# Chapter 1

## Introduction

When siting antennas on large structures, it is desirable to be able to quickly determine the clear line of sight transmission or reception paths for the antennas. If the structure under consideration is a space station, there will be many antennas to consider in an environment composed of a very large and complex array of living and working module, solar panels, and support structures. The antennas will potentially need to communicate with systems anywhere around the near zone of the structure and the complete far zone sphere. In short, a challenging problem.

In order to aid the antenna design engineer in the prediction of the near and far zone antenna patterns, antenna to antenna coupling, and radiation hazard considerations, for high frequency antennas in a complex environment, a couple of user oriented computer codes have been developed: the NEC - Basic Scattering Code (NEC-BSC) [1,2] and the Aircraft Code (NEWAIR) [3]. Both codes are based on the Uniform Geometrical Theory of Diffraction (UTD) [4], which is a high frequency ray optical method with corrections at shadow boundaries. The UTD is ideal for construction of efficient computer codes, such as these, for modeling the scattering from large structures. The NEC-BSC and NEWAIR are complementary codes, that is, the NEC-BSC is used when the antennas are not mounted on a curved surface, and the NEWAIR is used when the antennas are mounted on a curved surface. Both codes use plates to model flat structures, the NEC-BSC presently uses finite elliptic cylinders to model curved surfaces, and the NEWAIR presently uses ellipsoids.

Although the two UTD codes are presently very useful for predicting the performance of antennas in a complex environment, such as a space station, there are a few important considerations that should be taken into account. First, the present versions of these codes were not specifically developed for a space station application. The NEC-BSC was developed for ships and the NEWAIR for aircraft. Second and most importantly, even though they run fast for large size structures in terms of a wavelength, as compared with computer codes using other theories, such as method of moments; a problem with as many structural pieces as a space station can take a very long time to calculate a volumetric pattern. This means that the problem of antenna siting in a large structural environment should be viewed as a multiple stepped procedure to optimize results for minimum time and cost.

The design procedure for antenna siting can be viewed as a three step process, as far as the computer codes are concerned. First, it can generally be assumed that a good antenna location will provide a clear line of sight path between transmitter and receiver over the desired range of operation. This can best be accomplished using an obscuration code, which

is the goal of this computer code and document. This code will provide a volumetric shadow map of the projected shadow of a structure onto the far zone sphere centered at the antenna location. It is very fast running on space station applications and can be run interactively providing nearly immediate answers depending on the overall useage of the computer.

Second, a worst case code could be developed that will predict not only the clear line of sight regions, but will also map out the maximum values of the various field terms, such as the reflected and diffracted lobes. These scattered fields can cause undesired lobes to show up in the region of interest. This type of code will not only provide an answer to the question of where the optimum location for an antenna system should be, but also how it should be oriented at that position and what the gain and side lobe levels would be optimum. It can be designed to run at a little additional time cost over the obscuration code.

The final step would be to run a field prediction code such as the NEC-BSC and NEWAIR codes or their future versions optimized for the space station. This would be the confirmation phase of the design procedure to make sure that no surprises occur in the volumetric patterns. At this stage, it does not matter that the codes take a little longer to run, especially for the wealth of information that they produce. Of course, these results can be used to compare with measured results on scale models to validate the measurements and vice versa.

This document is concerned with the obscuration code, referred to here as "SHADOW". It has been specifically design with space station applications in mind. It directly solves for a shadow map by projecting the border of multiple sided flat plates and composite cone frusturns of elliptic cross section onto the far zone sphere. It then fills between the borders based on a pixel resolution and window size specified by the user. The definition of the geometry is based on a subset of the command word input system used for the UTD codes. This means that as the engineer proceeds through a design scenario progressing through the different levels of codes, there will be a minimum amount of conversion of input information.

The obscuration code has proven to be so efficient, that it was felt that it could be of great benefit to the design engineer to be able to run it in an interactive mode. Unfortunately, interactive procedures are not generally transportable between different computer systems. Because of the wide availability of DEC VAX computers in the engineering environment, and because of the ease of developing an interactive system on a VAX, the interactive features have been developed using devise dependent software for the VAX. The non-interactive and interactive parts of the code have been kept separate, however, so that the code can be run non-interactively without much change.

This document is divided into two parts. Part I is a user manual, that treats the code more or less as a black box device. It is about all that will be need for the average user to get started and obtain results. Chapter 2 describes the method that is used to obtain the shadow. The overall view of the operation of the code is given in Chapter 3. It describes the non-interactive and interactive commands in a qualitative way. A dictionary of all the non-interactive commands needed in the SHADOW code is given in Chapter 4. It gives the details for inputting each command. Chapter 5 provides the details for the interactive commands. The output features are interpreted in Chapter 6. Examples on how to use the code are given in Chapter 7. When first learning how to use the code, it is essential to be able to reproduce some of these examples to be sure that the code is functioning properly

on your system.

Part II of this document is a code manual. It goes into more specific information about the coding itself. It is of importance primarily for people implementing the code on a new system, for debugging errors, or for making changes in how the code operates. An overview of how the code is organized is given in Chapter 9. A listing of the code is given in Chapter 10. It is broken up into three parts for the non-interactive, FORTRAN 77 subroutines and into the interactive VAX dependent subroutines. The implementation of the code on a VAX is given in Chapter 11 and a brief description of implementing the code on a non-VAX computer is given in Chapter 12. A listing of an NCAR plotting code for the shadow map is given in Chapter 13.

## Chapter 2

### Method

The first gauge of the ability of two antenna systems to communicate with one another at high frequencies is to determine if there is a clear line of sight path between them. This can be conveniently represented by a map of the projected shadow on the far zone sphere caused by the structures around an antenna's environment. One method of producing a shadow map is to choose an observation point on the far zone sphere and then determine if anything obscures the path and then move on to the next point. This method is slow, however, because there must be many repeated tests on the same blocking structures for the various observation point making up the shadow map.

In order to have quick turn around for antennas mounted on large structures, it is desirable to use a method that will directly produce the shadow projected onto the far zone sphere. This can be accomplished in a two step process. First the outside boundary of each individual piece making up the structure can be transformed from the  $x, y, z$  coordinate system into a sequence of lines in the  $\theta$  and  $\phi$  pattern coordinate system. The area of the shadow map between the boundary lines for each piece may then be filled by looking at the center location between the lines and a shadow check on that piece of the structure can be performed. This reduces the test on each piece of structure from once every observation point to a few tests every pattern cut line. The calculation time, in general, is reduced by about two orders of magnitude. For example, instead of taking two hours, a map can conservatively be produced in about one minutes or better. These numbers dependent on the geometry, the window size of the map, and the resolution desired.

There are two fundamental types of structural pieces presently available for modeling in this obscuration code, the multiple sided flat plate and the multiple rimmed composite cone frustum of elliptic cross section. More than one plate or cylinder can be specified to build up a complex structure. A plate can be defined by the location of its corners in a reference coordinate system. A cone frustum can be defined by the size of its major and minor radii for each rim making up the composite cylinder.

The boundary of the structures are traced onto the far zone sphere by defining a vector from the source position,  $\bar{R}_s$ , to some position along its outer boundary,  $\bar{R}_i$ , such that

$$\bar{R} = \bar{R}_i - \bar{R}_s.$$

In the case of the plate, the boundary is defined by some location along its edges, as illustrated in Figure 2.1. This vector can then be transformed into the pattern cut coordinate system, since the pattern may be defined relative to a different set of axes. The vector can

Figure 2.1: Geometry showing the projection of the plate edge onto the far zone sphere.

then be transformed onto the two dimensional far zone sphere by

$$\theta = \arctan \left( \hat{\rho} \cdot \bar{R} / \hat{z} \cdot \bar{R} \right)$$

and

$$\phi = \arctan \left( \hat{y} \cdot \bar{R} / \hat{x} \cdot \bar{R} \right).$$

The position of the vector along the edge is defined by starting at a corner and then incrementing the edge in steps of  $\delta t$  along the edge. In order to provide the most efficient performance and the best image of the shadow on the map, it is necessary to define  $\delta t$  as a function of the chosen resolution desired for the map,  $\delta\alpha$ , the distance,  $R$ , from the source to the edge point and the relative position of the projected shadow point with respect to the polar caps, *the Greenland effect*.

The resolution,  $\delta\alpha$  is chosen to be the minimum of the two specified incremental values of  $\theta$  and  $\phi$ . The distance  $R$  is defined as  $R = |\bar{R}_s - \bar{R}_i|$ . Assuming that the resolution increment is small and the distance is relatively large, the value of the edge increment is given by

$$\delta t = \delta\alpha R \sin \theta.$$

The new edge point then becomes

$$\bar{R}_{i+1} = \bar{R}_i + \delta t \hat{e},$$

where  $\hat{e}$  is the edge vector pointing from the first corner to the second corner making up the edge.

The composite cone frustum can be done in the same way as the plate. In fact the end caps can be defined as plates with curved edges and the curved surfaces are added as edges whose corners are the tangent points illustrated in Figure 2.2.

Once a give plate or cylinder outer boundary is transformed onto the shadow map and stored in pixels of the desired resolution, the fill process can begin. The pixel array is considered one row at a time in a scanning operation from the one range of theta embodied in the pixel array to the other. The direction of the scan and the order in which rows are scanned is arbitrary. The fill process is the same for each scan line in the pixel array so that no logical interaction between lines takes place. The process is similar to the way in which a television paints pictures one row at a time on the screen. As the scan proceeds say from left to right, unlit pixels between object boundaries on the line which correspond to regions in the interior of the object are turned on creating an area fill. The decision to light a group of pixels on a given row is not made by testing each pixel individually for obscuration but by making a single test between the pixels which represent boundaries of the projected regions. In this way, only a single test is made to determine whether a whole group of pixels represent the interior or exterior of a region. This is one major key to the sizable reduction of processor time achieved.

The shadow test for a plate is made by first projecting the vector chosen at the mid point of the scan line,  $\hat{r}$ , onto the plane of the plate to find its intersection point, as shown in Figure 2.3, that is

$$\bar{R}_t = \bar{R}_s - \frac{[\hat{n} \cdot (\bar{R}_s - \bar{C}_1)] \hat{r}}{\hat{n} \cdot \hat{r}}.$$

Figure 2.2: Geometry showing the projection of a cone frustum onto the far zone sphere.

Figure 2.3: Intersection of observation direction vector with plate.

Now, using an idea based on Cauchy's formula from complex variables, that is,

$$\oint_C f(z) dz = \begin{cases} 0, & \text{no pole in } f(z) \\ 2\pi j, & \text{one pole in } f(z) \end{cases}$$

the intersection point can be tested to see whether or not it falls within the limits of the plate. This is illustrated in Figure 2.4.

It is easy to show that

$$\theta_m = \arctan \left[ \frac{[(\bar{C}_m - \bar{R}_t) \times (\bar{C}_{m+1} - \bar{R}_t)] \cdot \hat{n}}{(\bar{C}_m - \bar{R}_t) \cdot (\bar{C}_{m+1} - \bar{R}_t)} \right]$$

which leads to the test, if

$$\left| \sum_{m=1}^M \theta_m \right| = \begin{cases} < \pi, & \text{no hit occurs} \\ > \pi, & \text{a hit occurs} \end{cases}$$

The end caps of the cone frustum cylinders can be done in the same way, by projecting the hit point in the plane of the end cap. The hit point distance can be tested from the center of the disk to see if it falls within the finite limits of a disk to simplify things a little. The curved surface test is a different matter, but still quite easy to accomplish. A vector on the surface of the cone frustum can be represented as

$$\bar{R}_c = \bar{R} + \bar{R}_s$$

or

$$\bar{R}_c = (R \cos \phi \sin \theta + x_s)^2 \hat{x} + (R \sin \phi \sin \theta + y_s)^2 \hat{y} + (R \cos \theta + z_s)^2 \hat{z}.$$

The geometry is illustrated in Figure 2.5. The point defined by  $\bar{R}_c$  should satisfy the equation for a cone, that is,

$$\frac{(R \cos \theta + x_s)^2}{a_j^2} + \frac{(R \sin \phi \sin \theta + y_s)^2}{b_j^2} - \lambda_j^2 (R \cos \theta + z_s) = 0$$

where

$$\lambda_j (R \cos \theta + z_s) = \left[ 1 + \frac{1}{a_j} \tan \theta_j (R \cos \theta + z_s - z_j) \right].$$

The distance R is unknown in this equation, since we know the direction to the observer,  $\theta$  and  $\phi$ , but not the distance to the hit point. We can solve for R, however, from the above equations using

$$\alpha R^2 + 2\beta R + \gamma = 0,$$

where

$$\alpha = \frac{\cos^2 \phi \sin^2 \theta}{a_j^2} + \frac{\sin^2 \phi \sin^2 \theta}{b_j^2} - \frac{\tan^2 \theta_j \cos^2 \theta}{a_j^2},$$

$$\beta = \frac{x_s \cos \phi \sin \theta}{a_j^2} + \frac{y_s \sin \phi \sin \theta}{b_j^2} - \tan \theta_j \cos \theta \lambda_j(z_s),$$

(a) RAY HITS PLATE

(b) RAY DOES NOT HIT PLATE

Figure 2.4: The geometry for deciding whether a ray does or does not hit the plate.

Figure 2.5: Geometry illustrating the hit point on a cone frustum segment.

and

$$\gamma = \frac{x_o^2}{a_j^2} + \frac{y_o^2}{b_j^2} - \lambda_j^2(z_o).$$

If the value of R is real, then the hit point is on the finite cone frustum and therefore the ray from the source to observer is shadowed. If the actual hit point is desired it should be noted that there are two values found from this equation, and that the right hit point can be found from the one representing the shortest distance. If the value of R is imaginary, however, this indicates that the hit point is off the real boundary of the cone frustum and therefore the ray is not shadowed. If R is real, an additional test must be made to decide whether the hit point is between the finite length bounds of the frustum.

The basic theory discussed here is rather straight forward. The implementation, of course, requires a lot of other considerations to be user friendly and as general purpose as possible. The next chapter will go into more detail about how the code interfaces with the operator.

## Chapter 3

### Principle of Operation

#### 3.1 Overview

The Obscuration Code is intended to be an efficient means of determining the clear line of sight path for an antenna mounted in a complex environment. This code produces a shadow map of the geometry for a given source location. The configuration is defined using a command word system as discussed below. The geometry of the structure is defined by using plates and cylinders. It is thought that the obscuration code is just one step in a total evaluation scheme. The next step would be to either look at a "worst case" map that projects the location of the maximum lobes on to a volumetric map or to calculate the fields using a code like the NEC-BSC. In any case, the real fields should be calculated as the final step whether an intermediate one is used or not. For this reason, the geometry definition is based on the NEC-BSC code method of inputting information.

The obscuration code, however, is a very efficient means of providing a shadow map. It can be run in a matter of minutes or less for a given shadow map. It is, therefore, felt that it can be most efficiently run interactively, that is with the user sitting at a terminal changing antenna locations, looking at the resultant maps, deciding where to try the next antenna location until the desired optimum spot is found to achieve a given performance. For this reason the code has been developed in two pieces. One is a standard FORTRAN 77 part that does the essential shadowing calculations. The second is an interactive part that allows the user to change the source locations and window size without leaving the code. Unfortunately, this second part of the code is by nature device dependent. This part has been written for the DEC VAX series of computers using version 4 of VMS. It uses system handlers for defining the commands discussed in the sections below for the interactive commands and the keypad mode. The keys on the keypad of VT100 or VT200 series terminals can be used to represent the typed commands. This will simplify the use of the code by reducing the amount of typing necessary.

This chapter tries to give a brief overview of the specifics needed to run the code by treating it as a black box. It is intended to just get the user comfortable with the overall philosophy of the obscuration code.

## 3.2 Modeling the Structures

The building blocks available for the obscuration code are composed of pieces that are an extension of version 2 of the NEC-BSC [1]. Structures can be modeled using multiple sided flat plates and multiple rimmed cone frustum cylinders. The plates can be used individually to model things like solar panels or together to form box like structures to model things like the mast, etc. The cone frustums are a new feature here, and can be handy for modeling living modules, etc. Examples of space station models are given in Chapter 7.

Unlike the NEC-BSC, there are no real restrictions on how these structures are defined. Since the code just looks at each defined piece of the modeled structure individually, casts its shadow, then moves on to the next piece, it does not have to properly account for the wedge angles and other geometrical features needed in field calculations in the NEC-BSC. If one is setting up a model, however, it still might be useful to use the same modeling considerations as the NEC-BSC, such as defining the corners of a plate so the normals point in the region of space in which the source is located. It is assumed that the obscuration code phase of the design procedure will be followed by calculating the fields for the antenna on the structure using a code such as the NEC-BSC.

The number of plates and cylinders that can be used in the models is dictated only by the size of the dimensions implemented in the array for defining the geometry in the code. For convenience, these parameters are located in one file in the code so they only need to be changed in one spot. The details are given in Part II.

More information on how models are to be constructed are given in the section below on the non-interactive commands and in Chapter 4 where these commands are defined in more detail.

## 3.3 Running the Code

The first step of course is to get the code implemented on your system. The details of how to accomplish this are given in Part II. In order to use the full interactive features of the code, it is necessary to use the code on a DEC VAX. Many of the interactive features use VAX dependent implementations from version 4 of the VMS operating system. The code has been divided into standard FORTRAN 77 files and VAX dependent files, however, so that the code can be used without the interactive features on other systems. A slightly different main program needs to be used as provided in Part II. In addition, the non FORTRAN 77 INCLUDE statement has been used in the non interactive file. Many systems have this feature, so it was left in as a convenience. If the user system does not, it is easy to remove by hard wiring the lines in the appropriate file in place of the INCLUDE statement. Most of the information, here, will assume that the full features of the code will be able to be used.

The first step in using the code is to create a file that contains the basic structure definitions using the non-interactive commands discussed in the next section. The command defining the source location and window size of the shadow map can also be defined in this input file or added and changed in the interactive session. Of course, if you are running non-interactively, then all the data must be input from the input file.

Once the input file has been created or chosen from some stored files, the obscuration

code can be executed. It will read the input file from logical unit #5. An interactive command allows the user to connect the chosen input file to this logical unit number. The code then proceeds to read the input information and produce an output that is sent to the terminal (logical unit #6) representing how the code has interpreted the input. In this process, it is converting all the input into a standard reference coordinate system and into a common set of units which is meters. If there is a typographical error or other error in the input set the code will indicate so and stop execution at that point.

If the code completes the input, it will wait for the next instruction. For example, the output file name can be connect to the logical unit which is #7 for the line printer output and logical unit #10 for the plotter output. The antenna position can now be defined or modified and the desired window changed. The code can than be told to proceed to produce a shadow map.

When the code has completed the shadow calculation, the user can change the source location, the window of the map, or input another structure and run the code again; or he can print the map out. The map is an array of pixels (doubly dimensioned character array) that are in general either a blank representing a clear path or a character representing a blocked path. The character is normally a uniform character such as an "X". There is an option to tag a particular plate with a character that you define, or the code will letter each plate and cylinder separately. This is useful to determine which plates get in the way or for debugging purposes. More details on this will be given in Chapter 6.

### 3.4 Non-Interactive Commands

The non-interactive commands needed in this code are a subset and a slight extension of those used in version 2 of the NEC-BSC [1]. The total list of the available non-interactive commands are given in Table 3.1. Only the commands of interest to the obscuration code are defined in this manual. The rest can be found in reference [1] or in later reports and manuals for newer versions of the codes. This section is intended to give the user a brief overview of the specific commands of interest with the details coming in the next Chapter.

The input commands words are intended to make it convenient for the user to define the geometry of the structure without having to define information not needed or repeat information already defined. They are two letter pairs. The rest of the characters on a command word line can be used for comments, since only the first two letters are interpreted.

There is a place in the code to place default data that will be present without a call to the command. This is convenient when a specific resolution sized of the shadow map is desired as a default, for example. The default window can be initial theta angles of 0 to 180 in steps of 2 degrees and initial phi angles of 0 to 360 in steps of 2 degrees by defining the proper variables in this default section. A call to the VF command will over ride this data if it is specified in the input set.

The geometry information is by default assumed to be in meters in a definition coordinate system that is initially the reference coordinate system. The units can be changed using the UN command to either inches or feet or back to meters again. Once the UN command is specified all information after that command is assumed to be in those units unless changed by another call to UN. There is also provision for using any conversion fac-

COMMAND	DEFINITION	LOCATION
BP	back or bistatic scatter	[1]
CC	cone frustum geometry	pg 24
CE	last or only comment	pg 30 or [1]
CG	cylinder geometry	pg 27 or [1]
CM	comment card	pg 30 or [1]
EN	end execution	pg 30 or [1]
FM	swept frequencies	[1]
FR	frequency	[1]
GP	infinite ground plane	pg 31 or [1]
GR	range gate	not documented
LP	line printer output	[1]
NC	next set of cylinders	pg 32 or [1]
NG	no ground plane	pg 32 or [1]
NP	next set of plates	pg 32 or [1]
NR	next set of receivers	[1]
NS	next set of sources	pg 32 or [1]
NX	next problem	pg 32 or [1]
PD	far zone pattern cut	[1]
PF	far zone cut (non integer)	not documented
PG	plate geometry	pg 33 or [1]
PN	near zone pattern cut	[1]
PP	plotter output	[1]
PR	gain or coupling factors	[1]
RA	receiver array geometry	[1]
RD	far zone range	[1]
RG	receiver geometry	[1]
RM	NEC-MOM receiver input	[1]
RT	rotate-translate geometry	pg 36 or [1]
SA	source array geometry	[1]
SG	source geometry	pg 38 or [1]
SM	NEC-MOM source input	[1]
TO	test options	[1]
UF	model scale factor	pg 42 or [1]
UN	units of geometry	pg 42 or [1]
US	units of source size	[1]
VD	volumetric cut (integer)	not documented
VF	volumetric far zone cut	pg 44
VN	volumetric near zone cut	not documented
VP	volumetric plotter output	not documented
XQ	execute code	pg 47 or [1]

Table 3.1: Table of non-interactive commands.

tor desired. It is input using the UF command and is a scale factor multiplying times all the input dimensions in whatever unit have been defined. The code then takes the input information and changes it internally and stores it in meters, in order to have a uniform system in which to operate. The input dimensions and the internal dimensions are output in the feed back print out sent to a file so the user can see what happened. The dimensions of the source itself, that is length and width not its position, is handled with a default of wavelengths. This can be changed with the US. The length and width of the source is not important in this code so it can be ignored here.

The reference coordinate system is really whatever is convenient for the user. The definition coordinate system is the same as this initial reference system or it can be changed using the rotate translate command RT. The RT command allows the user to relocate the origin and orientation of the definition coordinate system with respect to the reference coordinate system. The definition system stays as defined for all subsequent geometry input until it is changed. The RT command's definition is always referenced to the reference coordinate system NOT to itself, that is, one does not put in inverse locations and angles to undo the command, but resets it to the zero position of the origin and the z-axis and x-axis of the reference coordinate system. Note that all angles are assumed to be input in degrees. The coordinate axes are input in a uniform way through out the code by treating the new axes vectors as if they were radial vectors in the system being used. That is the z-axis is defined using a theta and phi angle relative to the reference coordinate system in the RT command and likewise the x-axis is treated as a radial vector. The y-axis is defined by a cross product between the x and z axes. The code checks that the x and z axes were defined orthogonal to one another. If not an error message will result and the code will stop.

The geometry commands are the PG command for the plates, the GP command for the infinite ground plane, the CG command for an elliptic cylinder, and the CC command for the cone frustum cylinders. The plates are defined by inputting the number and location of their corners in the definition system. The ground plane is defined as a infinite plane lying in the x-y plane of the definition coordinate system. The elliptic cylinder definition is base on the location of its origin and the orientation of its z- and x-axes relative to the definition coordinate system. In addition, the radius along its cylinder x-axis and the radius along its cylinder y-axis, along with the z-axis position and angular orientation of its end caps are needed. The cone frustum's definition is similar except that the number of rims making up the cylinder need to be specified and the orientation of the rims does not, since they can't be cut at an angle as in the elliptic cylinder case. For the plates and cylinders the code automatically adds up the number of calls to the commands and counts that as the number of plates or cylinders specified. Only one infinite ground plane can be defined.

The location of the sources are specified by their location, type, orientation, and relative weights using the SG command. Only the location information is important to the obscuration code. Each source specified is automatically counted and remember as the number of sources. Unlike the plates and cylinders, the obscuration code only calculates one source at a time for a shadow map. In non-interactive mode, it does one source at a time producing a map for each. In interactive mode, it takes the first one as the default source and then each subsequent one needs to be interactively input. Receivers are not recognized by the shadow code, so if in reality you are studying a receiver, it must be input as a source not a

receiver for shadowing purposes.

In order to negate already defined commands for the geometry which is automatically increasing their number, a series of commands have been implemented. The plates can be reset to zero using the NP command. The ground plane with NG, the cylinders with NC, the sources with NS, and the entire run can be reset with the NX command.

The code is told to go and execute the interactive mode if it is available, or to go and execute the shadow calculations if the interactive mode has not been implemented using the XQ command. The EN command tells it to exit back to the operating system.

The next section will discuss an overview of the interactive commands and examples of these commands are given in Chapter 7.

### 3.5 Interactive Commands

The interactive commands provided by the code under VMS are designed to allow easy specification of commonly changed parameters with a syntax which is well-known to users of VMS, the DCL command interpreter syntax. To acquaint the reader with the appearance of these commands, they are summarized below. Detailed descriptions of each command complete with examples can be found in the Chapter 5 on interactive commands. A list of the available interactive commands are given in Table 3.2.

There are interactive commands to allow the user to control the operation of the code or to change or view the geometry. The SHADOW command produces the shadow map. The HELP command gives a descriptions of the commands. The EXIT command exits the user back to the operating system. The SPAWN command allows the use of DCL command while the user is still in the shadow code.

The rest of the commands either allow the user to change the geometry, with the SHOW commands, or see the present status of the geometry, with the SET commands. Most of them have a non-interactive command to which they are at least somewhat associated. The SET UNITS command allows the units of the antenna location to be chosen, similar to the UN command. The SET SCALE\_FACTOR command is like the UF command, which allows an arbitrary scale factor for the geometry to be chosen. The SET COORDINATES command allows the definition coordinate system to be change, like in the RT command. The SET ANTENNA command enables the user to interactively specify the antenna location in the definition coordinate system. It is related to the SG command. The SET PATTERN\_CUT command allow the user to specify the orientation of the pattern coordinate system in the reference coordinate system. The SET WINDOW command enables the initial, final and incremental angles of the shadow map to be specified. These two commands are related to the VF command.

The next four commands do not have non-interactive commands to which they are related. The SET INPUT command allows the user to specify what file containing the non-interactive commands is to be read. The SET OUTPUT command enables the specification of which output files are to be assigned and their names. The SET FILL\_CHARACTER command allows the user to define the symbols that are used for the plate and cylinder shadows. The SET KEYPAD\_MODE command enables the VT100 keypad to be used for command definitions as is discussed in the next section, otherwise, the keypad can be used for numerical input. These four commands are discussed much more thoroughly in

### 3.6 Keypad Use

The definable keypad functions are available for the interactive version of the code only. The keypad definitions are made possible through the use of an integrated VMS screen/terminal management package called SMG. It is a collection of runtime library routines which perform terminal I/O and intercept the special sequences transmitted by the keypad keys. When one of these keys are pressed, the text definition associated with the key is substituted onto the command line. All of this I/O is transparent to the user so that he need only worry about making the initial keypad definitions. For more information about SMG, the reader is referred to the VMS runtime library reference manual.

The keypad definitions are initialized by a text file containing suitable "DEFINE/KEY" commands. The file is called SHADOW.KPD and must reside in the default directory of the user running the code. There is a template file provided with the code which may be customized by the user. The predefined definitions of the VT100 keypad are shown in Table 3.3. Note that the "gold" enables the lower case action in the top row, that is, in most case the "SHOW" operation instead of the "SET" operation.

## Chapter 4

### Non-Interactive Commands

The non interactive commands discussed in this chapter are a subset of the commands used for the NEC-BSC2. The shadow code will recognize the entire set of NEC-BSC2 commands plus a few new ones. The new commands and some of the old ones that are pertinent to this code will be described here. The following sections define in detail each command word and the variables associated with them. This chapter is organized in alphabetical order of the commands. It is intended to be used as a reference for the user. Chapter 7 will give specific examples using this input method.

The method used to input data into the computer is presently based on a command word system. This is especially convenient when more than one problem is to be analyzed during a computer run. The code stores the previous input data such that one need only input that data which has to be changed from the previous execution. Also, there is a default list of data so for any given problem the amount of data that needs to be input has been shortened. The command word options presently available are listed in Table 3.1 on page 16. The colon after the command word is not necessary and is sometimes used just to illustrate the separation between the command word and the space where comments can be inserted.

In this system, all linear dimensions may be specified in either meters, inches, or feet and all angular dimensions are in degrees. All the dimensions are eventually referred to a fixed cartesian coordinate system used as a common reference for the source and scattering structures. There is, however, a geometry definition coordinate system that may be defined using the RT command. This command enables the user to rotate and translate the coordinate system to be used to input any selected data set into the best coordinate system for that particular geometry. Once the RT command is used all the input following the command will be in that rotated and translated coordinate system until the RT command is called again. See below for more details. There is also a separate coordinate system that can be used to define a pattern coordinate system. This is discussed in more detail in terms of the VF command.

It is felt that the maximum usefulness of the computer code can be achieved using it on an interactive computer system. As a consequence, all input data are defined in free format such that the operator need only put commas between the various inputs. This allows the user on an interactive terminal to avoid the problems associated with typing in the field length associated with a fixed format. This method also is useful on batch processing computers. Note that all read statements are made on unit #5, i.e., READ(5,\*), where

the "\*" symbol refers to free format. Other machines, however, may have different symbols representing free format.

In all the following discussions associated with logical variables a "T" will imply true, and an "F" will imply false. The complete words true and false need not be input since most compilers just consider the first character in determining the state of the logical variable.

## 4.1 Command CC: Cone Frustum Geometry

This command enables the user to define the geometry of the finite elliptic conical cylinder structures to be considered. The geometry is illustrated in Figure 4.1. One call to this command defines one cylinder. The number of cylinders in the structure are automatically counted by the number of calls to this command.

---

**READ: (XCL(N,MC),N=1,3)**

\_\_\_\_\_ where \_\_\_\_\_

**XCL(N,MC)** This is a doubly dimensioned real variable. It is used to specify the location of the origin of the MCth elliptic cylinder relative to the definition coordinate system. It is input on a single line with the real numbers being the x,y,z coordinates of the origin which correspond to N=1,2,3, respectively.

---

**READ: TCLZ, PCLZ, TCLX, PCLX**

\_\_\_\_\_ where \_\_\_\_\_

**TCLZ,PCLZ** These are real variables. They are input in degrees as spherical angles that define the  $z_c$ -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.

**TCLX,PCLX** These are real variables. They are input in degrees as spherical angles that define the  $x_c$ -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.

Note that the new  $x_c$ -axis and  $z_c$ -axis must be defined orthogonal to each other. The new  $y_c$ -axis is found from the cross product of the  $x_c$ - and  $z_c$ -axes. \_\_\_\_\_

**READ: NEC(MC)**

\_\_\_\_\_ where \_\_\_\_\_

**NEC(MC)** This is a dimensioned integer variable which defines the number of edges the conical cylinder has.

---

**READ: AC(NC,MC), BC(NC,MC), ZC(NC,MC)**

\_\_\_\_\_ where \_\_\_\_\_

- AC(NC,MC)** This is a double dimensioned real variable which defines the radius of the NCth rim on the  $x_c$ -axis of the MCth elliptic cylinder.
- BC(NC,MC)** This is a double dimensioned real variable which defines the radius of the NCth rim on the  $y_c$ -axis of the MCth elliptic cylinder.
- ZC(NC,MC)** This is a double dimensioned real variable which defines the z position of the NCth rim along the  $z_c$ -axis of the MCth elliptic cylinder.

Note that the program will keep increasing the number of cylinders in the solution by the number of calls to this command unless the NC or NX commands are called to reinitialize the cylinder geometry. Also, the ellipticity of a conical structure should remain the same for the entire length of that structure. The most positive rim should be defined first until all NC rims are defined in descending order.

Figure 4.1: Definition of finite cylinder geometry composed of cone frustum segments with elliptic cross section.

## 4.2 Command CG: Cylinder Geometry

This command enables the user to define the geometry of the finite elliptic cylinder structures to be considered. The geometry is illustrated in Figure 4.2. One call to this command defines one cylinder. The number of cylinders in the structure are automatically counted by the number of calls to this command.

---

READ: (XCL(N,MC),N=1,3)

\_\_\_\_\_ where \_\_\_\_\_

**XCL(N,MC)** This is a doubly dimensioned real variable. It is used to specify the location of the origin of the MCth elliptic cylinder relative to the definition coordinate system. It is input on a single line with the real numbers being the x,y,z coordinates of the origin which correspond to N=1,2,3, respectively.

---

READ: TCLZ, PCLZ, TCLX, PCLX

\_\_\_\_\_ where \_\_\_\_\_

**TCLZ,PCLZ** These are real variables. They are input in degrees as spherical angles that define the  $z_c$ -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.

**TCLX,PCLX** These are real variables. They are input in degrees as spherical angles that define the  $x_c$ -axis of the cylinder coordinate system as if it was a radial vector in the definition coordinate system.

Note that the new  $x_c$ -axis and  $z_c$ -axis must be defined orthogonal to each other. The new  $y_c$ -axis is found from the cross product of the  $x_c$ - and  $z_c$ -axes. \_\_\_\_\_

READ: AC(1,MC), BC(1,MC)

\_\_\_\_\_ where \_\_\_\_\_

**AC(1,MC)** This is a double dimensioned real variable which defines the radius of the MCth elliptic cylinder on the  $x_c$ -axis of the cylinder.

**BC(1,MC)** This is a double dimensioned real variable which defines the radius of the MCth elliptic cylinder on the  $y_c$ -axis of the cylinder.

---

READ: ZCN, THTN, ZCP, THTP

\_\_\_\_\_ where \_\_\_\_\_

**ZCN** This is a real variable that defines the position the center of the most negative end cap on the  $z_c$ -axis of the cylinder.

**THTN** This is a real variable. It is input in degrees and defines the angle the surface of the most negative end cap makes with the positive  $z_c$ -axis in the  $x_c$ - $z_c$  plane.

**ZCP** This is a real variable that defines the position of the center of the most positive end cap on the  $z_c$ -axis of the cylinder.

**THTP** This is a real variable. It is input in degrees and defines the angle the surface of the most positive end cap makes with the positive  $z_c$ -axis in the  $x_c$ - $z_c$  plane.

Note that the program will keep increasing the number of cylinders in the solution by the number of calls to this command unless the NC or NX commands are called to reinitialize the cylinder geometry.

Figure 4.2: Definition of finite elliptic cylinder geometry.

### 4.3 Command CM: and CE: Comments

These commands enable the user to place comment cards in the input and output data in order to help identify the computer runs for present and future reference.

---

**READ: (IR(I), I=1,36)**

\_\_\_\_\_ where \_\_\_\_\_

**IR(I)** This is a CHARACTER\*2 dimensioned array used to store the command word and comments. Each card should have CM or CE on them followed by an alphanumeric string of characters. The CM command implies that there will be another comment card following it. The last comment card must have the CE command on it. If there is only one comment card the CE command must be used.

Note that it is possible to place comments to the right of all the command words, if desired.

### 4.4 Command EN: End Program

This command enables the user to terminate the execution of the scattering code.

## 4.5 Command GP: Ground Plane

This command enables the user to specify an infinite ground plane in the  $x_t$ - $y_t$  plane.

---

READ: LSLAB(MPDX)

\_\_\_\_\_ where \_\_\_\_\_

**LSLAB(MPDX)** This is a dimensioned integer variable. It is used to define the type of plate desired as follows:

0 = Perfectly conducting metallic plate

-3 = Dielectric half space

Note that if LSLAB(MPDX)=0 the code will skip around the READ statement for the dielectric information, therefore, the next line defining the dielectric properties should not be placed in the input data set.

---

READ: ERSLAB(1,MPDX), TESLAB(1,MPDX),  
URSLAB(1,MPDX), TMSLAB(1,MPDX)

\_\_\_\_\_ where \_\_\_\_\_

**ERSLAB(1,MPDX)** This is a doubly dimensioned variable. It is used to specify the relative dielectric constant of the half space.

**TESLAB(1,MPDX)** This is a doubly dimensioned variable. It is used to specify the dielectric loss tangent if the number is positive or the conductivity if the number is negative of the half space.

**URSLAB(1,MPDX)** This is a doubly dimensioned variable. It is used to specify the relative permeability constant of the half space.

**TMSLAB(1,MPDX)** This is a doubly dimensioned variable. It is used to specify the permeability loss tangent of the half space.

#### **4.6 Command NC: Next Set of Cylinders**

This command enables the user to initialize the cylinder data. All of the cylinders are removed from the problem unless they are respecified following this command.

#### **4.7 Command NG: No Ground Plane**

This command enables the user to initialize the infinite ground plane. The ground plane is removed from the problem unless it is respecified following this command.

#### **4.8 Command NP: Next Set of Plates**

This command enables the user to initialize the plate data. All of the plates are removed from the problem unless they are respecified following this command.

#### **4.9 Command NS: Next Set of Sources**

This command enables the user to initialize the source data. All of the sources are removed from the problem unless they are respecified following the command.

#### **4.10 Command NX: Next Problem**

This command enables the user to initialize the commands to their default conditions specified in the list at the beginning of the main program.

## 4.11 Command PG: Plate Geometry

This command enables the user to define the geometry of the flat plate structures to be considered. The geometry is illustrated in Figure 4.3. One call to this command defines one plate. The number of plates in the structure are automatically counted by the number of calls to this command.

---

**READ: MEP(MP), LSLAB(MP)**

\_\_\_\_\_ where \_\_\_\_\_

**MEP(MP)** This is a dimensioned integer variable. It is used to define the number of corners (or edges) on the MPth plate.

**LSLAB(MP)** This is a dimensioned integer variable. It is used to define the type of plate desired as follows:

- 1 = Transparent thin dielectric slab
- 0 = Perfectly conducting metallic plate
- 2 = Dielectric covered plate

Note that if LSLAB(MP)=0 the code will skip to the read statements associated with the corners XX(N,ME,MP). Therefore, the information for the different slab layers should not be put in the data list for the perfectly conducting plate.

---

**READ: NSLAB(MP)**

\_\_\_\_\_ where \_\_\_\_\_

**NSLAB(MP)** This is a dimensioned integer variable. It is used to define the number of dielectric layers on the MPth plate.

---

**READ: DSLAB(NS,MP), ERSLAB(NS,MP), TESLAB(NS,MP),  
URSLAB(NS,MP), TMSLAB(NS,MP)**

\_\_\_\_\_ where \_\_\_\_\_

**DSLAB(NS,MP)** This is a doubly dimensioned variable. It is used to specify the thickness of the NSth layer.

**ERSLAB(NS,MP)** This is a doubly dimensioned variable. It is used to specify the relative dielectric constant of the NSth layer.

**TESLAB(NS,MP)** This is a doubly dimensioned variable. It is used to specify the dielectric loss tangent if the number is positive or the conductivity if the number is negative of the NSth layer.

**URSLAB(NS,MP)** This is a doubly dimensioned variable. It is used to specify the relative permeability constant of the NSth layer.

**TMSLAB(NS,MP)** This is a doubly dimensioned variable. It is used to specify the permeability loss tangent of the NSth layer.

Note there will be NSLAB(MP) number of lines of the above data.

---

**READ: (XX(N,ME,MP),N=1,3)**

\_\_\_\_\_ where \_\_\_\_\_

**XX(N,ME,MP)** This is a triply dimensioned real variable. It is used to specify the location of the M<sup>th</sup> corner of the MP<sup>th</sup> plate. It is input on a single line with the real numbers being the x,y,z coordinates of the corner, in the specified coordinate system, which corresponds to N=1,2,3, respectively, in the array. For example, the array will contain the following for plate #1 and corner #2 located at x=2., y=4., z=6.:

XX(1,2,1)=2.

XX(2,2,1)=4.

XX(3,2,1)=6.

This data is input as: 2.,4.,6.

This read statement will be called MEP(MP) times so that all the corners are defined. As an example, the input data for the flat plate structure given in Figure 4.3, is given by

4,0	:corners and type of plate
1., 1., 0.	:corner #1
-1., 1., 0.	:corner #2
-1.,-1., 0.	:corner #3
1.,-1., 0.	:corner #4.

See elsewhere for further details on how to number the corners. Note that the program will keep increasing the number of plates in the solution by the number of calls to this command unless the NP or NX commands are called to reinitialize the plate geometry.

Figure 4.3: Definition of flat plate geometry.

## 4.12 Command RT: Rotate-Translate Geometry

This command enables the user to translate and/or rotate the coordinate system used to define the input data in order to simplify the specification of the plate, cylinder, and source geometries. The geometry is illustrated in Figure 4.4.

---

**READ: (TR(N),N=1,3)**

\_\_\_\_\_ where \_\_\_\_\_

**TR(N)** This is a dimensioned real variable. It is used to specify the origin of the new coordinate system to be used to input the data for the source or the scattering structures. It is input on a single line with the real numbers being the x,y,z coordinates of the new origin which corresponds to N=1,2,3, respectively.

---

**READ: THZP, PHZP, THXP, PHXP**

\_\_\_\_\_ where \_\_\_\_\_

**THZP,PHZP** These are real variables. They are input in degrees as spherical angles that define the z-axis of the new coordinate system as if it was a radial vector in the reference coordinate system.

**THXP,PHXP** These are real variables. They are input in degrees as spherical angles that define the x-axis of the new coordinate system as if it was a radial vector in the reference coordinate system.

The new x-axis and z-axis must be defined orthogonal to each other. The new y-axis is found from the cross product of the x- and z-axis. All the subsequent inputs will be made relative to this new coordinate system, which is shown as  $x_t, y_t, z_t$ , unless command RT is called again and redefined.

Figure 4.4: Definition of rotate-translate coordinate system geometry.

## 4.13 Command SG: Source Geometry

This command enables the user to specify the location and type of source to used. The geometry is illustrated in Figure 4.5 and 4.6. One call to this command defines one source. The number of sources in the problem are automatically counted by the number of calls to this command and the SA command.

---

**READ: (XSS(N,MS),N=1,3)**

\_\_\_\_\_ where \_\_\_\_\_

**XSS(N,MS)** This is a doubly dimensioned real array which is used to define the x,y,z location of the MSt<sup>h</sup> element in the definition coordinate system. Again, a single line of data contains the x,y,z (N=1,2,3) locations.

---

**READ: THSZ, PHSZ, THSX, PHSX**

\_\_\_\_\_ where \_\_\_\_\_

**THSZ,PHSZ** These are real variables which are used to define the orientation of the MSt<sup>h</sup> element in the definition coordinate system. They are input in degrees as spherical angles that define a radial direction which is parallel to the MSt<sup>h</sup> current flow for a dipole antenna or which is parallel to the length of an aperture antenna.

**THSX,PHSX** These are real variables which are used to define the orientation of the MSt<sup>h</sup> element in the definition coordinate system. They are input in degrees as spherical angles that define a radial direction which is parallel to the MSt<sup>h</sup> elements aperture width or which is parallel to a slot's width. For a dipole antenna, these angles can be made in a convenient direction.

The x-axis and z-axis specified by these angles must be defined orthogonal to each other. The y-axis is found by the cross product of the x- and z-axes.

---

**READ: IMS(MS), HS(MS), HAWS(MS)**

\_\_\_\_\_ where \_\_\_\_\_

**IMS(MS)** This is an integer array which is used to define the MSt<sup>h</sup> element's source type. The details of the different types of sources are given elsewhere. The designations are defined as follows:

**IMS(MS)<0** for an electric element

**IMS(MS)>0** for a magnetic element

$|IMS(MS)|=1$  for a uniform current distribution  
 $|IMS(MS)|=2$  for a piece-wise sinusoidal distribution  
 $|IMS(MS)|=3$  for a TE01 cosine current distribution

**HS(MS)** This is a real array which is used to input the length of the MSt<sup>h</sup> element.

**HAWS(MS)** This is a real array which is used to input the width of the MSt<sup>h</sup> element in the case of an aperture antenna. If  $HAWS(MS)=0$ , then it is assumed to be a dipole.

Note that the units of the variable  $HS(MS)$  and  $HAWS(MS)$  can be specified by the US command. If wavelength is chosen as the units then all the sources must be specified in wavelengths.

---

**READ: WMS, WPS**

\_\_\_\_\_ where \_\_\_\_\_

**WMS, WPS** These are real variables used to define the excitation associated with the MSt<sup>h</sup> element. The magnitude is given by WMS and the phase in degrees by WPS.

Note that the program will keep increasing the number of sources in the solution by the number of calls to this command unless the NS or NX commands are called to reinitialize the source geometry.

Figure 4.5: Definition of source geometry for dipole antennas.

Figure 4.6: Definition of source geometry for aperture antennas.

#### 4.14 Command UF: Scale Factor

This command enables the user to scale the linear dimensions that follow the command by the factor specified.

---

READ: UNITF

\_\_\_\_\_ where \_\_\_\_\_

**UNITF** This is a real variable that is used as a scale factor for all the linear dimensions that follow the command.

#### 4.15 Command UN: Units of Geometry

This command enables the user to specify the units of all the linear dimensions to be input after the command is called. (The exceptions are the source length HS and width HAWS, and receiver length HR and width HAWR, see command US.)

---

READ: IUNIT

\_\_\_\_\_ where \_\_\_\_\_

**IUNIT** This is an integer variable that indicates the units for the input data that follows, such that

1= meters

2= feet

3= inches

#### 4.16 Command US: Units of Source

This command enables the user to specify the units of the source length HS and width HAWS or receiver length HR and width HAWR to be input after the command is called. These variables are in the commands SG, SA, RG, and RA.

---

READ: IUNST

\_\_\_\_\_ where \_\_\_\_\_

**IUNST** This is an integer variable that indicates the units for the input data HS, HAWS, HR, HAWR that follows, such that if

0= wavelengths

1= meters

2= feet

3= inches

Note that if the units are specified to be wavelengths for one source it must be wavelengths for all the sources specified.

## 4.17 Command VF: Far Zone Volumetric Pattern

This command enables the user to define the far zone volumetric pattern coordinate system, the pattern cut, and the angular range that is desired. The geometry is illustrated in Figure 4.7.

---

READ: THCZ, PHCZ, THCX, PHCX

\_\_\_\_\_ where \_\_\_\_\_

**THCZ,PHCZ** These are real variables. They are input in degrees as spherical angles that define the  $z_p$ -axis of the pattern coordinate system as if it was a radial vector in the reference coordinate system.

**THCX,PHCX** These are real variables. They are input in degrees as spherical angles that define the  $x_p$ -axis of the pattern coordinate system as if it was a radial vector in the reference coordinate system.

Note that the new  $x_p$ -axis and  $z_p$ -axis must be defined orthogonal to each other. The new  $y_p$ -axis is found from the cross product of the  $x_p$ - and  $z_p$ -axes.

READ: LCNPAT, TPPD, TPPV, NPV

\_\_\_\_\_ where \_\_\_\_\_

**LCNPAT** This is a logical variable that defines the pattern cut desired, such that

**T=** The theta angle is held fixed while the phi angle is varied. The theta angle will then be incremented and another cut will be calculated.

**F=** The phi angle is held fixed while the theta angle is varied. The phi angle will then be incremented and another cut will be calculated.

**TPPD** This is a real variable. It defines the starting angle of the "fixed" angle specified by LCNPAT.

**TPPV** This is a real variable. It defines the incremental angle of the "fixed" angle specified by LCNPAT.

**NPV** This is an integer variable. It defines the number of pattern points of the "fixed" angle specified by LCNPAT.

---

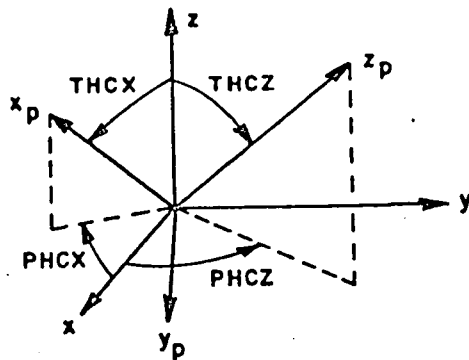

READ: TPPS, TPPI, NPN

\_\_\_\_\_ where \_\_\_\_\_

**TPPS** This is a real variable. It defines the starting angle of the "varying" angle specified by LCNPAT.

**TPPI** This is a real variable. It defines the incremental angle of the "varying" angle specified by LCNPAT.

**NPN** This is a integer variable. It defines the anumber of pattern points of the "varying" angle specified by LCNPAT.

a. Definition of pattern coordinate system.

b. Conic pattern cut, LCNPAT=.TRUE., TPPD=THP.

c. Constant Phi pattern cut, LCNPAT=.FALSE., TPPD=PHP.

Figure 4.7: Definition of volumetric pattern coordinate system.

#### 4.18 Command XQ: Execute Code

This command is used to execute the code so that the results may be computed. After execution the code returns for another possible command word.

## Chapter 5

### Interactive Commands

#### 5.1 Overview

Facilities for interactive programs vary greatly from one operating system to the next with little or no standardization between systems. In spite of this, it was felt that the users of this code would benefit immensely from an interactive mode of operation. In order for the code to have interactive capability without an excessive amount of development time, the developers have used many features of the DEC VAX/VMS operating system. Since many engineers presently have access to the DEC VAX, it is felt that this will lead to reasonable transportability of the interactive mode for this code.

This decision has several ramifications for users of the SHADOW code. It means that the commands described in this chapter do not exist on computers that don't run VAX/VMS Version 4.0 or greater. It also means that this code has been separated into two parts, one standard FORTRAN 77 and the other VMS dependent containing the interactive facility, with a slightly different main program for the non-interactive code.

#### 5.2 Command Descriptions

This section describes the interactive SHADOW commands in detail complete with examples for each. The syntax of the interactive commands is that of the Digital Command Language or DCL and for obvious reasons familiarity with the syntax of DCL is assumed throughout this chapter. For details about the utilities used to perform this DCL style command parsing, readers are referred to the VMS documentation concerning the Command Definition Utility or CDU.

---

## EXIT

Causes the program to exit.

---

### FORMAT

EXIT

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

None.

---

### DESCRIPTION

All output files are closed, and control is returned to DCL.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

```
$ RUN SHADOW
SHADOW>
SHADOW> EXIT
$
```

This example shows how to exit the program.

---

## HELP

Displays information about SHADOW commands or help text from any other library you specify.

---

FORMAT	HELP help-item				
	<table><tr><td>Command Qualifiers</td><td>Defaults</td></tr><tr><td>/LIBRARY[=library-name]</td><td>/LIB=SYS\$DISK: [ ]SHADOW</td></tr></table>	Command Qualifiers	Defaults	/LIBRARY[=library-name]	/LIB=SYS\$DISK: [ ]SHADOW
Command Qualifiers	Defaults				
/LIBRARY[=library-name]	/LIB=SYS\$DISK: [ ]SHADOW				

---

restrictions           The indicated help files must exist.

---

prompts               None.

---

command parameters    help-item  
                      The help-item is a keyword which is the item you want help on.

---

DESCRIPTION           The SHADOW help command adheres to the conventions of VMS help libraries in form and content.

---

COMMAND QUALIFIERS    /LIBRARY[=library-name]  
                      /NOLIBRARY  
  
                      Controls whether an alternate help library will be used in the search for topics. This qualifier must appear immediately after the HELP command or it will be interpreted as part of the help-item. If you specify /NOLIBRARY then no library will be searched.

---

## EXAMPLES

SHADOW> HELP SET OUTPUT

. (SET OUTPUT help message)

Topic? EXIT

. (EXIT help message)

Topic? <RETURN>

SHADOW> HELP/LIBR=HELPLIB LOGOUT

. (LOGOUT help message from the system help library)

Topic? <RETURN>  
SHADOW>

The above examples show how to get help about shadow topics and how to access other VMS help libraries with the HELP command

---

## SHADOW

Initiates the obscuration calculation for the current antenna location and input geometry.

---

FORMAT SHADOW

---

Command Qualifiers	Defaults
None.	None.

---

restrictions None. Command may be abbreviated "S".

---

prompts None.

---

command parameters None.

---

DESCRIPTION The commands which alter parameters, such as SET WINDOW and SET ANTENNA do not initiate shadowing calculations automatically. This is to avoid redundant calculations when several parameters are changed at once. Once desired parameters are set, the SHADOW command performs the obscuration calculations and outputs the result.

---

COMMAND QUALIFIERS None.

---

## EXAMPLES

SHADOW> SET ANTENNA

Input antenna location in meters: 11,22,32

Antenna in RCS (meters): 11.00000 22.00000 32.00000

Definit system (meters): 11.00000 22.00000 32.00000

SHADOW> SHAD

Working...

SHADOW> SET ANTENNA

Input antenna location in meters: 10,20,30

Antenna in RCS (meters): 10.00000 20.00000 30.00000

Definit system (meters): 10.00000 20.00000 30.00000

SHADOW> S

Working...

SHADOW>

The above commands all calculate the projected shadows for two different antenna locations on given input geometry. The results all go into the same output file, because no "SET OUTPUT" command was executed in between "SHADOW" commands.

---

## SPAWN

Creates a subprocess for executing DCL commands without exiting the SHADOW program. This command is useful for executing DCL commands without reinitializing the context of a SHADOW program session.

---

### FORMAT

SPAWN command-string

---

Command Qualifiers	Defaults
None.	None.

---

### restrictions

A few restrictions are imposed by VMS.

- oThe RESOURCE\_WAIT state must be enabled for the spawning process.
- oRequires TMPMBX or PRMMBX user privileges.
- oSPAWN does not manage terminal characteristics.

Command may be abbreviated "\$ ", where the blank after the \$ is necessary.

---

### prompts

None.

---

### command parameters

command-string

Specifies a DCL command string to be executed in the context of the subprocess. SHADOW will wait until the subprocess completes executing. If command-string is blank, the subprocess will prompt for commands repeatedly.

---

### DESCRIPTION

The details of the spawn command are exactly as documented in the DCL dictionary, volume 2 of the VAX/VMS documentation set.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

```
SHADOW> SPAWN SHOW USERS
      VAX/VMS Interactive Users
      11-DEC-1985 08:34:18.72
      Total number of interactive users = 5
      Username      Process Name      PID      Terminal
```

SHADOW> SPAWN

\$ SHO TIME

11-DEC-1985 08:36:13

\$ LOG

LT6199\_1 job terminated at 11-DEC-1985 08:36:20.90

SHADOW>

The above spawn command illustrate how DCL commands may be executed without exiting the SHADOW program.

---

## SET ANTENNA\_LOCATION

Determines the location of the source point, or the center of the far-zone sphere for subsequent shadowing calculations.

---

### FORMAT

SET ANTENNA

---

Command Qualifiers

None.

Defaults

None.

---

### restrictions

Its recommended that the antenna not be placed in the interior of a cylinder. Unusual results may occur if this is done.

---

### prompts

Input antenna location in meters:

Input antenna location in feet :

Input antenna location in inches:

---

### command parameters

None.

---

### DESCRIPTION

The antenna location consists of the (x,y,z) components of a vector in the current units and definition coordinate system, set by the SET UNITS and the SET COORDINATE commands, respectively. The command does NOT accept the antenna location on the command line, but prompts for it instead. The input syntax for the numbers is that of an unformatted FORTRAN read.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SET ANTENNA

Input antenna location in meters: 10,20,30

Antenna in RCS (meters):      10.00000      20.00000      30.00000

Definit system (meters):      10.00000      20.00000      30.00000

This example sets the antenna location to 10.,20.,30. (x,y,z) in the current units, which are meters.

---

## EXAMPLES

SHADOW> SET UNIT FEET

SHADOW> SET ANT

Input antenna location in feet : 10,20,30

Antenna in RCS (meters):	3.04800	6.09600	9.14400
--------------------------	---------	---------	---------

Definit system (feet ):	10.00000	20.00000	30.00000
-------------------------	----------	----------	----------

SHADOW>

This example shows how the antenna location is interpreted in the units of feet.

---

## SET COORDINATES

Sets up a coordinate transformation to be applied to subsequent geometry.

---

### FORMAT

SET COORDINATES

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

The specified coordinate axes must be orthogonal to one another.

---

### prompts

Please input a translation vector in feet:  
Please input THZP,PHZP,THXP,PHXP in degrees:

---

### command parameters

None.

---

### DESCRIPTION

The antenna location may be specified relative to an alternative coordinate system. This coordinate system is established via the SET COORDINATES command. It does not affect the pattern cut coordinate system.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SET COOR

Please input a translation vector in feet : 100,200,300

Please input THZP,PHZP,THXP,PHXP in degrees: 0, -54, 265.5, 45

```
* The following rotations are used for ALL subsequent inputs: *
* VRS(1,1)= -0.70711 VRS(1,2)= -0.70711 VRS(1,3)= 0.00000 *
* VRS(2,1)= 0.70711 VRS(2,2)= -0.70711 VRS(2,3)= 0.00000 *
* VRS(3,1)= 0.00000 VRS(3,2)= 0.00000 VRS(3,3)= 1.00000 *
```

The above example shows how a default coordinate system may be established. The program echoes the established coordinate axes. These may be re-examined at any time with the SHOW COORDINATE command.

---

## SET FILL\_CHARACTER

Allows selection of the characters used to fill the output. Can be used to highlight particular elements of a geometry.

---

### FORMAT

SET FILL [tag-character]

---

Command Qualifiers	Defaults
/SEQUENTIAL	None.
/PLATE=(num[,char])	None.
/CYLINDER=(num[,char])	None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

tag-character

Is any single ASCII character. If a lowercase letter is desired, enclose the letter in double quotes, i.e. "a". The default is "X".

---

### DESCRIPTION

In order to better trace portions of a geometry through the shadowing process, the ability to tag a particular cylinder or plate has been added. The tag setting remains in effect until altered by a subsequent "SET FILL" command. The highlighted plate or cylinder appears in its entirety in the output regardless of its actual position in the hierarchy of obscuration. This allows the user to be absolutely certain of the shadowing caused by the particular highlighted geometry.

There are three tagging modes available. One is sequential tagging. In this mode, the code attempts to assign a unique character in the output to each plate/cylinder in the input. Plates are numbered beginning with "A" and increasing through the ASCII character sequence, and cylinders are treated the same way beginning with "1".

The second mode causes all parts of the geometry to be shaded with a single specified character such as "X". In this total obscuration mode, any one part of the input geometry is not easily identified — rather the total obscuration is presented homogeneously. It is specified using SET FILL without qualifiers. The third mode is the same as the second mode, but with the added feature of one single plate (or cylinder) highlighted with a different character. In this mode the relation of one part of the geometry to the rest is clearly

visible. This mode can be very helpful when isolating particular parts of a geometry that are shadowing the source.

---

**COMMAND  
QUALIFIERS**

**/SEQUENTIAL  
/SEQUENTIAL**

The **/SEQUENTIAL** qualifier selects the first mode of obscuration, sequential tagging of the input geometry. This qualifier may not be specified with a tag-character parameter nor with any of the other qualifiers.

**/PLATE=num  
/PLATE=(num, char)**

The **/PLATE** qualifier selects the third mode of obscuration, homogenous tagging with highlighting of a particular plate.

The num argument is the number of the plate to be tagged. It is a required argument. The char argument is the ASCII character to be used when tagging the plate. It is optional, and defaults to "P" if unspecified.

This qualifier may not be specified in combination with other qualifiers. It is mutually exclusive with the **/CYLINDER** qualifier.

**/CYLINDER=num  
/CYLINDER=(num, char)**

The **/CYLINDER** qualifier selects the third mode of obscuration, homogenous tagging with highlighting of a particular cylinder. It works exactly like the **/PLATE** qualifier.

The num argument is the number of the cylinder to be tagged. It is a required argument. The char argument is the ASCII character to be used when tagging the cylinder. It is optional, and defaults to "C" if unspecified.

This qualifier may not be specified in combination with other qualifiers. It is mutually exclusive with the **/PLATE** qualifier.

---

**EXAMPLES**

```
SHADOW> set fill
No individual plates/cylinders are tagged
All geometry marked by [X]
```

```
SHADOW> set fill $
No individual plates/cylinders are tagged
All geometry marked by [$]
```

```
SHADOW> set fill * /plate=6
Plate 6 is tagged with [P]
```

All other geometry tagged with [\*]

```
SHADOW> set fill * /plate=(7,%)  
Plate 7 is tagged with [%]  
All other geometry tagged with [*]
```

```
SHADOW> set fill Q /cyl=(2,$)  
Cylinder 2 tagged with [$]  
All other geometry tagged with [Q]
```

```
SHADOW> set fill /plate=9 /cyl=4  
%CLI-W-CONFLICT, illegal combination of command elements
```

```
SHADOW> set fill Q /cyl=(2,$) /seq  
%CLI-W-MAXPARM, too many parameters - reenter command with fewer parameters
```

```
SHADOW> set fill /seq ! Q /cyl=(2,$) /seq  
All cylinders/plates sequentially tagged
```

The above examples are obvious except possibly the last three. They show that the qualifiers are not allowed in combination, that the /SEQUENTIAL qualifier does not allow specification of a fill character, and that the DCL syntax ignores everything after an exclamation point.

---

## SET INPUT\_SET

Reads an input set from a named file

---

**FORMAT** SET INPUT\_SET filename

---

Command Qualifiers	Defaults
None.	None.

---

**restrictions** The named input file must exist.

---

**prompts** input set:

---

**command parameters** filename  
The name of the input set. It may be any valid VMS filename, including a logical name. The default filetype is .INP.

---

**DESCRIPTION** The set output command has the dual role of designating an input file and simultaneously causing that input set to be read and prepared for subsequent shadow commands. The current output files are NOT affected by this command so that several outputs may be concatenated. Normally though, this command would be entered after a SET OUTPUT command.

---

**COMMAND QUALIFIERS** None.

---

### EXAMPLES

```
SHADOW> SET OUT AN5S1
Plotting file is: USER1:[RJM.NAS]AN5S1.PLT;1
Printer file is: _NLAO:[ ]FOR007.DAT;
Input echo file: USER1:[RJM.NAS]AN5S1.LIS;1
SHADOW> SET INPUT AN5S1
The current input set is
USER1:[RJM.NAS]AN5S1.INP;1
```

The SET OUTPUT command is used to set the output files – the printer output is discarded by default. The input set AN5S1.INP is then read and processed by the SET INPUT command.

---

## SET KEYPAD\_MODE

Causes the keypad state to change to non-numeric.

---

<b>FORMAT</b>	<b>SET [NO]KEYPAD</b>				
	<hr/>				
	<table><tr><td><b>Command Qualifiers</b></td><td><b>Defaults</b></td></tr><tr><td>None.</td><td>None.</td></tr></table>	<b>Command Qualifiers</b>	<b>Defaults</b>	None.	None.
<b>Command Qualifiers</b>	<b>Defaults</b>				
None.	None.				
	<hr/>				
<b>restrictions</b>	None.				
	<hr/>				
<b>prompts</b>	None.				
	<hr/>				
<b>command parameters</b>	None.				

---

**DESCRIPTION** The keypad of most DEC terminals can be in one of two states, numeric mode or keypad mode. In numeric mode, the keypad buttons represent the numbers and symbols printed on the keys. In keypad mode, the keys may be defined to provide functions, in much the same way as they do in DCL.

SET KEYPAD enables the defined-key feature of SHADOW, and SET NOKEYPAD returns the keypad to numeric-entry mode.

The keypad definitions are made in a session startup file called SHADOW.KPD; in the current default directory.

---

<b>COMMAND QUALIFIERS</b>	None.
---------------------------	-------

---

### EXAMPLES

```
SHADOW> SET KEYPAD
The keyboard is in keypad mode.
SHADOW> SET NOKEYPAD
The keyboard is not in keypad mode.
```

---

## SET OUTPUT

Determines the names of new output files and closes current output files.

---

### FORMAT

SET OUTPUT filename

---

#### Command Qualifiers

/PLOTTABLE  
/PRINTABLE  
/ECHOING

#### Defaults

/PLOTTABLE  
/NOPRINTABLE  
/ECHOING

---

### restrictions

The filename must be a valid VMS filename.

---

### prompts

filename:

---

### command parameters

filename

The name(s) of the newly created output file(s).

---

### DESCRIPTION

There are three different outputs from the shadow program. One is an echo of the input set from the input processor. Another is a line printer output of the shadow map. The third is an output suitable for input to a separate plotting program. The set output command opens these files for the code. The name of the file opened is specified as the filename parameter. The filetypes are set by the command automatically, so that only the filename need be specified.

---

### COMMAND QUALIFIERS

/PLOTTABLE  
/NOPLOTTABLE

Causes a plottable output file to be produced. This is the default. Specifying /NOPLOT will override this default.

/PRINTABLE  
/NOPRINTABLE

Causes an output file to be produced which is suitable for printing on a standard line printer. /NOPRINT is the default. Specifying /PRINT will override this default.

/ECHOING  
/NOECHOING

Causes the input echo to be saved in a file when a new input set is

read. /ECHOING is the default. Specifying /NOECHO will override this default.

---

## EXAMPLES

```
SHADOW> SET OUT AN5S1
Plotting file is: USER1:[RJM.NAS]AN5S1.PLT;1
Printer file is: _NLAO:[]FOR007.DAT;
Input echo file: USER1:[RJM.NAS]AN5S1.LIS;1
SHADOW> SET OUT AN5S1 /PRINT
Plotting file is: USER1:[RJM.NAS]AN5S1.PLT;2
Printer file is: USER1:[RJM.NAS]AN5S1.PRT;1
Input echo file: USER1:[RJM.NAS]AN5S1.LIS;2
SHADOW> SET OUT AN5S1 /NO PLOT /NOECHO /PRINT
Plotting file is: _NLAO:[]FOR010.DAT;
Printer file is: USER1:[RJM.NAS]AN5S1.PRT;2
Input echo file: _NLAO:[]FOR006.DAT;
SHADOW> SET OUT AN5S1
Plotting file is: USER1:[RJM.NAS]AN5S1.PLT;3
Printer file is: _NLAO:[]FOR007.DAT;
Input echo file: USER1:[RJM.NAS]AN5S1.LIS;3
```

The above examples show the operation of the SET OUTPUT command. Note that the printer file is not produced by default, and the device NLAO: (the null device) is where the output is discarded:

---

## SET PATTERN\_CUT

Specifies the pattern cut coordinate system.

---

### FORMAT

SET PATTERN\_CUT

---

Command Qualifiers

Defaults

None.

None.

---

### restrictions

The specified coordinate axes must be orthogonal.

---

### prompts

Please input THZP,PHZP,THXP,PHXP in degrees:

---

### command parameters

None.

---

### DESCRIPTION

The shadow map window is specified relative to the pattern-cut coordinate system. This system can be changed to facilitate easier specification of this window relative to the blocking object coordinate system.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SET PAT

Please input THZP,PHZP,THXP,PHXP in degrees: 0, -54, 265.5, 45, 0, 135

```
*   The following rotations are used for ALL subsequent inputs:   *
*   VPC(1,1)= -0.70711  VPC(1,2)= -0.70711  VPC(1,3)=  0.00000    *
*   VPC(2,1)=  0.70711  VPC(2,2)= -0.70711  VPC(2,3)=  0.00000    *
*   VPC(3,1)=  0.00000  VPC(3,2)=  0.00000  VPC(3,3)=  1.00000    *
```

The pattern-cut coordinate system shown has been set up.

---

## SET SCALE\_FACTOR

Sets a new value for the uniform scale factor.

---

### FORMAT

SET SCALE\_FACTOR

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

The scale factor may not be specified on the command line.

---

### prompts

Please input a uniform scale factor:

---

### command parameters

None.

---

### DESCRIPTION

In order to allow for more flexibility in specifying input, an additional scale factor may be applied to numerical inputs. The default value of this command is 1.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SET SCALE

Please input a uniform scale factor: 5.5

The uniform scale factor is 5.5000000

The uniform scale factor has been changed to 5.5.

---

## SET UNITS

Sets the default units for the entry of numeric values. Allowable units are Meters, Feet, Inches.

---

### FORMAT

SET UNITS keyword

---

Command Qualifiers

None.

Defaults

None.

---

### restrictions

None.

---

### prompts

\_inches, feet, or meters:

---

### command parameters

Keyword may be one of the following:

- o METERS
- o FEET
- o INCHES

---

### DESCRIPTION

When the antenna location is set, these are the units applied to the specified position. Internal calculations are always done in meters.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SET UNI FEET

This example sets the default units to feet.

---

## SET WINDOW

Sets parameters for windowing of the output.

---

### FORMAT

SET WINDOW

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

The maximum span of theta must be less than 180 degrees. The maximum span of phi must be less than 360 degrees. The maximum resolution is a function of the specified range for both theta and phi. None of these parameters is specified on the command line.

---

### prompts

Please enter a new range for theta (lower,higher):  
Please enter a new THETA resolution in degrees/pixel:  
Please enter a new range for phi (lower,higher):  
Please enter a new PHI resolution in degrees/pixel:

---

### command parameters

None.

---

### DESCRIPTION

In order to be more flexible on the presentation of the output, a windowing feature was included so that portions of theta-phi space may be mapped onto a larger output surface. The set window command does this by prompting for the desired range of displayed theta and phi, and the desired levels of resolution. The default window displays the entire range of theta and phi at a resolution of 2 degrees/pixel in both directions.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SET WINDOW

The current range of theta in degrees is 0.000000E+00 to 180.0000  
with a resolution of 2.000000 degrees/pixel.

The current range of phi in degrees is 0.000000E+00 to 360.0000  
with a resolution of 2.000000 degrees/pixel.

Please enter a new range for theta (lower,higher): 30,40

Please enter a new THETA resolution in degrees/pixel: .5

Please enter a new range for phi (lower,higher): 45,90

Please enter a new PHI resolution in degrees/pixel: .5  
The current range of theta in degrees is 30.00000 to 40.00000  
with a resolution of 0.500000 degrees/pixel.  
The current range of phi in degrees is 45.00000 to 90.00000  
with a resolution of 0.500000 degrees/pixel.

The set window command above first displays the current window settings (which also happen to be the default settings), then prompts for new values. The new values are then also shown.

---

## SHOW ANTENNA\_LOCATION

Display the current antenna position.

---

### FORMAT

SHOW ANTENNA\_LOCATION

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

None.

---

### DESCRIPTION

The antenna location is displayed in both the current default units and the Reference Coordinate System.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SHO ANT

Antenna in RCS (meters):	2.00000	3.00000	4.00000
Definit system (meters):	2.00000	3.00000	4.00000

This command displays the current antenna location in both the reference coordinate systems (RCS) and the current default units, which are also meters in this example.

---

## SHOW COORDINATES

Displays the default transformation applied to antenna placement commands.

---

FORMAT	SHOW COORDINATES	
	Command Qualifiers	Defaults
	None.	None.
restrictions	None.	
prompts	None.	
command parameters	None.	
DESCRIPTION	The antenna location is input in terms of an antenna coordinate system. This command displays the orientation of this system.	
COMMAND QUALIFIERS	None.	

---

### EXAMPLES

SHADOW> SHO COORD

```
* VRS(1,1)= 1.00000 VRS(1,2)= 0.00000 VRS(1,3)= 0.00000 *
```

```
* VRS(2,1)= 0.00000 VRS(2,2)= 1.00000 VRS(2,3)= 0.00000 *
```

```
* VRS(3,1)= 0.00000 VRS(3,2)= 0.00000 VRS(3,3)= 1.00000 *
```

In this example, the antenna coordinate system is coincident with the reference coordinate system.

---

## SHOW FILL\_CHARACTER

Displays the current output fill modes.

---

### FORMAT

SHOW FILL

---

Command Qualifiers

Defaults

None.

None.

---

restrictions

None.

---

prompts

None.

---

command  
parameters

None.

---

### DESCRIPTION

The output may be generated in one of three modes. For a detailed description of the possible modes, see the SET FILL command.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

```
SHADOW> SHOW FILL
```

```
Plate 6 is tagged with [P]
```

```
All other geometry tagged with [*]
```

In the above example, the sixth plate of the input set is tagged with the ASCII character "P". The SET FILL command has many more examples.

---

## SHOW INPUT\_SET

Displays the name of the file from which the current geometry was defined.

---

### FORMAT

SHOW INPUT\_SET

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

None.

---

### DESCRIPTION

The input set is determined with the SET INPUT command. The SHOW INPUT command echoes this input set filename.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SHOW INPUT

The current input set is  
USER1: [RJM.NAS]AN5S1.INP;1

---

## SHOW KEYPAD\_MODE

Displays the current state of the keyboard.

---

### FORMAT

SHOW KEYPAD\_MODE

---

Command Qualifiers	Defaults
None.	None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

None.

---

### DESCRIPTION

The keypad of most DEC terminals can be in one of two states, numeric mode or keypad mode. In numeric mode, the keypad buttons represent the numbers and symbols printed on the keys. In keypad mode, the keys may be defined to provide functions, in much the same way as they do in DCL. The keypad definitions are established by a startup file called SHADOW.KPD in the current default directory.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SHOW KEYPAD

The keyboard is not in keypad mode.

The keypad was not in keypad mode in this example.

---

## SHOW OUTPUT

Displays the names of the current output files.

---

FORMAT SHOW OUTPUT

---

Command Qualifiers	Defaults
None.	None.

---

restrictions None.

---

prompts None.

---

command parameters None.

---

DESCRIPTION There are three possible output files produced by the shadow program. One is for plotting with a separate plotting program and has a filetype of .PLT. The second is a line-printer formatted output with a filetype of .PRT. The third is the input set listing echo, which may be redirected into a file. Its filetype is .LIS.

---

COMMAND QUALIFIERS None.

---

### EXAMPLES

```
SHADOW> SET OUTPUT EXAMPLE3 /PRINT
SHADOW> SHOW OUTPUT
Plotting file is: USER1:[RJM.NAS]EXAMPLE3.PLT;1
Printer file is: USER1:[RJM.NAS]EXAMPLE3.PRT;1
Input echo file: USER1:[RJM.NAS]EXAMPLE3.LIS;1
```

This example shows how a SET OUTPUT command creates the names shown for output files. See the SET OUTPUT command description for more details.

---

## SHOW PATTERN\_CUT

Displays the pattern-cut coordinate system transformation matrix.

---

### FORMAT

SHOW PATTERN\_CUT

---

Command Qualifiers  
None.

Defaults  
None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

None.

---

### DESCRIPTION

The shadow map window is specified relative to the pattern-cut coordinate system. This system can be changed to facilitate easier specification of this window relative to the blocking object's coordinate system, that is, the reference coordinate system. For more information, see the SET PATTERN command on page 66.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SHOW PATT

```
*   The following rotations are used for ALL subsequent inputs:   *
*   VPC(1,1)= -0.70711  VPC(1,2)= -0.70711  VPC(1,3)=  0.00000   *
*   VPC(2,1)=  0.70711  VPC(2,2)= -0.70711  VPC(2,3)=  0.00000   *
*   VPC(3,1)=  0.00000  VPC(3,2)=  0.00000  VPC(3,3)=  1.00000   *
```

The pattern-cut coordinate system shown has been set up.

---

## SHOW SCALE\_FACTOR

Displays the uniform scale factor currently in effect.

---

FORMAT	SHOW SCALE_FACTOR	
	Command Qualifiers	Defaults
	None.	None.
restrictions	None.	
prompts	None.	
command parameters	None.	
DESCRIPTION	The SET SCALE_FACTOR command can set a uniform scale factor on subsequent antenna inputs. It allows an extra scaling on the inputs.	
COMMAND QUALIFIERS	None.	

---

### EXAMPLES

```
SHADOW> SHOW SCALE
The uniform scale factor is 1.00000000
```

The above scale factor is the default. It has not been changed with SET SCALE.

---

## SHOW UNITS

Displays the current units in effect. Valid units are meters, feet, and inches.

---

### FORMAT

#### SHOW UNITS

---

Command Qualifiers	Defaults
None.	None.

---

### restrictions

None.

---

### prompts

None.

---

### command parameters

None.

---

### DESCRIPTION

There are three different units in which antenna locations may be specified. This command displays the units currently in effect. The SET UNITS command changes the default units.

---

### COMMAND QUALIFIERS

None.

---

### EXAMPLES

SHADOW> SHOW UNITS

The current units are feet

---

## SHOW WINDOW

Displays the current window parameters.

---

FORMAT	SHOW WINDOW				
	<table><tr><td>Command Qualifiers</td><td>Defaults</td></tr><tr><td>None.</td><td>None.</td></tr></table>	Command Qualifiers	Defaults	None.	None.
Command Qualifiers	Defaults				
None.	None.				
restrictions	None.				
prompts	None.				
command parameters	None.				
DESCRIPTION	The output can be windowed onto a smaller range of theta or phi, with any desired resolution. The parameters for this windowing are established by the SET WINDOW command.				
COMMAND QUALIFIERS	None.				

---

### EXAMPLES

SHADOW> SHOW WIND

The current range of theta in degrees is 0.000000E+00 to 180.0000  
with a resolution of 2.000000 degrees/pixel.  
The current range of phi in degrees is 0.000000E+00 to 360.0000  
with a resolution of 2.000000 degrees/pixel.

In this case, the window is set to its default range with a resolution of two degrees/pixel.

## Chapter 6

### Interpretation of the Output

The final product of the obscuration code, SHADOW, is a map of the projected shadow of a defined object onto the far zone sphere with its center at the antenna location. The map is composed of pixels with the size and range specified by the user. The obscuration code provides complete control over the parameters needed to define the map and provides a line printer output or a plottable file that can be used by an external plotting code. This chapter outlines the details of defining, obtaining, and interpreting the shadow map.

For this discussion, the far zone sphere can be viewed as being ironed out into a flat plane, that is, a Mercator's projection with the angle phi along the x axis and the angle theta along the y axis. Using the VF non-interactive command or the SET WINDOW interactive command, the user can choose starting angles, incremental step size which is the resolution of the map, and the total number of steps or pixels for both the theta and phi angles. This, of course, also dictates the stopping angles of the map which it computes. The default is for theta to vary from 0 to 180 degrees in steps of 2 degrees for a total of 91 pixels, and for phi to vary from 0 to 360 in steps of 2 for a total of 181 pixels. The interactive command SET WINDOW allows these parameters to be changed at any time during a session. It asks for the starting and stopping angle and the resolution which is the step size and it computes the number of pixels for each angle. These angles are defined with respect to the pattern coordinate system, which is specified by the first set of angles in the VF command or by the SET PATTERN command. The default is for the pattern coordinate system to be the same as the reference coordinate system.

As discussed in Chapter 2, the code computes the shadow by first projecting the objects border onto the far zone sphere and then filling in between the borders. A pixel is considered to be filled if the border at least passes through more than half the distance to the center of a pixel. It determines this by rounding the theta and phi angles defining the border to the nearest integer with respect to the resolution size of the pixel, which is the step size. This sometimes appears to produce a ragged border around the edges of the shadow if the border is very curved. Note that a straight edged plate projects a shadow that is curved in border. In addition, this is dependent on the coordinate system in which the shadow is viewed. Chapter 7 presents specific examples of these types of maps.

The shadow is represented by an ASCII character being placed in an array corresponding to the integerized theta and phi angles. A clear viewing point is left blank. The choice of the character that is placed in the pixel can be controlled by the user. The default is for an "X" to be used as a fill character. Interactively this can be changed using the SET FILL

command. Noninteractively, these are hard-wired into the source code.

For debugging purposes or so that the user can get a feel for which plates and cylinders are shadowing which regions of space a highlighting feature has been provided. The SET FILL/SEQUENTIAL command tags each plate and cylinder with its own unique fill character. The first plate starts with "A" and each succeeding plate is incremented up by one ASCII character. The first cylinder starts with "1" and each succeeding cylinder is incremented up by one ASCII character. Note that if there are a lot of plates and/or cylinders, the fill characters will eventually get into some of the more seldom used ASCII characters. Also note that in this mode of filling, the code superimposes the latest calculated shadow for a plate or cylinder on top of the shadow map. This means that the character in a pixel for a finished map will represent the last object that the code calculated a shadow for and not the object that is located closest to the observer.

In order to get around the ambiguous behavior of highlighting the plates and cylinders by order of processing rather than by location, the user can instead use the standard fill character for all plates and cylinders and highlight one particular specified object. The command SET FILL/PLATE = (number,character) or SET FILL/CYLINDER = (number,character) will highlight the chosen plate or cylinder against the regular fill character. The plate or cylinder options are mutually exclusive. It represents the shadow of the whole plate or cylinder that is tagged. A non interactive command has not been provided for these fill features. The user can change the fill characters and mode in the INIT subroutine.

The output that the user sees can come in three forms. The first type of output comes from an echo of the command set that is read from the input file on logical unit #5. The output is sent to logical unit #6, which is normally assigned to a default file type of .LIS on a VAX in the interactive mode. An ASCII file of the shadow map is written to logical unit #7, which is normally assigned to a default file type of .PRT on a VAX. A binary file of the shadow map that can be used to transfer information to another code to plot the map is sent to logical unit #10, which is normally assigned to a default file type of .PLT on a VAX.

In the interactive mode, the input set can be opened using the SET OUTPUT command. The output files can be opened and closed using the SET OUTPUT /ECHOING, /PRINTABLE, /PLOTTABLE commands, respectively. In the non-interactive mode, they can be controlled by using system commands, such as ASSIGN on the VAX. In the interactive mode, the output files should generally be set first, so that the code will have the desired information as to where to sent the echo back information. In addition, once the code is run and it is desired to see the results, it is possible to print or plot the results using the SPAWN ("\$") command. The files that are desired to be printed or plotted, however, must be closed first, that is, the SET OUTPUT command should be given again reassigning the files to another name, a null device, or the printing device. This will close the files and allow them to be accessed. Of course, it is important to remember to reopen them after the user is finished and wants to run more results. Presently, the echo, printable, and plottable map files will accumulate information until they are closed.

Generally, the code will be used to produce plottable files of the shadow maps with the printable file being used for debug purposes. Plotted maps are small and nicer to look at. Unfortunately, graphical routines are presently system dependent. A plotting code for a NCAR [5], has been provided, however, in Chapter 13. This is one example of how the

data of the shadow map can be plotted. Examples of both the printed and plotted maps are illustrated in the examples of Chapter 7. It should be noted that due to the limited amount of space across the width of a line printer, a printed map will be broken up into widths that will fit onto the width of the paper if it is too wide. The map will come out in as many strips as necessary to produce the whole map. Plotted maps should not have this problem since the individual pixels can be graphed very close together.

## Chapter 7

### Examples

The following examples are used to illustrate the various features of the SHADOW computer code. Each example is designed to show how a set of non-interactive and interactive commands can be put together to solve a problem. The beginner can use the examples in this chapter to learn more about the code. In addition, these examples can be used to ensure that the code is operating correctly on your system. These examples were run on a DEC VAX 11/780 computer using version 4 of the VMS operating system.

The shadow maps shown here are presented mostly with the line printer output, since this is generally the most transportable. Plotted output would normally be preferred in a design situation. A few examples of this type of output are also given.

## 7.1 Example 1: A Plate

The first example is a four-cornered plate centered at the origin and situated in the X-Y plane. The antenna is located on the positive Z axis. It was generated with the following input files and commands. The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT PLAEX1/NO PLOT/PRINT
SHADOW> SET INP PLAEX
SHADOW> SET UNI METERS
SHADOW> SET WIND
          90, 180
          1.0
          0., 360
          5.
SHADOW> SET ANT
SHADOW> 0,0,8
SHADOW> SHADOW
SHADOW> EXIT
$
```

The input set defining the plate was the following:

```
CM: SIMPLE PLATE TEST SET
CE: RCS INPUT SET
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.
4,0
-10.0, +10.0, 0.0
-10.0, -10.0, 0.0
+10.0, -10.0, 0.0
+10.0, +10.0, 0.0
XQ:
EN:
```

The output this produced was the following:

ANTENNA (RCS) = ( 0.0000, 0.0000, 8.0000 ) IN METERS INPUT SET: USER1:[RJM.WAS.MAN]PLAEX.INP;6

PHI	THETA (DEGREES)

## 7.2 Example 2: A Different Plate

This example is another four-cornered plate, but this time the antenna is located at the origin, and the plate is centered along the positive Y axis and is normal to it.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT PLAEX2/NO PLOT/PRINT
SHADOW> SET INP PLAEX2
SHADOW> SET UNI METERS
SHADOW> SET WIND
                0, 180
                2.0
                0., 180
                5.
SHADOW> SET ANT
                0,0,0
SHADOW> SHADOW
SHADOW> EXIT
$ EXIT
```

The input set defining the plate was the following:

```
CM: SIMPLE PLATE TEST SET
CE: RCS INPUT SET
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.
4 0
-10.0, 8, +10.0
-10.0, 8, -10.0
+10.0, 8, -10.0
+10.0, 8, +10.0
XQ:
EN:
```

The output generated by the code was the following:

ANTENNA (RCS) = ( 0.0000, 0.0000, 0.0000 ) IN METERS INPUT SET: USER1:[RJM.NAS.MAN]PLAEX2.INP;2

PHI	THETA (DEGREES)									
	0.00	20.00	40.00	60.00	80.00	100.00	120.00	140.00	160.00	180.00

165.00										
170.00										
175.00										
180.00										

### 7.3 Example 3: The First Plate Revisited

The current example is deceptive. Both the input geometry and the source location are identical with the first plate example, but the obscuration output is identical to the second example! A closer of the input sets reveals the the two examples are really the same geometry, but defined in different orientations with respect to the Reference Coordinate System. The third example takes advantage of this fact and uses the SET PATTERN.CUT command to reorient the coordinate system of the antenna. The result is that while the geometry is defined the same as the first example, the output resembles the second example. The commands to generate the example were:

```
$ RUN SHADOW
SHADOW> SET OUT PLAEX3/NO PLOT/PRINT
SHADOW> SET INP PLAEX
SHADOW> SET UNI METERS
SHADOW> SET WIND
      0,180
      2.0
      0.,180
      5.
SHADOW> SET ANT
      0,0,8
SHADOW> SET PATT
      90., +90., 90., 0.
SHADOW> SHADOW
SHADOW> EXIT
$ EXIT
```

The input set defining the plate was the same one used in example one. It is:

```
CM: SIMPLE PLATE TEST SET
CE: RCS INPUT SET
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.
4 0
-10.0, +10.0, 0.0
-10.0, -10.0, 0.0
+10.0, -10.0, 0.0
+10.0, +10.0, 0.0
XQ:
EH:
```

The output generated by the code was the following:

ANTENNA (RCS) = ( 0.0000, 0.0000, 8.0000 ) IN METERS      INPUT SET: USER1:[RJM,NAS,MAN]PLAEX.INP;8

	THETA (DEGREES)

## 7.4 Example 4: A Non-Interactive Version of Example 1

This example illustrates an input set for non-interactive use of the code. The main program has been changed to the non-interactive version and non-interactive subroutines were not linked into the code. The input set is the same as Example 1, except that the source and window have been define using the SG and VF commands, respectively. Note that these commands can also be used in the interactive mode also to hard wire the antenna location and window as a default case. The output is not shown here because it is identical to that of Example 1.

The input set defining the plate is the following:

```
CM: SIMPLE PLATE TEST SET
CE: RCS INPUT SET
UN:
1
PG: THE PLATE IS 400 SQUARE-METERS.
4 0
-10.0, +10.0, 0.0
-10.0, -10.0, 0.0
+10.0, -10.0, 0.0

## 7.5 Example 5: An Elliptic Cylinder

This example consists of one elliptic cylinder centered on the origin with its axis directed along the Y axis. Three different source locations are presented with this single example.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT CYLEX1/NO PLOT/PRINT
SHADOW> SET INP CYLEX1
SHADOW> SET UNI METERS
SHADOW> SET WIND
130,180
0.55555556
0.,360
5.
!
! An overhead view of the cylinder, which is centered on the origin,
! with radii of 1 and 1, with a length of 1 meter.
!
SHADOW> SET ANT
0,0,4
SHADOW> SHADOW
!
! A broadside look at the cylinder.
!
SHADOW> SET WIND
45,135
1.0
220.,310
1.25
SHADOW> SET ANT
0,4,0
SHADOW> SHADOW
!
! Now a look at the same geometry along the axis of the cylinder.
!
SHADOW> SET ANT
4,0,0
SHADOW> SET WIND
45,135
1.0
130.,220
1.25
SHADOW> SHADOW
SHADOW> EXIT
$ EXIT
```

The input set defining the plate was the following:

## 7.7 Example 7: A Space Station Model

This example uses a space station, shown in Figure 7.1, that has been provided by NASA, Langley. The computer model is illustrated in Figure 7.2. It is an demonstrates how to use the windowing and highlighting commands (SET FILL) to effectively show obscuration.

The commands were:

```
$ RUN SHADOW
SHADOW> SET OUT AN5S1 /PRINT/NOECHO
SHADOW> SET INP AN5S1
SHADOW> SET UNI FEET
SHADOW> SET WIND
0.180
2.0
20.,290
2.5
!
! Display ONLY plate 6.
!
SHADOW> SET FILL " " /PLATE=6
SHADOW> SET ANT
25. 15. 256.5
SHADOW> SHADOW
!
! Now make plate 6 stand out from the crowd.
!
SHADOW> SET FILL "!" /PLATE=(6,$)
SHADOW> SET ANT
25. 15. 256.5
SHADOW> SHADOW
$ EXIT
```

## 7.8 Example 8: Another Look at the Space Station

This example presents a full view of the space station in the previous, except that the output is generated with the NCAR graphics interface. The non-interactive input is the same. The standard fill character procedure is used and a complete window is displayed with two degree resolution in theta and phi. The NCAR plot has been obtained using the plotting code in Chapter 13. The shadow map produced is shown in Figure 7.3

## Chapter 8

### Introduction

The obscuration code SHADOW, is designed to produce a projected shadow map onto the far zone radiation sphere of an antenna in a complex environment. The map is efficiently calculated by directly tracing the outer boundaries of the multisided flat plates and composite cone frustum cylinders onto theta - phi space and then filling between the boundaries along raster lines. The code has been developed to be interactively run on a DEC VAX computer. It can, also, be run non-interactively on any other computer by simply substituting the small main program and leaving out the interactive subroutines.

Part I of this manual is a user's guide which treats the code from the users standpoint without much particular details about the coding. Part II, given here, is intended to give some details about the internal workings of the code. It gives more specific information about the coding itself. It is of importance primarily for people implementing the code on a new system, for debugging errors, or for making changes in how the code operates. An overview of how the code is organized is given in Chapter 9. A listing of the code is given in Chapter 10. It is broken up into three parts for the non-interactive, FORTRAN 77 subroutines and into the interactive VAX dependent subroutines. The implementation of the code on a VAX is given in Chapter 11 and a brief description of implementing the code on a non-VAX computer is given in Chapter 12. A listing of an NCAR plotting code for the shadow map is given in Chapter 13.

## Chapter 9

### Code Organization

The obscuration code SHADOW is designed to produce a projected shadow map onto the far zone radiation sphere of an antenna in a complex environment. The map is efficiently calculated by directly tracing the outer boundaries of the multisided flat plates and composite cone frustum cylinders onto theta - phi space and then filling between the boundaries along raster lines.

The code has been developed with efficiency and ease of use as primary considerations. Often with other similar codes the engineer is not part of a tight interactive design loop. In order to facilitate this capability, while maintaining necessary transportability, the code has been split into two versions so that it can be run in two different modes, interactively or non-interactively depending on the computer being used. In both versions the flow of program control is basically the same. The main program either accepts interactive commands from the terminal and acts on those commands, or reads a different set of non-interactive commands from the input file and processes those. In both cases, the main program loops on input commands and calls appropriate subroutines for the creation and output of the shadow map.

The map creation is broken down into separate phases for each class of geometry being processed. Plates and elliptic cylinders are the two phases currently implemented. Each processing phase works by projecting each member of each class of geometry onto the far-zone sphere. The code implements the shadow map by mapping the far zone sphere in theta-phi space into a rectangular character array. The size of the array and hence the angular resolution of the resulting map is determined by the user at run time. After a member is projected, the far-zone grid (array) is processed in a raster-scan fashion to implement an area fill for the member. In this way every geometric entity is processed and included in the array. After all items of all classes have been processed, the output routines format and display/dump the resulting map. The main program then readies itself to execute yet another command or commands.

The source code is also organized into two groups of files depending upon the desired mode of operation. The code is organized this way so that minimum source modification is necessary in order to run in either interactive (in the case of a VAX computer) or non-interactive modes. The chapter on Non-VAX implementation describes the conversion of the source to non-interactive mode in detail.

Since the map computation and display routines are identical for both modes of operation, the transportability of generated results depends on the numerical behavior of the

target machine and not on implementational differences between the interactive and non-interactive versions.

## Chapter 10

### Listings of the Code

This chapter describes the operation of the routines and functions used by the program. Each listing is presented in alphabetical order and is preceded where appropriate by a short explanation of methods used.

#### 10.1 VAX/VMS Subroutines

The following routines are for the interactive implementations of the code. They are used in conjunction with the routines in this chapter that are common to both versions.

---

#### MAIN PROGRAM

This is the main routine for the interactive versions of the program. It calls a one-time initialization routine and then executes commands until finished. There is another slightly different main program for the non-interactive code.

```

0204      C!!! Choose a source location from stored positions.
0205      DO 1200 MS=1,MSX
0206      DO 1000 N=1,3
0207      1000 ANTENN(N)=XSS(N,MS)
0208      C!!! Initialize graphics information.
0209      CALL INITGF
0210      C!!! Calculate shadow of plates.
0211      CALL DOPLAS
0212      C!!! Calculate shadow of cylinders.
0213      CALL DOCYLS
0214      C!!! Write out maps to printer and plotter files.
0215      CALL WRTOUT
0216      1200 CONTINUE
```

0217 C!!! Read more command information.  
0218 CALL ABSCRE  
0219 C!!! Return to execute next shadow map.  
0220 IF(LRET) GO TO 100  
0221 STOP  
0222 END

## 10.3 Subroutines common to both modes

The following routines are used by both the interactive and non-interactive implementations of the code. They are written in transportable FORTRAN-77.

### SUBROUTINE ABSCIN

This is the input-set processor routine. It reads commands from the input file which define the input geometry.

```
0001 C-----
0002 SUBROUTINE ABSCIN
0003 C!!!
0004 C!!! THE NEC - BASIC SCATTERING CODE (NEC-BSC) WAS WRITTEN
0005 C!!! AT THE OHIO STATE UNIVERSITY ELECTROSCIENCE LABORATORY.
0006 C!!! ANY PROBLEMS OR COMMENTS CAN BE REFERRED TO:
0007 C!!!
0008 C!!! RONALD J. MARHEFKA
0009 C!!! ELECTROSCIENCE LABORATORY
0010 C!!! 1320 KINNEAR RD.
0011 C!!! COLUMBUS, OHIO 43212
0012 C!!! PHONE: (614) 422-5752
0013 C!!!
0014 C!!! THIS IS A PORTION OF THE MAIN PROGRAM OF THE NEC-BSC.
0015 C!!! IT READS IN THE INPUT AND PASSES THE GEOMETRY INFORMATION
0016 C!!! TO THE SHADOW CALCULATION PART OF THIS OBSCURATION CODE.
0017 C!!! IT READS LOCATIONS OF SOURCES A NUMBER OF FINITE
0018 C!!! PLATES AND/OR A SET OF FINITE
0019 C!!! ELLIPTIC CYLINDERS AND CONE FRUSTUM SECTIONS.
0020 C!!! THE PLATES ARE DEFINED
0021 C!!! BY THEIR CORNER LOCATIONS. THEY CAN BE PERFECTLY
0022 C!!! CONDUCTING, MULTI LAYERED DIELECTRIC SLABS, OR COATED
0023 C!!! METAL PLATES. AN INFINITE GROUND PLANE CAN ALSO BE
0024 C!!! ADDED. THE CYLINDERS ARE DEFINED BY THEIR ORIGIN,
0025 C!!! AXES DIRECTIONS, AND BY THE RADIUS ON THEIR MAJOR
0026 C!!! AND MINOR AXES AND THE ENDCAPS AND FRUSTUM RIMS ARE DEFINED BY
0027 C!!! THEIR POSITION ON THE CYLINDER AXIS AND THE ANGLE
0028 C!!! OF THEIR SURFACES WITH THE CYLINDER AXIS IN THE X-Z
0029 C!!! CYLINDER PLANE. THE CYLINDERS MUST BE PERFECTLY
0030 C!!! CONDUCTING. AS DIMENSIONED, IT CAN HANDLE 75 PLATES
0031 C!!! WITH A MAXIMUM OF 12 CORNERS PER PLATE, WITH 5 LAYERS
0032 C!!! OF DIELECTRIC AND 5 CYLINDERS, WITH 10 RIMS
0033 C!!! ALSO 30 TRANSMITTING
0034 C!!! ELEMENTS AND 30 RECEIVING ELEMENTS CAN BE INPUT.
0035 C!!! NOTE THAT THE LIMITS ON THE NUMBER OF PLATES,
0036 C!!! CORNERS, LAYERS, CYLINDERS, SOURCES, AND RECEIVERS
0037 C!!! ARE ONLY DUE TO THE SIZE OF THE ARRAYS.
0038 C!!! THE LINEAR DIMENSIONS ARE INPUT IN METERS UNLESS
0039 C!!! SPECIFIED OTHERWISE. THE ANGULAR DIMENSIONS
0040 C!!! ARE IN DEGREES.
0041 C!!!
0042 C!!! NOTE THAT COMMENTS ARE INDICATED IN DIFFERENT FORMS:
0043 C!!! C!!! IMPLIES EXPLANATION OF PROGRAM SECTION
0044 C!!! C$$$ IMPLIES DESCRIPTION OF INPUT DATA
0045 C!!! C=== IMPLIES COMMAND INPUT SECTION
0046 C!!! C--- IMPLIES BEGINNING OF SUBROUTINE
0047 C!!! C+++ IMPLIES SPECIFICATION OF MAXIMUM DIMENSIONS
0048 C!!! CXXX means lines were not needed for SHADOW program
0049 C!!! CFFF means lines were not implemented for current version
0050 C!!!
```

## Chapter 11

### VAX Implementation

This chapter describes the VAX/VMS implementation of the shadow program. The program has been split into two parts which are not used together. When the computer environment is the VAX/VMS operating system, then the more flexible interactive mode described in this chapter should be used. Assuming that the required files have been properly restored from the distribution medium, there are procedures provided to accomplish assembly of the code with minimum user effort.

#### 11.1 Assembling the Code

On a VAX/VMS computer system, the following files are required to build and use the code. Both the interactive and non-interactive versions of the code can be run in any of the standard VMS ways, that is interactively, in a batch queue mode, or in a DCL subprocess. The actual building of the program takes place by invoking the procedure SHABLD.COM. The resulting executable file SHADOW.EXE can then be run with the RUN command.

**SHABLD.COM** A DCL command procedure to compile and link the files. This is the main assembly command file.

**SHACMD.CLD** A VMS Command Language Definition file used to define the interactive commands available.

**SHACOM.FOR** The one include file for the code common blocks. The other include statements that appear in the code reference system libraries.

**SHADNI.FOR** This contains the alternate code that is to be used when a non-interactive code is desired.

**SHADNW.FOR** This contains code that is very much dependent on the facilities of VMS and has been separated as such. It is an essential part of the interactive program.

**SHADOW.FOR** This is the main body of the code and is common to both interactive and non-interactive versions. It is standard FORTRAN-77.

**SHADOW.HLB** This is the VMS-format help library containing descriptions and examples of interactive commands.

**SHADOW.KPD** This is an initialization file used by the interactive program to equivalence certain functions to keys of the user's choice.

**SHAPLT.COM** This is a DCL command procedure invoking the NCAR graphics plotting software.

**SHAPLT.FOR** This is the FORTRAN program which reads the output produced by the code and calls appropriate NCAR routines to make a plot.

**LABEL.DAT** This file is read by the SHAPLT program in order to label the NCAR plots.

## 11.2 Running the Code

In order to run the code on VMS, the executable file created by the SHABLD procedure is necessary. The program is then run with the dcl RUN command.

A typical interactive session with the program might consist of the following elements in their approximate order of execution.

**OUTPUT FILES** Establish a set of output files with the SET OUTPUT command. The output files are of three types. Using the qualifiers of the SET OUTPUT command, any desired combination of output files may be generated.

**PROCESS AN INPUT** Issue a SET INPUT command which reads the geometry from the specified file. In order for the program to process input sets, this command must be issued prior to any mapping commands. This command is usually executed once per session.

**DEFINE A WINDOW** Using the SET WINDOW command, establish the angular range of interest. When the program begins, the size of the window is set to the full angular extent of the far-zone sphere. By specifying a smaller angular range, the user examines portions of the geometry in greater detail.

**DEFINE A SOURCE** With the SET ANTENNA command, establish the location of the source. This command is one of the more frequently entered commands. It applies units and coordinate transformations that apply from the set units and set coordinates command.

**HIGHLIGHT ITEMS** With the SET FILL command, the user may optionally cause parts of the geometry to be marked. This very useful command may be executed at any time before a SHADOW command.

**GENERATE A MAP** Cause the generation of a shadow map by issuing a SHADOW command. The shadow command is used after the user has set all desired parameters including the window and the antenna location. Without executing this command, the code does not calculate any shadowing.

**REPEAT ANY OF THE ABOVE** Perform one or more of the above actions repeatedly to obtain several maps. Most of the commands above may be executed in any order provided that the SHADOW command is executed last.

**EXIT** Terminate the shadow session with an EXIT command. An acceptable alternate mode of exit is eof, or control-Z.

In order to make life easier by reducing the number of keystrokes required to enter interactive commands, a facility is provided with which the user may associate whole command strings with a single key. When the shadow program begins executing, it loads a set of predefined key definitions from a file. The user may edit this file to customize the keypad definitions to his/her liking. Since the file is loaded automatically, the only restriction on its use is that it must exist in the current process default directory and must be accessible at run time. The details about these interface routines and what they do may be found in the VAX/VMS Runtime Library Reference Manual.

### 11.3 Modifying the code

Modifications to the source code by the user can be performed, but of course the outcome cannot be predicted beforehand. One predictable user modification is changing the program's PARAMETER statements in the include file SHACOM.FOR. This would be necessary (and sufficient) to allow the program to deal with a greater number of plates or to construct a shadow map with greater resolution than the current maximum.

## Chapter 12

### Non-VAX Implementation

This chapter discusses how to implement the code on a different computer than a VAX. The obscuration code, SHADOW, has been separated into two main parts. The FORTRAN 77 part, is not VAX dependent and is contained in a file called SHADOW.FOR. Most of the rest of the files are VAX dependent and are used mostly for interactive features. Although, it is possible that other types of machines will have similar routines that will allow interactive manipulation, it is not possible here to suggest how this may be accomplished. It is assumed that the easiest way to use SHADOW on a non-VAX would be to run it in a non-interactive mode.

The main program in the default version of the file SHADOW.FOR is designed to be used with the non-FORTRAN 77 interactive version. A file called SHADNI.FOR contains a main program designed to be used in a non-interactive mode. It is listed in section 10.2. The main programs can be easily exchanged.

Note that the only other part of the code is this part that is non-FORTRAN 77 is the INCLUDE statement. This has been retained because many computer systems support this statement. It is used to include the lines of code in the named file in the spot that it is called as if the lines had been in that spot. It provides a powerful means of putting commonly defined parameters used throughout the code in one place. In this case, it is used to include the file SHACOM.FOR which contains COMMON blocks and PARAMETER statements that define the dimensions of arrays that store the geometry. If it is desired to increase the number of plates, edges per plate, cylinders, or rims per cylinder, etc; they can be changed in one spot. Please see the listing for this file elsewhere in this manual. The INCLUDE statement can be easily removed by hardwiring the contents of the file SHACOM.FOR into the text at the main program and the subroutines ABSCIN, CAPINT, CYLINT, CYLROT, DOCYLS, DOCYL, DOPLAS, DOPLA, GEOM, INITGF, PLAINT, SCAN, SCANC, SPANC, and WRTOUT.

The code can now be compiled, linked, and run. The user communicates with the code through the non-interactive commands. This allows almost the same capability. The only information that does not have a command to change its behavior is the fill options and the input and output file names. The fill options can be accessed through the main program. The listing below has comment lines referring to the place that the fill operations may be changed.

The input and output files can be named using assignments to the logical unit numbers for the given operation. The input file is read on logical unit #5. The echo file is written

on logical unit #6. The printable shadow map is written on logical unit #7. The plottable shadow map is written on logical unit #10. On a VAX the ASSIGN VMS command would be used.

Note that the user can specify more than one source. The non-interactive operation will run a shadow map for each source individually. The receiver will not be counted. If the user wants to look at the shadow map for a receiver, they should be treated in this code as if they are a transmitter (source).

## Chapter 13

### NCAR Plot Program

The shadow map can be plotted using graphical means. The SHADOW code will write a unformatted file that can be used for interfacing to special purpose plotting programs. It writes this file on logical unit #10. In the interactive mode the file name is specified by using the SET OUTPUT commands /PLOTTABLE option. In the non-interactive mode the file name is specified using an assign statement.

There are many ways to plot the resulting shadow map. Presently, there is little standardization between system for plotting. This may change with the advent of GKS, but for now, it can not be assumed that different organizations have compatible plotting capabilities. This chapter suggests one possible means to plot the output. It uses the National Center for Atmospheric Research (NCAR) graphics package [5]. It has been tried on The Ohio State University ElectroScience Laboratory's computer system and NASA Langley Research Center's computer system, both VAX 11/780s, with almost the same results. It is still not possible, however, to assume that it will run everywhere the same way.

The program is listed for the convenience of possible users, knowing that some conversion may be necessary. The code is written in basic NCAR subroutine calls. Consult your local system information on how to link to your systems NCAR graphics subroutines. In addition, it is not written completely in standard FORTRAN 77. There are a few VAX extensions used, such as some of the options in the OPEN subroutine and some comment lines use the non-standard exclamation point. These changes will be minor.

Note that the plot of the shadow map will have grid lines. There is another option given for a map without grid lines. This can be used by commenting out the call to subroutine GRIDL, and uncommenting the call to subroutine PERIML.

The file name containing the maps to be plotted are placed in the first line of a file named LABEL.DAT. The LABEL.DAT file also contains the header information to be placed at the top of the plot for future identification and reference. The code will loop through the specified shadow map file until all the shadow map contained in the file are plotted. A sample version of a LABEL.DAT file is given after the code listing. It shows a shadow map being read off of file FOR010.DAT which contains two shadow maps.

Listing of code to plot shadow map using NCAR:

```

16. Abstract  The Obscuration Code, referred to as SHADOW, is a user-oriented computer code to determine the cast shadow of an antenna in a complex environment onto the far zone sphere. The surrounding structure can be composed of multiple composite cone frustrums and multiple sided flat plates. These structural pieces are ideal for modeling space station configurations. The means of describing the geometry input is compatible with the NEC - Basic Scattering Code. In addition, an interactive mode of operation has been provided for DEC VAX computers.  The first part of this document is a User's Manual designed to give a description of the method used to obtain the shadow map, to provide an overall view of the operation of the computer code, to instruct a user in how to model structures, and to give examples of inputs and outputs. The second part is a Code Manual that details how to set up the interactive and non-interactive modes of the code and provides a listing and brief description of each of the subroutines.
