

HYPER-LUMINOUS INFRARED GALAXIES

An X-ray view

Ángel Ruiz Camuñas

F. Panessa, F. Carrera

Cargèse – 7 April 2006

HLIRGs: Introduction

- LIRGs: $L_{\text{IR}} > 10^{11} L_\odot$
- ULRGs: $L_{\text{IR}} > 10^{12} L_\odot$
- HLIRGs: $L_{\text{IR}} > 10^{13} L_\odot$

HLIRGs: Introduction

- ~50 detected HLIRGs, ~100-200 estimated with $60\mu\text{m}$ flux >200 mJy over the whole sky.
- Unique laboratories to investigate extremely high star formation ($\sim 1000 M_{\odot}/\text{yr}$) and its connection to supermassive black holes.
- Evolutionary connection: QSO \leftrightarrow ULIRG \leftrightarrow HLIRG
- Cosmic X-ray and infrared background.

HLIRGs: Introduction

Three hypothesis:

- A. **High-luminosity tail of the ULIRGs:** starburst and/or AGN triggered by interactions and mergers.
- B. **Very young galaxies** during their maximal star formation episode.
- C. IR emission via **other mechanism** (different new class of object): e.g. transient IR luminous phase in the QSO evolution.

HLIRGs: Samples

- Sub-samples from Rowan-Robinson (2000):
- Farrah et al. 2002:
 - Detected HLIRGs in FIR or submm surveys. Complete, homogeneous and unbiased to AGNs.
 - (8 sources with our own XMM data in the future)

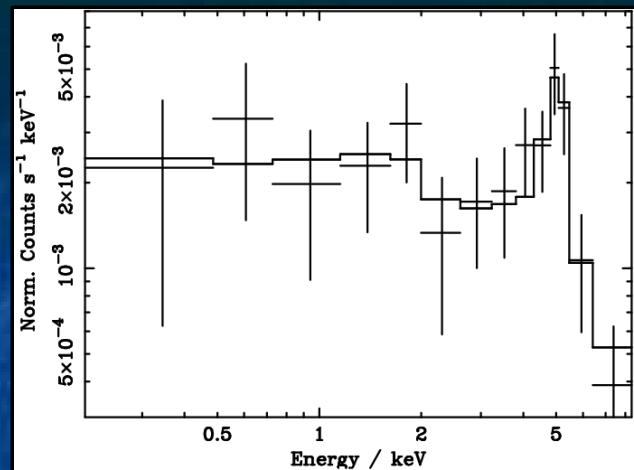

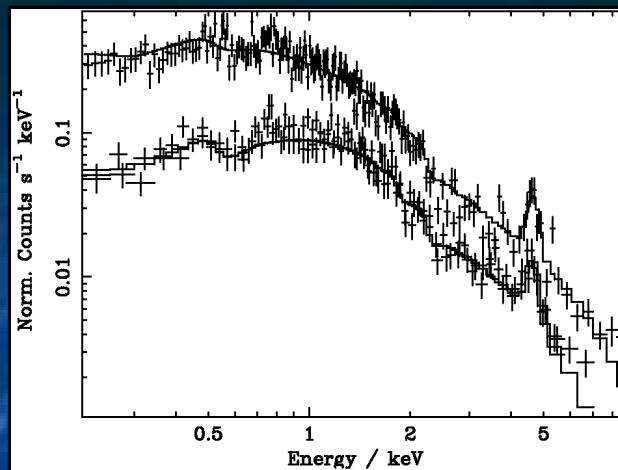

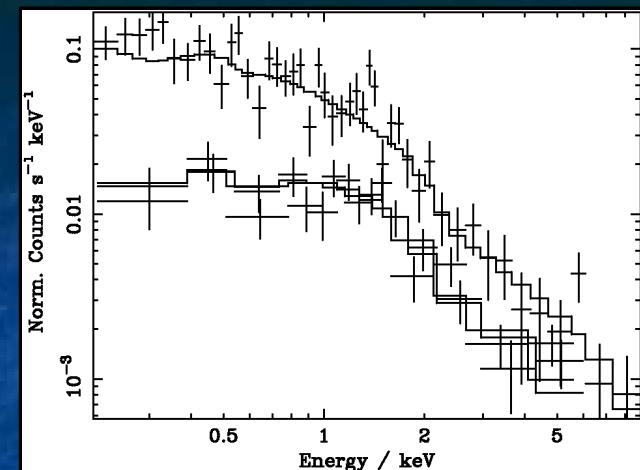

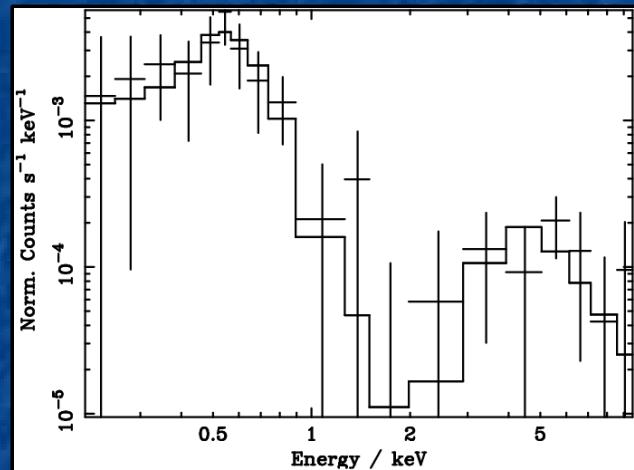

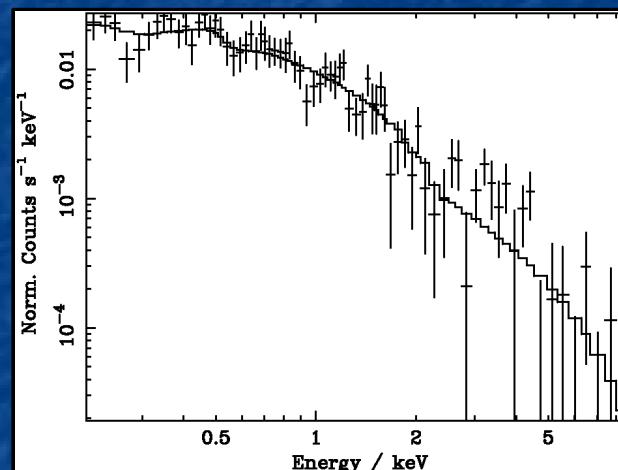

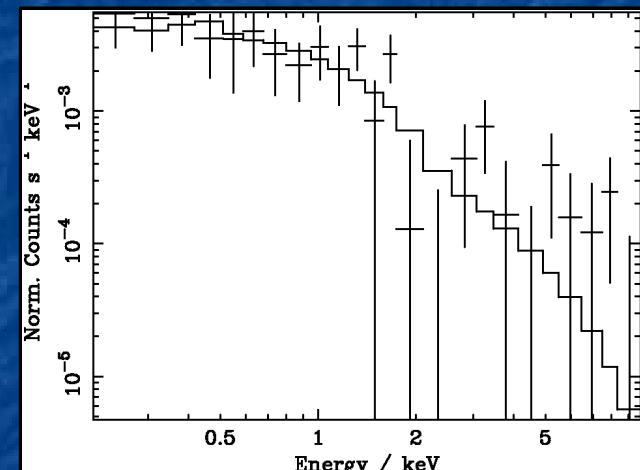

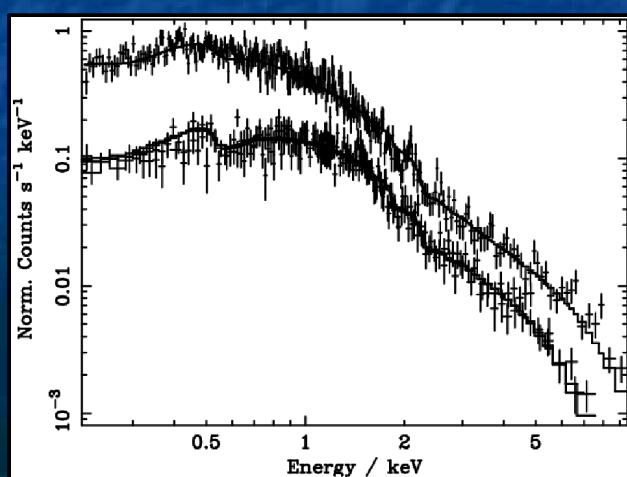

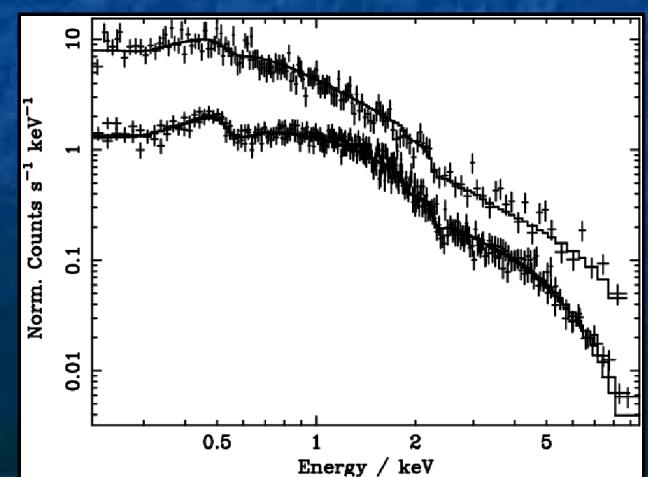

- **XMM-sample:**
 - All sources with **public data in the XMM-Newton archive** in December 2004, and redshift between ~0.3 y ~1.5.
(9 sources, 2 from Farrah sample)
 - Previous results suggest that some sources could be highly obscured and no direct X-ray emission is detected: **Compton-thick sources**.
 - Franceschini et al. 2003: **ULIRGs comparison sample**.

HLIRGs: Sample

<i>Source</i>	<i>Type</i>	<i>z</i>	RA	DEC
IRAS F00235+1024	Starburst	0.575	00 26 06.5	+10 41 32
IRAS 00182-7112	LINER	0.327	00 20 34.7	-70 55 27
IRAS 09104+4109	Seyfert 2	0.442	09 13 45.4	+40 56 28

IRAS 18216+6418	QSO	0.297	18 21 57.3	+64 20 36

HLIRGs: Objectives

- Determine the **relative contribution of AGN and starburst emission** to the bolometric luminosity and their interplay.
- X-ray study contributes:
 - Search of “hard” (2-10 keV) **non thermal emission** (associated to AGN or HMXB from the starburst).
 - Search of “soft” (0.2-2 keV) emission using thermal models (probably associated to starburst): **Thermal emission**.
 - Search of **absorption features** and FeK emission lines.

QSO

HLIRGs: Discussion (I)

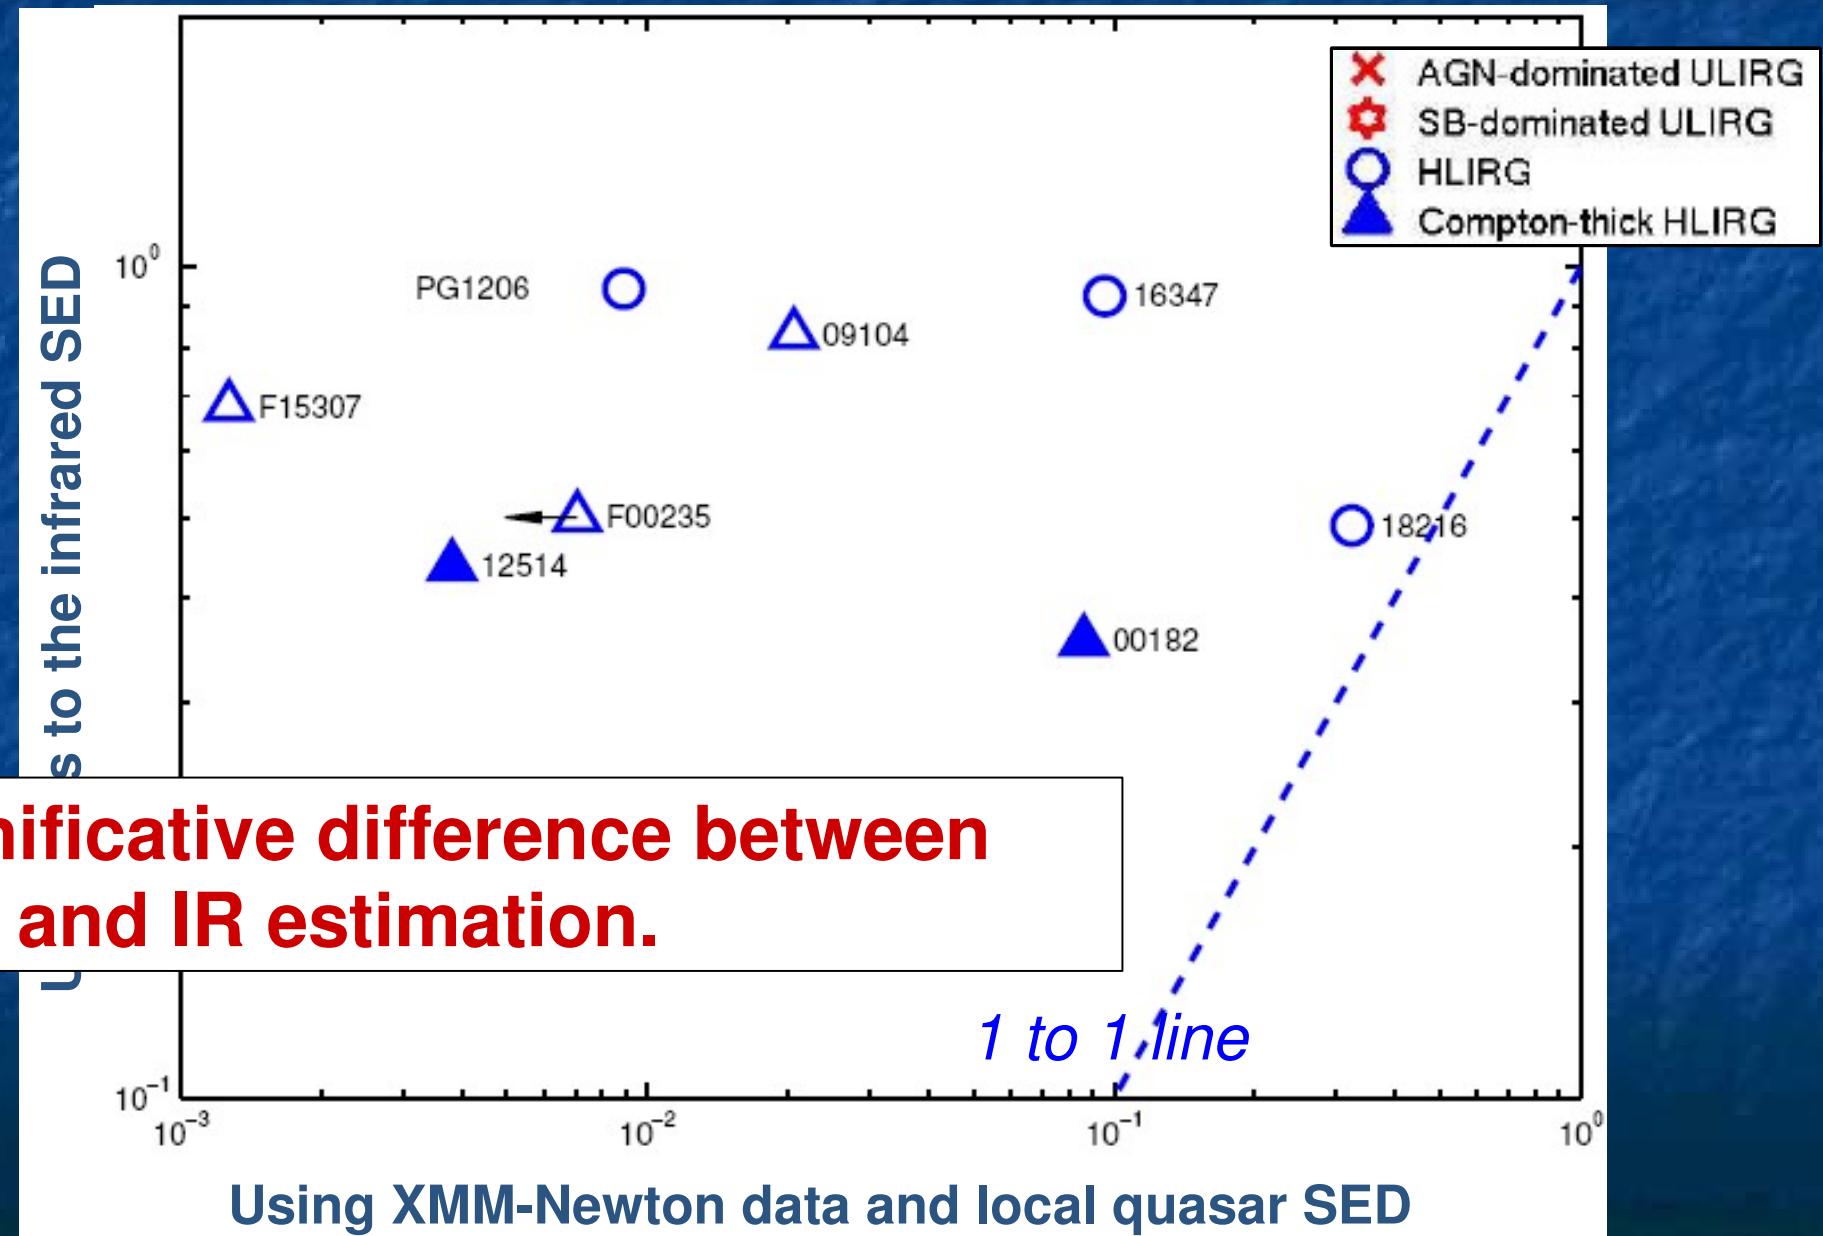

HLIRGs: Discussion (II)

AGN and QSO X-ray / infrared luminosity ratio SED
Starburst / infrared luminosity ratio SED
Elvis et al (1994)
Rowan-Robinson (2000)

HLIRGs: Discussion (II)

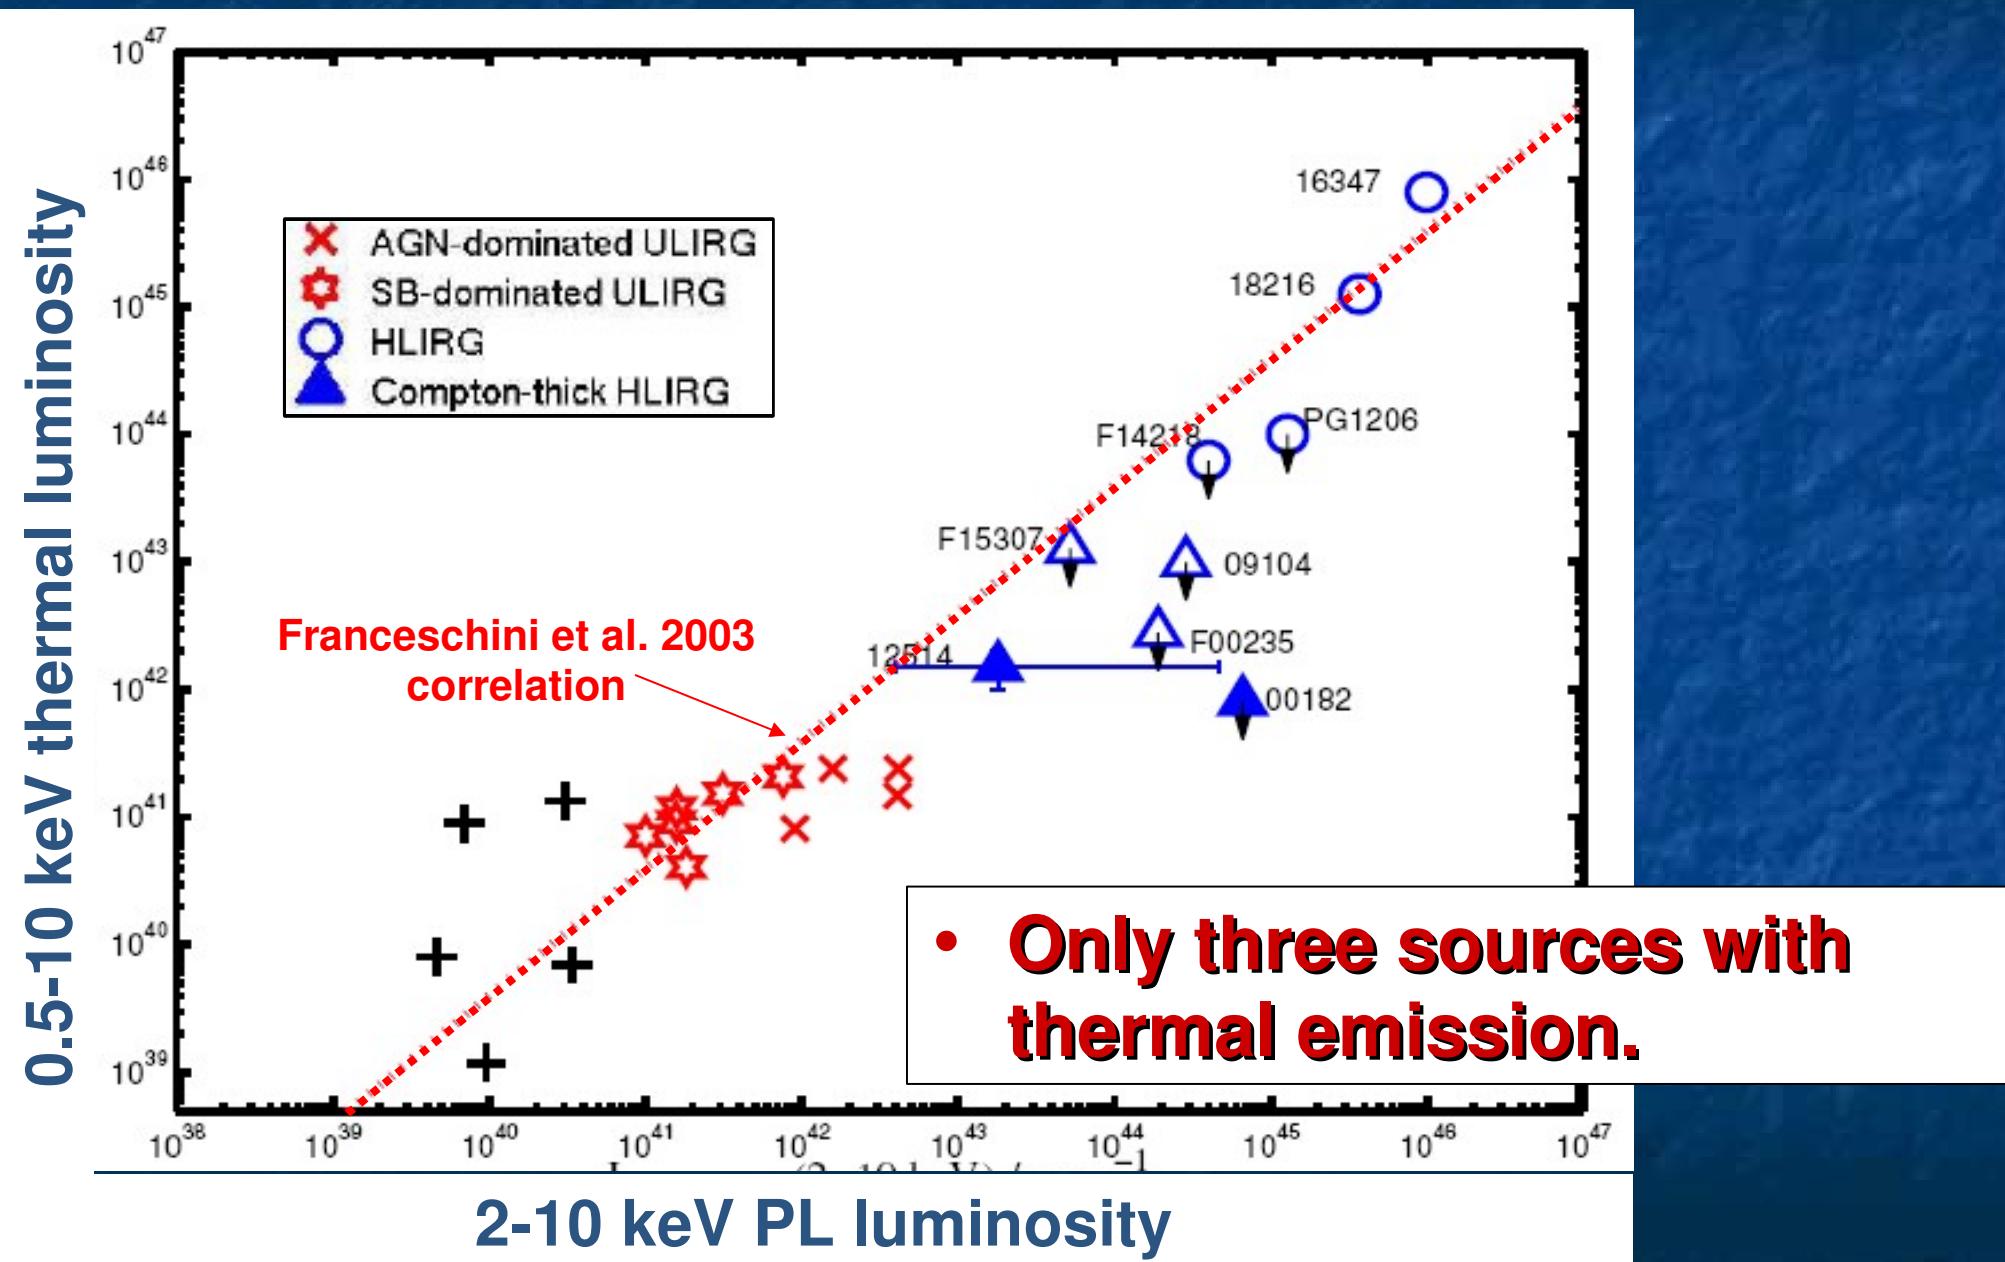

Relative contribution to the infrared emission from the AGN

HLIRGs: Discussion (II)

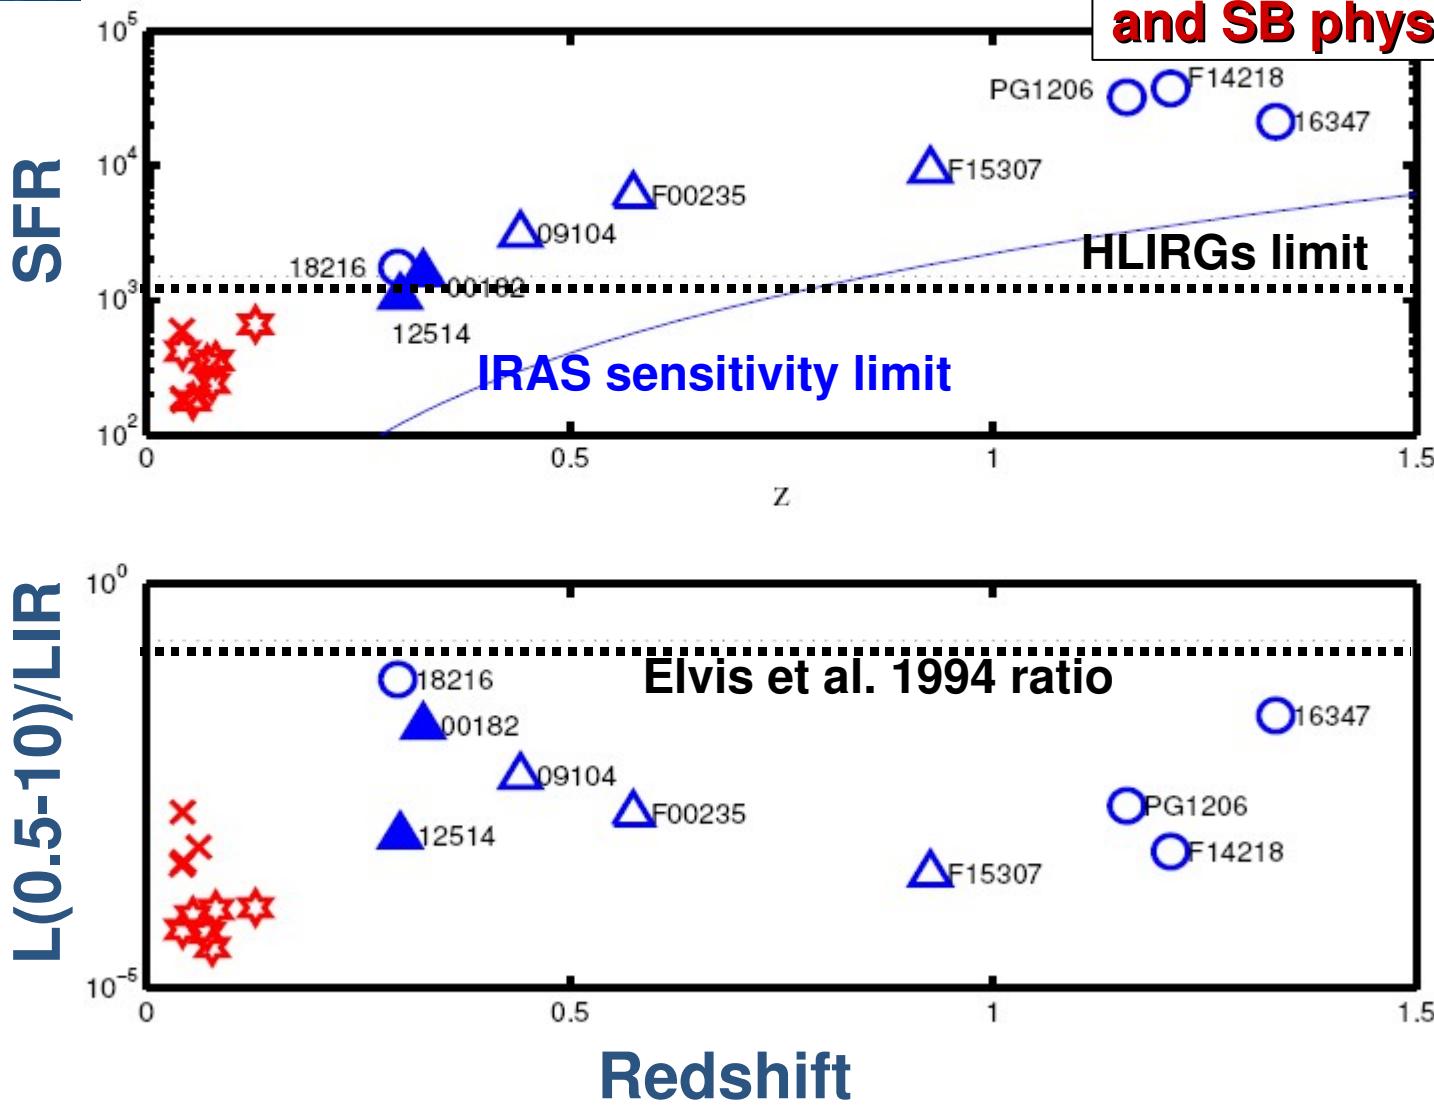

- Two hypothesis:
 - AGN in HLIRGs have a **different SED** from a local QSO (Elvis et al. 1994).
 - **Compton-thick** sources.
- Source by source analysis.

HLIRGs: Discussion (III)

HLIRGs: Discussion (IV)

- SFR evolution probably due to selection effects.
- XR/IR ~constant with $z \rightarrow$ AGN and SB physically connected.

HLIRGs: Conclusion

- Heterogeneous sources.
- Thermal component detected only in three sources. Two of them can not be starburst.
- “**Mixed**” AGN + starburst **sources**.
- Local quasars SED not valid in **three** sources (intrinsic AGN infrared excess).
- Absorption detected with XMM data only on two sources. Multi-wavelength analysis reveals **five Compton-thick sources**.
- Estimating the AGN contribution is hard with X-ray observations only.
- This results in detail will be **publish** in A. Ruiz et al. **2006** (in preparation).
