## THE STANDARD ATMOSPHERE.

## (Discussion.)

With the advance of aeronautics and the science of artillery, engineers and specialists in these fields have come to require a specific knowledge of the varying states of the atmosphere from the ground to very great elevations. This has led to the introduction of a conventional term commonly known as the standard atmosphere, which pretends to specify the normal or average condition. As is well known, the "standard atmosphere" is never found; that is to say, at no time or place do "standard" or average conditions of all of the meteorological elements at all altitudes simultaneously occur. Nevertheless it is proper, and in certain fields (especially those of aviation and ordnance) it is necessary, to adopt so-called "standard" values, and it is desirable to have these represent as closely as possible true mean values in order that corrections due to departures from these means may be comparatively small in most cases. It would be advantageous, so far as accuracy is concerned, to use at least three sets of "standard" conditions-one for summer, one for winter, and a third for spring and autumn; but this would complicate the matter, so far as practical use is concerned, and the usual custom is, therefore, to adopt one set of values only and to use this set in com-
puting a formula whose constants define the "standard atmosphere." As already stated, the values adopted for this purpose should be as nearly as possible true annual averages. These the meteorologist can furnish for many regions, principally for Europe and the United States, yet we find not infrequently "investigators" picking out a few observations here and there and spending (in effect wasting) much time and energy in computing formule for general application based thereon. An instance of this practice is to be found in a recent paper by M. Soreau, ${ }^{1}$ in which he essays to establish "standard" free-air conditions. Unfortunately his results are based upon only 40 sounding balloon records, whereas some hundreds might have been used. Worse still, these 40 soundings are very poorly distributed as to season. There are 15 in the cold months January and February, 23 in the transitional months March to May, and only 2 in the one summer month of June, and even these 2 are in the early part of that month. It is not surprising, therefore, to find that the pressures at all heights above the surface are considerably below true annual averages.

Using his means M. Soreau evolves the following empiric equation:

$$
Z=5\left(3064-1.73 P-0.0011 P^{3}\right) \log \frac{760}{P},
$$

in which $Z$ is the desired altitude and $P$ the observed pressure. He states that this formula fits his mean values well, which is not surprising, since it is based upon them. It does not, however, fit any other values that have been published. Applied to those for Europe given by Dines, ${ }^{3}$ the errors in determining $Z$ are about 1.3 per cent; applied to those for the United States, ${ }^{3}$ the errors are nearly 4 per cent. It is not to be expected, of course, that a single formula will apply to different, widely separated localities, but a formula for use in Europe should certainly be based upon representative European data. Otherwise, the conclusions mislead those not faniliar with meteorological data. In a more recent note Rateau, ${ }^{4}$ calls attention to discrepancies in Soreau's values and those given by Lapresle for Lindenberg, and expresses the hope that further information as to average free-air conditions may be obtained. As a matter of fact there is already sufficient information for this particular purpose, so far as Europe is concerned.

Naturally, the remainder of M. Soreau's paper, in which he discusses the relations between $\lambda$ and $\mu$ ( $\lambda$ being the ratio of the specific gravily at $Z$ altitude to that at the surface, and $\mu$ the corresponding ratio of pressures) is of little value, since it is based upon incomplete data.

Finally, a more acceptable discussion of the subject has been made by Prof. Pericle Gamba, who has employed a large number of observations in several countries, resulting in a reasonably close representation of the average conditions in the free air. Prof. Toussaint ${ }^{5}$ has utilized Gamba's analysis of the meteorological data in the formulation of a proposed interallied agreement as to the law of decrease of temperature with increase of altitude.

[^0]Toussaint proposes the adoption of a "law" of linear decrease of temperature with altitude, starting at a temperature of $15^{\circ} \mathrm{C}$. at sea level and attaining $-50^{\circ} \mathrm{C}$. at an altitude of 10,000 meters. This "law" is expressed by the formula $t=1.5-0.0065 Z$, in which $t=$ temperature in ${ }^{\circ} \mathrm{C}$. and $Z=$ altitude in meters.
Using this formula for computing the "standard" temperature for various heights, and assuming further that the atmosphere is dry and that gravity remains constant at all levels, the author quickly determines the appropriate values of pressure and density. The results are given, in abridged form, in the following table:

| Altitude above mean sea level. | Pressure. | Tem-perature. | Density. |
| :---: | :---: | :---: | :---: |
| m. 0 | mm. | ${ }^{\circ} \mathrm{C}$. 15 | $\begin{aligned} & \mathrm{kg} . c u . m . \\ & 1.225 \end{aligned}$ |
| 500 | 714.2 | 13 | 1.185 |
| 1, (00) | 673.4 | 9 | 1.112 |
| 1,500 | 634 | 6 | 1. 0 (1) |
| 2,100 | 585.2 | 2 | 1.008 |
| 2,5011 | 5 H 0 | -1 | 0.937 |
| 3,010 | 52.57 | - 5 | 0.907 |
| 3,510 | 493 | -8 | 0.865 |
| 4,000 | 462.2 | -11 | 0.820 |
| 4,500 | 432.2 | -14 | 0.77 S |
| 5,000 | 405 | -18 | 0.735 |
| ti, $\mathrm{OHO}_{0}$ | 353.5 | -24 | 0.680 |
| 7,000 | 307.8 | -31 | 0.585 |
| S, 010 | 2461.9 | -37 | 0.505 |
| 4,0911 10,000 | 230.4 | $-44$ | 0.467 |
| 10,000 | 198.2 | -50 | 0.413 |

Although the adopted rate of temperature decrease is arbitrary, the resulting values nevertheless agree quite well with annual means as published by various investigators for Europe and the United States. (Cf. references in footnotes 2 and 3.) Prof. Toussaint remarks:
lt has been found preferable to tako a linear law rather than to seek an equation approximate to Prof. Gamba's curve, for the following reason:

In order to deline the standard atmosphere, what is needed is not an evart reprosentation oi that curve. hit merely a law that can be conveniently applied and which is sufficiently in concordance with the means adlerrel to. Iy this methot, corrections due to temperature will he as small as possible in caleulations of airplane performances, and will he easy to calculate. The proposed law scems likely to realize such conditions.
The deviation is of some slight importance only at altitudea below 1.001 metors. which altitudes are of little interest in aserial navigation. The simplicity of the iormula largely compensates this inconvenience.

It must he remarked. however, that since the isothernal lavers seem to commonoe in Furopean reurions, at an altitude of ahout $1,1,000$ meturs it would he danererous to extrapolate ahove that altitude.

Whan it locomes an ordinary oremurence for airplanes to attain that altitucte. it will he necessary to morlify the law. but it suffires for the machines now in use.
It should be further remarked that the proposal is improperly referred to as a "law." A law is supposed to define something that is exact, within reasonable limits, whereas the actual conditions at different times and places will differ widely from this or any other assumed rate of decrease. "Standard atmosphere" is probably the best expression. It is to be hoped, though, that not even that term will be adopted, until all, or at any rate most, countries have agreed to use the same values.W. R. Grequ.

## INTERVALS BETWEEN BEGINNING OF RAINFALLIN WEST AND CENTRAL FRANCE.

A letter received from Albert Jagot, of Le Mans, France, gives an account of some interesting studies on the intervals between rainfall at Nantes and Le Mans and between Brest and Le Mans. By grouping lowpressure locations and high-pressure locations he has
