1"
         STOP RUN.
     END PROGRAM COBDUMP1.
```

Figure 79. COBOL program COBDUMP1 calling COBDUMP2

COBOL program that calls the Language Environment CEE3DMP callable service

In the example in Figure 80 on page 213, program COBDUMP2 calls the Language Environment dump service CEE3DMP.

```
CBL  TEST(STMT,SYM),RENT
     IDENTIFICATION DIVISION.
       PROGRAM-ID.   COBDUMP2.
       AUTHOR. USER NAME

     ENVIRONMENT DIVISION.
     INPUT-OUTPUT SECTION.
     FILE-CONTROL.
         SELECT OPTIONAL IOFSS1 ASSIGN AS-ESDS1DD
             ORGANIZATION SEQUENTIAL ACCESS SEQUENTIAL.

     DATA DIVISION.
     FILE SECTION.
     FD  IOFSS1 GLOBAL.
       1 IOFSS1R PIC X(40).

     WORKING-STORAGE SECTION.
       01  TEMP4.
           05  A-1 OCCURS 2 TIMES.
               10  A-2 OCCURS 2 TIMES.
                   15 A-3V PIC X(3).
                   15 A-6  PIC X(3).
     77   DMPTITLE   PIC X(80).
     77   OPTIONS    PIC X(255).
     77   FC         PIC X(12).

     LINKAGE SECTION.
     01   SALARY-RECORD.
      02    NAME   PIC X(10).
      02    DEPT   PIC 9(4).
      02    SALARY PIC 9(6).

     PROCEDURE DIVISION USING SALARY-RECORD.
     START-SEC.
         DISPLAY "STARTING TEST COBDUMP2"
         MOVE "COBOL DUMP" TO DMPTITLE.
         MOVE "XXX" TO A-6(1, 1).
         MOVE "YYY" TO A-6(1, 2).
         MOVE "ZZZ" TO A-6(2, 1).
         MOVE " BLOCKS STORAGE PAGE(55) FILES" TO OPTIONS.
         CALL "CEE3DMP" USING DMPTITLE, OPTIONS, FC.
         DISPLAY "END OF TEST COBDUMP2"
         GOBACK.
     END PROGRAM COBDUMP2.
```

Figure 80. COBOL program COBDUMP2 calling the Language Environment dump service CEE3DMP

Sample Language Environment dump with COBOL-specific information

The call in program COBDUMP2 to CEE3DMP generates a Language Environment dump, shown in Figure 81 on page 214. The dump includes a traceback section, which shows the names of both programs; a section on register usage at the time the dump was generated; and a variables section, which shows the storage and data items for each program. Character fields in the dump are indicated by single quotes. For an explanation of these sections of the dump, see “Finding COBOL information in a dump” on page 215.

```

Figure 81. Sections of the Language Environment dump called from COBDUMP2 (Part 2 of 2)

Finding COBOL information in a dump

Like the standard Language Environment dump format, dumps generated from COBOL programs contain:

- Control block information for active programs
- Storage for each active program
- Enclave-level data
- Process-level data

Control block information for active routines

The Control Blocks for Active Routines section of the dump, shown in Figure 82 on page 216, displays the following information for each active COBOL program:

- DSA
- Program name and date/time of compile
- COBOL compiler Version, Release, Modification, and User Level
- COBOL compile Options
- COBOL control blocks TGT and CLLE. The layout of the TGT can be found by looking at the compiler listing of the COBOL program. The CLLE is a COBOL control block that is allocated by the COBOL runtime for each program. The CLLE is dumped for IBM service personnel use.

Figure 82. Control block information for active COBOL routines

Storage for each active routine

The Storage for Active Routines section of the dump, shown in Figure 83 on page 217, displays the following information for each COBOL program:

- Program name
- Contents of the base locators for files, WORKING-STORAGE, LINKAGE SECTION, LOCAL-STORAGE SECTION, variably-located areas, and EXTERNAL data.
- File record contents.
- WORKING-STORAGE, including the base locator for WORKING-STORAGE (BLW) and program class storage.

```
:
  Storage for Active Routines:
    COBDUMP2:
      Contents of base locators for files are:
           0-0001E038

      Contents of base locators for WORKING-STORAGE are:
           0-114A41D8

      Contents of base locators for the LINKAGE SECTION are:
           0-00000000        1-114A4120

      No indexes were used in this program.

      No variably-located areas were used in this program.

      No EXTERNAL data was used in this program.

      No OBJECT instance data were used in this program.

      No LOCAL-STORAGE was used in this program.

      No DSA indexes were used in this program.

      No FACTORY data was used in this program.

      No XML data was used in this program.

Figure 83. Storage for active COBOL programs (Part 2 of 2)

Enclave-level data

The Enclave Control Blocks section of the dump, shown in Figure 84 on page 219, displays the following information:

- RUNCOM control block. The RUNCOM is a control block that is allocated by the COBOL runtime to anchor enclave level resources. The RUNCOM is dumped for IBM service personnel use.
- Storage for all run units
- COBOL control blocks FCB, FIB, and GMAREA. The FCB, FIB, and GMAREA are control blocks used for COBOL file processing. These control blocks are dumped for IBM service personnel use.

Figure 84. Enclave-level data for COBOL programs

Process-level data

The Process Control Block section of the dump, shown in Figure 85, displays COBOL process-level control blocks THDCOM, COBCOM, COBVEC, and ITBLK.

In a non-CICS environment, the ITBLK control block only appears when a VS COBOL II program is active. In a CICS environment, the ITBLK control block always appears.

COBOL control blocks THDCOM, COBCOM, COBVEC and ITBLK are dumped for IBM service personnel use.

Figure 85. Process-level control blocks for COBOL programs

Debugging example COBOL programs

The following examples help demonstrate techniques for debugging COBOL programs. Important areas of the dump output are highlighted. Data unnecessary to debugging has been replaced by vertical ellipses.

Subscript range error

Figure 86 on page 221 illustrates the error of using a subscript value outside the range of an array. This program was compiled with LIST, TEST(STMT,SYM), and SSRANGE. The SSRANGE compiler option causes the compiler to generate code that checks (during run time) for data that has been stored or referenced outside of its defined area because of incorrect indexing and subscripting. The SSRANGE option takes effect during run time, unless you specify CHECK(OFF) as a run-time option.

The program was run with TERMTHDACT(TRACE) to generate the traceback information shown in Figure 87 on page 222.

```
CBL  LIST,SSRANGE,TEST(STMT,SYM)
     ID DIVISION.
     PROGRAM-ID. COBOLX.
     ENVIRONMENT DIVISION.
     DATA DIVISION.
     WORKING-STORAGE SECTION.
     77  J     PIC 9(4) USAGE COMP.
     01  TABLE-X.
      02  SLOT PIC 9(4) USAGE COMP OCCURS 8 TIMES.
     PROCEDURE DIVISION.
         MOVE 9 TO J.
         MOVE 1 TO SLOT (J).
         GOBACK.
```

Figure 86. COBOL example of moving a value outside an array range

To understand the traceback information and debug this program, use the following steps:

1. Locate the current error message in the Condition Information for Active Routines section of the Language Environment traceback, shown in Figure 87 on page 222. The message is `IGZ0006S The reference to table SLOT by verb number 01 on line 000011 addressed an area outside the region of the table.` The message indicates that line 11 was the current COBOL statement when the error occurred. For more information about this message, see *z/OS Language Environment Run-Time Messages*.
2. Statement 11 in the traceback section of the dump occurred in program COBOLX.

```

*/ COBOLX
```

Figure 88. COBOL listing for COBOLX

4. Find the values of the local variables in the Parameters, Registers, and Variables for Active Routines section of the traceback, shown in Figure 87 on page 222. J, which is of type PIC 9(4) with usage COMP, has a 9 value. J is the index to the array SLOT.

   The array SLOT contains eight positions. When the program tries to move a value into the J or 9th element of the 8-element array named SLOT, the error of moving a value outside the area of the array occurs.

Calling a nonexistent subroutine

Figure 89 demonstrates the error of calling a nonexistent subroutine in a COBOL program. In this example, the program COBOLY was compiled with the compiler options LIST, MAP and XREF. The TEST option was also specified with the suboptions NONE and SYM. Figure 89 shows the program.

```
 CBL  LIST,MAP,XREF,TEST(NONE,SYM)
      ID DIVISION.
      PROGRAM-ID. COBOLY.
      ENVIRONMENT DIVISION.
      DATA DIVISION.
      WORKING-STORAGE SECTION.
      77  SUBNAME PIC X(8) USAGE DISPLAY VALUE 'UNKNOWN'.
      PROCEDURE DIVISION.
          CALL SUBNAME.
          GOBACK.
```

Figure 89. COBOL example of calling a nonexistent subroutine

To understand the traceback information and debug this program, use the following steps:

1. Locate the error message for the original condition under the Condition Information for Active Routines section of the dump, shown in Figure 90. The message is `CEE3501S The module UNKNOWN  was not found.` For more information about this message, see *z/OS Language Environment Run-Time Messages*.
2. Note the sequence of calls in the Traceback section of the dump. COBOLY called IGZCFCC; IGZCFCC (a COBOL library subroutine used for dynamic calls) called IGZCLDL; then IGZCLDL (a COBOL library subroutine used to load library routines) called CEESGLT, a Language Environment condition handling routine.

   This sequence indicates that the exception occurred in IGZCLDL when COBOLY was attempting to make a dynamic call. The call statement in COBOLY is located at offset +0000036E.

```

Figure 90. Sections of Language Environment dump for COBOLY

3. Use the offset of X'36E' from the COBOL listing, shown in Figure 91 on page 225, to locate the statement that caused the exception in the COBOLY program. At offset X'36E' is an instruction for statement 8. Statement 8 is a call with the identifier SUBNAME specified.

4. Find the value of the local variables in the Parameters, Registers, and Variables for Active Routines section of the dump, shown in Figure 92. Notice that the value of SUBNAME with usage DISP, has a value of 'UNKNOWN'.

   Correct the problem by either changing the subroutine name to one that is defined, or by ensuring that the subroutine is available at compile time.

Figure 92. Parameters, registers, and variables for active routines section of dump for COBOLY

Divide-by-zero error

The following example demonstrates the error of calling an assembler routine that tries to divide by zero. Both programs were compiled with TEST(STMT,SYM) and run with the TERMTHDACT(TRACE) run-time option. Figure 93 on page 227 shows the main COBOL program (COBOLZ1), the COBOL subroutine (COBOLZ2), and the assembler routine.

Figure 93. Main COBOL program, COBOL subroutine, and assembler routine

To debug this application, use the following steps:

1. Locate the error message for the current condition in the Condition Information section of the dump, shown in Figure 94 on page 228. The message is `CEE3209S The system detected a fixed-point divide exception (System Completion Code=0C9).`

   For additional information about this message, see *z/OS Language Environment Run-Time Messages*.
2. Note the sequence of calls in the call chain. COBOLZ1 called IGZCFCC, which is a COBOL library subroutine used for dynamic calls; IGZCFCC called COBOLZ2; COBOLZ2 then called IGZCFCC; and IGZCFCC called ASSEMZ3. The exception occurred at this point, resulting in a call to CEEHDSP, a Language Environment condition handling routine.

   The call to ASSEMZ3 occurred at statement 11 of COBOLZ2. The exception occurred at offset +64 in ASSEMZ3.

```

*/ COBOLZ2
```

Figure 95. COBOL listing for COBOLZ2

4. Check offset +64 in the listing for the assembler routine ASSEMZ3, shown in Figure 96 on page 230.

   This shows an instruction to divide the contents of register 4 by the variable pointed to by register 6. You can see the two instructions preceding the divide instruction load register 6 from the first word pointed to by register 1 and prepare register 6 for the divide. Because of linkage conventions, you can infer that register 1 contains a pointer to a parameter list that passed to ASSEMZ3. Register 6 points to a 0 value because that was the value passed to ASSEMZ3 when it was called by a higher level routine.

   Note: To translate assembler instructions, see *z/Architecture Principles of Operation, SA22-7832.*

Chapter 6. Debugging Fortran routines

This chapter provides information to help you debug applications that contain one or more Fortran routines. It includes the following topics:

- Determining the source of errors in Fortran routines
- Using Fortran compiler listings
- Generating a Language Environment dump of a Fortran routine
- Finding Fortran information in a dump
- Examples of debugging Fortran routines

Determining the source of errors in Fortran routines

Most errors in Fortran routines can be identified by the information provided in Fortran run-time messages, which begin with the prefix FOR.

The Fortran compiler cannot identify all possible errors. The following list identifies several errors not detected by the compiler that could potentially result in problems:

- Failing to assign values to variables and arrays before using them in your program.
- Specifying subscript values that are not within the bounds of an array. If you assign data outside the array bounds, you can inadvertently destroy data and instructions.
- Moving data into an item that is too small for it, resulting in truncation.
- Making invalid data references to EQUIVALENCE items of differing types (for example, integer or real).
- Transferring control into the range of a DO loop from outside the range of the loop. The compiler issues a warning message for all such branches if you specify OPT(2), OPT(3), or VECTOR.
- Using arithmetic variables and constants that are too small to give the precision you need in the result. For example, to obtain more than 6 decimal digits in floating-point results, you must use double precision.
- Concatenating character strings in such a way that overlap can occur.
- Trying to access services that are not available in the operating system or hardware.
- Failing to resolve name conflicts between Fortran and C library routines using the procedures described in *z/OS Language Environment Programming Guide*.

Identifying run-time errors

Fortran has several features that help you find run-time errors. Fortran run-time messages are discussed in *z/OS Language Environment Run-Time Messages*. Other debugging aids include the optional traceback map, program interruption messages, abnormal termination dumps, and operator messages.

- The optional traceback map helps you identify where errors occurred while running your application. The TERMTHDACT(TRACE) run-time option, which is set by default under Language Environment, generates a dump containing the traceback map.

  You can also get a traceback map at any point in your routine by invoking the ERRTRA subroutine.
- Program interruption messages are generated whenever the program is interrupted during execution. Program interruption messages are written to the Language Environment message file.

The program interruption message indicates the exception that caused the termination; the completion code from the system indicates the specification or operation exception resulting in termination.

- Program interruptions causing an abnormal termination produce a dump, which displays the completion code and the contents of registers and system control fields.

  To display the contents of main storage as well, you must request an abnormal termination (ABEND) dump by including a SYSUDUMP DD statement in the appropriate job step. The following example shows how the statement can be specified for IBM-supplied cataloged procedures:

  ```
  //GO.SYSUDUMP DD SYSOUT=A
  ```

- You can request various dumps by invoking any of several dump service routines while your program runs. These dump service routines are discussed in "Generating a Language Environment dump of a Fortran routine" on page 235.
- Operator messages are displayed when your program issues a PAUSE or STOP *n* statement. These messages help you understand how far execution has progressed before reaching the PAUSE or STOP statement.

  The operator message can take the following forms:

n	String of 1–5 decimal digits you specified in the PAUSE or STOP statement. For the STOP statement, this number is placed in R15.
'message'	Character constant you specified in the PAUSE or STOP statement.
0	Printed when a PAUSE statement containing no characters is executed (not printed for a STOP statement).

  A PAUSE message causes the program to stop running pending an operator response. The format of the operator's response to the message depends on the system being used.
- Under Language Environment, error messages produced by Language Environment and Fortran are written to a common message file. Its ddname is specified in the MSGFILE run-time option. The default ddname is SYSOUT.

  Fortran information directed to the message file includes:

  - Error messages resulting from unhandled conditions
  - Printed output from any of the dump services (SDUMP, DUMP/PDUMP, CDUMP/CPDUMP)
  - Output produced by a WRITE statement with a unit identifier having the same value as the Fortran error message unit
  - Output produced by a WRITE statement with * given as the unit identifier (assuming the Fortran error message unit and standard print unit are the same unit)
  - Output produced by the PRINT statement (assuming the Fortran error message unit and the standard print unit are the same unit)

  For more information about handling message output using the Language Environment MSGFILE run-time option, see *z/OS Language Environment Programming Guide*.

Using Fortran compiler listings

Fortran listings provide you with:
- The date of compilation including information about the compiler
- A listing of your source program
- Diagnostic messages telling you of errors in the source program
- Informative messages telling you the status of the compilation

The following table contains a list of the contents of the various compiler-generated listings that you might find helpful when you use information in dumps to debug Fortran programs.

Table 17. Compiler-generated Fortran listings and their contents

Name	Contents	Compiler Option
Diagnostic message listing	Error messages detected during compilation.	FLAG
Source program	Source program statements.	SOURCE
Source program	Source program statements and error messages.	SRCFLG
Storage map and cross reference	Variable use, statement function, subprogram, or intrinsic function within a program.	MAP and XREF
Cross reference	Cross reference of names with attributes.	XREF
Source program map	Offsets of automatic and static internal variables (from their defining base).	MAP
Object code	Contents of the program control section in hexadecimal notation and translated into a pseudo-assembler format. To limit the size of the object code listing, specify the statement or range of statements to be listed; for example, LIST(20) or LIST(10,30).	LIST
Variable map, object code, static storage	Same as MAP and LIST options above, plus contents of static internal and static external control sections in hexadecimal notation with comments.	MAP and LIST
Symbolic dump	Internal statement numbers, sequence numbers, and symbol (variable) information.	SDUMP

Generating a Language Environment dump of a Fortran routine

To generate a dump containing Fortran information, call either DUMP/PDUMP, CDUMP/CPDUMP, or SDUMP.

DUMP/PDUMP and CDUMP/CPDUMP produce output that is unchanged from the output generated under Fortran. Under Language Environment, however, the output is directed to the message file.

When SDUMP is invoked, the output is also directed to the Language Environment message file. The dump format differs from other Fortran dumps, however, reflecting a common format shared by the various HLLs under Language Environment.

You cannot make a direct call to CEE3DMP from a Fortran program. It is possible to call CEE3DMP through an assembler routine called by your Fortran program. Fortran programs are currently restricted from directly invoking Language Environment callable services.

DUMP/PDUMP	Provides a dump of a specified area of storage.
CDUMP/CPDUMP	Provides a dump of a specified area of storage in character format.
SDUMP	Provides a dump of all variables in a program unit.

DUMP/PDUMP subroutines

The DUMP/PDUMP subroutine dynamically dumps a specified area of storage to the system output data set. When you use DUMP, the processing stops after the dump; when you use PDUMP, the processing continues after the dump.

Syntax

CALL {DUMP | PDUMP} (a_1, b_1,k_1, a_2,b_2, k_2,...**)**

a and *b*
Variables in the program unit. Each indicates an area of storage to be dumped. Either *a* or *b* can represent the upper or lower limit of the storage area.

k The dump format to be used. The values that can be specified for *k*, and the resulting dump formats, are:

Value	Format Requested
0	Hexadecimal
1	LOGICAL*1
2	LOGICAL*4
3	INTEGER*2
4	INTEGER*4
5	REAL*4
6	REAL*8
7	COMPLEX*8
8	COMPLEX*16
9	CHARACTER
10	REAL*16
11	COMPLEX*32
12	UNSIGNED*1
13	INTEGER*1
14	LOGICAL*2
15	INTEGER*8
16	LOGICAL*8

Usage considerations for DUMP/PDUMP

A load module or phase can occupy a different area of storage each time it is executed. To ensure that the appropriate areas of storage are dumped, the following conventions should be observed.

If an array and a variable are to be dumped at the same time, a separate set of arguments should be used for the array and for the variable. The specification of limits for the array should be from the first element in the array to the last element. For example, assume that A is a variable in common, B is a real number, and

TABLE is an array of 20 elements. The following call to the storage dump routine could be used to dump TABLE and B in hexadecimal format, and stop the program after the dump is taken:

```
CALL DUMP(TABLE(1),TABLE(20),0,B,B,0)
```

If an area of storage in common is to be dumped at the same time as an area of storage not in common, the arguments for the area in common should be given separately. For example, the following call to the storage dump routine could be used to dump the variables A and B in REAL*8 format without stopping the program:

```
CALL PDUMP(A,A,6,B,B,6)
```

If variables not in common are to be dumped, each variable must be listed separately in the argument list. For example, if R, P, and Q are defined implicitly in the program, the statement

```
CALL PDUMP(R,R,5,P,P,5,Q,Q,5)
```

should be used to dump the three variables in REAL*4 format. If the statement

```
CALL PDUMP(R,Q,5)
```

is used, all main storage between R and Q is dumped, which might or might not include P, and could include other variables.

CDUMP/CPDUMP subroutines

The CDUMP/CPDUMP subroutine dynamically dumps a specified area of storage containing character data. When you use CDUMP, the processing stops after the dump; when you use CPDUMP, the processing continues after the dump.

Syntax

CALL {CDUMP | CPDUMP} (a_1, b_1, a_2, b_2,...**)**

a and *b*
: Variables in the program unit. Each indicates an area of storage to be dumped. Either *a* or *b* can represent the upper or lower limit of each storage area.

The dump is always produced in character format. A dump format type (unlike for DUMP/PDUMP) must not be specified.

Usage considerations for CDUMP/CPDUMP

A load module can occupy a different area of storage each time it is executed. To ensure that the appropriate areas of storage are dumped, the following conventions should be observed.

If an array and a variable are to be dumped at the same time, a separate set of arguments should be used for the array and for the variable. The specification of limits for the array should be from the first element in the array to the last element. For example, assume that B is a character variable and TABLE is a character array of 20 elements. The following call to the storage dump routine could be used to dump TABLE and B in character format, and stop the program after the dump is taken:

```
CALL CDUMP(TABLE(1), TABLE(20), B, B)
```

SDUMP subroutine

The SDUMP subroutine provides a symbolic dump that is displayed in a format dictated by variable type as coded or defaulted in your source. Data is dumped to the error message unit. The symbolic dump is created by program request, on a program unit basis, using CALL SDUMP. Variables can be dumped automatically after abnormal termination using the compiler option SDUMP. For more information on the SDUMP compiler option, see *VS FORTRAN Version 2 Programming Guide for CMS and MVS.*

Items displayed are:

- All referenced, local, named, and saved variables in their Fortran-defined data representation
- All variables contained in a static common area (blank or named) in their Fortran-defined data representation
- All variables contained in a dynamic common area in their Fortran-defined data representation
- Nonzero or nonblank character array elements only
- Array elements with their correct indexes

The amount of output produced can be very large, especially if your program has large arrays, or large arrays in common blocks. For such programs, you might want to avoid calling SDUMP.

Syntax

CALL SDUMP [(*rtn*$_1$**,***rtn*$_2$**,...)]**

rtn*$_1$**,rtn*$_2$**,...**

Names of other program units from which data will be dumped. These names must be listed in an EXTERNAL statement.

Usage considerations for SDUMP

- To obtain symbolic dump information and location of error information, compilation must be done either with the SDUMP option or with the TEST option.
- Calling SDUMP and specifying program units that have not been entered gives unpredictable results.
- Calling SDUMP with no parameters produces the symbolic dump for the current program unit.
- An EXTERNAL statement must be used to identify the names being passed to SDUMP as external routine names.
- At higher levels of optimization (1, 2, or 3), the symbolic dump could show incorrect values for some variables because of compiler optimization techniques.
- Values for uninitialized variables are unpredictable. Arguments in uncalled subprograms or in subprograms with argument lists shorter than the maximum can cause the SDUMP subroutine to fail.
- The display of data can also be invoked automatically. If the run-time option TERMTHDACT(DUMP) is in effect and your program abends in a program unit compiled with the SDUMP option or with the TEST option, all data in that program unit is automatically dumped. All data in any program unit in the save area traceback chain compiled with the SDUMP option or with the TEST option is also dumped. Data occurring in a common block is dumped at each occurrence, because the data definition in each program unit could be different.

Examples of calling SDUMP from the main program and from a subprogram follow. Figure 100 on page 240 shows a sample program calling SDUMP and Figure 101 on page 241 shows the resulting output that is generated. In the main program, the statement

```
EXTERNAL PGM1,PGM2,PGM3
```

makes the address of subprograms PGM1, PGM2, and PGM3 available for a call to SDUMP as follows:

```
CALL SDUMP (PGM1,PGM2,PGM3)
```

This causes variables in PGM1, PGM2, and PGM3 to be printed.

In the subprogram PGM1, the statement

```
EXTERNAL PGM2,PGM3
```

makes PGM2 and PGM3 available. (PGM1 is missing because the call is in PGM1.) The statements

```
CALL SDUMP
CALL SDUMP (PGM2,PGM3)
```

dump variables PGM1, PGM2, and PGM3.

```

Figure 102. Sections of the Language Environment dump

Understanding the Language Environment traceback table

Examine the traceback section of the dump, labeled with **[1]** in Figure 102, for condition information about your routine and information about the statement number and address where the exception occurred. The traceback section helps you locate where an error occurred in your program. The information in this section begins with the most recent program unit and ends with the first program unit.

Identifying condition information

The section labeled **[2]** in Figure 102 shows the condition information for the active routines, indicating the program message, program unit name, the statement number, and the offset within the program unit where the error occurred.

Identifying variable information

The local variable section of the dump, shown in the section labeled **[3]** in Figure 102 on page 242, contains information on all variables and arrays in each program unit in the save area chain, including the program causing the dump to be invoked. The output shows variable items (one line only) and array (more than one line) items.

Use the local variable section of the dump to identify the variable name, type, and value at the time the dump was called. Variable and array items can contain either character or noncharacter data, but not both.

Identifying file status information

The section labeled **[4]** in Figure 102 on page 242 shows the file status and attribute section of the dump. This section displays the total number of units defined, the default units for error messages, and the default unit numbers for formatted input or formatted output.

Examples of debugging Fortran routines

This section contains examples of Fortran routines and instructions for using information in the Language Environment dump to debug them.

Calling a nonexistent routine

Figure 103 illustrates an error caused by calling a nonexistent routine. The options in effect at compile time appear at the top of the listing.

```

```

Figure 104. Sections of the Language Environment dump resulting from a call to a nonexistent routine

To understand the traceback section, and debug this example routine, do the following:

1. Find the Current Condition information in the Condition Information for Active Routines section of the dump. The message is CEE3201S. The system detected an operation exception at statement 3. For more information about this message, see *z/OS Language Environment Run-Time Messages*. This section of the dump also provides such information as the name of the active routine and the current statement number at the time of the dump.
2. Locate statement 3 in the routine shown in Figure 103 on page 243. This statement calls subroutine SUBNAM. The message CEE3201S in the Condition Information section of the dump indicates that the operation exception was generated because of an unresolved external reference.
3. Check the linkage editor output for error messages.

Divide-by-zero error

Figure 105 demonstrates a divide-by-zero error. In this example, the main Fortran program passed 0 to subroutine DIVZEROSUB, and the error occurred when DIVZEROSUB attempted to use this data as a divisor.

    The default unit for formatted sequential input is 5.
```

Figure 106. Language Environment dump from divide-by-zero Fortran example

To debug this application, do the following:

1. Locate the error message for the current condition in the Condition Information section of the dump, shown in Figure 106. The message is CEE3209S. The system detected a fixed-point divide exception. See *z/OS Language Environment Run-Time Messages* for additional information about this message.
2. Note the sequence of the calls in the call chain:
   a. DIVZERO called AFHLCLNR, which is a Fortran library subroutine.
   b. AFHLCLNR called DIVZEROSUB.

Note: When a program-unit name is longer than 7 characters, the name as it appears in the dump consists of the first 4 and last 3 characters concatenated together.

c. DIVZEROSUB attempted a divide-by-zero operation at statement 5.

d. This resulted in a call to CEEHDSP, a Language Environment condition handling routine.

3. Locate statement 5 in the Fortran listing for the DIVZEROSUB subroutine in Figure 106 on page 246. This is an instruction to divide the contents of DIVIDEND(3) by DIVISOR.
4. Since DIVISOR is a parameter of subroutine DIVZEROSUB, go to the Parameters section of the dump shown in Figure 106 on page 246. The parameter DIVISOR shows a value of 0.
5. Since DIVISOR contains the value passed to DIVZEROSUB, check its value. ANY_NUMBER is the actual argument passed to DIVZEROSUB, and the dump and listing of DIVZERO indicate that ANY_NUMBER had value 0 when passed to DIVZEROSUB, leading to the divide-by-zero exception.

Chapter 7. Debugging PL/I for MVS & VM routines

This chapter contains information that can help you debug applications that contain one or more PL/I for MVS & VM routines. Following a discussion about potential errors in PL/I for MVS & VM routines, the first part of this chapter discusses how to use compiler-generated listings to obtain information about PL/I for MVS & VM routines, and how to use PLIDUMP to generate a Language Environment dump of a PL/I for MVS & VM routine. The last part of the chapter provides examples of PL/I for MVS & VM routines and explains how to debug them using information contained in the traceback information provided in the dump. The topics covered are listed below.

- Determining the source of errors in PL/I for MVS & VM routines
- Using PL/I for MVS & VM compiler listings
- Generating a Language Environment dump of a PL/I for MVS & VM routine
- Finding PL/I for MVS & VM information in a dump
- Debugging example of PL/I for MVS & VM routines

Determining the source of errors in PL/I for MVS & VM routines

Most errors in PL/I for MVS & VM routines can be identified by the information provided in PL/I run-time messages, which begin with the prefix IBM. For a list of these messages, see *z/OS Language Environment Run-Time Messages*.

A malfunction in running a PL/I for MVS & VM routine can be caused by:

- Logic errors in the source routine
- Invalid use of PL/I for MVS & VM
- Unforeseen errors
- Invalid input data
- Compiler or run-time routine malfunction
- System malfunction
- Unidentified routine malfunction
- Overlaid storage

Logic errors in the source routine

Errors of this type are often difficult to detect because they often appear as compiler or library malfunctions.

Some common errors in source routines are:

- Incorrect conversion from arithmetic data
- Incorrect arithmetic and string manipulation operations
- Unmatched data lists and format lists

Invalid use of PL/I for MVS & VM

A misunderstanding of the language or a failure to provide the correct environment for using PL/I for MVS & VM can result in an apparent malfunction of a PL/I for MVS & VM routine.

Any of the following, for example, might cause a malfunction:

- Using uninitialized variables
- Using controlled variables that have not been allocated
- Reading records into incorrect structures
- Misusing array subscripts
- Misusing pointer variables
- Incorrect conversion

- Incorrect arithmetic operations
- Incorrect string manipulation operations

Unforeseen errors

If an error is detected during run time and no ON-unit is provided in the routine to terminate the run or attempt recovery, the job terminates abnormally. However, the status of a routine at the point where the error occurred can be recorded by using an ERROR ON-unit that contains the statements:

```
ON ERROR
 BEGIN;
  ON ERROR SYSTEM;
  CALL PLIDUMP;         /*generates a dump*/
  PUT DATA;             /*displays variables*/
 END;
```

The statement ON ERROR SYSTEM ensures that further errors do not result in a permanent loop.

Invalid input data

A routine should contain checks to ensure that any incorrect input data is detected before it can cause the routine to malfunction.

Use the COPY option of the GET statement to check values obtained by stream-oriented input. The values are listed on the file named in the COPY option. If no file name is given, SYSPRINT is assumed.

Compiler or run-time routine malfunction

If you are certain that the malfunction is caused by a compiler or run-time routine error, you can either open a PMR or submit an APAR for the error. See *PL/I for MVS & VM Diagnosis Guide* for more information about handling compiler and run-time routine malfunctions. Meanwhile, you can try an alternative way to perform the operation that is causing the trouble. A bypass is often feasible, since the PL/I for MVS & VM language frequently provides an alternative method of performing operations.

System malfunction

System malfunctions include machine malfunctions and operating system errors. System messages identify these malfunctions and errors to the operator.

Unidentified routine malfunction

In most circumstances, an unidentified routine malfunction does not occur when using the compiler. If your routine terminates abnormally without an accompanying Language Environment run-time diagnostic message, the error causing the termination might also be inhibiting the production of a message. Check for the following:

- Your job control statements might be in error, particularly in defining data sets.
- Your routine might overwrite main storage areas containing executable instructions. This can happen if you have accidentally:
  - Assigned a value to a nonexistent array element. For example:

```
DCL ARRAY(10);

⋮
DO I = 1 TO 100;
ARRAY(I) = VALUE;
```

To detect this type of error in a compiled module, set the SUBSCRIPTRANGE condition so that each attempt to access an element outside the declared range of subscript values raises the SUBSCRIPTRANGE condition. If there is no ON-unit for this condition, a diagnostic message is printed and the ERROR condition is raised. This facility, though expensive in run time and storage space, is a valuable routine-testing aid.

– Used an incorrect locator value for a locator (pointer or offset) variable. This type of error can occur if a locator value is obtained by means of record-oriented transmission. Ensure that locator values created in one routine, transmitted to a data set, and subsequently retrieved for use in another routine, are valid for use in the second routine.
– Attempted to free a nonbased variable. This can happen when you free a based variable after its qualifying pointer value has been changed. For example:

```
DCL A STATIC,B BASED (P);
ALLOCATE B;
P = ADDR(A);
FREE B;
```

– Used the SUBSTR pseudovariable to assign a string to a location beyond the end of the target string. For example:

```
DCL X CHAR(3);
I=3
SUBSTR(X,2,I) = 'ABC';
```

To detect this type of error, enable the STRINGRANGE condition during compilation.

Storage overlay problems

If you suspect an error in your PL/I for MVS & VM application is a storage overlay problem, check for the following:

- The use of a subscript outside the declared bounds (check the SUBSCRIPTRANGE condition)
- An attempt to assign a string to a target with an insufficient maximum length (check the STRINGSIZE condition)
- The failure of the arguments to a SUBSTR reference to comply with the rules described for the SUBSTR built-in function (check the STRINGRANGE condition)
- The loss of significant last high-order (left-most) binary or decimal digits during assignment to an intermediate result or variable or during an input/output operation (check the SIZE condition)
- The reading of a variable-length file into a variable
- The misuse of a pointer variable
- The invocation of a Language Environment callable service with fewer arguments than are required

The first four situations are associated with the listed PL/I for MVS & VM conditions, all of which are disabled by default. If you suspect one of these problems exists in your routine, use the appropriate condition prefix on the suspected statement or on the BEGIN or PROCEDURE statement of the containing block.

The fifth situation occurs when you read a data record into a variable that is too small. This type of problem only happens with variable-length files. You can often isolate the problem by examining the data in the file information and buffer.

The sixth situation occurs when you misuse a pointer variable. This type of storage overlay is particularly difficult to isolate. There are a number of ways pointer variables can be misused:

- When a READ statement runs with the SET option, a value is placed in a pointer. If you then run a WRITE statement or another READ SET option with another pointer, you overlay your storage if you try to use the original pointer.
- When you try to use a pointer to allocate storage that has already been freed, you can also cause a storage overlay.
- When you attempt to use a pointer set with the ADDR built-in function as a base for data with different attributes, you can cause a storage overlay.

The seventh situation occurs when a Language Environment callable service is passed fewer arguments than its interface requires. The following example might cause a storage overlay because Language Environment assumes that the fourth item in the argument list is the address of a feedback code, when in reality it could be residue data pointing anywhere in storage.

Invalid calls:

```
DCL CEEDATE ENTRY OPTIONS(ASM);
CALL CEEDATE(x,y,z);      /* invalid */
```

Valid calls:

```
DCL CEEDATE ENTRY(*,*,*,* OPTIONAL) OPTIONS(ASM);
CALL CEEDATE(x,y,z,*);    /* valid   */
CALL CEEDATE(x,y,z,fc);   /* valid   */
```

Using PL/I for MVS & VM compiler listings

The following sections explain how to generate listings that contain information about your routine. PL/I for MVS & VM listings show machine instructions, constants, and external or internal addresses that the linkage editor resolves. This information can help you find other information, such as variable values, in a dump of a PL/I for MVS & VM routine.

The PL/I compiler listings included below are from the PL/I for MVS & VM product.

Generating PL/I for MVS & VM listings and maps

The following table shows compiler-generated listings that you might find helpful when you use information in dumps to debug PL/I for MVS & VM routines. For more information about supported compiler options that generate listings, reference the *PL/I for MVS & VM Programming Guide*.

Table 18. Compiler-generated PL/I for MVS & VM listings and their contents

Name	Contents	Compiler Option
Source program	Source program statements	SOURCE
Cross reference	Cross reference of names with attributes	XREF and ATTRIBUTES
Aggregate table	Names and layouts of structures and arrays	AGGREGATE
Variable map	Offsets of automatic and static internal variables (from their defining base)	MAP

Table 18. Compiler-generated PL/I for MVS & VM listings and their contents (continued)

Name	Contents	Compiler Option
Object code	Contents of the program control section in hexadecimal notation and translated into a pseudo-assembler format. To limit the size of the object code listing, specify a certain statement or range of statements to be listed; for example, LIST(20) or LIST(10,30).	LIST
Variable map, object code, static storage	Same as MAP and LIST options above, plus contents of static internal and static external control sections in hexadecimal notation with comments	MAP and LIST

Finding information in PL/I for MVS & VM listings

Figure 107 shows an example PL/I for MVS & VM routine that was compiled with LIST and MAP.

```
*PROCESS SOURCE, LIST, MAP;

                  SOURCE LISTING

   STMT

      1  |EXAMPLE: PROC OPTIONS(MAIN);
      2  |           DCL EXTR ENTRY EXTERNAL;
      3  |           DCL A FIXED BIN(31);
      4  |           DCL B(2,2)  FIXED BIN(31) STATIC EXTERNAL INIT((4)0);
      5  |           DCL C CHAR(20) STATIC INIT('SAMPLE CONSTANT');
      6  |           DCL D FIXED BIN(31) STATIC;
      7  |           DCL E FIXED BIN(31);
      8  |           FETCH EXTR;
      9  |           CALL EXTR(A,B,C,D,E);
     10  |           DISPLAY(C);
     11  |         END;
```

Figure 107. PL/I for MVS & VM routine compiled with LIST and MAP

Figure 108 on page 254 shows the output generated by the LIST and MAP options for this routine, including the static storage map, variable storage map, and the object code listing. The sections following this example describe the contents of each type of listing.

Figure 108. Compiler-generated listings from example PL/I for MVS & VM routine (Part 2 of 2)

Static internal storage map

To get a complete variable storage map and static storage map, but not a complete LIST, specify a single statement for LIST to minimize the size of the listing; for example, LIST(1).

Each line of the static storage map contains the following information:

1. Six-digit hexadecimal offset.
2. Hexadecimal text, in 8-byte sections where possible.
3. Comment, indicating the type of item to which the text refers. The comment appears on the first line of the text for an item.

Some typical comments you might find in a static storage listing:

Table 19. Typical comments in a PL/I for MVS & VM static storage listing

Comment	Explanation
A..*xxx*	Address constant for *xxx*
COMPILER LABEL CL.*n*	Compiler-generated label *n*
CONDITION CSECT	Control section for programmer-named condition
CONSTANT	Constant
CSECT FOR EXTERNAL VARIABLE	Control section for external variable
D..*xxx*	Descriptor for *xxx*
DED..*xxx*	Data element descriptor for *xxx*
DESCRIPTOR	Data descriptor
ENVB	Environment control block
FECB..*xxx*	Fetch control block for *xxx*
DCLCB	Declare control block
FED..*xxx*	Format element descriptor for *xxx*

Table 19. Typical comments in a PL/I for MVS & VM static storage listing (continued)

Comment	Explanation
KD..*xxx*	Key descriptor for *xxx*
LOCATOR..*xxx*	Locator for *xxx*
ONCB	ON statement control block
PICTURED DED..*xxx*	Pictured data element descriptor for *xxx*
PROGRAM ADCON	Program address constant
RD..*xxx*	Record descriptor for *xxx*
SYMBOL TABLE ELEMENT	Symbol table address
SYMBOL TABLE..*xxx*	Symbol table for *xxx*
SYMTAB DED..*xxx*	Symbol table DED for *xxx*
USER LABEL..*xxx*	Source program label for *xxx*
xxx	Variable with name *xxx*. If the variable is not initialized, no text appears against the comment. There is also no static offset if the variable is an array (the static offset can be calculated from the array descriptor, if required).

Variable storage map

For automatic and static internal variables, the variable storage map contains the following information:

- PL/I for MVS & VM identifier name
- Level
- Storage class
- Name of the PL/I for MVS & VM block in which it is declared
- Offset from the start of the storage area, in both decimal and hexadecimal form

If the LIST option is also specified, a map of the static internal and external control sections, called the static storage map, is also produced.

Object code listing

The object code listing consists of the machine instructions and a translation of these instructions into a form that resembles assembler and includes comments, such as source program statement numbers.

The machine instructions are formatted into blocks of code, headed by the statement or line number in the PL/I for MVS & VM source program listing. Generally, only executable statements appear in the listing. DECLARE statements are not normally included. The names of PL/I for MVS & VM variables, rather than the addresses that appear in the machine code, are listed. Special mnemonics are used to refer to some items, including test hooks, descriptors, and address constants.

Statements in the object code listing are ordered by block, as they are sequentially encountered in the source program. Statements in the external procedure are given first, followed by the statements in each inner block. As a result, the order of statements frequently differs from that of the source program.

Every object code listing begins with the name of the external procedure. The actual entry point of the external procedure immediately follows the heading comment `REAL ENTRY`. The subsequent machine code is the prolog for the block,

which performs block activation. The comment PROCEDURE BASE marks the end of the prolog. Following this is a translation of the first executable statement in the PL/I for MVS & VM source program.

Following are the comments used in the listing:

Table 20. Comments in a PL/I for MVS & VM object code listing

Comment	Function
BEGIN BLOCK *xxx*	Indicates the start of the begin block with label *xxx*
BEGIN BLOCK NUMBER *n*	Indicates the start of the begin block with number *n*
CALCULATION OF COMMONED EXPRESSION FOLLOWS	Indicates that an expression used more than once in the routine is calculated at this point
CODE MOVED FROM STATEMENT NUMBER *n*	Indicates object code moved by the optimization process to a different part of the routine and gives the number of the statement from which it originated
COMPILER GENERATED SUBROUTINE *xxx*	Indicates the start of compiler-generated subroutine *xxx*
CONTINUATION OF PREVIOUS REGION	Identifies the point at which addressing from the previous routine base recommences
END BLOCK	Indicates the end of a begin block
END INTERLANGUAGE PROCEDURE *xxx*	Identifies the end of an ILC procedure *xxx*
END OF COMMON CODE	Identifies the end of code used in running more than one statement
END OF COMPILER GENERATED SUBROUTINE	Indicates the end of the compiler-generated subroutine
END PROCEDURE	Identifies the end of a procedure
END PROGRAM	Indicates the end of the external procedure
INITIALIZATION CODE FOR *xxx*	Indicates the start of initialization code for variable *xxx*
INITIALIZATION CODE FOR OPTIMIZED LOOP FOLLOWS	Indicates that some of the code that follows was moved from within a loop by the optimization process
INTERLANGUAGE PROCEDURE *xxx*	Identifies the start of an implicitly generated ILC procedure *xxx*
METHOD OR ORDER OF CALCULATING EXPRESSIONS CHANGED	Indicates that the order of the code following was changed to optimize the object code
ON-UNIT BLOCK NUMBER *n*	Indicates the start of an ON-unit block with number *n*
ON-UNIT BLOCK END	Indicates the end of the ON-unit block
PROCEDURE *xxx*	Identifies the start of the procedure labeled *xxx*
PROCEDURE BASE	Identifies the address loaded into the base register for the procedure
PROGRAM ADDRESSABILITY REGION BASE	Identifies the address where the routine base is updated if the routine size exceeds 4096 bytes and consequently cannot be addressed from one base
PROLOGUE BASE	Identifies the start of the prolog code common to all entry points into that procedure
REAL ENTRY	Precedes the actual executable entry point for a procedure

Table 20. Comments in a PL/I for MVS & VM object code listing (continued)

Comment	Function
STATEMENT LABEL *xxx*	Identifies the position of source program statement label *xxx*
STATEMENT NUMBER *n*	Identifies the start of code generated for statement number *n* in the source listing

In certain cases the compiler uses mnemonics to identify the type of operand in an instruction and, where applicable, follows the mnemonic by the name of a PL/I for MVS & VM variable.

Table 21. PL/I for MVS & VM mnemonics

Mnemonic	Explanation
A..*xxx*	Address constant for *xxx*
ADD..*xxx*	Aggregate descriptor for *xxx*
BASE..*xxx*	Base address of variable *xxx*
BLOCK.*n*	Identifier created for an otherwise unlabeled block
CL.*n*	Compiler-generated label number *n*
D..*xxx*	Descriptor for *xxx*
DED..*xxx*	Data element descriptor for *xxx*
HOOK...ENTRY	Debugging tool block entry hook
HOOK...BLOCK-EXIT	Debugging tool block exit hook
HOOK...PGM-EXIT	Debugging tool program exit hook
HOOK...PRE-CALL	Debugging tool pre-call hook
HOOK...INFO	Additional pre-call hook information
HOOK...POST-CALL	Debugging tool post call hook
HOOK...STMT	Debugging tool statement hook
HOOK...IF-TRUE	Debugging tool IF true hook
HOOK...IF-FALSE	Debugging tool ELSE hook
HOOK...WHEN	Debugging tool WHEN true hook
HOOK...OTHERWISE	Debugging tool OTHERWISE true hook
HOOK...LABEL	Debugging tool label hook
HOOK...DO	Debugging tool iterative DO hook
HOOK...ALLOC	Debugging tool ALLOCATE controlled hook
WSP.*n*	Workspace, followed by identifying number *n*
L..*xxx*	Length of variable *xxx*
PR..*xxx*	Pseudoregister vector slot for *xxx*
LOCATOR..*xxx*	Locator for *xxx*
RKD..*xxx*	Record or key descriptor for *xxx*
VO..*xxx*	Virtual origin for *xxx* (the address where element 0 is held for a one-dimensional array, element 0,0 for a two-dimensional array, and so on)

Generating a Language Environment dump of a PL/I for MVS & VM routine

To generate a dump of a PL/I for MVS & VM routine, you can call either the Language Environment callable service CEE3DMP or PLIDUMP. For information about calling CEE3DMP, see “Generating a Language Environment dump with CEE3DMP” on page 35.

PLIDUMP syntax and options

PLIDUMP calls intermediate PL/I for MVS & VM library routines, which convert most PLIDUMP options to CEE3DMP options. The following list contains PLIDUMP options and the corresponding CEE3DMP option, if applicable.

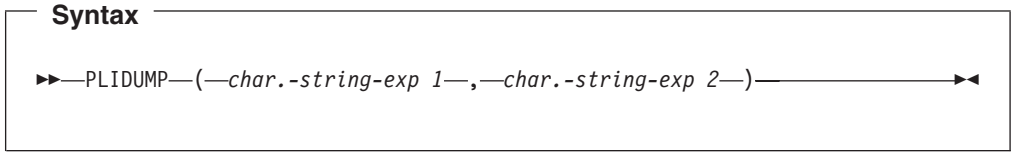
Some PLIDUMP options do not have corresponding CEE3DMP options, but continue to function as PL/I for MVS & VM default options. The list following the syntax diagram provides a description of those options.

PLIDUMP now conforms to National Language Support standards.

PLIDUMP can supply information across multiple Language Environment enclaves. If an application running in one enclave fetches a main procedure (an action that creates another enclave), PLIDUMP contains information about both procedures.

The syntax and options for PLIDUMP are shown below.

Syntax



char.-string-exp 1

A dump options character string consisting of one or more of the following:

A All. Results in a dump of all tasks including the ones in the WAIT state.

B BLOCKS (PL/I for MVS & VM hexadecimal dump). Dumps the control blocks used in Language Environment and member language libraries. For PL/I for MVS & VM, this includes the DSA for every routine on the call chain and PL/I for MVS & VM ″global″ control blocks, such as Tasking Implementation Appendage (TIA), Task Communication Area (TCA), and the PL/I Tasking Control Block (PTCB). PL/I file control blocks and file buffers are also dumped if the F option is specified.

C Continue. The routine continues after the dump.

E Exit. The enclave terminates after the dump. In a multitasking environment, if PLIDUMP is called from the main task, the enclave terminates after the dump. If PLIDUMP is called from a subtask, the subtask and any subsequent tasks created from the subtask terminate after the dump. In a multithreaded environment, if PLIDUMP is called from the Initial Process Thread (IPT), the enclave terminates after the dump. If PLIDUMP is called from a non-IPT, only the non-IPT terminates after the dump.

F FILE INFORMATION. A set of attributes for all open files is given. The contents of the file buffers are displayed if the B option is specified.

H STORAGE in hexadecimal. A SNAP dump of the region is produced. A ddname of CEESNAP must be provided to direct the CEESNAP dump report.

K BLOCKS (when running under CICS). The Transaction Work Area is included.

Note: This option is not supported under Enterprise PL/I.

NB NOBLOCKS.

NF NOFILES.

NH NOSTORAGE.

NK NOBLOCKS (when running under CICS).

NT NOTRACEBACK.

O THREAD(CURRENT). Results in a dump of only the current task or current thread (the invoker of PLIDUMP).

S Stop. The enclave terminates after the dump. In a multitasking environment, regardless of whether PLIDUMP is called from the main task or a subtask, the enclave terminates after the dump. In a multithreaded environment, regardless of whether PLIDUMP is called from the IPT or a non-IPT, the enclave terminates after the dump (in which case there is no fixed order as to which thread terminates first).

T TRACEBACK. Includes a traceback of all routines on the call chain. The traceback shows transfers of control from either calls or exceptions. BEGIN blocks and ON-units are also control transfers and are included in the trace. The traceback extends backwards to the main program of the current thread.

T, F, C, and A are the default options.

char.-string-exp 2
A user-identified character string up to 80 characters long that is printed as the dump header.

PLIDUMP usage notes

If you use PLIDUMP, the following considerations apply:

- If a routine calls PLIDUMP a number of times, use a unique user-identifier for each PLIDUMP invocation. This simplifies identifying the beginning of each dump.
- In MVS or TSO, you can use ddnames of CEEDUMP, PLIDUMP, or PL1DUMP to direct dump output. If no ddname is specified, CEEDUMP is used.
- The data set defined by the PLIDUMP, PL1DUMP, or CEEDUMP DD statement should specify a logical record length (LRECL) of at least 131 to prevent dump records from wrapping.
- When you specify the H option in a call to PLIDUMP, the PL/I for MVS & VM library issues an OS SNAP macro to obtain a dump of virtual storage. The first invocation of PLIDUMP results in a SNAP identifier of 0. For each successive invocation, the ID is increased by one to a maximum of 256, after which the ID is reset to 0.
- Support for SNAP dumps using PLIDUMP is provided only under MVS. SNAP dumps are not produced in a CICS environment.

– If the SNAP does not succeed, the CEE3DMP DUMP file displays the message:

```
Snap was unsuccessful
```

Failure to define a CEESNAP data set is the most likely cause of an unsuccessful CEESNAP.

– If the SNAP is successful, CEE3DMP displays the message:

```
Snap was successful; snap ID = nnn
```

where *nnn* corresponds to the SNAP identifier described above. An unsuccessful SNAP does not result in an incrementation of the identifier.

- To ensure portability across system platforms, use PLIDUMP to generate a dump of your PL/I for MVS & VM routine.

Finding PL/I for MVS & VM information in a dump

The following sections discuss PL/I-specific information located in the following sections of a Language Environment dump:

- Traceback
- Control Blocks for Active Routines
- Control Block Associated with the Thread
- File Status and Attributes

Traceback

Examine the traceback section of the dump, shown in Figure 109 on page 262, for condition information about your routine and information about the statement number and address where the exception occurred.

```

Figure 109. Traceback section of dump

PL/I for MVS & VM task traceback

A task traceback table is produced for multitasking programs showing the task invocation sequence (trace). For each task, the thread ID, CAA address (identified by TCA address in the dump), event variable address, task variable address, and absolute priority appear in the traceback table. An example is shown in Figure 110 on page 263.

```

Figure 110. Task traceback section (Part 2 of 2)

Condition information

If the dump was called from an ON-unit, the type of ON-unit is identified in the traceback as part of the entry information. For ON-units, the values of any relevant condition built-in functions (for example, ONCHAR and ONSOURCE for conversion errors) appear. In cases where the cause of entry into the ON-unit is not stated, usually when the ERROR ON-unit is called, the cause of entry appears in the condition information.

Statement number and address where error occurred

This information, which is the point at which the condition that caused entry to the ON-unit occurred, can be found in the traceback section of the dump.

If the condition occurs in compiled code, and you compiled your routine with either GOSTMT or GONUMBER, the statement numbers appear in the dump. To identify the assembler instruction that caused the error, use the traceback information in the dump to find the program unit (PU) offset of the statement number in which the error occurred. Then find that offset and the corresponding instruction in the object code listing.

Control blocks for active routines

This section shows the stack frames for all active routines, and the static storage. Use this section of the dump to identify variable values, determine the contents of parameter lists, and locate the timestamp.

Figure 111 on page 265 shows this section of the dump.

Figure 111. Control blocks for active routines section of the dump (Part 3 of 3)

Automatic variables

To find automatic variables, use an offset from the stack frame of the block in which they are declared. This information appears in the variable storage map generated when the MAP compiler option is in effect. If you have not used the MAP option, you can determine the offset by studying the listing of compiled code instructions.

Static variables

If your routine is compiled with the MAP option, you can find static variables by using an offset in the variable storage map. If the MAP option is not in effect, you can determine the offset by studying the listing of compiled code.

Based variables

To locate based variables, use the value of the defining pointer. Find this value by using one of the methods described above to find static and automatic variables. If the pointer is itself based, you must find its defining pointer and follow the chain until you find the correct value.

The following is an example of typical code for X BASED (P), with P AUTOMATIC:

```
58 60 D 0C8        L 6,P

58 E0 6 000        L 14,X
```

P is held at offset X'C8' from register 13. This address points to X.

Take care when examining a based variable to ensure that the pointers are still valid.

Area variables

Area variables are located using one of the methods described above, according to their storage class.

The following is an example of typical code: for an area variable A declared AUTOMATIC:

```
41 60 D 0F8        LA 6,A
```

The area starts at offset X'F8' from register 13.

Variables in areas

To find variables in areas, locate the area and use the offset to find the variable.

Contents of parameter lists

To find the contents of a passed parameter list, first find the register 1 value in the save area of the calling routine's stack frame. Use this value to locate the parameter list in the dump. If R1=0, no parameters passed. For additional information about parameter lists, see *PL/I for MVS & VM Programming Guide*.

Timestamp

If the TSTAMP compiler installation option is in effect, the date and time of compilation appear within the last 32 bytes of the static internal control section. The last three bytes of the first *word* give the offset to this information. The offset indicates the end of the timestamp. Register 3 addresses the static internal control section. If the BLOCK option is in effect, the timestamp appears in the static storage section of the dump.

Control blocks associated with the thread

This section of the dump, shown in Figure 112 on page 269, includes information about PL/I for MVS & VM fields of the CAA and other control block information.

Figure 112. Control blocks associated with the thread section of the dump (Part 2 of 2)

The CAA

The address of the CAA control block appears in this section of the dump. If the BLOCK option is in effect, the complete CAA (including the PL/I for MVS & VM implementation appendage) appears separately from the body of the dump. Register 12 addresses the CAA.

File status and attribute information

This part of the dump includes the following information:

- The default and declared attributes of all open files
- Buffer contents of all file buffers
- The contents of FCBs, DCBs, DCLCBs, IOCBs, and control blocks for the process or enclave

PL/I for MVS & VM contents of the Language Environment trace table

Language Environment provides three PL/I for MVS & VM trace table entry types that contain character data:

- Trace entry 100 occurs when a task is created.
- Trace entry 101 occurs when a task that contains the tasking CALL statements is terminated.

- Trace entry 102 occurs when a task that does not contain a tasking CALL statement is terminated.

The format for trace table entries 100, 101, and 102 is:

```
—>(100) NameOfCallingTask NameOfCalledTask OffsetOfCallStmt
            UserAgrPtr CalledTaskPtr TaskVarPtr EventVarPtr
            PriorityPtr CallingR2-R5 CallingR12-R14

—>(101) NameOfReturnTask ReturnerR2-R5 ReturnerR12-R14

—>(102) NameOfReturnTask
```

For more information about the Language Environment trace table format, see “Understanding the trace table entry (TTE)” on page 126.

Debugging example of PL/I for MVS & VM routines

This section contains examples of PL/I for MVS & VM routines and instructions for using information in the Language Environment dump to debug them. Important areas in the source code and in the dump for each routine are highlighted.

Subscript range error

Figure 113 on page 272 illustrates an error caused by an array subscript value outside the declared range. In this example, the declared array value is 10.

This routine was compiled with the options LIST, TEST, GOSTMT, and MAP. It was run with the TERMTHDACT(TRACE) option to generate a traceback for the condition.

Figure 114. Sections of the Language Environment dump (Part 2 of 2)

To debug this routine, use the following steps:

1. In the dump, PLIDUMP was called by the ERROR ON-unit in statement 6. The traceback information in the dump shows that the exception occurred following statement 11.
2. Locate the Original Condition message in the Condition Information for Active Routines section of the dump. The message is `IBM0421S ONCODE=520 The SUBSCRIPTRANGE condition was raised.` This message indicates that the exception occurred when an array element value exceeded the subscript range value (in this case, 10). For more information about this message, see *z/OS Language Environment Run-Time Messages*.
3. Locate statement 9 in the routine in Figure 113 on page 272. The instruction is `Array_End = 20`. This statement assigns a 20 value to the variable `Array_End`.
4. Statement 10 begins the DO-loop instruction `Do I = 1 to Array_End`. Since the previous instruction (statement 9) specified that `Array_End = 20`, the loop in statement 10 should run until `I` reaches a 20 value.

The instruction in statement 2, however, declared a 10 value for the array range. Therefore, when the I value reached 11, the SUBSCRIPTRANGE condition was raised.

The following steps provide another method for finding the value that raised the SUBSCRIPTRANGE condition.

1. Locate the offset of variable I in the variable storage map in Figure 113 on page 272. Use this offset to find the I value at the time of the dump. In this example, the offset is X'C8'.
2. Now find offset X'C8' from the start of the stack frame for the entry EXAMPLE in Figure 114 on page 273.

   The block located at this offset contains the value that exceeded the array range, X'B' or 11.

Calling a nonexistent subroutine

Figure 115 demonstrates the error of calling a nonexistent subroutine. This routine was compiled with the LIST, MAP, and GOSTMT compiler options. It was run with the TERMTHDACT(DUMP) run-time option to generate a traceback.

Figure 116. Sections of the Language Environment dump (Part 2 of 2)

To understand the traceback and debug this example routine, use the following steps:

1. Find the Current Condition message in the Condition Information for Active Routines section of the dump. The message is `CEE3201S. The system detected an Operation exception.` For more information about this message, see *z/OS Language Environment Run-Time Messages*.

   This section of the dump also provides such information as the name of the active routine and the current statement number at the time of the dump. The Location section indicates that the exception occurred at offset X'-20900D2C' within entry EXAMPLE1 and that there might have been a bad branch from offset X'+000000C0' statement 7 within entry EXAMPLE1 .
2. Locate statement 7 in the routine (Figure 115 on page 275). This statement calls subroutine Prog01. The message CEE3201S, which indicates an operations exception, was generated because of an unresolved external reference.
3. Check the linkage editor output for error messages.

Divide-by-zero error

Figure 117 on page 278 demonstrates a divide-by-zero error. In this example, the main PL/I for MVS & VM routine passed bad data to a PL/I for MVS & VM

subroutine. The bad data in this example is 0, and the error occurred when the subroutine SUB1 attempted to use this data as a divisor.

Figure 117. PL/I for MVS & VM routine with a divide-by-zero error

Since variables are not normally displayed in a PLIDUMP dump, this routine included a PUT DATA statement, which generated a listing of arguments and variables used in the routine. Figure 118 shows this output.

```
1Sample Starting
 Sub1 Starting        A_NUMBER=             0 MY_NAME='Tery Gillaspy' AN_ARRAY(1)=  1
 AN_ARRAY(2)=          3                      AN_ARRAY(3)=             5;
```

Figure 118. Variables from routine SAMPLE

The routine in Figure 117 on page 278 was compiled with the LIST compiler option, which generated the object code listing shown in Figure 119.

Figure 120. Language Environment dump from example PL/I for MVS & VM routine (Part 3 of 3)

To understand the dump information and debug this routine, use the following steps:

1. Notice the title of the dump:`PLIDUMP called from error ON-unit`. This was the title specified when PLIDUMP was invoked, and it indicates that the ERROR condition was raised and PLIDUMP was called from within the ERROR ON-unit.
2. Locate the messages in the Condition Information section of the dump.

   There are two messages. The current condition message indicates that a prior condition was promoted to the ERROR condition. The promotion of a condition occurs when the original condition is left unhandled (no PL/I for MVS & VM ON-units are assigned to gain control). The original condition message is `CEE3209S. The system detected a Fixed Point divide exception`. The original condition usually indicates the actual problem. For more information about this message, see *z/OS Language Environment Run-Time Messages*.
3. In the traceback section, note the sequence of calls in the call chain. SAMPLE called SUB1 at statement 11, and SUB1 raised an exception at statement 15, PU offset X'3CE'.
4. Find the statement in the listing for SUB1 that raised the ZERODIVIDE condition. If SUB1 was compiled with GOSTMT and SOURCE, find statement 15 in the source listing.

   Since the object listing was generated in this example, you can also locate the actual assembler instruction causing the exception at offset X'3CE' in the object listing for this routine, shown in Figure 119 on page 279. Either method shows that *divisor* was used as the divisor in a divide operation.
5. You can see from the declaration of SUB1 that *divisor* is a parameter passed from SAMPLE. Because of linkage conventions, you can infer that register 1 in the SAMPLE save area points to a parameter list that was passed to SUB1. *divisor* is the first parameter in the list.
6. In the SAMPLE DSA, the R1 value is X'20900590'. This is the address of the parameter list, which is located in static storage.

7. Find the parameter list in the stack frame; the address of the first parameter is X'20B42400' and the value of the first parameter is X'00000000'. Thus, the exception occurred when SAMPLE passed a 0 value used as a divisor in subroutine SUB1.

Chapter 8. Debugging Enterprise PL/I routines

This chapter contains information that can help you debug applications that contain one or more Enterprise PL/I routines. Following a discussion about potential errors in Enterprise PL/I routines, the first part of this chapter discusses how to use compiler-generated listings to obtain information about Enterprise PL/I routines, and how to use PLIDUMP to generate a Language Environment dump of an Enterprise PL/I routine. The last part of the chapter provides examples of Enterprise PL/I routines and explains how to debug them using information contained in the traceback information provided in the dump. The topics covered are listed below.

- Determining the source of errors in Enterprise PL/I routines
- Using Enterprise PL/I compiler listings
- Generating a Language Environment dump of an Enterprise PL/I routine
- Finding Enterprise PL/I information in a dump
- Debugging example of Enterprise PL/I routines

Determining the source of errors in Enterprise PL/I routines

Most errors in Enterprise PL/I routines can be identified by the information provided in Enterprise PL/I run-time messages, which begin with the prefix IBM. For a list of these messages, see *z/OS Language Environment Run-Time Messages*.

A malfunction in running an Enterprise PL/I routine can be caused by:

- Logic errors in the source routine
- Invalid use of Enterprise PL/I
- Unforeseen errors
- Invalid input data
- Compiler or run-time routine malfunction
- System malfunction
- Unidentified routine malfunction
- Overlaid storage

Logic errors in the source routine

Errors of this type are often difficult to detect because they often appear as compiler or library malfunctions.

Some common errors in source routines are:

- Incorrect conversion from arithmetic data
- Incorrect arithmetic and string manipulation operations
- Unmatched data lists and format lists

Invalid use of Enterprise PL/I

A misunderstanding of the language or a failure to provide the correct environment for using Enterprise PL/I can result in an apparent malfunction of an Enterprise PL/I routine.

Any of the following, for example, might cause a malfunction:

- Using uninitialized variables
- Using controlled variables that have not been allocated
- Reading records into incorrect structures
- Misusing array subscripts
- Misusing pointer variables
- Incorrect conversion
- Incorrect arithmetic operations

- Incorrect string manipulation operations

Unforeseen errors

If an error is detected during run time and no ON-unit is provided in the routine to terminate the run or attempt recovery, the job terminates abnormally. However, the status of a routine at the point where the error occurred can be recorded by using an ERROR ON-unit that contains the statements:

```
ON ERROR
 BEGIN;
  ON ERROR SYSTEM;
  CALL PLIDUMP;         /*generates a dump*/
  PUT DATA;             /*displays variables*/
 END;
```

The statement ON ERROR SYSTEM ensures that further errors do not result in a permanent loop.

Invalid input data

A routine should contain checks to ensure that any incorrect input data is detected before it can cause the routine to malfunction.

Use the COPY option of the GET statement to check values obtained by stream-oriented input. The values are listed on the file named in the COPY option. If no file name is given, SYSPRINT is assumed.

Compiler or run-time routine malfunction

If you are certain that the malfunction is caused by a compiler or run-time routine error, you can either open a PMR or submit an APAR for the error. Meanwhile, you can try an alternative way to perform the operation that is causing the trouble. A bypass is often feasible, since the Enterprise PL/I language frequently provides an alternative method of performing operations.

System malfunction

System malfunctions include machine malfunctions and operating system errors. System messages identify these malfunctions and errors to the operator.

Unidentified routine malfunction

In most circumstances, an unidentified routine malfunction does not occur when using the compiler. If your routine terminates abnormally without an accompanying Language Environment run-time diagnostic message, the error causing the termination might also be inhibiting the production of a message. Check for the following:

- Your job control statements might be in error, particularly in defining data sets.
- Your routine might overwrite main storage areas containing executable instructions. This can happen if you have accidentally:
  - Assigned a value to a nonexistent array element. For example:

    ```
    DCL ARRAY(10);

    .
    .
    .
    DO I = 1 TO 100;
    ARRAY(I) = VALUE;
    ```

    To detect this type of error in a compiled module, set the SUBSCRIPTRANGE condition so that each attempt to access an element outside the declared

range of subscript values raises the SUBSCRIPTRANGE condition. If there is no ON-unit for this condition, a diagnostic message is printed and the ERROR condition is raised. This facility, though expensive in run time and storage space, is a valuable routine-testing aid.

– Used an incorrect locator value for a locator (pointer or offset) variable. This type of error can occur if a locator value is obtained by means of record-oriented transmission. Ensure that locator values created in one routine, transmitted to a data set, and subsequently retrieved for use in another routine, are valid for use in the second routine.

– Attempted to free a nonbased variable. This can happen when you free a based variable after its qualifying pointer value has been changed. For example:

```
DCL A STATIC,B BASED (P);
ALLOCATE B;
P = ADDR(A);
FREE B;
```

– Used the SUBSTR pseudovariable to assign a string to a location beyond the end of the target string. For example:

```
DCL X CHAR(3);
I=3
SUBSTR(X,2,I) = 'ABC';
```

To detect this type of error, enable the STRINGRANGE condition during compilation.

Storage overlay problems

If you suspect an error in your Enterprise PL/I application is a storage overlay problem, check for the following:

- The use of a subscript outside the declared bounds (check the SUBSCRIPTRANGE condition)
- An attempt to assign a string to a target with an insufficient maximum length (check the STRINGSIZE condition)
- The failure of the arguments to a SUBSTR reference to comply with the rules described for the SUBSTR built-in function (check the STRINGRANGE condition)
- The loss of significant last high-order (left-most) binary or decimal digits during assignment to an intermediate result or variable or during an input/output operation (check the SIZE condition)
- The reading of a variable-length file into a variable
- The misuse of a pointer variable
- The invocation of a Language Environment callable service with fewer arguments than are required

The first four situations are associated with the listed Enterprise PL/I conditions, all of which are disabled by default. If you suspect one of these problems exists in your routine, use the appropriate condition prefix on the suspected statement or on the BEGIN or PROCEDURE statement of the containing block.

The fifth situation occurs when you read a data record into a variable that is too small. This type of problem only happens with variable-length files. You can often isolate the problem by examining the data in the file information and buffer.

The sixth situation occurs when you misuse a pointer variable. This type of storage overlay is particularly difficult to isolate. There are a number of ways pointer variables can be misused:

- When a READ statement runs with the SET option, a value is placed in a pointer. If you then run a WRITE statement or another READ SET option with another pointer, you overlay your storage if you try to use the original pointer.
- When you try to use a pointer to allocate storage that has already been freed, you can also cause a storage overlay.
- When you attempt to use a pointer set with the ADDR built-in function as a base for data with different attributes, you can cause a storage overlay.

The seventh situation occurs when a Language Environment callable service is passed fewer arguments than its interface requires. The following example might cause a storage overlay because Language Environment assumes that the fourth item in the argument list is the address of a feedback code, when in reality it could be residue data pointing anywhere in storage.

Invalid calls:

```
DCL CEEDATE ENTRY OPTIONS(ASM);
CALL CEEDATE(x,y,z);      /* invalid */
```

Valid calls:

```
DCL CEEDATE ENTRY(*,*,*,* OPTIONAL) OPTIONS(ASM);
CALL CEEDATE(x,y,z,*);    /* valid   */
CALL CEEDATE(x,y,z,fc);   /* valid   */
```

Using Enterprise PL/I compiler listings

The following sections explain how to generate listings that contain information about your routine. Enterprise PL/I listings show machine instructions, constants, and external or internal addresses that the linkage editor resolves. This information can help you find other information, such as variable values, in a dump of an Enterprise PL/I routine.

Note: Enterprise PL/I shares a common compiler back-end with C/C++. The Enterprise PL/I assembler listing will, consequently, have a similar form to those from the XL C/C++ compiler.

The compiler listings included below are from the Enterprise PL/I product.

Generating Enterprise PL/I listings and maps

The following table shows compiler-generated listings that you might find helpful when you use information in dumps to debug Enterprise PL/I routines.

Table 22. Compiler-generated PL/I listings and their contents

Name	Contents	Compiler Option
Source program	Source program statements	SOURCE
Cross reference	Cross reference of names with attributes	XREF and ATTRIBUTES
Aggregate table	Names and layouts of structures and arrays	AGGREGATE
Variable map	Offsets of automatic and static internal variables (from their defining base)	MAP
Object code	Contents of the program control section in hexadecimal notation and translated into a pseudo-assembler format.	LIST

Table 22. Compiler-generated PL/I listings and their contents (continued)

Name	Contents	Compiler Option
Variable map, object code, static storage	Same as MAP and LIST options above, plus contents of static internal and static external control sections in hexadecimal notation with comments	MAP and LIST

Finding information in Enterprise PL/I listings

Figure 121 shows the first two pages of an example Enterprise PL/I routine that was compiled with the LIST, MAP and SOURCE options.

```
5655-H31  IBM(R) Enterprise PL/I for z/OS       V3.R6.M0 (Built:20070119)
                    Options Specified
  Install:
  Command: s
  Line.File Process Statements
     1.0    *PROCESS SOURCE LIST MAP;
  Install:

5655-H31  IBM(R) Enterprise PL/I for z/OS
 Compiler Source
    Line.File
       2.0
       3.0      EXAMPLE: PROC OPTIONS(MAIN);
       4.0        DCL EXTR ENTRY EXTERNAL;
       5.0        DCL A FIXED BIN(31);
       6.0        DCL B(2,2)  FIXED BIN(31) STATIC EXTERNAL INIT((4)0);
       7.0        DCL C CHAR(20) STATIC INIT('SAMPLE CONSTANT');
       8.0        DCL D FIXED BIN(31) STATIC;
       9.0        DCL E FIXED BIN(31);
      10.0        FETCH EXTR;
      11.0        CALL EXTR(A,B,C,D,E);
      12.0        DISPLAY(C);
      13.0      END;
```

Figure 121. Enterprise PL/I routine compiled with LIST, MAP, and SOURCE

Figure 122 on page 290 shows the output generated by the LIST and MAP options for this routine, including the pseudo-assembly listing, the external symbol dictionary and reference, the storage offset listing and the static and automatic storage maps. The sections following this example describe the contents of each type of listing.

```

Figure 122. Compiler-generated listings from example Enterprise PL/I routine (Part 4 of 4)

Pseudo assembly listing

The pseudo assembly listing consists of the machine instructions and a translation of these instructions into a form that resembles assembler code.

This listing always starts with a small section of non-executable data that records the date and time when the object was produced as well as the version of the compiler used to produce the object. This section ends with a service string which in the listing is followed by the build date for the compiler back-end that generated this part of the listing (and this date may be different from the build date for the compiler front-end that generated the first pages of the listing).

The majority of the pseudo assembly listing consists of the object code arranged in columns that specify for each instructions:

- Its offset.
- the instruction in object code format.
- Its associated line number.
- Its associated file number if non-zero (i.e. if from an include file).

- the instruction in mnemonic format.

External symbol dictionary

The external symbol dictionary lists all the external symbols generated for this compilation. For each symbol, it also lists its linkage type and size (in hex).

External symbol cross reference

The external symbol dictionary cross reference shows for each external symbol the name that will be visible externally to the linker.

Storage offset listing

Each line of the storage offset listing contains the following information for each user variable:

- Its name.
- the number of the block in which it was declared.
- the number of the file in which it was declared.
- the number of the line in which it was declared.
- Its class (automatic, static, etc).
- Its location (as appropriate for its class).
- Its byte length in decimal.

This list is sorted by block number and then by name within each block.

Static map

Each line of the static storage map contains the following information for each internal static variable:

- Its hexadecimal offset.
- Its byte length in hex.
- Its name.

This list is sorted by the offset of the variables in static.

This list of variables may also include compiler-generated variables.

Automatic map

Each line of the automatic storage map contains the following information, grouped by named block, for each automatic variable in that block:

- Its hexadecimal offset.
- Its byte length in hex.
- Its name.

These lists are sorted by the offset of the variables in automatic for each block.

These lists of variables may also include compiler-generated variables.

Generating a Language Environment dump of an Enterprise PL/I routine

To generate a dump of an Enterprise PL/I routine, you can call either the Language Environment callable service CEE3DMP or PLIDUMP. For information about calling CEE3DMP, see “Generating a Language Environment dump with CEE3DMP” on page 35.

PLIDUMP syntax and options

PLIDUMP calls intermediate Enterprise PL/I library routines, which convert most PLIDUMP options to CEE3DMP options. The following list contains PLIDUMP options and the corresponding CEE3DMP option, if applicable.

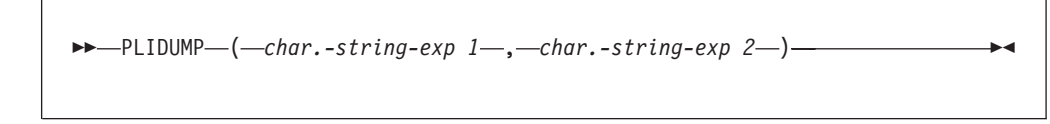
Some PLIDUMP options do not have corresponding CEE3DMP options, but continue to function as Enterprise PL/I default options. The list following the syntax diagram provides a description of those options.

PLIDUMP now conforms to National Language Support standards.

PLIDUMP can supply information across multiple Language Environment enclaves. If an application running in one enclave fetches a main procedure (an action that creates another enclave), PLIDUMP contains information about both procedures.

The syntax and options for PLIDUMP are shown below.

Syntax



char.-string-exp 1

A dump options character string consisting of one or more of the following:

A All. Results in a dump of all tasks including the ones in the WAIT state.

B BLOCKS (Enterprise PL/I hexadecimal dump). Dumps the control blocks used in Language Environment and member language libraries. For Enterprise PL/I, this includes the DSA for every routine on the call chain and Enterprise PL/I ″global″ control blocks, such as Tasking Implementation Appendage (TIA), Task Communication Area (TCA), and the PL/I Tasking Control Block (PTCB). Enterprise PL/I file control blocks and file buffers are also dumped if the F option is specified.

C Continue. The routine continues after the dump.

E Exit. The enclave terminates after the dump. In a multitasking environment, if PLIDUMP is called from the main task, the enclave terminates after the dump. If PLIDUMP is called from a subtask, the subtask and any subsequent tasks created from the subtask terminate after the dump. In a multithreaded environment, if PLIDUMP is called from the Initial Process Thread (IPT), the enclave terminates after the dump. If PLIDUMP is called from a non-IPT, only the non-IPT terminates after the dump.

F FILE INFORMATION. A set of attributes for all open files is given. The contents of the file buffers are displayed if the B option is specified.

H STORAGE in hexadecimal. A SNAP dump of the region is produced. A ddname of CEESNAP must be provided to direct the CEESNAP dump report.

K BLOCKS (when running under CICS). The Transaction Work Area is included.

Note: This option is not supported under Enterprise PL/I.

NB NOBLOCKS.

NF NOFILES.

NH NOSTORAGE.

NK NOBLOCKS (when running under CICS).

NT NOTRACEBACK.

O THREAD(CURRENT). Results in a dump of only the current task or current thread (the invoker of PLIDUMP).

S Stop. The enclave terminates after the dump. In a multitasking environment, regardless of whether PLIDUMP is called from the main task or a subtask, the enclave terminates after the dump. In a multithreaded environment, regardless of whether PLIDUMP is called from the IPT or a non-IPT, the enclave terminates after the dump (in which case there is no fixed order as to which thread terminates first).

T TRACEBACK. Includes a traceback of all routines on the call chain. The traceback shows transfers of control from either calls or exceptions. BEGIN blocks and ON-units are also control transfers and are included in the trace. The traceback extends backwards to the main program of the current thread.

T, F, C, and A are the default options.

char.-string-exp 2
A user-identified character string up to 80 characters long that is printed as the dump header.

PLIDUMP usage notes

If you use PLIDUMP, the following considerations apply:

- If a routine calls PLIDUMP a number of times, use a unique user-identifier for each PLIDUMP invocation. This simplifies identifying the beginning of each dump.
- In MVS or TSO, you can use ddnames of CEEDUMP, PLIDUMP, or PL1DUMP to direct dump output. If no ddname is specified, CEEDUMP is used.
- The data set defined by the PLIDUMP, PL1DUMP, or CEEDUMP DD statement should specify a logical record length (LRECL) of at least 131 to prevent dump records from wrapping.
- When you specify the H option in a call to PLIDUMP, the Enterprise PL/I library issues an OS SNAP macro to obtain a dump of virtual storage. The first invocation of PLIDUMP results in a SNAP identifier of 0. For each successive invocation, the ID is increased by one to a maximum of 256, after which the ID is reset to 0.
- Support for SNAP dumps using PLIDUMP is provided only under MVS. SNAP dumps are not produced in a CICS environment.
  - If the SNAP does not succeed, the CEE3DMP DUMP file displays the message:

    ```
    Snap was unsuccessful
    ```

    Failure to define a CEESNAP data set is the most likely cause of an unsuccessful CEESNAP.
  - If the SNAP is successful, CEE3DMP displays the message:

    ```
    Snap was successful; snap ID = nnn
    ```

where *nnn* corresponds to the SNAP identifier described above. An unsuccessful SNAP does not result in an incrementation of the identifier.

- To ensure portability across system platforms, use PLIDUMP to generate a dump of your Enterprise PL/I routine.

Finding Enterprise PL/I information in a dump

The following sections discuss Enterprise PL/I-specific information located in the following sections of a Language Environment dump:

- Traceback
- Control Blocks for Active Routines
- Control Block Associated with the Thread
- File Status and Attributes

Traceback

Examine the traceback section of the dump, shown in Figure 123 on page 298, for condition information about your routine and information about the statement number and address where the exception occurred.

```

Figure 123. Traceback section of dump

Condition information

If the dump was called from an ON-unit, the type of ON-unit is identified in the traceback as part of the entry information. For ON-units, the values of any relevant condition built-in functions (for example, ONCHAR and ONSOURCE for conversion errors) appear. In cases where the cause of entry into the ON-unit is not stated, usually when the ERROR ON-unit is called, the cause of entry appears in the condition information.

Statement number and address where error occurred

This information, which is the point at which the condition that caused entry to the ON-unit occurred, can be found in the traceback section of the dump.

If the condition occurs in compiled code, and you compiled your routine with either GOSTMT or GONUMBER, the statement numbers appear in the dump. To identify the assembler instruction that caused the error, use the traceback information in the dump to find the program unit (PU) offset of the statement number in which the error occurred. Then find that offset and the corresponding instruction in the object code listing.

Control blocks for active routines

This section shows the stack frames for all active routines, and the static storage. Use this section of the dump to identify variable values, determine the contents of parameter lists, and locate the timestamp.

Figure 124 on page 300 shows this section of the dump.

Figure 124. Control blocks for active routines section of the dump

Automatic variables

To find automatic variables, use an offset from the stack frame of the block in which they are declared. This information appears in the variable storage map generated when the MAP compiler option is in effect. If you have not used the MAP option, you can determine the offset by studying the listing of compiled code instructions.

Static variables

If your routine is compiled with the MAP option, you can find static variables by using an offset in the variable storage map. If the MAP option is not in effect, you can determine the offset by studying the listing of compiled code.

Based variables

To locate based variables, use the value of the defining pointer. Find this value by using one of the methods described above to find static and automatic variables. If the pointer is itself based, you must find its defining pointer and follow the chain until you find the correct value.

The following is an example of typical code for X BASED (P), with P AUTOMATIC:

```
58 60 D 0C8        L 6,P

58 E0 6 000        L 14,X
```

P is held at offset X'C8' from register 13. This address points to X.

Take care when examining a based variable to ensure that the pointers are still valid.

Area variables

Area variables are located using one of the methods described above, according to their storage class.

The following is an example of typical code: for an area variable A declared AUTOMATIC:

```
41 60 D 0F8        LA 6,A
```

The area starts at offset X'F8' from register 13.

Variables in areas

To find variables in areas, locate the area and use the offset to find the variable.

Contents of parameter lists

To find the contents of a passed parameter list, first find the register 1 value in the save area of the calling routine's stack frame. Use this value to locate the parameter list in the dump. If R1=0, no parameters passed.

Control blocks associated with the thread

This section of the dump, shown in Figure 125 on page 302, includes information about Enterprise PL/I fields of the CAA and other control block information.

Figure 125. Control blocks associated with the thread section of the dump (Part 2 of 2)

The CAA

The address of the CAA control block appears in this section of the dump. If the BLOCK option is in effect, the complete CAA (including the Enterprise PL/I implementation appendage) appears separately from the body of the dump. Register 12 addresses the CAA.

File status and attribute information

This part of the dump includes the following information:

- The default and declared attributes of all open files
- Buffer contents of all file buffers
- The contents of FCBs, DCBs, DCLCBs, IOCBs, and control blocks for the process or enclave

Enterprise PL/I contents of the Language Environment trace table

Language Environment provides three Enterprise PL/I trace table entry types that contain character data:

- Trace entry 100 occurs when a task is created.
- Trace entry 101 occurs when a task that contains the tasking CALL statements is terminated.
- Trace entry 102 occurs when a task that does not contain a tasking CALL statement is terminated.

The format for trace table entries 100, 101, and 102 is:

```
—>(100) NameOfCallingTask NameOfCalledTask OffsetOfCallStmt
           UserAgrPtr CalledTaskPtr TaskVarPtr EventVarPtr
           PriorityPtr CallingR2-R5 CallingR12-R14

—>(101) NameOfReturnTask ReturnerR2-R5 ReturnerR12-R14

—>(102) NameOfReturnTask
```

For more information about the Language Environment trace table format, see “Understanding the trace table entry (TTE)” on page 126.

Debugging example of Enterprise PL/I routines

This section contains examples of Enterprise PL/I routines and instructions for using information in the Language Environment dump to debug them. Important areas in the source code and in the dump for each routine are highlighted.

Subscript range error

Figure 126 on page 305 illustrates an error caused by an array subscript value outside the declared range. In this example, the declared array value is 10.

This routine was compiled with the options LIST, TEST, GONUMBER, and MAP. It was run with the TERMTHDACT(TRACE) option to generate a traceback for the condition.

Figure 127. Sections of the Language Environment dump (Part 2 of 2)

To debug this routine, use the following steps:

1. In the dump, PLIDUMP was called by the ERROR ON-unit in statement 9. The traceback information in the dump shows that the exception occurred following statement 16.

Note: In the LE dumps, the columns and messages refer to ″statements″, but the numbers are actually (for Enterprise PL/I) the line numbers from the source file.

2. Locate the Original Condition message in the Condition Information for Active Routines section of the dump. The message is `IBM0421S ONCODE=520 The SUBSCRIPTRANGE condition was raised.` This message indicates that the exception occurred when an array element value exceeded the subscript range value (in this case, 10). For more information about this message, see *z/OS Language Environment Run-Time Messages*.
3. Locate statement 14 in the routine in Figure 126 on page 305. The instruction is `Array_End = 20`. This statement assigns a 20 value to the variable `Array_End`.
4. Statement 15 begins the DO-loop instruction `Do I = 1 to Array_End`. Since the previous instruction (statement 14) specified that `Array_End = 20`, the loop in statement 10 should run until `I` reaches a 20 value.

   The instruction in statement 4, however, declared a 10 value for the array range. Therefore, when the I value reached 11, the SUBSCRIPTRANGE condition was raised.

The following steps provide another method for finding the value that raised the SUBSCRIPTRANGE condition.

1. Locate the offset of variable I in the storage offset listing in Figure 126 on page 305. Use this offset to find the I value at the time of the dump. In this example, the offset is X'E8'.
2. Now find offset X'E8' from the start of the stack frame for the entry EXAMPLE in Figure 127 on page 306.

   The block located at this offset contains the value that exceeded the array range, X'B' or 11.

Calling a nonexistent subroutine

Figure 128 on page 309 demonstrates the error of calling a nonexistent subroutine. This routine was compiled with the LIST, MAP, and GONUMBER compiler options. It was run with the TERMTHDACT(DUMP) run-time option to generate a traceback.

Figure 129. Sections of the Language Environment dump (Part 2 of 2)

To understand the traceback and debug this example routine, use the following steps:

1. Find the Current Condition message in the Condition Information for Active Routines section of the dump. The message is `CEE3201S  The system detected an Operation exception.` For more information about this message, see *z/OS Language Environment Run-Time Messages*.

   This section of the dump also provides such information as the name of the active routine and the current statement number at the time of the dump. The Location section indicates that the exception occurred at offset X'-0B9009A8' within entry EXAMPLE1 and that there may have been a bad branch from offset X'+000001AE' statement 12 within entry EXAMPLE1 .
2. Locate statement 12 in the routine (Figure 128 on page 309). This statement calls subroutine Prog01. The message CEE3201S, which indicates an operations exception, was generated because of an unresolved external reference.

3. Check the linkage editor output for error messages.

Divide-by-zero error

Figure 130 demonstrates a divide-by-zero error. In this example, the main Enterprise PL/I routine passed bad data to an Enterprise PL/I subroutine. The bad data in this example is 0, and the error occurred when the subroutine SUB1 attempted to use this data as a divisor.

Figure 130. Enterprise PL/I routine with a divide-by-zero error

Since variables are not normally displayed in a PLIDUMP dump, this routine included a PUT DATA statement, which generated a listing of arguments and variables used in the routine. Figure 131 shows this output.

```
1Sample Starting
 Sub1 Starting        A_NUMBER=            0 MY_NAME='Tery Gillaspy' AN_ARRAY(1)=  1
 AN_ARRAY(2)=          3                     AN_ARRAY(3)=             5;
```

Figure 131. Variables from routine SAMPLE

The routine in Figure 130 on page 312 was compiled with the LIST compiler option, which generated the object code listing shown in Figure 132.

Figure 133. Language Environment dump from example Enterprise PL/I routine (Part 2 of 2)

To understand the dump information and debug this routine, use the following steps:

1. Notice the title of the dump: `PLIDUMP called from error ON-unit`. This was the title specified when PLIDUMP was invoked, and it indicates that the ERROR condition was raised and PLIDUMP was called from within the ERROR ON-unit.
2. Locate the messages in the Condition Information section of the dump.

   There are two messages. The current condition message indicates that a prior condition was promoted to the ERROR condition. The promotion of a condition occurs when the original condition is left unhandled (no Enterprise PL/I ON-units are assigned to gain control). The original condition message is `CEE3209S The system detected a fixed-point divide exception`. The original condition usually indicates the actual problem. For more information about this message, see *z/OS Language Environment Run-Time Messages*.
3. In the traceback section, note the sequence of calls in the call chain. SAMPLE called SUB1 at statement 19, and SUB1 raised an exception at statement 27, PU offset X'1C6'.
4. Find the statement in the listing for SUB1 that raised the ZERODIVIDE condition. If SUB1 was compiled with GOSTMT and SOURCE, find statement 27 in the source listing.

   Since the object listing was generated in this example, you can also locate the actual assembler instruction causing the exception at offset X'1C6' in the object listing for this routine, shown in Figure 132 on page 313. Either method shows that *divisor* was loaded into register 2 (r2) and used as the divisor in a divide operation.
5. You can see from the declaration of SUB1 that *divisor* is a parameter passed from SAMPLE. Because of linkage conventions, you can infer that register 1 in the SAMPLE save area points to a parameter list that was passed to SUB1. *divisor* is the first parameter in the list.
6. In the SAMPLE DSA, the R1 value is X'11A3B450'. This is the address of the parameter list, which is located in static storage.
7. Find the parameter list in the stack frame; the address of the first parameter is X'11A3B484' and the value of the first parameter is X'00000000'. Thus, the exception occurred when SAMPLE passed a 0 value used as a divisor in subroutine SUB1.

Chapter 9. Debugging under CICS

This chapter provides information for debugging under the Customer Information Control System (CICS). The following sections explain how to access debugging information under CICS, and describe features unique to debugging under CICS.

Use the following list as a quick reference for debugging information:
- Language Environment run-time messages (CESE transient data queue)
- Language Environment traceback (CESE transient data queue)
- Language Environment dump output (CESE transient data queue)
- CICS Transaction Dump (CICS DFHDMPA or DFHDMPB data set)
- Language Environment abend and reason codes (system console)
- Language Environment return codes to CICS (system console)

If the EXEC CICS HANDLE ABEND command is active and the application, or CICS, initiates an abend or application interrupt, then Language Environment does not produce any run-time messages, tracebacks, or dumps.

If EXEC CICS ABEND NODUMP is issued, then no Language Environment dumps or CICS transaction dumps are produced.

Accessing debugging information

The following sections list the debugging information available to CICS users, and describe where you can find this information.

Under CICS, the Language Environment run-time messages, Language Environment traceback, and Language Environment dump output are written to the CESE transient data queue. The transaction identifier, terminal identifier, date, and time precede the data in the queue. For detailed information about the format of records written to the transient data queue, see *z/OS Language Environment Programming Guide*.

The CESE transient data queue is defined in the CICS destination control table (DCT). The CICS macro DFHDCT is used to define entries in the DCT. See *CICS Resource Definition Guide* for a detailed explanation of how to define a transient data queue in the DCT. If you are not sure how to define the CESE transient data queue, see your system programmer.

Locating Language Environment run-time messages

Under CICS, Language Environment run-time messages are written to the CESE transient data queue. A sample Language Environment message that appears when an application abends due to an unhandled condition from an EXEC CICS command is:

```
P039UTV9 19910916145313 CEE3250C The System or User ABEND AEI0 was issued.
P039UTV9 19910916145313          From program unit UT9CVERI at entry point UT9CVERIT
                                 +0000011E at P039UTV9 19910916145313
                                 at offset address 0006051E.
```

Locating the Language Environment traceback

Under CICS, the Language Environment traceback is written to the CESE transient data queue. Because Language Environment invokes your application routine, the Language Environment routines that invoked your routine appear in the traceback. Figure 134 on page 318 shows an example Language Environment traceback

written to the CESE transient data queue. Data unnecessary for this example has been replaced by ellipses.

Figure 134. Language Environment traceback written to the transient data queue

Locating the Language Environment dump

Under CICS, the Language Environment dump output is written to the CESE transient data queue. For active routines, the Language Environment dump contains the traceback, condition information, variables, storage, and control block information for the thread, enclave, and process levels. Use the Language Environment dump with the CICS transaction dump to locate problems when operating under CICS.

For a sample Language Environment dump, see “Understanding the Language Environment dump” on page 43.

Using CICS transaction dump

The CICS transaction dump is generated to the DFHDMPA or DFHDMPB data set. The offline CICS dump utility routine converts the transaction dump into formatted, understandable output.

The CICS transaction dump contains information for the storage areas and resources associated with the current transaction. This information includes the Communication Area (COMMAREA), Transaction Work Area (TWA), Exec Interface Block (EIB), and any storage obtained by the CICS EXEC commands. This information does not appear in the Language Environment dump. It can be helpful to use the CICS transaction dump with the Language Environment dump to locate problems when operating under CICS.

When the location of an error is uncertain, it can be helpful to insert EXEC CICS DUMP statements in and around the code suspected of causing the problem. This generates CICS transaction dumps close to the error for debugging reference.

For information about interpreting CICS dumps, see *CICS Problem Determination Guide*

Using CICS register and program status word contents

When a routine interrupt occurs (code = ASRA) and a CICS dump is generated, CICS formats the contents of the program status word (PSW) and the registers at the time of the interrupt. This information is also contained in the CICS trace table entry marked `SSRP * EXEC* – ABEND DETECTED`. For the format of the information contained in this trace entry, see *CICS Data Areas*, KERRD - KERNEL ERROR DATA.

The address of the interrupt can be found from the second word of the PSW, giving the address of the instruction following the point of interrupt. The address of the entry point of the function can be subtracted from this address. The offset compared to this listing gives the statement that causes the interrupt.

For C routines, you can find the address of the entry point in register 3.

If register 15 is corrupted, the contents of the first load module of the active enclave appear in the program storage section of the CICS transaction dump.

Using Language Environment abend and reason codes

An application can end with an abend in two ways:

- User-specified abend (that is, an abend requested by the assembler user exit or the ABTERMENC run-time option).
- Language Environment-detected unrecoverable error (in which case there is no Language Environment condition handling).

When Language Environment detects an unrecoverable error under CICS, Language Environment terminates the transaction with an EXEC CICS abend. The abend code has a number between 4000 and 4095. A write-to-operator (WTO) is performed to write a CEE1000S message to the system console. This message contains the abend code and its associated reason code. The WTO is performed only for unrecoverable errors detected by Language Environment. No WTO occurs for user-requested abends.

Although this type of abend is performed only for unrecoverable error conditions, an abend code of 4000–4095 does not necessarily indicate an internal error within Language Environment. For example, an application routine can write a variable outside its storage and corrupt the Language Environment control blocks.

Possible causes of a 4000–4095 abend are corrupted Language Environment control blocks and internal Language Environment errors. For more information about abend codes 4000–4095, see *z/OS Language Environment Run-Time Messages*. Following is a sample Language Environment abend and reason code. Abend codes appear in decimal, and reason codes appear in hexadecimal.

```
12.34.27 JOB05585  IEF450I XCEPII03 GO CEPII03 - ABEND=S000 U4094 REASON=0000002C
```

Using Language Environment return codes to CICS

When the Language Environment condition handler encounters a severe condition that is specific to CICS, the condition handler generates a CICS-specific return code. This return code is written to the system console.

Possible causes of a Language Environment return code to CICS are:

- Incorrect region size
- Incorrect DCT
- Incorrect CSD definitions

For a list of the reason codes written only to CICS, see *z/OS Language Environment Run-Time Messages*. Following is a sample of a return code that was returned to CICS

```
 +DFHAP1200I
LE03CC01 A CICS request to Language Environment has failed.  Reason
code '0012030'.
```

Activating Language Environment feature trace records under CICS

Activating Language Environment feature trace records under CICS will allow users to monitor and determine the activity of a transaction. By activating the feature trace records, Level 2 trace points are added insideLanguage Environment at these significant points:

- Event Handle
- Set anchor
- Gives R13 and parameters before call

These trace points are useful for any support personnel that needs to know what happpened inside Language Environment from a CICS call.

The function will be enabled by the existing CICS transactions. A user must enable the AP domain level 2 in order to include the Language Environment trace points. For more information on activating the CICS trace, see *CICS Diagnosis Reference*.

Every time CICS calls Language Environment, the feature trace is activated under the Extended Run-Time Library Interface (ERTLI). The trace can bee seen in CICS transaction dumps. Feature trace entries are formatted in a similar way to CICS trace items. There are three formats: ABBREV, SHORT & FULL. The ABBREV version just formats the heading line for each trace point and is laid out in a similar way to CICS trace entries. For example,

```

```

Figure 135. CICS trace output in the ABBREV format.

The Domain Name field is replaced with a ″Feature″ short name (for example, Lang.Env.) and module name (for example, CEE.....) which are coded into the ″Feature Trace″ initialization (short name) and header formatting call (module name). See the following macro example.

The FULL version includes the heading from the ABBREV version and then dumps each captured block in Hex and Character formats. For example:

```
AP 1948 APLI EVENT CALL-TO-LE/370 - Rununit_Initialization    Program_name(NAMETEST)

Figure 136. CICS trace output in the FULL format.

The first block is used for the feature trace information. It contains the name of the off-line formatting module and the short name used in the formatted heading line. The other 6 blocks are available for user data.

The SHORT version is a cross between the ABBREV and FULL versions.

For more information about the CICS trace, see *CICS Diagnosis Reference*.

Ensuring transaction rollback

If your application does not run to normal completion and there is no CICS transaction abend, take steps to ensure that transaction rollback (the backing out of any updates made by the malfunctioning application) takes place.

There are two ways to ensure that a transaction rollback occurs when an unhandled condition of severity 2 or greater is detected:

- Use the ABTERMENC run-time option with the ABEND suboption (ABTERMENC(ABEND))
- Use an assembler user exit that requests an abend for unhandled conditions of severity 2 or greater

The IBM-supplied assembler user exit for CICS (CEECXITA), available in the Language Environment SCEESAMP sample library, ensures that a transaction abend and rollback occur for all unhandled conditions of severity 2 or greater. For more information about the assembler user exit, see "Invoking the assembler user exit" on page 23 and *z/OS Language Environment Programming Guide*.

Finding data when Language Environment returns a nonzero return code

Language Environment does not write any messages to the CESE transient data queue. Following is the output generated when Language Environment returns a nonzero reason code to CICS and the location where the output appears:

Table 23. Finding data when Language Environment returns a nonzero return code

Output Message	Location	Issued By
DFHAC2206 14:43:54 LE03CC01 Transaction UTV2 has failed with abend AEC7. Resource backout was successful.	User's terminal	CICS
DFHAP1200I LE03CC01 A CICS request to the Language Environment has failed. Reason code '0012030'.	System console	CICS
DFHAC2236 06/05/91 14:43:48 LE03CC01 Transaction UTV2 abend AEC7 in routine UT2CVERI term P021 backout successful.	Transient data queue CSMT	CICS

Finding data when Language Environment abends internally

Language Environment does not write any messages to the CESE transient data queue. Following is the output generated when Language Environment abends internally and the location where the output appears:

Table 24. Finding data when Language Environment abends internally

Displaying and modifying run-time options with the CLER transaction

The CICS transaction (CLER) allows you to display all the current Language Environment run-time options for a region, and to also have the capability to modify a subset of these options.

The CLER transaction can be used to:

- Display the current run-time options in effect for the region.
- Modify the following subset of the region run-time options:
  - ALL31(ON|OFF)
  - CBLPSHPOP(ON|OFF)
  - CHECK(ON|OFF)
  - INFOMSGFILTER(ON|OFF)
  - RPTOPTS(ON|OFF)
  - RPTSTG(ON|OFF)
  - TERMTHDACT(QUIET|MSG|TRACE|DUMP|UAONLY|UATRACE|UADUMP|UAIMM)
  - TRAP(ON|OFF)
- Write the current region run-time options to the CESE queue for printing.

The CLER transaction is conversational; it presents the user with commands for the terminal display. The run-time options that can be modified with this transaction are only in effect for the duration of the running region.

The CLER transaction must be defined in the CICS CSD (CICS System Definition file). The following definitions are required, and are in the Language Environment CEECCSD job in the SCEESAMP data set:

```
DEFINE PROGRAM(CEL4RTO) GROUP(CEE) LANGUAGE(ASSEMBLER) EXECKEY(CICS)
DEFINE MAPSET(CELCLEM) GROUP(CEE)
DEFINE MAPSET(CELCLRH) GROUP(CEE)
DEFINE TRANS(CLER) PROG(CEL4RTO) GROUP(CEE)
```

Use the CEECCSD job to activate these definitions, or you must define them dynamically with the CICS CEDA transaction.

Note: If the run-time option ALL31 is modified to OFF, the stack is forced to BELOW. When the stack is modified to BELOW, it will remain below for the duration of the region, even if you set ALL31 back to ON. A warning message, asking if you want to continue, is presented on the panel if the run-time option ALL31 is set to OFF or CBLPSHPOP, RPTOPTS, and RPTSTG are set to ON.

To send the run-time option report to the CESE queue for output display or printing, press `PF10` on the panel which displays the run-time option report.

For detailed information on the use of CLER, select `PF1` from the main menu that is displayed when the CLER transaction is invoked.

Part 3. Debugging Language Environment AMODE 64 applications

This part provides specific information for debugging applications written to make use of the memory address space above the 2 GB bar.

Chapter 10. Preparing your AMODE 64 application for debugging

This chapter describes options and features that you can use to prepare your AMODE 64 application for debugging. The following topics are covered:

- Compiler options for C, C++
- Language Environment run-time options
- Use of storage in routines
- Options for modifying exception handling
- Assembler user exits
- Enclave termination behavior
- Language Environment feedback codes and condition tokens

Setting compiler options

The following sections discuss language-specific compiler options important to debugging routines in Language Environment. These sections cover only the compiler options that are important to debugging. For a complete list of compiler options, refer to the appropriate HLL publications.

The use of some compiler options (such as DEBUG) can affect the performance of your routine. You must set these options before you compile. In some cases, you might need to remove the option and recompile your routine before delivering your application.

XL C and XL C++ compiler options for AMODE 64 applications

When compiling an application using the LP64 compiler option, you cannot use the TEST compiler option. You must instead use the DEBUG(FORMAT(DWARF)) compiler option.

When the GONUMBER compiler option is used with LP64, it will produce executables with additional debug information. This is used by Language Environment to produce statement numbers in the Language Environment dump (CEEDUMP). Statement numbers in the CEEDUMP are also produced if the DEBUG compiler option or the `c89 -g` option is used.

For a detailed explanation of the debugging options for XL C/C++ and Inter-procedural Analysis (IPA), see *z/OS XL C/C++ User's Guide* and *z/OS XL C/C++ Programming Guide*.

Using Language Environment run-time options

There are several run-time options that affect debugging in Language Environment. The TEST run-time option, for example, can be used with a debugging tool to specify the level of control in effect for the debugging tool when the routine being initialized is started. The DYNDUMP, HEAPCHK, TERMTHDACT, TRACE, and TRAP options affect exception handling.

The following Language Environment run-time options affect debugging:

CEEDUMP Specifies options to control the processing of the Language Environment dump report.

DYNDUMP	Provides a way to obtain IPCS readable dumps of user applications that would ordinarily be lost due to the absence of a SYSMDUMP, SYSUDUMP, or SYSABEND DD statement
HEAPCHK	Determines whether additional heap check tests are performed.
INFOMSGFILTER	Filters user specified informational messages from stderr. **Note:** Affects only those messages generated by Language Environment and any routine that calls `__le_msg_get_and_write()`. Other routines that write to stderr, such as `__le_msg_write()`, do not have a filtering option.
PROFILE	Controls the use of an optional profiler tool, which collects performance data for the running application. When this option is in effect, the profiler is loaded and the debugger cannot be loaded. If the TEST option is in effect when PROFILE is specified, the profiler tool will not be loaded.
RPTOPTS	Causes a report to be produced which contains the run-time options in effect. See "Determining run-time options in effect" below.
RPTSTG	Generates a report of the storage used by an enclave. See "Controlling storage allocation" on page 331.
STORAGE	Specifies that Language Environment initializes all heap and stack storage to a user-specified value.
TERMTHDACT	Controls response when an enclave terminates due to an unhandled condition of severity 2 or greater.
TEST	Specifies the conditions under which a debugging tool assumes control.
TRACE	Activates Language Environment run-time library tracing and controls the size of the trace table, the type of trace, and whether the trace table should be dumped unconditionally upon termination of the application.
TRAP	When TRAP is set to ON, Language Environment traps routine interrupts and abends, and optionally prints trace information or invokes a user-written exception handling routine. With TRAP set to OFF, the operating system handles all interrupts and abends. You should generally set TRAP to ON, or your run-time results can be unpredictable.

For a more detailed discussion of these run-time options, see *z/OS Language Environment Programming Reference*.

Determining run-time options in effect

The run-time options in effect at the time the routine is run can affect routine behavior. Use RPTOPTS(ON) to generate an options report in the Language Environment message file when your routine terminates. The options report lists run-time options, and indicates where they were set.

Figure 137 on page 331 shows a sample options report.

Figure 137. 64–bit options report

Controlling storage allocation

The following run-time options control storage allocation:

- HEAP64
- HEAPPOOLS64
- IOHEAP64
- LIBHEAP64
- STACK64
- THREADSTACK64

z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode provides useful tips to assist with the tuning process. Appropriate tuning is necessary to avoid performance problems.

To generate a report of the storage a routine (or more specifically, an enclave) used during its run, specify the RPTSTG(ON) run-time option. The storage report, generated during enclave termination provides statistics that can help you understand how space is being consumed as the enclave runs. If storage management tuning is desired, the statistics can help you set the corresponding storage-related run-time options for future runs.

Figure 138 on page 332 shows a sample storage report.

End of Storage Report
```

Figure 138. 64–bit storage report (Part 3 of 3)

For storage statistics and heap storage statistics, see *z/OS Language Environment Programming Reference* in topic “Storage statistics for AMODE 64 applications”.

HeapPools storage statistics

The HEAPPOOLS run-time option (for C/C++ applications only) controls usage of the heap pools storage algorithm at the enclave level. The heap pools algorithm allows for the definition of one to twelve heap pools, each consisting of a number of storage cells of a specified length. For further details regarding HeapPools storage statistics in the storage report, see “HeapPools storage statistics” on page 466.

Modifying exception handling behavior

Setting the exception handling behavior of your routine affects the response that occurs when the routine encounters an error.

You can modify exception handling behavior in the following ways:
- Application program interfaces (API)
- User-written exception handlers
- POSIX functions (used to specifically set signal actions and signal masks)

Language Environment application program interfaces (API)

You can use the following APIs to modify exception handling:

__cabend()	Terminates an enclave using an abend.
__le_cib_get()	Returns a pointer to a condition information block (CIB) associated with a given condition token. The CIB contains detailed information about the condition.
__set_exception_handler()	Activates a routine to handle an exception.
__reset_exception_handler()	Removes handling of an exception by any routine.

Language Environment run-time options

These Language Environment run-time options can affect your routine’s exception handling behavior:

TERMTHDACT Sets the level of information that is produced when a condition of severity 2 or greater remains unhandled within the enclave. The possible parameter settings for different levels of information are:
- QUIET for no information
- MSG for message only
- TRACE for message and a traceback
- DUMP for message, traceback, and Language Environment dump
- UAONLY for message and a system dump of the user address space
- UATRACE for message, Language Environment dump with traceback information only, and a system dump of the user address space
- UADUMP for message, traceback, Language Environment dump, and system dump
- UAIMM for a system dump of the user address space of the original abend or program interrupt prior to the Language Environment condition manager processing the condition.

TRAP(ON) Fully enables the Language Environment exception handler. This causes the Language Environment exception handler to intercept error conditions and routine interrupts.

When TRAP(ON, NOSPIE) is specified, Language Environment handles all program interrupts and abends through an ESTAE. Use this feature when you do not want Language Environment to issue an ESPIE macro.

During normal operation, you should use TRAP(ON) when running your applications.

TRAP(OFF) Disables the Language Environment condition handler from handling abends and program checks/interrupts. ESPIE is not issued with TRAP(OFF).

Specify TRAP(OFF) when you do not want Language Environment to issue an ESPIE.

When TRAP(OFF), TRAP(OFF,SPIE), or TRAP(OFF,NOSPIE) is specified and either a program interrupt or abend occurs, the user exit for termination is ignored.

TRAP(OFF) can cause several unexpected side effects. It is not supported in AMODE 64 production execution.

For further information, see the TRAP run-time option in *z/OS Language Environment Programming Reference*.

Customizing exception handlers

User-written exception handlers permit you to customize exception handling for certain conditions. You can register a user-written exception handler for the current stack frame by using the `__set_exception_handler()` API.

For more information about user-written exception handlers and the Language Environment condition manager, see *z/OS XL C/C++ Programming Guide*.

Using condition information

If a condition that might require attention occurs while an application is running, Language Environment builds a condition token. The condition token contains 16 bytes (128 bits) of information about the condition that Language Environment or your routines can use to respond appropriately. Each condition is associated with a single Language Environment run-time message.

You can use this condition information in two ways:

- To specify the feedback code parameter when calling Language Environment services (see “Using the feedback code parameter”).
- To code a symbolic feedback code in a user-written exception handler (see “Using the symbolic feedback code” on page 338).

Using the feedback code parameter

The feedback code is an optional parameter of the Language Environment APIs. For C/C++ applications, this parameter is optional. For more information about **feedback codes** and condition tokens, see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode*.

When you provide the feedback code (**fc**) parameter, the API in which the condition occurs sets the feedback code to a specific value called a condition token.

The condition token does not apply to asynchronous signals. For a discussion of the distinctions between synchronous signals and asynchronous signals with POSIX(ON), see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode* .

When you do not provide the **fc** parameter, any nonzero condition is signaled and processed by Language Environment exception handling routines. If you have registered a user-written exception handler, Language Environment passes control to the handler, which determines the next action to take. If the condition remains unhandled, Language Environment writes a message to stderr. The message is the translation of the condition token into English (or another supported national language).

Language Environment provides APIs that can be used to convert condition tokens to routine variables, messages, or signaled conditions. The following table lists these Language Environment APIs and their functions.

__le_msg_write()	Writes a message string to stderr
__le_msg_get_and_write()	Takes a message associated with a condition and writes it to stderr
__le_msg_get()	Retrieves, formats, and stores message data for a condition
__le_msg_add_insert()	Creates a message insert

For more information on these APIs, see *z/OS XL C/C++ Programming Guide*.

There are two types of condition tokens. Case 1 condition tokens contain condition information, including the Language Environment message number. All Language Environment APIs and most application routines use case 1 condition tokens. Case 2 condition tokens contain condition information and a user-specified class and cause code. Application routines, user-written exception handlers, assembler user exits, and some operating systems can use case 2 condition tokens.

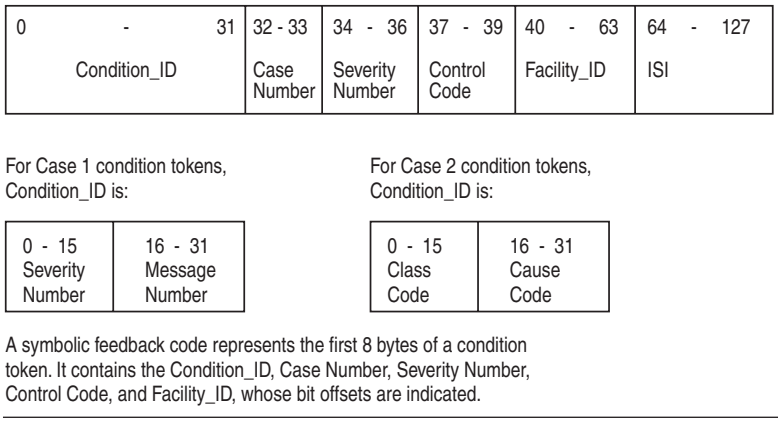

Figure 139. Language Environment condition token

For example, in the condition token: X'0003032D 59C3C5C5 00000000 00000000'

- X'0003' is severity.
- X'032D' is message number 813.
- X'59' are hexadecimal flags for case, severity, and control.
- X'C3C5C5' is the CEE facility ID.
- X'00000000 00000000' is the instance specific information (ISI). (In this case, no ISI was provided.)

If a Language Environment traceback or dump is generated while a condition token is being processed or when a condition exists, Language Environment writes the run-time message to the condition section of the traceback or dump. If a condition is detected when a Language Environment API is invoked without a feedback code, the condition token is passed to the Language Environment condition manager. If a condition is severity 0 or 1, Language Environment resumes without issuing a message. For conditions of severity 2 or greater, Language Environment issues a message and terminates. For a list of Language Environment run-time messages and corrective information, see *z/OS Language Environment Run-Time Messages*.

If a second condition is raised while Language Environment is attempting to handle a condition, the message `CEE0374C CONDITION = <message no.>` is displayed using a write-to-operator (WTO). The message number in the CEE0374C message indicates the original condition that was being handled when the second condition was raised. This can happen when a critical error is signaled (for example, when internal control blocks are damaged).

If the output for this error message appears several times in sequence, the conditions appear in order of occurrence. Correcting the earliest condition can cause your application to run successfully.

Using the symbolic feedback code

The symbolic feedback code represents the first 8 bytes of a 16-byte condition token. You can think of the symbolic feedback code as the nickname for a condition. As such, the symbolic feedback code can be used in user-written exception handlers to screen for a given condition, even if it occurs at different locations in an application.

For more details on symbolic feedback codes, see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode*.

Chapter 11. Classifying AMODE 64 application errors

This chapter describes errors that commonly occur in Language Environment AMODE 64 applications. It also explains how to use run-time messages and abend codes to obtain information about errors in your application.

Identifying problems in routines

The following sections describe how you can identify errors in Language Environment routines. Included are common error symptoms and solutions.

Language Environment module names

You can identify Language Environment-supplied module elements by any of the following three-character prefixes:

- CEE (Language Environment)
- CEL (Language Environment)
- EDC (C/C++)

Module elements or text files with other prefixes are not part of the Language Environment product for AMODE 64 applications.

Common errors in routines

These common errors have simple solutions:

- If you receive abend U4093, reason X'224' (548 decimal), then make sure you use MEMLIMIT to allow access to above the 2 GB bar. For more information, see *z/OS MVS Programming: Extended Addressability Guide*.
- If you do not have enough virtual storage, increase your region size or decrease your storage usage (stack size) by using the storage-related run-time options and callable services. (See “Controlling storage allocation” on page 331 for information about using storage in routines.)
- If you do not have enough disk space, increase your disk allocation.
- If executable files are not available, check your executable library to ensure that they are defined. For example, check your STEPLIB or JOBLIB definitions.

If your error is not caused by any of the items listed above, examine your routine or routines for changes since the last successful run. If there have been changes, review these changes for errors that might be causing the problem. One way to isolate the problem is to branch around or comment out recent changes and rerun the routine. If the run is successful, the error can be narrowed to the scope of the changes.

Changes in optimization levels, addressing modes, and input/output file formats can also cause unanticipated problems in your routine.

In most cases, generated condition tokens or run-time messages point to the nature of the error. The run-time messages offer the most efficient corrective action. To help you analyze errors and determine the most useful method to fix the problem, Table 26 on page 340 lists common error symptoms, possible causes, and programmer responses.

Table 26. Common error symptoms, possible causes, and programmer responses

Error Symptom	Possible Cause	Programmer Response
Numbered run-time message appears	Condition raised in routine	For any messages you receive, read the Programmer Response. For information about message structure, see "Interpreting run-time messages" below.
User abend code < 4000	a) A non-Language Environment abend occurred b) The assembler user exit requested an abend for an unhandled condition of severity ≥2	See the Language Environment abend codes in *z/OS Language Environment Run-Time Messages*. Check for a subsystem-generated abend or a user-specified abend.
User abend code ≥ 4000	a) Language Environment detected an error and could not proceed b) An unhandled software-raised condition occurred c) The assembler user exit requested an abend for an unhandled condition of severity 4	For any abends you receive, read the appropriate explanation listed in the abend codes section of *z/OS Language Environment Run-Time Messages*.
System abend with TRAP(OFF)	Cause depends on type of malfunction	Respond appropriately. Refer to the messages and codes book of the operating system.
System abend with TRAP(ON)	System-detected error	Refer to the messages and codes book of the operating system.
No response (wait/loop)	Application logic failure	Check routine logic.
Unexpected message (message received was not from most recent service)	Condition caused by something related to current service	Generate a traceback using `cdump()` or `ctrace()`.
Incorrect output	Incorrect file definitions, storage overlay, incorrect routine mask setting, references to uninitialized variables, data input errors, or application routine logic error	Correct the appropriate parameters.
No output	Incorrect ddname or file definitions	Correct the appropriate parameters.
Nonzero return code from enclave	The return code was issued by the application routine	Check the application for the meaning of the return code.

Interpreting run-time messages

The first step in debugging your routine is to look up any run-time messages. Run-time messages are written to the C stderr stream.

Run-time messages provide users with additional information about a condition, and possible solutions for any errors that occurred. They can be issued by Language Environment common routines or language-specific run-time routines and contain a message prefix, message number, severity code, and descriptive text.

In the following example Language Environment message:

```
CEE3206S The system detected a specification exception (System Completion Code=0C6).
```

- The message prefix is CEE.
- The message number is 3206.
- The severity code is S.

- The message text is “The system detected a specification exception (System Completion Code=0C6)”.

Language Environment messages can appear even though you made no explicit calls to Language Environment services. C/C++ run-time library routines commonly use the Language Environment services. This is why you can see Language Environment messages even when the application routine does not directly call common run-time services.

Message prefix

The message prefix indicates the Language Environment component that generated the message. The message prefix is the first three characters of the message number and is also the facility ID in the condition token. See the following table for more information about Language Environment run-time messages.

Message Prefix	Language Environment Component
CEE	Common run time
EDC	C/C++ run time

The messages for the various components can be found in *z/OS Language Environment Run-Time Messages*.

Message number

The message number is the 4-digit number following the message prefix. Leading zeros are inserted if the message number is less than four digits. It identifies the condition raised and references additional condition and programmer response information.

Severity code

The severity code is the letter following the message number and indicates the level of attention called for by the condition. Messages with severity “I” are informational messages and do not usually require any corrective action. In general, if more than one run-time message appears, the first noninformational message indicates the problem. For a complete list of severity codes, severity values, condition information, and default actions, see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode*.

Message text

The message text provides a brief explanation of the condition.

Understanding abend codes

Under Language Environment, abnormal terminations generate abend codes. There are two types of abend codes: 1) user abends (Language Environment and user-specified) and 2) system abends. User abends follow the format of U*dddd*, where *dddd* is a decimal user abend code. System abends follow the format of S*hhh*, where *hhh* is a hexadecimal abend code. Language Environment abend codes are usually in the range of 4000 to 4095. However, some subsystem abend codes can also fall in this range. User-specified abends use the range of 0 to 3999.

Example abend codes are:

```
User (Language Environment) abend code:U4041
User-specified abend code:U0005
System abend code:S80A
```

The Language Environment API __cabend() terminates your application with an abend. You can set the clean_up parameter value to determine how the abend is processed and how Language Environment handles the raised condition. For more information about __cabend() and clean_up, see *z/OS XL C/C++ Run-Time Library Reference*.

User abends

If you receive a Language Environment abend code, see *z/OS Language Environment Run-Time Messages* for a list of abend codes, error descriptions, and programmer responses.

System abends

If you receive a system abend code, look up the code and the corresponding information in the publications for the system you are using.

When a system abend occurs, the operating system can generate a system dump. System dumps are written to ddname SYSMDUMP, SYSABEND, or SYSUDUMP. If the DYNDUMP run-time option is used, the system dump can be written without the ddname specified. System dumps show the memory state at the time of the condition. See “Generating a system dump” on page 362 for more information about system dumps.

Chapter 12. Using Language Environment AMODE 64 debugging facilities

This chapter describes methods of debugging AMODE 64 routines in Language Environment. Currently, most problems in Language Environment and member language routines can be determined through the use of a debugging tool or through information provided in the Language Environment dump.

Debugging tools

You can use **dbx** to debug Language Environment applications. *z/OS UNIX System Services Command Reference* has information on **dbx** subcommands, while *z/OS UNIX System Services Programming Tools* contains usage information.

Language Environment dumps

The following sections provide information about using the Language Environment dump service, and describe the contents of the Language Environment dump.

Generating a Language Environment dump with TERMTHDACT

The TERMTHDACT run-time option produces a dump during program checks or abnormal terminations. You must use TERMTHDACT(DUMP) in conjunction with TRAP(ON) to generate a Language Environment dump.

You can use TERMTHDACT to produce a traceback, Language Environment dump, or user address space dump when a thread ends abnormally because of an unhandled condition of severity 2 or greater. If this is the last thread in the process, the enclave goes away. A thread terminating in a non-POSIX environment is analogous to an enclave terminating. For information on enclave termination, see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode* .

The TERMTHDACT suboptions QUIET, MSG, TRACE, DUMP, UAONLY, UATRACE, UADUMP, and UAIMM control the level of information available. Following are the suboptions, the levels of information produced, and the destination of each.

Table 27. TERMTHDACT suboptions, level of information, and destinations

Suboption	Level of Information	Destination
QUIET	No information	No destination.
MSG	Message	Stderr
TRACE	Message and Language Environment dump containing only a traceback	Message goes to stderr. Traceback goes to CEEDUMP file.
DUMP	Message and complete Language Environment dump	Message goes to stderr. Language Environment dump goes to CEEDUMP file.

Table 27. TERMTHDACT suboptions, level of information, and destinations (continued)

Suboption	Level of Information	Destination
UAONLY	SYSMDUMP, SYSABEND dump, or SYSUDUMP depending on the DD card used in the JCL in z/OS. You will get a system dump of your user address space if the appropriate DD statement is used. **Note:** A Language Environment dump is not generated.	Language Environment generates a U4039 abend which allows a system dump of the user address space to be generated. For z/OS, the system dump is written to the ddname specified.
UATRACE	Message, Language Environment dump containing only a traceback, and a system dump of the user address space	Message goes to stderr. Traceback goes to CEEDUMP file. Language Environment generates a U4039 abend which allows a system dump of the user address space to be generated. For z/OS, the system dump is written to the ddname specified.
UADUMP	Message, Language Environment dump, and SYSMDUMP, SYSABEND dump, or SYSUDUMP depending on the DD card used in the JCL in z/OS.	Message goes to stderr. Language Environment dump goes to CEEDUMP file. Language Environment generates a U4039 abend which allows a system dump of the user address space to be generated. For z/OS, the system dump is written to the ddname specified.
UAIMM	Language Environment generates a system dump of the original abend/program interrupt of the user address space. You will get a system dump of your user address space if the appropriate DD statement is used. After the dump is taken by the operating system, Language Environment condition manager continues processing.	Message goes to stderr. User address space dump goes to ddname specified for z/OS.

The TRACE and UATRACE suboptions of TERMTHDACT use these dump options:

- CONDITION
- ENCLAVE(ALL)
- FILES
- FNAME(CEEDUMP)
- GENOPTS
- NOBLOCKS
- NOENTRY
- NOSTORAGE
- STACKFRAME(ALL)
- THREAD(ALL)
- TRACEBACK
- VARIABLES

The DUMP and UADUMP suboptions of TERMTHDACT use these dump options:

- BLOCKS
- CONDITION
- ENCLAVE(ALL)
- FILES

- FNAME(CEEDUMP)
- GENOPTS
- NOENTRY
- STACKFRAME(ALL)
- STORAGE
- THREAD(CURRENT)
- TRACEBACK
- VARIABLES

Considerations for setting TERMTHDACT options

- **z/OS UNIX Considerations**
  - The TERMTHDACT option applies when a thread terminates abnormally. Abnormal termination of a single thread causes termination of the entire enclave. If an unhandled condition of severity 2 or higher percolates beyond the first routine's stack frame, the enclave terminates abnormally.
  - If an enclave terminates due to a POSIX default signal action, then TERMTHDACT applies to conditions that result from software signals, program checks, or abends.
  - If running under a shell and Language Environment generates a system dump, then a core dump is generated to a file based on the kernel environment variable, _BPXK_MDUMP.
- **Preinitialized Environments for Authorized Programs Considerations**
  - The TERMTHDACT suboptions TRACE, DUMP, UADUMP, UATRACE are overridden to UAONLY.
  - For UAONLY, a U4039 abend is generated and an SVC dump of the U4039 abend with the title:

    ```
    COMPON=CEL,COMPID=568819801,ISSUER=CELAFRR ,MODULE=CELAEICT+????,
    ABEND=U4039,REASON=00000000
    ```

    is taken.
  - For UAIMM, an SVC dump of the original abend/program interrupt with a title like:

    ```
    COMPON=CEL,COMPID=568819801,ISSUER=CELAFRR ,MODULE=CELAEICT+????,
    ABEND=S00C9,REASON=00000009
    ```

    (where the ABEND and REASON values are those of the original abend/program interrupt) is taken.

For more information about the TERMTHDACT run-time option, see *z/OS Language Environment Programming Reference*.

Generating a Language Environment dump with language-specific functions

C/C++ routines can use the functions `cdump()`, `csnap()`, and `ctrace()` to produce a Language Environment dump. For more information on these functions, see "Generating a Language Environment dump of a C/C++ routine" on page 438.

Understanding the Language Environment dump

The Language Environment dump service generates output of data and storage from the Language Environment run-time environment on an enclave basis. This output contains the information needed to debug most basic routine errors.

Figure 142 on page 349 illustrates a dump for enclave main. The example shows full use of the TERMTHDACT dump options. Ellipses are used to summarize some

sections of the dump and information regarding unhandled conditions may not be present at all. Sections of the dump are numbered to correspond with the descriptions given in “Sections of the Language Environment dump” on page 357.

The CEE3DMP was generated by the C program CELQSAMP shown in Figure 140 on page 347. CELQSAMP uses the DLL CELQDLL shown in Figure 141 on page 349.

```
#pragma options(SERVICE("1.8"),NOOPT,GONUM)
#pragma runopts(TERMTHDACT(UADUMP),POSIX(ON))
#pragma runopts(TRACE(ON,1M,NODUMP,LE=1),HEAPCHK(ON))
#pragma runopts(RPTSTG(ON))
#define _OPEN_THREADS
#include <pthread.h>
#include <stdio.h>
#include <stdlib.h>
#include <dll.h>

typedef void* FUNC(void *);

[14]CEE3846I CEEDUMP Processing completed.
```

Figure 142. Example dump using CEE3DMP (Part 9 of 9)

Sections of the Language Environment dump

The sections of the dump listed here appear independently of the Language Environment-conforming languages used.

[1] Page Heading

The page heading section appears on the top of each page of the dump and contains:

- CEE3DMP identifier
- Title

  For dumps generated as a result of an unhandled condition, the title is “Condition processing resulted in the Unhandled condition.”

- Product abbreviation of Language Environment
- Version number
- Release number
- Date
- Time
- Page number

For CEEDUMPs produced under a batch environment, the following items are displayed:

- ASID

  Describes the address space ID.
- Job ID

  Describes the JES Job ID.
- Job name

  Describes the job name.
- Step name:

  Describes the job's step name in which the CEEDUMP was produced.
- UserID:

  Describes the TSO userid who issued the job.

For jobs running with POSIX(ON), the following additional items are displayed:

- PID

  Displays the associated process ID.
- Parent PID

  Displays the associated parent PID.

For CEEDUMPs produced under the z/OS UNIX shell, the following items are displayed:

- ASID

  Describes the address space ID.
- PID

  Displays the associated process ID.
- Parent PID

  Displays the associated parent PID.
- User name

  Contains the userid associated to the CEEDUMP.

[2] CEE3845I CEEDUMP Processing started.

Message CEE3845I identifies the start of the Language Environment dump processing. Similarly, message CEE3846I identifies the end of the dump processing, Message number CEE3845I can be used to locate the start of the next CEEDUMP report when scanning forward in a data set that contains several CEEDUMP reports.

[3] Enclave Information

These sections show information that is specific to an enclave.

[3] Enclave Identifier

This statement names the enclave for which information in the dump is provided.

[4] - [10] Thread Information

These sections show information that is specific to a thread. When multiple threads are dumped, these sections will appear for each thread.

[4] Information for thread

This section shows the system identifier for the thread. Each thread has a unique identifier.

[5] Traceback

For all active routines in a particular thread, the traceback section shows routine information in three parts. The first part contains:

- DSA number

  A number assigned to the information for this active routine by dump processing. The number is used to associate information from the first part of the traceback with information in the second and third parts of the traceback.
- Entry

  For C/C++ routines, this is the function name. If a function name or entry point was not specified for a particular routine, then the string '** NoName **' will appear.
- Entry point offset
- Statement number

  Refers to the line number in the source code (program unit) in which a call was made or an exception took place. The statement number appears only if your routine was compiled with the options required to generate statement numbers. These options are described under "XL C and XL C++ compiler options for AMODE 64 applications" on page 329.
- Load module

  The load module name displayed can be a partitioned data set member or an UNIX executable file. The load module name is also displayed in the third part of the traceback (see below for details).
- Program unit

  The primary entry point of the external procedure. For C routines, this is the compile unit name. For Language Environment-conforming assemblers, this is the ENTNAME = value on the CELQPRLG macro.

  If your routine was compiled with the compile options to generate statement numbers then the program unit name displayed under this column will appear as follows:

  – If your compiled routine is in a partitioned data set then only the member will be output.
  – If your compiled routine is in a sequential data set then only the last qualifier will be shown.
  – If your compiled routine is in an UNIX filename then only what fits of the filename will be displayed in a line.

  Look for the complete name of the program unit in the Fully Qualified Names section of the traceback, if your routine was compiled using compile options to generate statement numbers.
- Service level

The latest service level applied to the compile unit (for example, for IBM products, it would be the PTF number).

- Status

  Routine status can be call or exception.

The second part contains:

- DSA number

  A number assigned to the information for this active routine by dump processing. The number is used to associate information from the first part of the traceback with information in the second and third parts of the traceback.
- Stack frame (DSA) address
- Entry point address
- Program unit address
- Program unit offset

  The offset of the last instruction to run in the routine. If the offset is a negative number, zero, or a very large positive number, the routine associated with the offset probably did not allocate a save area or the routine could have been called using SVC-assisted linkage. Adding the program unit address to the offset gives you the location of the current instruction in the routine. This offset is from the starting address of the routine.
- Compile Date
- Attributes

  The attributes of the compile unit including whether character data is being treated as EBCDIC or ASCII and whether floating point data is being treated as IEEE or hexadecimal.

The third part, which is also referred to as 'Fully Qualified Names' section, contains the following:

- DSA number
- Entry
- Program unit

  Similar to the Program Unit column in part 1 except that the server name and the complete program unit (PU) name will be displayed. A PU name will appear here only if it was compiled using compile options to produce statement numbers.
- Load Module

  The complete pathname of a load module name residing in an UNIX filename will be displayed here if available. The load module's full pathname will be displayed if the PATH environment variable is set such that the pathname of the load module's directory appears before the current directory (.). For load modules found in data sets, the same output shown in the traceback part 1 will also be displayed here.

[6] Condition Information for Active Routines

This section displays the following information for all conditions currently active on the call chain:

- Statement showing failing routine and stack frame address of routine
- Condition information block (CIB) address
- Current condition, in the form of a Language Environment message for the condition raised or a Language Environment abend code, if the condition was caused by an abend

- Location

  For the failing routine, this is the program unit, entry routine, statement number, and offset.
- Machine state, which shows:
  - Instruction length counter (ILC)
  - Interruption code
  - *Program status word (PSW)*
  - Contents of GPRs 0–15. Contents of floating point content register (FPC) and floating point registers FPR 0-15.
  - Storage dump near condition (2 hex-bytes of storage near the PSW)
  - Storage pointed to by General Purpose Registers

  These values are the current values at the time the condition was raised.

[7] Parameters, Registers, and Variables for Active Routines

For each active routine, this section shows:

- Routine name and stack frame address
- Saved registers

  This lists the contents of GPRs 0–15 at the time the routine received control. The saved registers are those saved by the DSA-owning routine on entry. Register 7 is the return address back to the caller of the DSA-owning routine. Register 6 may be the entry point of the DSA-owning routine. (This is not true when the Branch Relative and Save instruction is used to implement the call. The non-volatile floating-point registers that are saved in the stack frame. The registers are only displayed if the program owning the stack frame saved them. Dashes are displayed in the registers when the register values are not saved.
- Storage pointed to by the saved registers

  Treating the saved contents of each register as an address, 32 bytes before and 64 bytes after the address shown.

[8] Control Blocks for Active Routines

For each active routine controlled by the STACKFRAME option, this section lists contents of related control blocks. The Language Environment-conforming language determines which language-specific control blocks appear. The possible control blocks are:

- Stack frame
- Condition information block
- Language-specific control blocks

[9] Storage for Active Routines

This displays local storage for each active routine. The storage is dumped in hexadecimal, with EBCDIC translations on the right side of the page. There can be other information, depending on the language used. For C/C++ routines, this is the stack frame storage.

[10] Control Blocks Associated with the Thread

This section lists the contents of the Language Environment common anchor area (CAA), thread synchronization queue element (SQEL) and dummy stack frame. Other language-specific control blocks can appear in this section.

[11] Enclave Control Blocks

This section lists the contents of the Language Environment enclave data block (EDB) and enclave member list (MEML). The information presented may vary depending on which run-time options are set.

- If the POSIX run-time option is set to ON, this section lists the contents of the mutex and condition variable control blocks, the enclave level latch table, and the thread synchronization trace block and trace table.
- If DLLs have been loaded, this section shows information for each DLL including the DLL name, load address, use count, writeable static area (WSA) address, and the thread id of the thread that loaded the DLL.
- If the HEAPCHK run-time option is set to ON, this section shows the contents of the HEAPCHK options control block (HCOP) and the HEAPCHK element tables (HCEL). A HEAPCHK element table contains the location and length of all allocated storage elements for a heap in the order that they were allocated.
- When the *call-level* suboption of the HEAPHCK run-time option is set, any unfreed storage, which would indicate a storage leak, would be displayed in this area. The traceback could then be used to identify the program which did not free the storage.
- If the TRACE run-time option is set to ON, this section shows the contents of the Language Environment trace table.

Other language-specific control blocks can appear in this section.

[12] Run-Time Options Report

This section lists the Language Environment run-time options in effect when the routine was executed.

[13] Process Control Blocks

This section lists the contents for the Language Environment process control block (PCB), process member list (MEML), and if the POSIX run-time option is set to ON, the process level latch table. Other language-specific control blocks can appear in this section.

[14] CEE3846I CEEDUMP Processing completed.

Message CEE3846I identifies the end of the Language Environment dump processing. Similarly, message CEE3845I identifies the start of the dump processing, Message number CEE3846I can be used to locate the end of the previous CEEDUMP report when scanning backward in a data set that contains several CEEDUMP reports.

Generating a system dump

A system dump contains the storage information needed to diagnose errors. You can use Language Environment to generate a system dump through any of the following methods:

DYNDUMP(*hlq*,DYNAMIC,TDUMP)
: You can use the DYNDUMP run-time option to obtain IPCS readable dumps of user applications that would ordinarily be lost due to the absence of a SYSMDUMP, SYSUDUMP, or SYSABEND DD statement.

TERMTHDACT(UAONLY, UATRACE, or UADUMP)
You can use these run-time options, with TRAP(ON), to generate a system dump if an unhandled condition of severity 2 or greater occurs. For further details regarding the level of dump information produced by each of the TERMTHDACT suboptions, see “Generating a Language Environment dump with TERMTHDACT” on page 343.

TRAP(ON,NOSPIE) TERMTHDACT(UAIMM)
TRAP(ON,NOSPIE) TERMTHDACT(UAIMM) generates a system dump of the user address space of the original abend or program interrupt prior to the Language Environment condition manager processing the condition.

Abend Codes in Initialization Assembler User Exit
Abend codes listed in the initialization assembler user exit are passed to the operating system. The operating system can then generate a system dump.

__cabend()
You can use the `__cabend()` API to cause the operating system to handle an abend.

Refer to system or subsystem documentation for detailed system dump information.

The method for generating a system dump varies for each of the Language Environment run-time environments. The following sections describe the recommended steps needed to generate a system dump in batch and z/OS UNIX shell run-time environments. Other methods may exist, but these are the recommended steps for generating a system dump.

For details on setting Language Environment run-time options, see *z/OS Language Environment Programming Guide*.

Steps for generating a system dump in a batch run-time environment

Perform the following steps to generate a system dump in a batch run-time environment:

1. Specify run-time options TERMTHDACT(UAONLY, UADUMP, UATRACE, or UAIMM), and TRAP(ON). If you specify the suboption UAIMM then you must set TRAP(ON,NOSPIE). The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details on the TERMTHDACT suboptions, see “Generating a Language Environment dump with TERMTHDACT” on page 343.
2. Decide whether to include a SYSMDUMP DD card or use the DYNDUMP run-time option.
   - Include a SYSMDUMP DD card with the desired data set name and DCB information:

     `LRECL=4160, BLKSIZE=4160, and RECFM=FBS.`
   - Specify the DYNDUMP run-time option with the following information:

     `DYNDUMP (hlq,DYNAMIC,TDUMP)`
3. Rerun the program.

When you are done, you have a generated system dump in a batch run-time environment.

Steps for generating a system dump in a z/OS UNIX shell

Perform the following steps to generate a system dump from a z/OS UNIX shell:

- Using _BPXK_MDUMP
  1. Specify where to write the system dump
     - To write the system dump to a z/OS data set, issue the command:

       ```
       export _BPXK_MDUMP=filename
       ```

       where *filename* is a fully qualified data set name with DCB information: LRECL=4160, BLKSIZE=4160, and RECFM=FBS.

       Example:

       ```
       export _BPXK_MDUMP=hlq.mydump
       ```
     - To write the system dump to an HFS file, issue the command:

       ```
       export _BPXK_MDUMP=filename
       ```

       where *filename* is a fully qualified HFS filename.

       Example:

       ```
       export _BPXK_MDUMP=/tmp/mydump.dmp
       ```
  2. Specify Language Environment run-time options:

     ```
     export _CEE_RUNOPTS="termthdact(suboption)"
     ```

     where *suboption* = UAONLY, UADUMP, UATRACE, or UAIMM. If UAIMM is set, TRAP(ON,NOSPIE) must also be set. The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details regarding the TERMTHDACT suboptions, see “Generating a Language Environment dump with TERMTHDACT” on page 343.
  3. Rerun the program.

  When you are done, the system dump is written to the data set name or HFS file name specified.

  For additional BPXK_MDUMP information see *z/OS UNIX System Services Command Reference*.
- Using DYNDUMP
  1. Specify Language Environment run-time options:

     ```
     export _CEE_RUNOPTS="termthdact(suboption),DYNDUMP(hlq,DYNAMIC,TDUMP)"
     ```

     where:
     - *suboption* = UAONLY, UADUMP, UATRACE, or UAIMM. If UAIMM is set, TRAP(ON,NOSPIE) must also be set. The TERMTHDACT suboption determines the level of detail of the Language Environment formatted dump. For further details regarding the TERMTHDACT suboptions, see “Generating a Language Environment dump with TERMTHDACT” on page 343.
     - *hlq* is the high level qualifier for the dump data set to be created.
  2. Rerun the program.

  When you are done, the system dump is written to the name generated by the DYNDUMP run-time option.

  For additional DYNDUMP information see *z/OS Language Environment Programming Reference*.

Note: You can also specify the signal SIGDUMP on the kill command to generate a system dump of the user address space. For more information regarding the SIGDUMP signal, see *z/OS UNIX System Services Command Reference*.

Formatting and analyzing system dumps

You can use the Interactive Problem Control System (IPCS) to format and analyze system dumps. Language Environment provides an IPCS Verbexit LEDATA that can be used to format Language Environment control blocks.

For more information on using IPCS, refer to *z/OS MVS IPCS User's Guide*.

Preparing to use the Language Environment support for IPCS

Guidelines: Use the following guidelines before you use IPCS to format Language Environment control blocks:

- Ensure that your IPCS job can find the CEEIPCSP member.

  IPCS provides an exit control table with imbed statements to enable other products to supply exit control information. The IPCS default table, BLSCECT, normally in the SYS1.PARMLIB library, has the following entry for Language Environment:

  ```
  IMBED MEMBER(CEEIPCSP) ENVIRONMENT(IPCS)
  ```

  The Language Environment-supplied CEEIPCSP member, installed in the SYS1.PARMLIB library, contains the Language Environment-specific entries for the IPCS exit control table.
- Provide an IPCSPARM DD statement to specify the libraries containing the IPCS control tables.

  Example:

  ```
  //IPCSPARM  DD  DSN=SYS1.PARMLIB,DISP=SHR
  ```
- Ensure that your IPCS job can find the Language Environment-supplied ANALYZE exit routines installed in the SYS1.MIGLIB library.
- To aid in debugging system or address space hang situations, Language Environment mutexes, latches and condition variables can be displayed if the CEEIPSCP member you are using is updated to identify the Language Environment ANALYZE exit, by including the following statement:

  ```
  EXIT EP(CEEEANLZ) ANALYZE
  ```

Language Environment IPCS Verbexit – LEDATA

Use the LEDATA Verbexit to format data for Language Environment. This Verbexit provides information about the following topics:

- A summary of Language Environment at the time of the dump
- Run-time Options
- Storage Management Control Blocks
- Condition Management Control Blocks
- Message Handler Control Blocks
- C/C++ Control Blocks

Format

Syntax

VERBEXIT LEDATA ['parameter[,parameter]...']

- Report Type Parameters:
  - [**AUTH**]
  - [**NTHREADS**(*value*)]
  - [**SUM**]
  - [**HEAP** | **STACK** | **SM**]
  - [**HPT**(*value*)]
  - [**CM**]
  - [**MH**]
  - [**CEEDUMP**]
  - [**PTBL(value)**]
  - [**ALL**]
- Data Selection Parameters:
  - [**DETAIL** | **EXCEPTION**]
- Control Block Selection Parameters:
  - [**CAA**(*caa-address*)]
  - [**DSA**(*dsa-address*)]
  - [**TCB**(*tcb-address*)]
  - [**ASID**(*address-space-id*)]
  - [**LAA**(*laa-address*)]

Parameters

Report type parameters

Use these parameters to select the type of report. If you omit these parameters, the default is SUMMARY.

Address space report types: Use these parameters to select a report that shows the Language Environment activity for an address space. Only one of these reports may be specified.

NTHREADS(value)
Requests a report that shows the traceback for the TCBs in the address space. *value* is the number of TCBs for which the traceback will be displayed. If *value* is specified as asterisk (*), all TCBs will be displayed. The LAA, CAA, or TCB parameter can be used to limit the display to only TCBs that are part of the same enclave.

AUTH
Requests a report on all Preinitialized Environments for Authorized Programs control blocks for the address space. NTHREADS is ignored when AUTH is specified.

PTBL(value)
Requests that PreInit tables be formatted according to the following values:,

CURRENT
If current is specified, the PreInit table associated with the current or specified TCB is displayed.

address
If an address is specified, the PreInit table at that address is specified.

* All active and dormant PreInit tables within the current address space are displayed; this option is time-consuming.

ACTIVE
The PreInit tables for all TCBs in the address space are displayed.

Thread specific report types: Use these parameters to select reports that show Language Environment activity for a specific TCB. These report types are ignored if AUTH or NTHREADS is specified. You can specify as many of these reports as you wish.

SUMmary
Requests a summary of the Language Environment at the time of the dump. The following information is included:
- TCB address
- Address Space Identifier
- Language Environment Release
- Active members
- Formatted CAA, PCB, RCB, EDB, LAA and LCA
- Run-time Options in effect

HEAP | STACK | SM

HEAP
Requests a report on Storage Management control blocks pertaining to HEAP storage, as well as a detailed report on heap segments. The detailed report includes information about the free storage tree in the heap segment, and information about each allocated storage element.

Note: Language Environment does not provide support for alternative Vendor Heap Manager (VHM) data.

STACK
Requests a report on Storage Management control blocks pertaining to STACK storage.

SM
Requests a report on Storage Management control blocks. This is the same as specifying both HEAP and STACK.

HPT(value)
Requests that the heappools trace (if available) be formatted. If the value is 0 or *, the trace for every heappools poolid is formatted. If the value is a single number (1-12) the trace for the specific heappools poolid is formatted.

CM
Requests a report on Condition Management control blocks.

MH
Requests a report on Message Handler control blocks.

CEEdump
Requests a CEEDUMP-like report. Currently this includes the traceback, the Language Environment trace, and thread synchronization control blocks at process, enclave and thread levels.

ALL
Requests all above reports, as well as C/C++ reports.

Data selection parameters

Data selection parameters limit the scope of the data in the report. If no data selection parameter is selected, the default is DETAIL.

DETail
Requests formatting all control blocks for the selected components. Only significant fields in each control block are formatted.

Note: For the Heap and Storage Management Reports, the DETAIL parameter will provide a detailed heap segment report for each heap segment in the dump. The detailed heap segment report includes information on the free storage tree in the heap segments, and all allocated storage elements. This report will also identify problems detected in the heap management data structures. For more information about the Heap Reports, see "Understanding the HEAP LEDATA output" on page 384.

EXCeption
Requests validating all control blocks for the selected components. Output is only produced naming the control block and its address for the first control block in a chain that is invalid. Validation consists of control block header verification at the very least.

Note: For the Summary, CEEDUMP, C/C++ reports, the EXCEPTION parameter has not been implemented. For these reports, DETAIL output is always produced.

Control block selection parameters
Use these parameters to select the control blocks used as the starting points for formatting.

CAA(caa-address)
specifies the address of the CAA. If not specified, the CAA address is obtained from the LAA.

DSA(dsa-address)
specifies the address of the DSA. If not specified, the DSA address may be obtained from the TCB or the IPCS symbol REGGEN.

TCB(tcb-address)
specifies the address of the TCB. If not specified, the TCB address may be obtained from the CAA or the CVT.

LAA(laa-address)
specifies the address of the LAA. If not specified, the LAA address may be obtained from the TCB or the PSA.

ASID(address-space-id)
specifies the hexadecimal address space id. If not specified, the IPCS default address space id is used. This parameter is not needed when the dump only has one address space.

Understanding the Language Environment IPCS Verbexit LEDATA output

The Language Environment IPCS Verbexit LEDATA generates formatted output of the Language Environment run-time environment control blocks from a system dump. Figure 143 on page 369 illustrates the output produced when the LEDATA Verbexit is invoked with the ALL parameter. The system dump being formatted was obtained by specifying the TERMTHDACT(UADUMP) run-time option when running the program CELQSAMP in Figure 140 on page 347. "Sections of the Language Environment LEDATA Verbexit formatted output" on page 378 describes the information contained in the formatted output. Ellipses are used to summarize some sections of the dump.

For easy reference, the sections of the following dump are numbered to correspond with the descriptions in “Sections of the Language Environment LEDATA Verbexit formatted output” on page 378.

```

     Summary of analysis for Heap Segment 0000000108300000:
        Amounts of identified storage:  Free:00030F40          Allocated:000CF080          Total:000FFFC0
        Number of identified areas   :  Free:       1  Allocated:      12  Total:      13
        00000000 bytes of storage were not accounted for.
        No errors were found while processing this heap segment.

    Exiting Language Environment Data
```

Figure 143. Example of formatted output from LEDATA Verbexit (Part 10 of 10)

Sections of the Language Environment LEDATA Verbexit formatted output

The sections of the output listed here appear independently of the Language Environment-conforming languages used.

[1] - [8]CEEDUMP Formatted Control Blocks

These sections are included when the CEEDUMP parameter is specified on the LEDATA invocation.

[1] - [4] NTHREADS data

These sections are also includes, once for each thread, when the NTHREADS() parameter is specified on the LEDATA invocations. For a description of NTHREADS, see “Report type parameters” on page 366.

[1] Enclave Identifier

This statement names the enclave for which information is provided.

[2] Information for thread

This section shows the system identifier for the thread. Each thread has a unique identifier.

[3] Registers and PSW

This section displays the register and program status word (PSW) values that were used to create the traceback. These values may come from the TCB, the RTM2 work area, a linkage stack entry or output from the BPXGMSTA service. This section is not displayed when the DSA() parameter is specified on the LEDATA invocation.

[4] Traceback

For all active routines in a particular thread. The traceback section shows routine information in two parts. The first part contains:

- DSA number

  A number assigned to the information for this active routine by LEDATA. The number is only used to associate information from the first part of the traceback with information in the second part of the traceback.
- Entry

  For C/C++ routines, this is the function name. If a function name or entry point was not specified for a particular routine, then the string *** NoName ***** will appear.
- Entry point offset
- Load module
- Program unit

  The primary entry point of the external procedure. For C routines, this is the compile unit name. For Language Environment-conforming assemblers, this is the ENTNAME = value on the CELQPRLG macro.
- Service level

  The latest service level applied to the compile unit (for example, for IBM products, it would be the PTF number.
- Status

  Routine status can be call, exception, or running.

The second part contains:

- DSA number

  A number assigned to the information for this active routine by LEDATA. The number is only used to associate information from the first part of the traceback with information in the second part of the traceback.

- Stack frame (DSA) address
- Entry point address
- Program unit address
- Program unit offset

  The offset of the last instruction to run in the routine. If the offset is a negative number, zero, or a very large positive number, the routine associated with the offset probably did not allocate a save area, or the routine could have been called using SVC-assisted linkage. Adding the program unit address to the offset gives you the location of the current instruction in the routine. This offset is from the starting address of the routine.

[5] Control Blocks Associated with the Thread

This section lists the contents of the thread synchronization queue element (SQEL).

[6] Enclave Control Blocks

If the POSIX run-time option was set to ON, this section lists the contents of the mutex and condition variable control blocks, the enclave level latch table, and the thread synchronization trace block and trace table. If the HEAPCHK run-time option is set to ON, this section lists the contents of the HEAPCHK options control block (HCOP) and the HEAPCHK element tables (HCEL). A HEAPCHK element table contains the location and length of all allocated storage elements for a heap in the order that they were allocated.

[7] Language Environment Trace Table

If the TRACE run-time option was set to ON, this section shows the contents of the Language Environment trace table.

[8] Process Control Blocks

If the POSIX run-time option was set to ON, this section lists the contents of the process level latch table.

[9] - [17] Summary

These sections are included when the SUMMARY parameter is specified on the LEDATA invocation.

[9] Summary Header

The summary header section contains:
- Address of Thread control block (TCB)
- Release number
- Address Space ID (ASID)

[10] Active Members List

This list of active members is extracted from the enclave member list (MEML).

[11] CEELAA

This section formats the contents of the Language Environment library anchor area (LAA). See*z/OS Language Environment Vendor Interfaces* for a description of the fields in the LAA.

[12] CEELCA

This section formats the contents of the Language Environment library control area (LCA). See *z/OS Language Environment Vendor Interfaces* for a description of the fields in the LCA.

[13] CEECAA

This section formats the contents of the Language Environment common anchor area (CAA). See*z/OS Language Environment Vendor Interfaces* for a description of the fields in the CAA. If there is any, DLL failure data is also formatted.

[14] CEEPCB

This section formats the contents of the Language Environment process control block (PCB), and the process level member list.

[15] CEERCB

This section formats the contents of the Language Environment region control block (RCB).

[16] CEEEDB

This section formats the contents of the Language Environment enclave data block (EDB), and the enclave level member list.

[17] Run-Time Options

This section lists the run-time options in effect at the time of the dump, and indicates where they were set.

[18] Heap Storage Control Blocks

This section is included when the HEAP or SM parameter is specified on the LEDATA invocation.

This section formats the Enclave-level storage management control block (ENSQ) and for each different type of heap storage:

- Heap control block (HPCQ)
- Chain of heap anchor blocks (HANQ). A HANQ immediately precedes each segment of heap storage.

This section includes a detailed heap segment report for each segment in the dump. For more information about the detailed heap segment report, see “Understanding the HEAP LEDATA output” on page 384.

[19] Stack Storage Control Blocks

This section is included when the STACK or SM parameter is specified on the LEDATA invocation.

This section formats:

- Stack anchor (SANC)
- Chain of dynamic save areas (DSA)

[20] Condition Management Control Blocks

This section is included when the CM parameter is specified on the LEDATA invocation.

This section formats the chain of Condition Information Block Headers (CIBH) and Condition Information Blocks. The Machine State Information Block is contained with the CIBH starting with the field labeled MCH_EYE.

[21] Message Processing Control Blocks

This section is included when the MH parameter is specified on the LEDATA invocation.

[22] Preinitialization Information

This section is included when the PTBL parameter is specified on the LEDATA invocation.

This section formats information related to preinitialization. See section PTBL LEDATA output for more information. If the preinitialization service CELQPIPI was not used to initialize this environment, the message: `No PIPICB associated with CAA` is displayed instead.

PTBL LEDATA output

The Language Environment IPCS Verbexit LEDATA command generates formatted output of PreInit tables when the PTBL or ALL parameter are specified. If ALL is specified, PTBL defaults to CURRENT value. Figure 144 on page 383 illustrates the output produced when the Verbexit LEDATA command is invoked with the PTBL parameter.

```

| *Figure 144. Example of formatted PTBL output from LEDATA Verbexit (Part 2 of 2)*

Understanding the HEAP LEDATA output

The Language Environment IPCS Verbexit LEDATA generates a detailed heap segment report when the HEAP option is used with the DETAIL option, or when the SM,DETAIL option is specified. The detailed heap segment report is useful when trying to pinpoint damage because it provides very specific information. The report describes the nature of the damage, and specifies where the actual damage occurred. The report can also be used to diagnose storage leaks, and to identify heap fragmentation. Figure 145 on page 385 illustrates the output produced by specifying the HEAP option. “Heap report sections of the LEDATA output” on page 393 describes the information contained in the formatted output.

For easy reference, the sections of the dump are numbered to correspond with the description of each section that follows. Ellipses are used to summarize some sections of the dump.

Note: Language Environment does not provide support for alternative Vendor Heap Manager (VHM) data. LEDATA Verbexit will state that an alternative VHM is in use.

```

Figure 145. Example formatted detailed heap segment report from LEDATA Verbexit (Part 9 of 9)

Heap report sections of the LEDATA output

The Heap Report sections of the LEDATA output provide information for each heap segment in the dump. The detailed heap segment reports include information on the free storage tree in the heap segments, the allocated storage elements, and the cause of heap management data structure problems.

[1]Free Storage Tree Report

Within each heap segment, Language Environment keeps track of unallocated storage areas by chaining them together into a tree. Each free area represents a node in the tree. Each node contains a header, which points to its left and right child nodes. The header also contains the length of each child.

The LEDATA HEAP option formats the free storage tree within each heap, and validates all node addresses and lengths within each node. Each node address is validated to ensure that it:

- Falls on a doubleword boundary
- Falls within the current heap segment
- Does not point to itself
- Does not point to a node that was previously traversed

Each node length is validated to ensure that it:

- Is a multiple of 8
- Is not larger than the heap segment length
- Does not cause the end of the node to fall outside of the current heap segment
- Does not cause the node to overlap another node

If the formatter finds a problem, then it will place an error message describing the problem directly after the formatted line of the node that failed validation

[2]Heap Segment Map Report

The LEDATA HEAP option produces a report that lists all of the storage areas within each heap segment, and identifies the area as either allocated or freed. For each allocated area the contents of the first X'20' bytes of the area are displayed in order to help identify the reason for the storage allocation.

Each allocated storage element has a prefix used by Language Environment to manage the area. The prefix contains a pointer to the start of the heap segment followed by the length of the allocated storage element. For HEAP64 heaps, the prefix is 16 bytes, with 8-byte pointer and length fields. For HEAP31 and HEAP24 heaps, the pointer is 8 bytes with 4-byte pointer and length field. The formatter validates this header to ensure that its heap segment pointer is valid. The length is also validated to ensure that it:

- Is a multiple of 8
- Is not zero

- Is not larger than the heap segment length
- Does not cause the end of the element to fall outside of the current heap segment
- Does not cause the element to overlap a free storage node

If the heap_free_value of the STORAGE run-time option was specified, then the formatter also checks that the free storage within each free storage element is set to the requested heap_free_value. If a problem is found, then an error message describing the problem is placed after the formatted line of the storage element that failed validation.

Diagnosing heap damage problems

Heap storage errors can occur when an application allocates a heap storage element that is too small for it to use, and therefore, accidently overlays heap storage. If this situation occurs then some of the typical error messages generated are:

- The node address does not represent a valid node within the heap segment
- The length of the segment is not valid, or
- The heap segment pointer is not valid.

If one of the above error messages is generated by one of the reports, then examine the storage element that immediately precedes the damaged node to determine if this storage element is owned by the application program. Check the size of the storage element and ensure that it is sufficient for the program's use. If the size of the storage element is not sufficient then adjust the allocation size.

If an error occurs indicating that the node's pointers form a circular loop within the free storage tree, then check the Free Storage Tree Report to see if such a loop exists. If a loop exists, then contact the IBM support center for assistance because this may be a problem in the Language Environment heap management routines.

Additional diagnostic information regarding heap damage can be obtained by using the HEAPCHK run-time option. This option provides a more accurate time perspective on when the heap damage actually occurred, which could help to determine the program that caused the damage. For more information on HEAPCHK, see *z/OS Language Environment Programming Reference*.

Diagnosing storage leak problems

A storage leak occurs when a program does not return storage back to the heap after it has finished using it. To determine if this problem exists, do one of the following:

- The *call-level* suboption of the HEAPCHK run-time option causes a report to be produced in the CEEDUMP. Any still-allocated (that is, not freed) storage identified by HEAPCHK is listed in the report, along with the corresponding traceback. This shows any storage that wasn't freed, as well as all the calls that were involved in allocating the storage. For more information about the HEAPCHK run-time option, see *z/OS Language Environment Programming Reference* .
- Examine the Heap Segment Map report to see if any data areas, within the allocated storage elements, appear more frequently than expected. If they do, then check to see if these data areas are still being used by the application program. If the data areas are not being used, then change the program to free the storage element after it is done with it.

Diagnosing heap fragmentation problems

Heap fragmentation occurs when allocated storage is interlaced with many free storage areas that are too small for the application to use. Heap fragmentation could indicate that the application is not making efficient use of its heap storage. Check the Heap Segment Map report for frequent free storage elements that are interspersed with the allocated storage elements.

Understanding the HEAPPOOLS trace LEDATA output

The Language Environment IPCS Verbexit LEDATA generates a detailed HEAPPOOLS trace report when the HPT option is used. The argument *value* is the id of the pool to be formatted in the report.

Figure 146. Example formatted detailed HEAPPOOLS trace report from LEDATA Verbexit

[1] Trace Header

HEAPPOOLS trace header information.

[2] Pool Information

Information includes the number of the pool (POOLID) which is currently being formatted, the ASID, and the number of entries formatted and the total number of entries taken.

Note: The trace wraps for each poolid after 1024 enties have been taken.

[3] Timestamp

The time this trace entry was taken.

Note: The trace entries are formatted in reverse order (most recent trace entry first).

[4] Trace Table Entry contents

The individual trace entry:

- The TYPE - GET or FREE.
- The Cell within the pool being acted upon.
- The CPU and TCB which requested or freed the cell.
- A traceback at the time of the request. The number of entries in this traceback is limited by the HEAPCHK run-time option.

Understanding the C/C++-specific LEDATA output

The Language Environment IPCS Verbexit LEDATA generates formatted output of C/C++-specific control blocks from a system dump when the ALL parameter is specified and C/C++ is active in the dump. Figure 147 illustrates the C/C++-specific output produced. The system dump being formatted was obtained by specifying the TERMTHDACT(UADUMP) run-time option when running the program CELQSAMP Figure 5 on page 44. “C/C++-specific sections of the LEDATA output” on page 405 describes the information contained in the formatted output. Ellipses are used to summarize some sections of the dump.

For easy reference, the sections of the dump are numbered to correspond with the description of each section that follows.

```

Figure 147. Example formatted C/C++ output from LEDATA Verbexit (Part 9 of 9)

C/C++-specific sections of the LEDATA output

For the LEDATA output:

[1] CGEN

This section formats the C/C++-specific portion of the Language Environment common anchor area (CAA).

[2] CGENE

This section formats the extension to the C/C++-specific portion of the Language Environment common anchor area (CAA).

[3] CEDB

This section formats the C/C++-specific portion of the Language Environment enclave data block (EDB).

[4] CTHD

This section formats the C/C++ thread-level control block (CTHD).

[5] CPCB

This section formats the C/C++-specific portion of the Language Environment process control block (PCB).

[6] CIO

This section formats the C/C++ IO control block (CIO).

[7] File Control Blocks

This section formats the C/C++ file control block (FCB). The FCB and its related control blocks represent the information needed by each open stream.

Related Control Blocks

FSCE The file specific category extension control block. The FSCE represents the specific type of IO being performed. The following is a list of FSCEs that may be formatted.

OSNS — OS no seek

OSFS — OS fixed text

OSVF — OS variable text

OSUT — OS undefined format text

Other FSCEs will be displayed using a generic overlay.

OSIO The OS IO interface control block.

DCB The data control block. For more information about the DCB, refer to *z/OS DFSMS Macro Instructions for Data Sets*.

DCBE The data control block extension. For more information about the DCBE, refer to *z/OS DFSMS Macro Instructions for Data Sets*.

JFCB The job file control block (JFCB). For more information about the JFCB, refer to *z/OS MVS Data Areas, Vol 3 (IVT-RCWK)*.

Understanding the AUTH LEDATA output

The Language Environment IPCS Verbexit LEDATA generates formatted output of Preinitialized Environments for Authorized Programs-specific control blocks from a system dump when the AUTH parameter is specified. Figure Figure 148 on page 407 illustrates the output produced when the LEDATA verbexit is invoked with the AUTH parameter. Ellipses are used to summarize some sections of the dump.

For easy reference, the sections of the dump are numbered to correspond with the description of each section that follows.

```
     *******************************************************************************
                     Authorized Language Environment Control Blocks

Figure 148. Example of formatted AUTH output from LEDATA Verbexit (Part 4 of 4)

Sections of the AUTH LEDATA Verbexit formatted output

[1]ALEC

The ALEC is the anchor control block for all other Preinitialized Environments for Authorized Programs control blocks within the address space. The ALEC is located from the ASXB (Address Space Extension Block).

[2]Load Module Control Blocks

This section is the formatted representation of a table of ALMI control blocks. Each ALMI represents a module that was loaded by Preinitialized Environments for Authorized Programs.

[3]User Managed Control Blocks

This section contains control blocks for all user managed environments. A user managed environment is initialized when the CELAAUTH macro is invoked with REQUEST=USERINIT.

[4]-[5]Control Blocks for one user managed environment

These sections are repeated for each user managed environment that was initialized.

[4]ALEI

Each ALEI control block represents one environment.

[5]Routine Control Blocks

This section is the formatted representation of a table of ALRI control blocks. Each ALRI in this section represents a routine that was called by the user managed environment. Each ALRI appears in the table twice, once for the routine name and once for the routine address.

[6]System Managed Control Blocks

This section contains control blocks for all system managed environments. A set of system managed environments is initialized when the CELAAUTH macro is invoked with REQUEST=MNGDINIT.

[7]-[11]Control Blocks for one set of system managed environments that was initialized

These sections are repeated for each set of system managed environments that was initialized.

[7]ALES

Each ALES represents a set of system managed environments.

[8]-[11]Control blocks for one environment definition entry

These sections are repeated for every environment definition entry (AEDE) that was specified when the set of system managed environments was initialized.

[8]ETINDEX and ALESETE

The ETINDEX is the environment definition entry index value and the ALESETE represents the environment definition entry.

[9]Routine Control Blocks

This section is the formatted representation of a table of ALRI control blocks. Each ALRI in this section represents a routine that was called in one of the environments associated with the ETINDEX and ALESETE above. Each ALRI appears in the table twice, once for the routine name and once for the routine address.

[10]-[11]Control blocks for one system managed environment

These sections are repeated for every environment associated with the ETINDEX and ALESETE above.

[10]ALEI

Each ALEI control block represents one environment. The ALEIs in this section represent system managed environments.

[10]ALRI

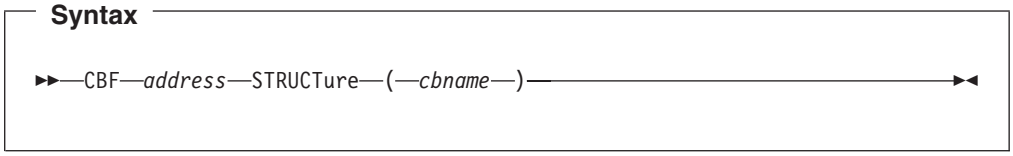
This section contains the ALRI control blocks for each routine that was called in the environment identified by the ALEI above. This section does not appear if the environment has not been used to call a routine.

Formatting individual control blocks

In addition to the full LEDATA output which contains many formatted control blocks, the IPCS Control block formatter can also format individual Language Environment control blocks.

The IPCS cbf command can be invoked from the ″IPCS Subcommand Entry″ screen, option 6 of the ″IPCS PRIMARY OPTION MENU″.

Syntax



address
The address of the control block in the dump. This is determined by browsing the dump or running the LEDATA Verbexit.

cbname
The name of the control block to be formatted. The control blocks that can be individually formatted are listed in Table 28 on page 413. In general, the name of each control block is similar to that used by the LEDATA Verbexit and is generally found in the control block's eyecatcher field. However, all control block

names are prefixed with CEE in order to uniquely define the Language Environment control block names to IPCS.

For an example of the display which is the result of the command, see Figure 149 :

CELALRI	Routine Information Block

Requesting a Language Environment trace for debugging

Language Environment provides an in-storage, wrapping trace facility that can reconstruct the events leading to the point where a dump is taken. Language Environment produces a trace table in its dump report when the TRACE run-time option is set to ON and:

- A thread ends abnormally because of an unhandled condition of severity 2 or greater and the TERMTHDACT run-time option is set to DUMP, UADUMP, TRACE, or UATRACE.
- An application terminates normally and the TRACE run-time option is set to DUMP (the default).

For more information about recording done by the TERMTHDACT run-time option or the TRACE run-time option, see *z/OS Language Environment Programming Reference*.

The TRACE run-time option activates Language Environment run-time library tracing and controls the size of the trace buffer, the type of trace events to record, and it determines whether a dump containing only the trace table should be unconditionally taken when the application (enclave) terminates. The trace table contents can be written out either upon demand or at the termination of an enclave.

The contents of the Language Environment dump depend on the values set in the TERMTHDACT run-time option. Under abnormal termination, the following dump contents are generated:

- TERMTHDACT(QUIET) generates a Language Environment dump containing the trace table only
- TERMTHDACT(MSG) generates a Language Environment dump containing the trace table only
- TERMTHDACT(TRACE) generates a Language Environment dump containing the trace table and the traceback
- TERMTHDACT(DUMP) generates a Language Environment dump containing thread/enclave/process storage and control blocks (the trace table is included as an enclave control block)
- TERMTHDACT(UAONLY) generates a system dump of the user address space

- TERMTHDACT(UATRACE) generates a Language Environment dump that contains traceback information, and a system dump of the user address space
- TERMTHDACT(UADUMP) generates a Language Environment dump containing thread/enclave/process storage and control blocks (the trace table is included as an enclave control block), and a user address space dump
- TERMTHDACT(UAIMM) generates a system dump of the user address space of the original abend or program interrupt that occurred prior to the Language Environment condition manager processing the condition.

  Note: TRAP(ON,NOSPIE) must be in effect. When TRAP(ON,SPIE) is in effect, UAIMM equals UAONLY results. For software raised conditions or signals, UAIMM is the same as UAONLY.

Under normal termination, with the TRACE run-time option set to DUMP, Language Environment generates a dump containing the trace table only, independent of the TERMTHDACT setting.

Language Environment quiesces all threads that are currently running except for the thread that issued the call to `cdump()`. When you call `cdump()` in a multithread environment, only the current thread is dumped. Enclave- and process-related storage could have changed from the time the dump request was issued.

Locating the trace dump

If your application is running under TSO or batch, and a CEEDUMP DD is not specified, Language Environment writes the CEEDUMP to the batch log (SYSOUT=* by default). You can change the SYSOUT class by specifying a CEEDUMP DD, or by setting the environment variable, *_CEE_DMPTARG=SYSOUT(x)*, where x is the preferred SYSOUT class.

If your application is running under z/OS UNIX and is either running in a child process, or if it is invoked by one of the `exec` family of functions, the dump is written to the z/OS UNIX file system. Language Environment writes the CEEDUMP to one of the following directories in the specified order:

1. The directory in environment variable *_CEE_DMPTARG*, if found
2. The current working directory, if the directory is not the root directory (/), the directory is writable, and the CEEDUMP path name does not exceed 1024 characters
3. The directory found in environment variable *TMPDIR* (an environment variable that indicates the location of a temporary directory if it is not /tmp)
4. The **/tmp** directory

The name of this file changes with each dump and uses the following format:

`/path/CEEDUMP.Date.Time.Pid`

path The path determined from the above algorithm.

Date The date the dump is taken, appearing in the format `YYYYMMDD` (such as 20040918 for September 18, 2004).

Time The time the dump is taken, appearing in the format `HHMMSS` (such as 175501 for 05:55:01 p.m.).

Pid The process ID the application is running in when the dump is taken.

Using the Language Environment trace table format in a dump report

The Language Environment trace table is established unconditionally at enclave initialization time if the TRACE run-time option is set to ON. All threads in the enclave share the trace table; there is no thread-specific table, nor can the table be dynamically extended or enlarged.

Understanding the trace table entry (TTE)

Each trace table entry is a fixed-length record consisting of a fixed-format portion (containing such items as the timestamp, thread ID, and member ID) and a member-specific portion. The member-specific portion has a fixed length, of which some (or all) can be unused. For information about how participating products use the trace table entry, refer to the product-specific documentation. The format of the trace table entry is as follows:

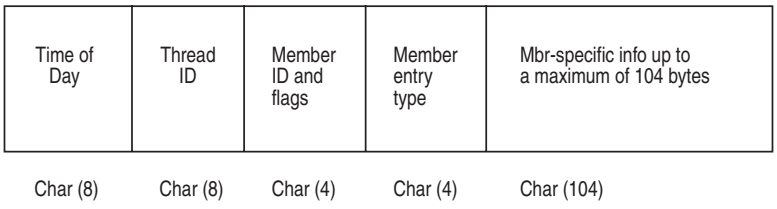

Figure 150. Format of the trace table entry

Following is a definition of each field:

Time The 64-bit value obtained from a store clock (STCK).

Thread ID The 8-byte thread ID of the thread that is adding the trace table entry.

Member ID and Flags
Contains 2 fields:

Member ID The 1-byte member ID of the member making the trace table entry, as follows:

ID	Name
01	CEL
03	C/C++
08	DCE
12	Sockets

Flags 24 flags reserved for internal use.

Member Entry Type
A number that indicates the type of the member-specific trace information that follows the field.

To uniquely identify the information contained in a specific TTE, you must consider Member ID as well as Member Entry Type.

Member-Specific Information
Based on the member ID and the member entry type, this field contains the specific information for the entry, up to 104 bytes.

For C/C++, the entry type of 1 is a record that records an invocation of a base C run-time library function. The entry consists of the name of the invoking function and the name of the invoked

function. Entry type 2 is a record that records the return from the base library function. It contains the returned value and the value of errno.

Member-specific information in the trace table entry

Global tracing is activated by using the LE=n suboption of the TRACE run-time option. This requests all Language Environment members to generate trace records in the trace table.

The settings for the global trace events are:

Level	Description
0	No global trace
1	Trace all run-time library (RTL) function entry and exits
2	Trace all RTL mutex init/destroy and lock/unlock
3	Trace all RTL function entry and exits, and all mutex init/destroy and lock/unlock
8	Trace all RTL storage allocation/deallocation

When LE=1 is specified: The following C/C++ records may be generated.

Table 30. LE=1 entry records

Member ID	Record Type	Description
03	00000001	Base C Library function Entry
03	00000002	Base C Library function Exit
03	00000003	Posix C Library function Entry
03	00000004	Posix C Library function Exit
03	00000005	XPLINK Base or Posix C Library function Entry
03	00000006	XPLINK Base or Posix C Library function Exit

For a detailed description of these records, see “C/C++ contents of the Language Environment trace tables” on page 448.

When LE=2 is specified: The following Language Environment records may be generated.

Table 31. LE=2 entry records

Member ID	Record Type	Class	Event	Description
01	00000101	LT	A	Latch Acquire
01	00000102	LT	R	Latch Release
01	00000103	LT	W	Latch Wait
01	00000104	LT	AW	Latch Acquire after Wait
01	00000106	LT	I	Latch Increment (Recursive)
01	00000107	LT	D	Latch Decrement (Recursive)

01	000008FD	RE	EO	Error - Already owned (not acquired)
01	000008FE	RE	EIN	Error - Initialization failed (duplicate)

The format for the Mutex – Condition Variable – Latch entries in the trace table is:

Table 32. Format of the mutex/CV/latch records

Class	Source		Event		Object Addr	Name1	Name2
unused							

Where each field represents:

Class Two character EBCDIC representation of the trace class.

- **LT** Latch
- **LE** Latch Exception
- **MX** Mutex
- **ME** Mutex Exception
- **CV** Condition Variable
- **CE** Condition Variable Exception

Source
One character EBCDIC representation of the event.

- **C** C/C++

Blank Blank character

Event Two character EBCDIC representation of the event. See Table 31 on page 417.

Object address
Fullword address of the mutex object.

Name 1
Optional eight character field containing the name of the function or object to be recorded.

Name 2
Optional eight character field containing the name of the function or object to be recorded.

When LE=3 is specified: The trace table will include the records generated by both LE=1 and LE=2.

When LE=8 is specified: The trace table will contain only storage allocation records. Currently this is only supported by C/C++.

Table 33. LE=8 entry records

Member ID	Record Type	Description
03	00000005	Storage allocation entry
03	00000006	Storage allocation exit

For a detailed description of these records, see “C/C++ contents of the Language Environment trace tables” on page 448.

Sample dump for the trace table entry

The following is an example of a dump of the trace table when you specify the LE=1 suboption (the library call/return trace):

```
Language Environment Trace Table:
  Most recent trace entry is at displacement: 002080
      Displacement                      Trace Entry in Hexadecimal                                  Trace Entry in EBCDIC

Chapter 13. Debugging AMODE 64 C/C++ routines

This chapter provides specific information to help you debug AMODE 64 applications that contain one or more C/C++ routines. It includes the following topics:

- Debugging C/C++ I/O routines
- Using XL C/C++ compiler listings
- Generating a Language Environment dump of a C/C++ routine
- Finding C/C++ information in a Language Environment dump
- Debugging example of C/C++ routines

There are several debugging features that are unique to C/C++ routines. Before examining the C/C++ techniques to find errors, you might want to consider the following areas of potential problems:

- To prevent errors which may result from differences in LP64 default argument types, you should include function prototypes for all C/C++ function calls. For C/C++ run-time library functions, see *z/OS XL C/C++ Run-Time Library Reference*.

  Note: `malloc()` is an example of a RTL function which needs this prototype to work correctly in LP64 applications.
- If you are using the `fetch()` function, refer to *z/OS XL C/C++ Programming Guide* to ensure that you are creating the fetchable module correctly.
- If you are using `DLL`s, refer to *z/OS XL C/C++ Programming Guide* to ensure that you are using the DLL correctly.
- Ensure that the entry point of the load module is CELQSTRT.
- If you suspect that you are using uninitialized storage, you may want to use the `STORAGE` run-time option.
- You should avoid:
  - Incorrect casting
  - Referencing an array element with a subscript outside the declared bounds
  - Copying a string to a target with a shorter length than the source string
  - Declaring but not initializing a pointer variable, or using a pointer to allocated storage that has already been freed

  If a routine exception occurred and you need more information than the condition handler provided, run your routine with the following run-time options, TRAP(ON, NOSPIE) and TERMTHDACT(UAIMM). Setting these run-time options generates a system dump of the user address space of the original abend or program interrupt prior to the Language Environment condition manager processing the condition. After the system dump is taken by the operating system the Language Environment condition manager continues processing.

Debugging C/C++ programs

You can use C/C++ conventions such as `__amrc` and `perror()` when you debug C/C++ programs.

Using the __amrc and __amrc2 structures to debug input/output

`__amrc`, a structure defined in **stdio.h**, can help you determine the cause of errors resulting from an I/O operation, because it contains diagnostic information (for example, the return code from a failed VSAM operation).

There are two structures:
- __amrc (defined by type __amrc_type
- __amrc2 (defined by type __amrc2_type)

The __amrc2_type structure contains secondary information that C can provide.

Because any I/O function calls, such as printf(), can change the value of __amrc or __amrc2, make sure you save the contents into temporary structures of __amrc_type and __amrc2_type respectively, before dumping them.

Figure 152 on page 427 shows the structure as it appears in **stdio.h**.

```
    typedef struct __amrctype {

[1]     union {

[2]        int      __error;
           struct {
             unsigned short __syscode,
                            __rc;
[3]        } __abend;
           struct {
              unsigned char __fdbk_fill,
                            __rc,
                            __ftncd,
                            __fdbk;
[4]        } __feedback;
           struct {
              unsigned short __svc99_info,
                             __svc99_error;
[5]        } __alloc;
[1]     } __code;
[6]     unsigned int      __RBA;
[7]     unsigned int      __last_op;
        struct {
         unsigned int   __len_fill; /* __len + 4       */
         unsigned int   __len;
         char           __str[120];
         unsigned int   __parmr0;
         unsigned int   __parmr1;
         unsigned int   __fill2[2];
         char           __str2[64];
[8]     } __msg;
         #if __EDC_TARGET >= 0x22080000
[9]      unsigned char        __rplfdbwd[4];  /*  rpl feedback word */
 #endif                        /*  __EDC_TARGET >= 0x22080000  */
 #if __EDC_TARGET >= 0x41080000
[10] #ifdef  __LP64
   unsigned long         __XRBA; /* 8 byte RBA                */

   char                  __amrc_pad[23];
    } __amrc_type;
```

Figure 152. __amrc structure

Figure 153 shows the __amrc2 structure as it appears in **stdio.h**.

```
    struct {
[12]       int        __error2;
                             char       __pad__error2[4];
[13]       FILE      *__fileptr;
[14]       int        __reserved{6};
    }
```

Figure 153. __amrc2 structure

[1] union { ... } __code
The error or warning value from an I/O operation is in __error, __abend, __feedback, or __alloc. Look at __last_op to determine how to interpret the __code union.

[2] __error A structure that contains error codes for certain macros or services your application uses. Look at __last_op to determine the error codes. __syscode is the system abend code.

[3] __abend A structure that contains the abend code when errno is set to indicate a recoverable I/O abend. __rc is the return code. For more information on abend codes, see *z/OS MVS System Codes*.

[4] __feedback A structure that is used for VSAM only. The __rc stores the VSAM register 15, __fdbk stores the VSAM error code or reason code, and __RBA stores the RBA after some operations.

[5] __alloc A structure that contains errors during fopen or freopen calls when defining files to the system using SVC 99.

[6] __RBA The RBA value returned by VSAM after an ESDS or KSDS record is written out. For an RRDS, it is the calculated value from the record number. In AMODE 64 applications, you can no longer use the address of _amrc._ RBA as the first argument to flocate(). Instead, _amrc._RBA must be placed into an unsigned long in order to make it 8 bytes wide, since flocate() is updated to indicate that size of (unsigned long) must be specified as the key length (second argument).

[7] __last_op A field containing a value that indicates the last I/O operation being performed by C/C++ at the time the error occurred. These values are shown in Table 34 on page 429.

[8] __msg May contain the system error messages from read or write operations emitted from the DFSMS/MVS SYNADAF macro instruction. Because the message can start with a hexadecimal address followed by a short integer, it is advisable to start printing at MSG+6 or greater so the message can be printed as a string. Because the message is not null-terminated, a maximum of 114 characters should be printed. This can be accomplished by specifying a printf format specifier as %.114s.

[9] __rplfdbwd This field contains feedback information related to a VSAM RLS failure. This is the feedback code from the IFGRPL control block.

[10]__XRBA This is the 8 byte relative byte address returned by VSAM after an ESDS or KSDS record is written out. For an RRDS, it is the calculated value from the record number. It may be used in subsequent calls to flocate().

[11] __amrc_noseek_to_seek
This field contains the reason for the switch from QSAM (noseek) to BSAM with NOTE and POINT macros requested (seek) by the XL C/C++ Run-Time Library. This field is set when system-level I/O macro processing triggers an ABEND condition. The macro name values (defined in stdio.h) for this field are as follows:

Macro	Definition
__AM_BSAM_NOSWITCH	No switch was made.
__AM_BSAM_UPDATE	The data set is open for update

Macro	Definition
__AM_BSAM_BSAMWRITE	The data set is already open for write (or update) in the same C process.
__AM_BSAM_FBS_APPEND	The data set is recfm=FBS and open for append
__AM_BSAM_LRECLX	The data set is recfm=LRECLX (used for VBS data sets where records span the largest blocksize allowed on the device)
__AM_BSAM_PARTITIONED_DIRECTORY	The data set is the directory for a regular or extended partitioned data set
__AM_BSAM_PARTITIONED_INDIRECT	The data set is a member of a partitioned data set, and the member name was not specified at allocation

[12] __error2 A secondary error code. For example, an unsuccessful rename or remove operation places its reason code here.

[13] __fileptr A pointer to the file that caused a SIGIOERR to be raised. Use an `fldata()` call to get the actual name of the file.

[14] __reserved
Reserved for future use.

__last_op values

The `__last_op` field is the most important of the `__amrc` fields. It defines the last I/O operation C/C++ was performing at the time of the I/O error. You should note that the structure is neither cleared nor set by non-I/O operations, so querying this field outside of a `SIGIOERR` handler should only be done immediately after I/O operations. Table 34 lists `__last_op` values you could receive and where to look for further information.

Table 34. __last_op values and diagnosis information

Value	Further Information
__IO_INIT	Will never be seen by SIGIOERR exit value given at initialization.
__BSAM_OPEN	Sets __error with return code from OS OPEN macro.
__BSAM_CLOSE	Sets __error with return code from OS CLOSE macro.
__BSAM_READ	No return code (either __abend (errno == 92) or __msg (errno == 66) filled in).
__BSAM_NOTE	NOTE returned 0 unexpectedly, no return code.
__BSAM_POINT	This will not appear as an error lastop.
__BSAM_WRITE	No return code (either __abend (errno == 92) or __msg (errno == 65) filled in).
__BSAM_CLOSE_T	Sets __error with return code from OS CLOSE TYPE=T.
__BSAM_BLDL	Sets __error with return code from OS BLDL macro.
__BSAM_STOW	Sets __error with return code from OS STOW macro.
__TGET_READ	Sets __error with return code from TSO TGET macro.
__TPUT_WRITE	Sets __error with return code from TSO TPUT macro.
__IO_DEVTYPE	Sets __error with return code from I/O DEVTYPE macro.
__IO_RDJFCB	Sets __error with return code from I/O RDJFCB macro.
__IO_TRKCALC	Sets __error with return code from I/O TRKCALC macro.

Table 34. __last_op values and diagnosis information (continued)

Value	Further Information
__IO_OBTAIN	Sets __error with return code from I/O CAMLST OBTAIN.
__IO_LOCATE	Sets __error with return code from I/O CAMLST LOCATE.
__IO_CATALOG	Sets __error with return code from I/O CAMLST CAT. The associated macro is CATALOG.
__IO_UNCATALOG	Sets __error with return code from I/O CAMLST UNCAT. The associated macro is CATALOG.
__IO_RENAME	Sets __error with return code from I/O CAMLST RENAME.
__SVC99_ALLOC	Sets __alloc structure with info and error codes from SVC 99 allocation.
__SVC99_ALLOC_NEW	Sets __alloc structure with info and error codes from SVC 99 allocation of NEW file.
__SVC99_UNALLOC	Sets __unalloc structure with info and error codes from SVC 99 unallocation.
__C_TRUNCATE	Set when C or C++ truncates output data. Usually this is data written to a text file with no newline such that the record fills up to capacity and subsequent characters cannot be written. For a record I/O file this refers to an `fwrite()` writing more data than the record can hold. Truncation is always rightmost data. There is no return code.
__C_FCBCHECK	Set when C or C++ FCB is corrupted. This is due to a pointer corruption somewhere. File cannot be used after this.
__C_DBCS_TRUNCATE	This occurs when writing DBCS data to a text file and there is no room left in a physical record for anymore double byte characters. A new-line is not acceptable at this point. Truncation will continue to occur until an SI is written or the file position is moved. Cannot happen if MB_CUR_MAX is 1.
__C_DBCS_SO_TRUNCATE	This occurs when there is not enough room in a record to start any DBCS string or else when a redundant SO is written to the file before an SI. Cannot happen if MB_CUR_MAX is 1.
__C_DBCS_SI_TRUNCATE	This occurs only when there was not enough room to start a DBCS string and data was written anyways, with an SI to end it. Cannot happen if MB_CUR_MAX is 1.
__C_DBCS_UNEVEN	This occurs when an SI is written before the last double byte character is completed, thereby forcing C or C++ to fill in the last byte of the DBCS string with a padding byte X'FE'. Cannot happen if MB_CUR_MAX is 1.
__C_CANNOT_EXTEND	This occurs when an attempt is made to extend a file that allows writing, but cannot be extended. Typically this is a member of a partitioned data set being opened for update.
__VSAM_OPEN_FAIL	Set when a low level VSAM OPEN fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_OPEN_ESDS	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_OPEN_RRDS	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_OPEN_KSDS	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_OPEN_ESDS_PATH	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.

Table 34. __last_op values and diagnosis information (continued)

Value	Further Information
__VSAM_OPEN_KSDS_PATH	Does not indicate an error; set when the low level VSAM OPEN succeeds, and the file type is ESDS.
__VSAM_MODCB	Set when a low level VSAM MODCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_TESTCB	Set when a low level VSAM TESTCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_SHOWCB	Set when a low level VSAM SHOWCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_GENCB	Set when a low level VSAM GENCB macro fails, sets __rc and __fdbk fields in the __amrc struct.
__VSAM_GET	Set when the last op was a low level VSAM GET; if the GET fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_PUT	Set when the last op was a low level VSAM PUT; if the PUT fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_POINT	Set when the last op was a low level VSAM POINT; if the POINT fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_ERASE	Set when the last op was a low level VSAM ERASE; if the ERASE fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_ENDREQ	Set when the last op was a low level VSAM ENDREQ; if the ENDREQ fails, sets __rc and __fdbk in the __amrc struct.
__VSAM_CLOSE	Set when the last op was a low level VSAM CLOSE; if the CLOSE fails, sets __rc and __fdbk in the __amrc struct.
__QSAM_GET	__error is not set (if abend (errno == 92), __abend is set, otherwise if read error (errno == 66), look at __msg.
__QSAM_PUT	__error is not set (if abend (errno == 92), __abend is set, otherwise if write error (errno == 65), look at __msg.
__QSAM_TRUNC	This is an intermediate operation. You will only see this if an I/O abend occurred.
__QSAM_FREEPOOL	This is an intermediate operation. You will only see this if an I/O abend occurred.
__QSAM_CLOSE	Sets __error to result of OS CLOSE macro.
__QSAM_OPEN	Sets __error to result of OS OPEN macro.
__CMS_OPEN	Sets __error to result of FSOPEN.
__CMS_CLOSE	Sets __error to result of FSCLOSE.
__CMS_READ	Sets __error to result of FSREAD.
__CMS_WRITE	Sets __error to result of FSWRITE.
__CMS_STATE	Sets __error to result of FSSTATE.
__CMS_ERASE	Sets __error to result of FSERASE.
__CMS_RENAME	Sets __error to result of CMS RENAME command.
__CMS_EXTRACT	Sets __error to result of DMS EXTRACT call.
__CMS_LINERD	Sets __error to result of LINERD macro.
__CMS_LINEWRT	Sets __error to result of LINEWRT macro.
__CMS_QUERY	__error is not set.

Table 34. __last_op values and diagnosis information (continued)

Value	Further Information
__HSP_CREATE	Indicates last op was a DSPSERV CREATE to create a hiperspace for a hiperspace memory file. If CREATE fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_DELETE	Indicates last op was a DSPSERV DELETE to delete a hiperspace for a hiperspace memory file during termination. If DELETE fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_READ	Indicates last op was a HSPSERV READ from a hiperspace. If READ fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_WRITE	Indicates last op was a HSPSERV WRITE to a hiperspace. If WRITE fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__HSP_EXTEND	Indicates last op was a HSPSERV EXTEND during a write to a hiperspace. If EXTEND fails, stores abend code in __amrc__code__abend__syscode, reason code in __amrc__code__abend__rc.
__LFS_OPEN	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_CLOSE	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_READ	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_WRITE	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_LSEEK	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.
__LFS_FSTAT	Sets __error with reason code from HFS services. Reason code from HFS services must be broken up. The low order 2 bytes can be looked up in *z/OS UNIX System Services Programming: Assembler Callable Services Reference*.

Displaying an error message with the perror() function

To find a failing routine, check the return code of all function calls. After you have found the failing routine, use the `perror()` function after the routine to display the error message. `perror()` displays the string that you pass to it and an error

message corresponding to the value of errno. perror() writes to the standard error stream (stderr). By default, the errno2 value will be appended to the end of the perror() string.

If you do not want the errno2 value appended to the perror() string, set the _EDC_ADD_ERRNO2 environment variable to 0.

Figure 154 is an example of a routine using perror().

```
#include <stdio.h>
int main(void){
   FILE *fp;

   fp = fopen("myfile.dat", "w");
   if (fp == NULL)
      perror("fopen error");
}
```

Figure 154. Example of a routine using perror()

Using __errno2() to diagnose application problems

Use the __errno2() function when diagnosing problems in an application program. This function enables z/OS XL C/C++ application programs to access additional diagnostic information, errno2 (errnojr), associated with errno. The __errno2 may be set by the z/OS XL C/C++ run-time library, z/OS UNIX callable services, or other callable services. The errno2 is intended for diagnostic display purposes only and is not a programming interface.

Note: Not all functions set errno2 when errno is set. In the cases where errno2 is not set, the __errno2() function may return a residual value. You may use the __err2ad() function to clear errno2 to reduce the possibility of a residual value being returned.

Figure 155 is an example of a routine using __errno2() and Figure 156 on page 434 shows the sample output from that routine.

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>

int main(void) {
  FILE *f;
  f = fopen("testfile.dat", "r")
  if (f==NULL) {
      perror("fopen() failed");
      printf("__errno2 = %08x\n", __errno2());
   }
   return 0;
}
```

Figure 155. Example of a routine using __errno2()

```
fopen() failed: EDC5129I No such file or directory. (errno2=0x05620062)
__errno2 = 05620062
```

Figure 156. Sample output of routine using __errno2()

Figure 157 is an example of a routine using the environment variable _EDC_ADD_ERRNO2 and Figure 158 shows the sample output from that routine.

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void) {
  FILE *fp;
  /* do NOT add errno2 to perror message */
  setenv("_EDC_ADD_ERRNO2", "0", 1);
  fp = fopen("testfile.dat", "r");
  if (fp == NULL)
      perror("fopen() failed");
  return 0;
}
```

Figure 157. Example of a routine using _EDC_ADD_ERRNO2

```
fopen() failed: EDC5129I No such file or directory.
```

Figure 158. Sample output of a routine using _EDC_ADD_ERRNO2

Figure 159 on page 435 is an example of a routine using __err2ad() in combination with __errno2() and Figure 160 on page 435 shows the sample output from that routine.

```
#pragma runopts(posix(on))
#define _EXT
#include <stdio.h>
#include <errno.h>
#include <stdlib.h>

int main(void) {
  FILE *f;
  setenv("_EDC_ADD_ERRNO2", "0", 1);
  f = fopen("testfile.dat", "r");
  if (f == NULL) {
    perror("fopen() failed");
    printf("__errno2 = %08x\n", __errno2());
  }
  /* reset errno2 to zero */
  *__err2ad() = 0x0;
  printf("__errno2 = %08x\n", __errno2());
  f = fopen(*testfile.dat", "r");

  if (fp == NULL) {
    perror("fopen() failed");
    printf(*__errno2 = %08x\n", __errno2());
  }
  return 0;
}
```

Figure 159. Example of a routine using __err2ad() in combination with __errno2()

```
fopen() failed: EDC5129I  No such file or directory.
__errno2 = 05620062
__errno2 = 00000000
fopen() failed: EDC5129I  No such file or directory.
__errno2 = 05620062
```

Figure 160. Sample output of routine using __err2ad() in combination with __errno2()

For more information about _EDC_ADD_ERRNO2, see *z/OS XL C/C++ Programming Guide*.

For more information about __errno2() and __err2ad(), see *z/OS XL C/C++ Run-Time Library Reference*.

Using C/C++ listings

For a detailed description of available listings, see *z/OS XL C/C++ User's Guide*.

Finding variables

You can determine the value of a variable in the routine at the point of interrupt by using the compiled code listing as a guide to its address, then finding this address in the Language Environment dump or system dump. The method you use depends on the storage class of variable.

It is possible for the routine to be interrupted before the value of the variable is placed in the location provided for it. This can explain unexpected values in the dump.

Steps for finding automatic variables

Perform the following steps to find automatic variables in the Language Environment dump or system dump:

1. Determine the name of the automatic variable and the function it is defined in. As an example, we will find the variable **aa** in the function **main** from the program **cdivzero** shown in Figure 58 on page 184.
2. From the compiler listing, locate the variable in the storage offset listing:

```
aa                  5823-0:10       Class = automatic,          Location = 2248(r4),         Length = 4
```

   The location is specified as decimal offset (base register). So variable **aa** is located at register 4 + 2248 (X'8C8').

3. From the Traceback (in the Language Environment dump or in the formatted output from the IPCS VERBEXIT LEDATA CEEDUMP subcommand for a system dump) locate the function:

```
DSA       Entry       E  Offset  Load Mod  Program Unit  Service  Status
00000004  main        +00000016  CDIVZERO                        Call

DSA       DSA Addr          E  Addr             PU Addr           PU Offset  Comp Date Attributes
00000004  00000001082FF180  000000002510000C0   0000000000000000  ********   20040408  XPLINK  EBCDIC  IEEE
```

   If the base register is r4, the register 4 value is always the DSA address for the function.

   If the base register is not r4, the register value must be located from saved registers.

   If the Status field indicates Exception, use the saved registers from when the condition occurred. In the Language Environment dump, the saved registers can be found in the Condition information associated with the DSA address in the Condition Information for Active Routines section. In the formatted output from the IPCS VERBEXIT LEDATA CM subcommand for a system dump, the saved registers can be found in the CIBH that has the DSA address as the value for the SV1 field.

   If the Status field indicates Call, use the saved registers from the DSA address that appears on the line above the function in the Traceback. In the Language Environment dump, the DSAs can be found in the ″Control Blocks for Active Routines″ section. In the formatted output from the IPCS VERBEXIT LEDATA 'STACK' subcommand for a system dump, the DSAs can be found in the ″DSA backchain″ section.

   Note: Some functions do not save all registers.

4. Add the register value to the offset of the variable to obtain the address of the variable. In the Language Environment dump, the contents of the variable can be read in the DSA Frame section corresponding to the function the variable is contained in. For a system dump, use the IPCS LIST subcommand to display the storage where the variable is located.

   The address for variable **aa** is X'1082FF080' + X'980' = X'1082FFA00'.

Restriction: The parameter value might never be stored, since the first few parameters might be passed in registers and there might be no need to save them.

Steps for finding C/C++ parameters

The C/C++ parameter list is always located in the caller's DSA at offset 2176 (X'880'). Parameters that are passed in registers are not always stored in the parameter list. The compiler option XPLINK(STOREARGS) can be used to ensure that all parameters are stored in the parameter list.

Perform the following steps to find parameters in the Language Environment dump or system dump:

1. Determine the name of the parameter and the function it is for. As an example, we will find the parameter **pp** for the function **funcb** from the program **cdivzero** shown in Figure 53. C routine with a divide-by-zero error.
2. From the compiler listing, locate the parameter in the storage offset listing:

```
pp                 5828-0:15       Class = parameter,          Location = 2432(r4),          Length = 8
```

3. From the Traceback (in the Language Environment dump or in the formatted output from the IPCS VERBEXIT LEDATA 'CEEDUMP' subcommand for a system dump) locate the function:

```
    DSA       Entry       E  Offset  Load Mod  Program Unit  Service  Status
    00000003  funcb       +0000002E  CDIVZERO                        Exception

    DSA       DSA Addr          E  Addr             PU Addr           PU Offset  Comp Date Attributes
    00000003  00000001082FF080  0000000025100108    0000000000000000  ********   20040408  XPLINK  EBCDIC  IEEE
```

   If the base register is r4, the register 4 value is always the DSA address for the function.

   If the base register is not r4, the register value must be located from saved registers.

   If the Status field indicates Exception, use the saved registers from when the condition occurred. In the Language Environment dump, the saved registers can be found in the Condition information associated with the DSA address in the ″Condition Information for Active Routines″ section. In the formatted output from the IPCS VERBEXIT LEDATA 'CM' subcommand for a system dump, the saved registers can be found in the CIBH that has the DSA address as the value for the SV1 field.

   If the Status field indicates Call, use the saved registers from the DSA address that appears on the line above the function in the Traceback. In the Language Environment dump, the DSAs can be found in the ″Control Blocks for Active Routines″ section. In the formatted output from the IPCS VERBEXIT LEDATA 'STACK' subcommand for a system dump, the DSAs can be found in the ″DSA backchain″ section.

   Note: Some functions do not save all registers.
4. Add the register value to the offset of the parameter to obtain the address of the parameter. In the Language Environment dump, the contents of the parameter can be read in the DSA Frame section corresponding to the function that passed the parameter. For a system dump, use the IPCS LIST subcommand to display the storage where the parameter is located.

   The address for parameter **pp** is X'1082FF080' + X'980' = X'1082FFA00'.

Steps for finding members of aggregates

You can define aggregates in any of the storage classes or pass them as parameters to a called function. The first step is to find the start of the aggregate. You can compute the start of the aggregate as described in previous sections, depending on the type of aggregate used.

The aggregate map provided for each declaration in a routine can further assist in finding the offset of a specific variable within an aggregate. Structure maps are generated using the AGGREGATE compiler option. Figure 161 on page 438 shows an example of an aggregate.

```
typedef struct {
     int asid;
     void *addr;
     asfAmodeType amode;
  } asfTargetRef;
  asfTargetRef  tempTargetRef;
```

Figure 161. Example code for structure variables

Figure 162 shows an example of aggregate map.

```
================================================================================
| Aggregate map for: struct with no tag #68            Total size: 24 bytes    |
|..............................................................................|

```

Figure 162. Example of aggregate map

To find the value of variable **tempTargetRef.addr**:

1. Locate the automatic variable **tempTargetRef** in the storage offset listing:

```
tempTargetRef       209-0:209       Class = automatic,          Location = 2264(r4),          Length = 24
```

   The variable **tempTargetRef** is located at register 4 + 2264 (X'8D8'). For this example, assume that the register 4 value is X'1082FD3E0'. The result is X'1082FDCB8'(X'1082FD3E0' + X'8D8'). This is the address of the value of the automatic variable **tempTargetRef** in the dump

2. Find the offset of addr in the Aggregate Map, shown in Figure Figure 162. The offset is 8. Add the offset from the Aggregate Map to the address of the **tempTargetRef** variable.

   The result is X'1082FDCC0' (X'1082FDCB8' + X'8'). This is the address of the value of **tempTargetRef.addr** in the dump

Generating a Language Environment dump of a C/C++ routine

You can use the `cdump()`, `csnap()`, and `ctrace()` C/C++ functions to generate a Language Environment dump of C/C++ routines.

cdump()

If your routine is running under z/OS, you can generate useful diagnostic information by using the `cdump()` function. `cdump()` produces a main storage dump with the activation stack.

When `cdump()` is invoked from a user routine, the C/C++ library issues an OS IEATDUMP macro to obtain a dump of virtual storage. You can use the Interactive Problem Control System (IPCS) to format and analyze IEATDUMP dumps.

The DD definition for CEESNAP must include the desired data set name and DCB information:

```
LRECL=4160,  BLKSIZE=4160, and RECFM=FBS
```

If the data set is not defined, or is not usable for any reason, `cdump()` returns a failure code of 1. This occurs even if the call to CEE3DMP is successful.

Because `cdump()` returns a code of 0 only if the IEATDUMP was successful or 1 if it was unsuccessful, you cannot distinguish whether a failure of `cdump()` occurred in the call to CEE3DMP or IEATDUMP. A return code of 0 is issued only if both IEATDUMP and CEE3DMP are successful.

Support for IEATDUMP dumps using the `_cdump` function is provided only under z/OS. In addition to a IEATDUMP dump, a Language Environment formatted dump is also taken.

csnap()

The `csnap()` function produces a condensed storage dump.

To use these functions, you must add `#include <ctest.h>` to your C/C++ code. The dump is directed to output *dumpname*, which is specified in a `//CEEDUMP DD` statement in JCL.

Refer to the *z/OS XL C/C++ Run-Time Library Reference* for more details about the syntax of these functions.

ctrace()

The `ctrace()` function produces a traceback and includes the offset addresses from which the calls were made.

Sample C routine that calls cdump()

Figure 163 on page 440 shows a sample C routine that uses the `cdump` function to generate a dump.

Figure 168 on page 444 shows the dump output.

```
#include <stdio.h>
#include <signal.h>
#include <stdlib.h>

void hsigfpe(int);
void hsigterm(int);
void atf1(void);

typedef int (*FuncPtr_T)(void);

int st1    =  99;
int st2    = 255;
int xcount =   0;

int main(void) {
  /*
   * 1) Open multiple files
   * 2) Register 2 signals
   * 3) Register 1 atexit function
   * 4) Fetch and execute a module
   */

  FuncPtr_T fetchPtr;
  FILE*     fp1;
  FILE*     fp2;
  int       rc;
  fp1 = fopen("myfile.data", "w");
  if (!fp1) {
    perror("Could not open myfile.data for write");
    exit(101);
  }

  fprintf(fp1, "record 1\n");
  fprintf(fp1, "record 2\n");
  fprintf(fp1, "record 3\n");

  fp2 = fopen("memory.data", "wb,type=memory");
  if (!fp2) {
    perror("Could not open memory.data for write");
    exit(102);
  }
  fprintf(fp2, "some data");
  fprintf(fp2, "some more data");
  fprintf(fp2, "even more data");

  signal(SIGFPE , hsigfpe);
  signal(SIGTERM, hsigterm);

  rc = atexit(atf1);
  if (rc) {
    fprintf(stderr, "Failed on registration of atexit function atf1\n");
    exit(103);
  }
```

Figure 163. Example C routine using cdump() to generate a dump (Part 1 of 2)

```
  fetchPtr = (FuncPtr_T) fetch("MODULE1");
  if (!fetchPtr) {
    fprintf(stderr, "Failed to fetch MODULE1\n");
    exit(104);
  }
  fetchPtr();
  return(0);
}

void hsigfpe(int sig) {
  ++st1;
  return;
}

void hsigterm(int sig) {
  ++st2;
  return;
}

void atf1() {
  ++xcount;
}
```

Figure 163. Example C routine using cdump() to generate a dump (Part 2 of 2)

Figure 164 shows a fetched C module:

```
#include <ctest.h>

#pragma linkage(func1, fetchable)
int func1(void) {
  __cdump("This is a sample dump");
  return(0);
}
```

Figure 164. Fetched module for C routine

Sample C++ routine that generates a Language Environment dump

Figure 165 on page 442 shows a sample C++ routine that uses a protection exception to generate a dump.

```
#include <iostream.h>
#include <ctest.h>
#include "stack.h"

int main() {
  cout << "Program starting:\n";
  cerr << "Error report:\n";

  Stack<int> x;
  x.push(1);
  cout << "Top value on stack : " << x.pop() << '\n';
  cout << "Next value on stack: " << x.pop() << '\n';
  return(0);
}
```

Figure 165. Example C++ routine with protection exception generating a dump

Figure 166 shows the template file stack.c

```
#ifndef __STACK__
  #include "stack.h"
#endif

template <class T> T Stack<T>::pop() {
  T value = head->value;
  head = head->next;

  return(value);
}
template <class T> void Stack<T>::push(T value) {
  Node* newNode  = new Node;
  newNode->value = value;
  newNode->next  = head;
  head = newNode;
}
```

Figure 166. Template file STACK.C

Figure 167 on page 443 shows the header file **stack.h**.

```
#ifndef __STACK_
  #define __STACK__
  template <class T> class Stack {
    public:
      Stack() {
        char* badPtr = 0; badPtr -= (0x01010101);
        head = (Node*) badPtr; /* head initialized to 0xFEFEFEFF */
      }
      T pop();
      void push(T);
    private:
      struct Node {
        T value;
        struct Node* next;
      }* head;
  };
#endif
```

Figure 167. Header file STACK.H

Sample Language Environment dump with C/C++-specific information

This sample dump was produced by compiling the routines shown in Figure 163 on page 440 and Figure 164 on page 441. They were both compiled using options LP64 and GONUM to produce statement numbers in the CEEDUMP. Notice the sequence of calls in the traceback section - CELQINIT is the Language Environment module that invokes the main entry. `main` calls `fetchPtr()` at statement number 60, which in turn, through @@FECBMODULE1 fetches the user-defined function `func1` shown in Figure 164 on page 441. `func1` calls the library routine `__cdump()` in statement number 5. The complete program unit names for `main` and `func1` are shown in the Fully Qualified Names section along with its load module name.

```
1CEE3DMP V1 R8.0: This is a sample dump                                  Wed Feb 22 21:31:53 2006            Page:    1

Figure 168. Example dump from sample C routine (Part 4 of 4)

C/C++ contents of the Language Environment trace tables

Language Environment provides four C/C++ trace table entry types that contain character data:

- Trace entry 5 occurs when a C library function is called.
- Trace entry 6 occurs when a C library function returns.

The format for trace table entry 5 is:

```
NameOfCallingFunction
-->(xxxx) NameOfCalledFunction<(input_parameters)>
```

or, for called functions calloc, free, malloc, and realloc:

```
NameOfCallingFunction
—>(xxx) NameOfCalledFunction<(input_parameters)>
```

In addition, when the call is due to one of these C++ operators:

```
-new,
-new[],
-delete,
-delete[]
```

then the C++ operator will appear and the format becomes:

```
NameOfCallingFunction
—>(xxx) NameOfCalledFunction<(input_parameters)>

NameOfC++Operator
```

The `input_parameters` and `NameOfC++Operator` only appear for the appropriate functions. The angle brackets (<>) indicate that this information does not always appear.

The format for trace table entry 6 is:

```
    <--(xxxx)
R1=xxxxxxxxxxxxxxxx R2=xxxxxxxxxxxxxxxx R3=xxxxxxxxxxxxxxxx
ERRNO=xxxxxxxx ERRNO2=xxxxxxxx
```

In the entry types, `(xxx)` and `(xxxx)` are numbers associated with the called library function and are used to associate a specific entry record with its corresponding return record.

For entry types 5 and 6, the number will be the same as the number of the function as seen in the C run-time library definition side-deck, SCEELIB dataset member CELQS003, on the IMPORT statement for that function.

Figure 169 on page 449 shows an XPLINK trace which has examples of the trace entries 5 and 6.

```
Language Environment Trace Table:

   Most recent trace entry is at displacement: 000680

     Displacement                    Trace Entry in Hexadecimal                          Trace Entry in EBCDIC

For more information about the Language Environment trace table format, see “Understanding the trace table entry (TTE)” on page 416.

Debugging examples of C/C++ routines

This section contains examples that demonstrate the debugging process for C/C++ routines. Important areas of the output are highlighted. Data unnecessary to the debugging examples has been replaced by ellipses.

Divide-by-zero error

Figure 170 on page 451 illustrates a C program that contains a divide-by-zero error. The code was compiled with `RENT` so static and external variables need to be calculated from the WSA field. The code was compiled with `LP64`, `GONUM` (`to produce statement numbers`) and `XREF`, `LIST` and `OFFSET` to generate a listing, which is used to calculate addresses of functions and data. The code was processed by the binder with `MAP` to generate a binder map, which is used to calculate the addresses of static and external variables. The program was created with the option TERMTHDACT(UADUMP) which produced both a Language environment dump and a system dump.

```
/* C Routine with a Divide-by-Zero Error */
#pragma options(noinline)
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
int statint = 73;
int fa;
int funcb(int *pp);
int main(void) {
  int aa, bb=1;
  aa = bb;
  aa = funcb(&aa);
  return(aa);
}
int funcb(int *pp) {
  int result;
  fa = *pp;
  result = fa/(statint-73);
  printf("Result = %d\n",result);
  return result;
}
```

Figure 170. C routine with a divide-by-zero error

To debug this routine, use the following steps:

1. Locate the Original Condition message in the Condition Information for Active Routines section of the dump. In this example, the message is `CEE3209S`. The system detected a fixed-point divide exception. This message indicates the error was caused by an attempt to divide by zero. For additional information about CEE3209S, see *z/OS Language Environment Run-Time Messages*.

   The traceback section of the dump indicates that the exception occurred at offset X'52' within function `funcb`. This information is used along with the compiler-generated Pseudo Assembly Listing to determine where the problem occurred.

   If the `GONUMBER` compiler option is specified, statement number information is in the dump. Figure 171 on page 452 shows the generated traceback from the dump.

```
CEE3DMP V1 R8.0: Condition processing resulted in the unhandled condition.         Tue Feb 21 16:50:50 2006            Page:    1

Figure 171. Sections of the dump from example C/C++ routine (Part 2 of 2)

2. In the traceback, statement number 12, corresponding to DSA 7, refers to line: `aa = funcb(&aa);` in the listing. This is were entry `funcb` is called. Similarly, statement number 18, corresponding to DSA 6, points to line: `result = fa/(statint-73);` in the listing. This line is where the divide by zero exception takes place.
3. Locate the instruction with the divide-by-zero error in the Pseudo Assembly Listing in Figure 172 on page 454.

   The offset (within `funcb`) of the exception from the traceback (X'52') reveals the divide instruction: `DR R6,R0` at that location. Instructions at offsets X'32' through X'58' refer to the `result = fa/(statint-73);` line of the C/C++ routine.

Figure 172. Pseudo assembly listing (Part 3 of 3)

4. Verify the value of the divisor `statint`. The procedure specified below is to be used for determining the value of static variables only. If the divisor is an automatic variable, there is a different procedure for finding the value of the variable.

   Because this routine was compiled with the RENT option, find the WSA address in the Enclave Control Blocks section of the dump. In this example, this address is X'108300050'. Figure 173 shows the WSA address.

```
Enclave Control Blocks:
  .
  .
  .
  DLL Information:
  WSA Addr          Module Addr          Thread ID         Use Count  Name
  0000000108300050                                         00000001   main
```

Figure 173. C/C++ CAA information in dump

5. Routines compiled with the RENT option must also be processed by the binder. The binder produces the Writable Static Map. Find the offset of `statint` in the Writable Static Map in Figure 174 on page 457. In this example, the offset is X'30'.

```
---------------
CLASS  C_WSA64           LENGTH =       38  ATTRIBUTES = MRG, DEFER , RMODE= 64
                         OFFSET =        0 IN SEGMENT 002       ALIGN = QDWORD
---------------

            CLASS
           OFFSET  NAME                TYPE    LENGTH   SECTION
                0  $PRIV000012      PART            10
               10  CDIVZERO#S       PART            20  CDIVZERO#C
               30  statint          PART             4  statint
               34  fa               PART             4  fa
```

Figure 174. Writable static map

6. Add the WSA address of X'108300050' to the offset of `statint`. The result is X'108300080'. This is the address of the variable `statint`, which is in the writable static area.
7. Use IPCS to display the writeable static area in the system dump. The value at location X'108300080' is X'49' (that is, `statint` is 73), and hence the fixed-point divide exception.

```

Figure 175. IPCS storage display of the writeable static area

Calling a nonexistent function

Figure 176 on page 458 demonstrates the error of calling a nonexistent function. This routine was compiled with the compiler options LP64, GONUM, LIST, OFFSET, and RENT and was run with the option TERMTHDACT(UADUMP).

```
/* C/C++ Example of Calling a Nonexistent Subroutine     */
/*       from LE Debugging Guide                         */
#pragma options(noinline)
#include <stdio.h>
#include <stdlib.h>
#include <errno.h>
#include <signal.h>
void funca(int* aa);
int (*func_ptr)(void)=0;
int main(void) {
  int aa;
  funca(&aa);
  printf("result of funca = %d\n",aa);
  return;
}
void funca(int* aa) {
  *aa = func_ptr();
  return;
}
```

Figure 176. C/C++ example of calling a nonexistent subroutine

To debug this routine, use the following steps:

1. Locate the Original Condition message in the Condition Information for Active Routines section of the dump, shown in Figure 177 on page 459. In this example, the message is `CEE3201S The system detected an operation exception (System Completion Code=0C1).` This message suggests that the error was caused by an attempt to branch to an unknown address. For additional information about CEE3201S, see *z/OS Language Environment Run-Time Messages*.

   The Location section of the dump indicates that the exception occurred at offset X'-209000D0'' within function `funca` and that there may have been a bad branch from statement 17 offset X'+00000036'' within function `funca`. The negative offset indicates that the offset cannot be used to locate the instruction that caused the error. Another indication of bad data is the value of X'00000002' in the instruction address of the PSW shown in the Condition Information section. This address indicates that an instruction in the routine branched outside the bounds of the routine.

   In the traceback, the statement number displayed for entry 'main' points to line 12 in the source code shown in Figure 176. This line contains the statement ″funca(&aa); ″ in which entry 'funca' is called. As message CEE3841I explains, for entry 'funca' no statement number could be displayed. In this example, this problem is caused because 'funca' has an invalid offset. For further information about this message see*z/OS Language Environment Run-Time Messages*.

Figure 178. Pseudo assembly listing (Part 2 of 2)

3. Find the offset of `func_ptr` in the Writable Static Map, shown in Figure 179 on page 464.

```
---------------
CLASS  C_WSA64          LENGTH =       48  ATTRIBUTES = MRG, DEFER , RMODE= 64
                        OFFSET =        0 IN SEGMENT 002       ALIGN = QDWORD
---------------

            CLASS
           OFFSET  NAME                TYPE    LENGTH   SECTION
                0  $PRIV000012      PART            10
               10  EXIST#S          PART            30  EXIST#C
               40  func_ptr         PART             8  func_ptr
```

Figure 179. Writable static map

4. Add the offset of `func_ptr` (X'40') to the address of WSA (X'108300050') (the WSA address was obtained from the dump report in Figure 178 on page 462). The result (X'108300090') is the address of the function pointer `func_ptr` in the writable static storage area. This value is 0, indicating the variable is uninitialized.

   Figure 180 shows the sections of the dump.

```
 LIST 01_08300050. ASID(X'00CC') LENGTH(X'0100') AREA

Figure 180. IPCS storage display of the writeable static area

Handling dumps written to the z/OS UNIX file system

When a z/OS UNIX C/C++ application program is running in an address space created as a result of a call to `spawnp()`, `vfork()`, or one of the `exec` family of functions, the SYSMDUMP DD allocation information is not inherited. Even though the SYSMDUMP allocation is not inherited, a SYSMDUMP allocation must exist in the parent in order to obtain a HFS storage dump. If the program terminates abnormally while running in this new address space, the kernel causes an unformatted storage dump to be written to an HFS file in the user's working directory. The file is placed in the current working directory or into /tmp if the current working directory is not defined. The file name has the following format:

```
/directory/coredump.pid
```

where directory is the current working directory or tmp, and pid is the hexadecimal process ID (PID) for the process that terminated. For details on how to generate the system dump, see "Steps for generating a system dump in a z/OS UNIX shell" on page 364.

To debug the dump, use the Interactive Problem Control System (IPCS). If the dump was written to an HFS file, you must allocate a data set that is large enough and has the correct attributes for receiving a copy of the HFS file. For example, from the ISPF DATA SET UTILITY panel you can specify a volume serial and data set name to allocate. Doing so brings up the DATA SET INFORMATION panel for specifying characteristics of the data set to be allocated. The following filled-in panel

shows the characteristics defined for the URCOMP.JRUSL.COREDUMP dump data set:

```
-------------------------  DATA SET INFORMATION  ----------------------
Command ===>

Data Set Name  . . . : URCOMP.JRUSL.COREDUMP

General Data                          Current Allocation
 Management class . . : STANDARD       Allocated cylinders : 30
 Storage class  . . . : OS390          Allocated extents . : 1
  Volume serial . . . : DPXDU1
  Device type . . . . : 3380
 Data class . . . . . :
  Organization  . . . : PS            Current Utilization
  Record format . . . : FB             Used cylinders. . . : 0
  Record length . . . : 4160           Used extents  . . . : 0
  Block size  . . . . : 4160
  1st extent cylinders: 30
  Secondary cylinders : 10
  Data set name type  :

  Creation date . . . : 2001/08/30
  Expiration date . . : ***None***

F1=Help     F2=Split     F3=End       F4=Return    F5=Rfind     F6=Rchange
F7=Up       F8=Down      F9=Swap     F10=Left     F11=Right    F12=Cancel
```

Figure 181. IPCS panel for entering data set information

Fill in the information for your data set as shown, and estimate the number of cylinders required for the dump file you are going to copy.

Use the TSO/E OGET or OCOPY command with the BINARY keyword to copy the file into the data set. For example, to copy the HFS memory dump file `coredump.00060007` into the data set URCOMP.JRUSL.COREDUMP just allocated, a user with the user ID URCOMP enters the following command:

```
OGET '/u/urcomp/coredump.00060007' 'urcomp.jrusl.coredump' BINARY
```

For more information on using the copy commands, see *z/OS UNIX System Services User's Guide*.

After you have copied the memory dump file to the data set, you can use IPCS to analyze the dump. Refer to "Formatting and analyzing system dumps" on page 365 for information about formatting Language Environment control blocks.

Multithreading consideration

Certain control blocks are locked while a dump is in progress. For example, a `csnap()` of the file control block would prevent another thread from using or dumping the same information. An attempt to do so causes the second thread to wait until the first one completes before it can continue.

Understanding C/C++ heap information in storage reports

Storage reports that contain specific C/C++ heap information can be generated in two ways:

- By setting the Language Environment RPTSTG(ON) run-time option for Language Environment created heaps
- By issuing a stand-alone call to the C function `__uheapreport()` for user–created heaps.

Details on how to request and interpret the reports are provided in the following sections.

Language Environment storage report with HeapPools statistics

To request a Language Environment storage report set RPTSTG(ON). If the C/C++ application specified the HEAPPOOLS64(ON) run-time option, then the storage report displays HeapPools statistics. For a sample storage report showing HeapPools statistics for a multithreaded C/C++ application, see Figure 138 on page 332.

The following describes the C/C++ specific heap pool information.

HeapPools storage statistics

The HEAPPOOLS64 run-time option controls usage of the heap pools storage algorithm at the enclave level. The heap pools algorithm allows for the definition of one to twelve heap pools, each consisting of a number of storage cells of a specified length.

Usage Note: The use of an alternative Vendor Heap Manager (VHM) overrides the use of the HEAPPOOLS64 run-time option.

HeapPools statistics:

- Pool *p* size: *ssss*
  - *p* — the number of the pool
  - *ssss* — the cell size specified for the pool.
- Successful Get Heap requests: *xxxx-yyyy n*
  - *xxxx* — the low side of the 8 byte range
  - *yyyy* — the high side of the 8 byte range
  - *n* — the number of requests in the 8 byte range.
- Requests greater than the largest cell size — the number of storage requests that are not satisfied by heap pools.

Note: Values displayed in the HeapPools Statistics report are not serialized when collected, therefore the values are not necessarily exact.

HeapPools summary: The HeapPools Summary displays a report of the HeapPool Statistics and provides suggested percentages for current cell sizes as well as suggested cell sizes.

- Specified Cell Size — the size of the cell specified in the HEAPPOOLS64 run-time option
- Element Size — the size of the cell plus any additional storage needed for control information or to maintain alignment
- Cells Per Extent — the cell pool count specified by the HEAPPOOLS64 run-time option
- Extents Allocated — the number of times that each pool allocated an extent in order to optimize storage usage. The extents allocated should be either one or two. If the number of extents allocated is too high, increase the cell count for the pool.
- Maximum Cells Used — the maximum number of cells used for each pool.
- Cells In Use — the number of cells that were never freed.

  Note: A large number in this field could indicate a storage leak.

- Suggested Cell Sizes — sizes that are calculated to optimally use storage (assuming that the application will __malloc/__free with the same frequency).

  Note: The suggested cell sizes are given with no cell counts because the usage of each new cell pool size is not known. If there are less than 12 cell sizes calculated, then the last pool size is set at 65536.

For more information about stack and heap storage for AMODE64 applications, see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode*.

C function __uheapreport() storage report

To generate a user-created heap storage report use the C function, `__uheapreport()`. Use the information in the report to assist with tuning your application's use of the user-created heap.

User-created HeapPools statistics

- Pool *p* size: *ssss*
  - *p* — the number of the pool
  - *ssss* — the cell size specified for the pool.
- Successful Get Heap requests: *xxxx-yyyy n*
  - *xxxx* — the low side of the range
  - *yyyy* — the high side of the range
  - *n* — the number of requests in the range.
- Requests greater than the largest cell size — the number of storage requests that are not satisfied by heap pools.

Note: Values displayed in the HeapPools Statistics report are not serialized when collected, therefore the values are not necessarily exact.

HeapPools summary

The HeapPools Summary displays a report of the HeapPool Statistics and provides suggested percentages for current cell sizes as well as suggested cell sizes.

- Cell Size — the size of the cell specified on the __ucreate() call
- Cells Per Extent — the cell pool count specified on the __ucreate() call
- Extents Allocated — the number of times that each pool allocated an extent in order to optimize storage usage.
- Maximum Cells Used — the maximum number of cells used for each pool.
- Cells In Use — the number of cells that were never freed.

  Note: A large number in this field could indicate a storage leak.
- Suggested Cell Sizes — sizes that are calculated to optimally use storage (assuming that the application will __umalloc/__ufree with the same frequency).

  Note: The suggested cell sizes are given with no cell counts because the usage of each new cell pool size is not known. If there are less than 12 cell sizes calculated, then the last pool size is set at 65536.

For more information on the `__uheapreport()` function, see *z/OS XL C/C++ Run-Time Library Reference*. For tuning tips, see *z/OS Language Environment Programming Guide for 64-bit Virtual Addressing Mode*.

A sample storage report generated by __uheapreport() is shown in Figure 182.

```
Storage Report for Enclave  Tue Apr 20 20:29:08 2004
Language Environment V01 R06.00

    HeapPools Statistics:
      Pool  1 size:    32
        Successful Get Heap requests:      -                        15
      Pool  2 size:   128
        Successful Get Heap requests:      -                        15
      Pool  3 size:   512
        Successful Get Heap requests:      -                        15
      Pool  4 size:  2048
        Successful Get Heap requests:      -                        15
      Pool  5 size:  8192
        Successful Get Heap requests:      -                        15
      Pool  6 size: 16384
        Successful Get Heap requests:      -                        15
      Requests greater than the largest cell size:                 0
    HeapPools Summary:
      Cell     Cells Per   Extents    Maximum        Cells In
      Size     Extent      Allocated  Cells Used     Use

Figure 182. Storage report generated by __uheapreport()

Appendix A. Diagnosing problems with Language Environment

This appendix provides information for diagnosing problems in the Language Environment product. It helps you determine if a correction for a product failure similar to yours has been previously documented. If the problem has not been previously reported, it tells you how to open a problem management record (PMR) to report the problem to IBM, and if the problem is with an IBM product, what documentation you need for an Authorized Program Analysis Report (APAR).

Diagnosis checklist

Step through each of the items in the diagnosis checklist below to see if they apply to your problem. The checklist is designed to either solve your problem or help you gather the diagnostic information required for determining the source of the error. It can also help you confirm that the suspected failure is not a user error; that is, it was not caused by incorrect usage of the Language Environment product or by an error in the logic of the routine.

1. If your failing application contains programs that were changed since they last ran successfully, review the output of the compile or assembly (listings) for any unresolved errors.
2. If there have not been any changes in your applications, check the output (job or console logs, CICS transient (CESE) queues) for any messages from the failing run.
3. Check the message prefix to identify the system or subsystem that issued the message. This can help you determine the cause of the problem. Following are some of the prefixes and their respective origins.

   EDC The prefix for C/C++ messages. The following series of messages are from the C/C++ run-time component of Language Environment: 5000 (except for 5500, which are from the DSECT utility), 6000, and 7000.

   IGZ The prefix for messages from the COBOL run-time component of Language Environment.

   FOR The prefix for messages from the Fortran run-time component of Language Environment.

   IBM The prefix for messages from the PL/I run-time component of Language Environment.

   CEE The prefix for messages from the common run-time component of Language Environment.
4. For any messages received, check for recommendations in the “Programmer Response” sections of the messages in this manual.
5. Verify that abends are caused by product failures and not by program errors. See the appropriate chapters in this manual for a list of Language Environment-related abend codes.
6. Your installation may have received an IBM Program Temporary Fix (PTF) for the problem. Verify that you have received all issued PTFs and have installed them, so that your installation is at the most current maintenance level.

7. The preventive service planning (PSP) bucket, an online database available to IBM customers through IBM service channels, gives information about product installation problems and other problems. Check to see whether it contains information related to your problem.
8. Narrow the source of the error.
   - If a Language Environment dump is available, locate the traceback in the Language Environment dump for the source of the problem.
   - For AMODE 64 applications, IBM recommends that you use the IPCS Verbexit IEDATA with the CEEDUMP option to format the traceback. Check the traceback for the source of the problem. For information on how to generate and use a Language Environment or system dump to isolate the cause of the error, see Chapter 3, “Using Language Environment debugging facilities,” on page 35 or Chapter 12, “Using Language Environment AMODE 64 debugging facilities,” on page 343.
   - Alternatively, in a non-XPLINK environment, you can follow the save area chain to find out the name of the failing module and whether IBM owns it. For information on finding the routine name, see “Locating the name of the failing routine for a non-XPLINK application.”
9. After you identify the failure, consider writing a small test case that re-creates the problem. The test case could help you determine whether the error is in a user routine or in the Language Environment product. Do not make the test case larger than 75 lines of code. The test case is not required, but it could expedite the process of finding the problem.

   If the error is not a Language Environment failure, refer to the diagnosis procedures for the product that failed.
10. Record the conditions and options in effect at the time the problem occurred. Compile your program with the appropriate options to obtain an assembler listing and data map. If possible, obtain the binder or linkage editor output listing. Note any changes from the previous successful compilation or run. For an explanation of compiler options, refer to the compiler-specific programming guide.
11. If you are experiencing a no-response problem, try to force a dump. For example, CANCEL the program with the dump option.
12. Record the sequence of events that led to the error condition and any related programs or files. It is also helpful to record the service level of the compiler associated with the failing program.

Locating the name of the failing routine for a non-XPLINK application

If a system dump is taken, follow the save area chain to find out the name of the failing routine and whether IBM owns it. Following are the procedures for locating the name of the failing routine, which is the primary entry point name.

1. Find the entry point associated with the current save area. The entry point address (EPA), located in the previous save area at displacement X'10', decimal 16, points to it.
2. Determine the entry point type, of which there are four:

Entry point type is...	If...
Language Environment conforming	The entry point plus 4 is X'00C3C5C5'.
Language Environment conforming OPLINK	The entry point plus 4 is X'01C3C5C5'. OPLINK linkage conventions are used.
C/C++	The entry point plus 5 is X'CE'.

Entry point type is...	If...
Nonconforming	The entry point is none of the above. Nonconforming entry points are for routines that follow the linking convention in which the name is at the beginning of the routine. X'47F0Fxxx' is the instruction to branch around the routine name.

For routines with Language Environment-conforming and C/C++ entry points, Language Environment provides program prolog areas (PPAs). PPA1 contains the entry point name and the address of the PPA2; PPA2 contains pointers to the timestamp, where release level keyword information is found, and to the PPA1 associated with the primary entry point of the routine.

If the entry point type of the failing routine is Language Environment-conforming, go to step 3.

If the entry point type is C/C++, go to step 5.

If the entry point type is nonconforming, go to step 6 on page 472.

3. If the entry point type is Language Environment-conforming, find the entry point name for the Language Environment or COBOL program.
   a. Use an offset of X'C' from the entry point to locate the address of the PPA1.
   b. In the PPA1, locate the offset to the length of the name. If OPLINK, then multiply the offset by 2 to locate the actual offset to the length of the name.
   c. Add this offset to the PPA1 address to find the halfword containing the length of the name, followed by the entry point name.

      The entry point name appears in EBCDIC, with the translated version in the right-hand margin of the system dump.
4. Find the Language Environment or COBOL program name.
   a. Find the address of the PPA2 at X'04' from the start of the PPA1.
   b. Find the address of the compilation unit's primary entry point at X'10' in the PPA2.
   c. Find the entry point name associated with the primary entry point as described above. The primary entry point name is the routine name.

   See *z/OS Language Environment Vendor Interfaces* for illustrations and details of:
   - the non-XPLINK Language Environment-conforming PPA1 and PPA2.
   - the XPLINK Language Environment-conforming PPA1, and the XPLINK PPA1 optional area fields.
   - the non-XPLINK Language Environment PPA2.
   - the Language Environment PPA2: Compile Unit Block for XPLINK.
   - the PPA2 timestamp and version information.
5. If the entry point type is C/C++, find the C/C++ routine name.
   a. Use the entry point plus 4 to locate the offset to the entry point name in the PPA1.
   b. Use this offset to find the length-of-name byte followed by the routine name.

      The routine name appears in EBCDIC, with the translated version in the right-hand margin.

   Figure 183 on page 472 illustrates the C PPA1.

C Routine Layout Entry and PPA1

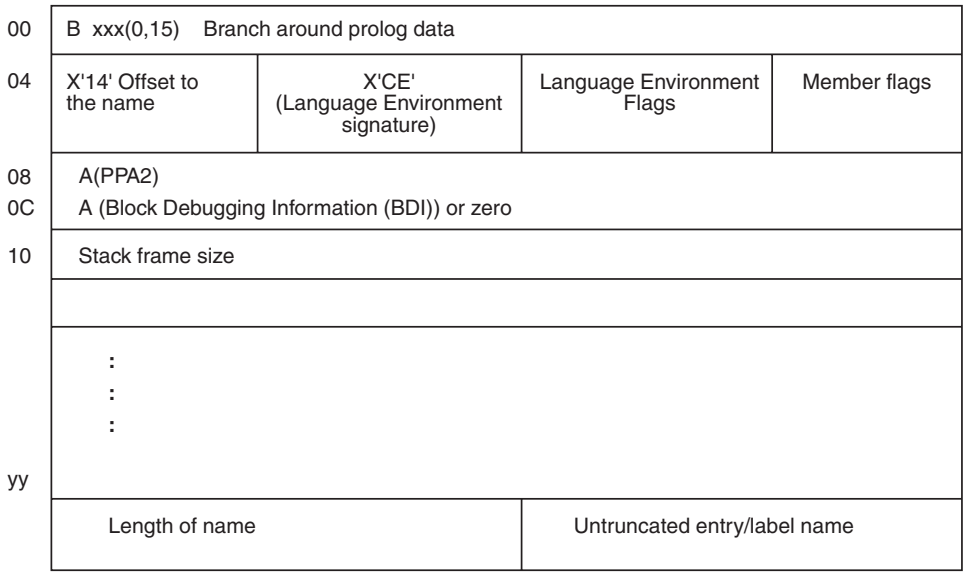

Figure 183. C PPA1

6. If the entry point type is nonconforming, find the PL/I routine name.
   a. Find the one byte length immediately preceding the entry point. This is the length of the routine name.
   b. Go back the number of bytes specified in the name length. This is the beginning of the routine name.
7. If the entry point type is nonconforming, find the name of the routine other than PL/I.
   a. Use the entry point plus 4 as the location of the entry point name.
   b. Use the next byte as the length of the name. The name directly follows the length of name byte. The entry point name appears in EBCDIC with the translated version in the right-hand margin.

   Figure 184 illustrates a nonconforming entry point type.

   Nonconforming entry points that can appear do not necessarily follow this linking convention. The location of data in these save areas can be unpredictable.

Searching the IBM Software Support Database

Failures in the Language Environment product can be described through the use of keywords. A keyword is a descriptive word or abbreviation assigned to describe one aspect of a product failure. A set of keywords, called a keyword string, describes the failure in detail. You can use a keyword or keyword string as a search argument against an IBM software support database, such as the Service Information Search (SIS). The database contains keyword and text information describing all current problems reported through APARs and associated PTFs. IBM Support Center personnel have access to the software support database and are responsible for storing and retrieving the information. Using keywords or a keyword string, they will search the database to retrieve records that describe similar known problems.

If you have IBMLink™ or some other connection to the IBM databases, you can do your own search for previously recorded product failures before calling the IBM Support Center.

If your keyword or keyword string matches an entry in the software support database, the search may yield a more complete description of the problem and possibly identify a correction or circumvention. Such a search may yield several matches to previously reported problems. Review each error description carefully to determine if the problem description in the database matches the failure.

If a match is not found, go to “Preparing documentation for an Authorized Program Analysis Report (APAR).”

Preparing documentation for an Authorized Program Analysis Report (APAR)

Refer to http://techsupport.services.ibm.com/guides/handbook.html for detailed information.

Prepare documentation for an APAR only after you have done the following:

- Eliminated user errors as a possible cause of the problem.
- Followed the diagnostic procedures.
- You or your local IBM Support Center has been unsuccessful with the keyword search.

Having met these criteria, follow the instructions below.

1. Report the problem to IBM.

   If you have not already done so, report the problem to IBM by opening a problem management record (PMR).

   If you have IBMLink or some other connection to IBM databases, you can open a PMR yourself. Or, the IBM Software Support Center can open the PMR after consulting with you on the phone. The PMR is used to document your problem and to record the work that the Support Center does on the problem. Be prepared to supply the following information:

   - Customer number
   - PMR number
   - Operating system
   - Operating system release level
   - Your current Language Environment maintenance level (PTF list and list of APAR fixes applied)

- Keyword strings you used to search the IBM software support database
- Processor number (model and serial)
- A description of how reproducible the error is. Can it be reproduced each time? Can it be reproduced only sometimes? Have you been unable to reproduce it? Supply source files, test cases, macros, subroutines, and input files required to re-create the problem. Test cases are not required, but can often speed the response time for your problem.

If the IBM Support Center concludes that the problem described in the PMR is a problem with the Language Environment product, they will work with you to open an APAR, so the problem can be fixed.

2. Provide APAR documentation. When you submit an APAR, you will need to supply information that describes the failure. Table 35 describes how to produce documentation required for submission with the APAR.

Table 35. Problem resolution documentation requirements

Item	Materials Required	How to Obtain Materials
1	Machine-readable source program, including macros, subroutines, input files, and any other data that might help to reproduce the problem.	IBM-supplied system utility program
2	Compiler listings: • Source listing • Object listing • Storage map • Traceback • Cross-reference listing • JCL listing and linkage editor listing • Assembler-language expansion	Use appropriate compiler options
3	Dumps • Language Environment dump • System dump	See instructions in Chapter 3, “Using Language Environment debugging facilities,” on page 35 (as directed by IBM support personnel).
4	Partition/region size/virtual storage size	
5	List of applied PTFs	System programmer
6	Operating instructions or console log	Application programmer
7	JCL statements used to invoke and run the routine, including all run-time options, in machine-readable form	Application programmer
8	System output associated with the MSGFILE run-time option.	Specify MSGFILE(SYSOUT)
9	Contents of the applicable catalog	
10	A hardcopy log of the events leading up to the failure.	Print out each display.

3. Submit the APAR documentation.

   When submitting material for an APAR to IBM, carefully pack and clearly identify any media containing source programs, job stream data, interactive environment information, data sets, or libraries.

   All magnetic media submitted must have the following information attached and visible:

- The APAR number assigned by IBM.
- A list of data sets on the tape (such as source program, JCL, data).
- A description of how the tape was made, including:
  - The exact JCL listing or the list of commands used to produce the machine-readable source. Include the block size, LRECL, and format of each file. If the file was unloaded from a partitioned data set, include the block size, LRECL, and number of directory blocks in the original data set.
  - Labeling information used for the volume and its data sets.
  - The recording mode and density.
  - The name of the utility program that created each data set.
  - The record format and block size used for each data set.

  Any printed materials must show the corresponding APAR number.

  The IBM service personnel will inform you of the mailing address of the service center nearest you.

  If an electronic link with IBM Service is available, use this link to send diagnostic information to IBM Service.

After the APAR is opened and the fix is produced, the description of the problem and the fix will be in the software support database in SIS, accessible through ServiceLink.

Appendix B. Accessibility

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products successfully. The major accessibility features in z/OS enable users to:

- Use assistive technologies such as screen readers and screen magnifier software
- Operate specific or equivalent features using only the keyboard
- Customize display attributes such as color, contrast, and font size

Using assistive technologies

Assistive technology products, such as screen readers, function with the user interfaces found in z/OS. Consult the assistive technology documentation for specific information when using such products to access z/OS interfaces.

Keyboard navigation of the user interface

Users can access z/OS user interfaces using TSO/E or ISPF. Refer to *z/OS TSO/E Primer*, *z/OS TSO/E User's Guide*, and *z/OS ISPF User's Guide Vol I* for information about accessing TSO/E and ISPF interfaces. These guides describe how to use TSO/E and ISPF, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

z/OS information

z/OS information is accessible using screen readers with the BookServer/Library Server versions of z/OS books in the Internet library at:

`http://www.ibm.com/servers/eserver/zseries/zos/bkserv/`

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used.
